Assistant Professor, Department of Computer Science and Engineering (Artificial Intelligence and Machine Learning), Easwari Engineering College, Ramapuram, Chennai, India[6]

***Abstract*—Brain image registration is fundamental for medical imaging to allow the matching of images from multiple modalities, temporal sequences, and people to offer spatial correlation. This is crucial for activities such as cohort studies, intervention recommendations, and treatment monitoring, where exact alignment assures consistent analysis. Notwithstanding their importance, modern brain image registration techniques have many shortcomings, including limited resistance to noise, misalignment in multi-modality images, and costly computational expenses. These limits may impede real-time clinical environment practical implementation and provide less than optimal registration accuracy. This study addresses these issues by means of an Improved Brain Image Registration Technique Using Machine Learning Algorithms (BIRT-MLA). The proposed architecture detects significant image properties by means of convolutional neural networks (CNNs), therefore enabling feature extraction. By applying a supervised learning method, it guarantees precise alignment even in noisy and demanding imaging situations by forecasting transformation parameters. Lowering the registration error by modern optimization techniques helps to save processing time and maintain remarkable accuracy even in this respect. Using CNNs, the proposed method helps to effectively classify brain images, thereby improving diagnostic support and the usefulness of registered images for downstream operations. Improving clinical judgment and simplifying processes rely on grouping registration and categorization into a logical sequence. By means of enhanced alignment precision, resistance to picture faults, and shortened computing time compared to current approaches, experimental findings expose the advantages of the suggested technology. This development may be very useful in clinical and experimental settings, thereby supporting the accuracy and efficiency of brain picture analysis.**

Keywords*—Machine learning algorithms; brain image registration; convolutional neural networks; deep learning; brain disease

I. Introduction

A. Background

Medical image registration, specifically that of the brain, has become an essential aspect of modern medical imaging [1]. It enables images to be aligned across various modalities, time points, and subjects. For accurate picture analysis in various medical practices, especially in the multi-modal medical aids, the spatial alignment of overlapping material is always a prerequisite [2]. Brain imaging in cohort studies, treatment-guided studies or therapy evaluative progress has one way or the other tried to rely on these brain imaging registrations [3]. To make the most helpful conclusions, assess differences, and adjust methods over time, other activities must be performed with great detail and consistency, especially the acquisition of the images [4]. Considering the increasing volume of multimodal brain imaging data together with the recent advances in imaging technologies, the requirement for robust and efficient image registration techniques has emerged [5]. However, current techniques cannot avoid noise, misalignment, and the complexity of multiple images [6]. Furthermore, the conventional techniques introduce traces of overhead which are a challenge to work with in a clinical environment owing to the high demand for image processing that is both accurate and quick [7].

Integrating machine learning into brain image registration provides promising answers to the numerous questions raised by this area of research [8]. Most especially convolutional neural networks but also other ML methods excel at feature extraction and even pattern recognition which is suitable for the challenging imaging data [9]. This has been made possible by ML which facilitates an improvement in the accuracy, robustness and efficiency of the brain image registration technique [10].

This study presents an Improved Brain Image Registration Technique Using Machine Learning Algorithms (BIRT-MLA), which is intended to improve on the drawbacks of the existing methods and also contribute to the development of approaches to brain imaging [11]. As the reliance on multimodal imaging in clinical and research settings continues to grow, improving the efficiency and accuracy of this registration process becomes even more critical [12]. When applied to real-time scenarios, traditional methods tend to be hampered by noise, high computing cost, and misalignment, and these are the same problems they encounter [13].

Motivation: Machine learning provides one opportunity of dealing with these issues, hence enabling building of high and robust systems for brain image registration, which in turn improves the diagnosis and treatment monitoring [14].

Problem statement: Many of the contemporary brain imaging transformations' solutions lack stability, accuracy, and computational efficiency, which makes their application difficult in clinical practice [15]. Such challenges encompass the sensitivity to noise, registration of multi-modality images, and prolonged response times [16]. These constraints make them less practically useful for real-time analysis and formulation of feedback, as well as give not the best registration results [17]. Enhancement of wider applicability and enhanced efficiency of brain image registration has to do with these problems.

B. Goal of this Paper

The evolution of the BIRT-MLA framework has inspired the idea of a new method based on machine learning for brain image registration. Using convolutional neural networks helps this system to provide strong feature extraction and perfect alignment.

By means of their decrease in the number of errors during the registration process as well as the expenditure of money on processing, the advanced optimization solutions discussed here serve to expand the applicability of the system in real-time environments.

C. Problem Statement and Significance

The simplification of clinical processes and the rise of diagnostic capacities are much influenced by the mix of registration and classification approaches.

The remainder of this study is structured as follows: In Section II, the related work of brain image registration is studied. In Section III, the proposed methodology of BIRT-MLA is explained. In Section IV, the efficiency of BIRT-MLA is discussed and analyzed. Finally, in Section V, the study is concluded with the future work in Section VI.

II. Related Work

Analyzing deep learning-based medical image registration approaches with an eye on advancements, obstacles, and new trends, it covers organ atlas creation and tumor growth monitoring, as well as the progress of DL-MIR and classifies techniques with reference to their therapeutic usefulness. Apart from interesting findings, the study shows future opportunities to improve clinical relevance and efficiency.

A. Comprehensive DL-MIR Review

Emphasizing those with significant methodological or functional breakthroughs, the present analysis looks at all deep learning-based medical image registration papers released since the present. It analyzes the use of deep learning methods in medical photo registration, therefore summarizing growing trends and problems [18]. The study identifies unmet clinical needs and offers ideas on potential future ways to advance the subject, thus ensuring relevance to real-world clinical applications and enabling the continuous advancement of image registration techniques.

B. DL-MIR Evolution Survey

The study methodically investigates the evolution of deep learning-based medical image registration across many years, including assessment of developments, challenges, and research patterns. Emphasizing relevant research challenges faced by practitioners, it focuses on clinical activities such as tumor growth monitoring, image fusion, and organ atlas development [19]. This study summarizes significant advancements, clarifies the quick adoption of deep learning, and offers future directions to meet unmet needs and forward the field of medical image registration to new degrees of usefulness.

C. DL-MIR Review with Categorization

In the present analysis, an overview of deep learning (DL)-based medical image registration methods is offered. We covered the most current developments in the medical sector of DL-based registration systems. Their methods, goals, and popularity led to dividing these strategies into seven categories [20]. Every area was carefully examined to highlight specific challenges and reveal notable accomplishments. Following the exhaustive study of every subject, a quick assessment was provided to underline its achievements and future prospects. We provided a complete comparison of DL-based techniques for brain and lung registration using benchmark data. At last, we investigated the data of every indicated research from many viewpoints to reveal the popularity and future direction of growth of DL-based medical image registration.

D. ML-DL Brain Disease Review

This effort compiles 147 recent works on machine learning and deep learning approaches for Parkinson's illness, brain tumors, epilepsy, and Alzheimer's disease detection. Analyzing 22 often-used datasets and feature extraction techniques in diagnosing brain diseases, it evaluates several methodologies, data modalities, and datasets [21]. The study discusses significant findings, points out challenges, and investigates the potential of artificial intelligence-based diagnostics. The objective is to highlight the most accurate techniques for the diagnosis of brain illnesses and provide recommendations for further advances in the field.

E. Deep Learning-Based Medical Image Registration

Under supervised, unsupervised, and iterative frameworks, deep learning-based medical image registration methods are investigated in this study. Among supervised methods are dual, completely, and weakly supervised registration [22].

Unsupervised methods rely on similarity-based and GAN-based registration techniques. Deep iterative registration brings deep similarity learning along with reinforcement learning. Stressing the lack of training datasets with known transformations as a main challenge, the work also explores monomodal and multimodal image registration across modalities, including X-ray, CT, ultrasonic, and MRI, therefore directing future research directions.

F. Deep Neural Networks for Medical Image Registration

This work rigorously assesses medical image registration using deep neural networks (MIR-DNN), underlining improvements enabled by many-core CPUs. Emphasizing the transformational potential of deep learning, it looks at modern methods, basic concepts, statistical analysis, and challenges [23]. Providing researchers with all the information they need, the review addresses original contributions, enabling strategies, and possible advances. The major focus is on the improvement of registration efficiency and effectiveness for image-guided treatments, thereby providing a foundation for further field research and development.

G. DL-Based Lung Image Registration

Aiming at DL-based lung image registration (DL-LIR), this work resolves problems like major deformities and motion discontinuities resulting from breathing and heart activity. It ranks techniques in three fully-supervised, weakly-supervised, and unsupervised categories [24]. It undertakes a comprehensive statistical analysis using publicly available datasets, loss functions, and measures. By means of a combination of conventional and DL-based techniques, the review highlights unresolved problems and proposes future paths to improve lung image registration accuracy and usefulness in clinical environments.

H. Learn2Reg Framework

The Learn2Reg challenge offers a consistent framework for evaluation of deformable 3D medical image registration systems across several challenges, anatomies (brain, abdomen, thorax), and imaging modalities (CT, MR, ultrasonic) as (L2R) Combining complementary measurements such as accuracy, resilience, plausible behavior, and runtime lets one assess registration performance all around. Emphasizing multi-task training, label monitoring, and transferability analysis, the challenge helps one to understand the trade-offs of conventional and deep-learning-based approaches [25]. This method helps experts evaluate and improve contemporary registration methods on therapeutically relevant data.

By means of thorough analysis of DL-MIR techniques, the research divides them into iterative, unsupervised, and supervised models. It underlines issues such as data limitation and distortion in lung imaging. Analyzing significant studies in many different disciplines allows the study to identify trends, unmet needs, and provide ideas for future advances to enhance therapeutic value and accuracy in medical image registration. Table I presents a comparison of existing methods.

TABLE I. THE COMPARISON OF EXISTING METHODS

S. No	Methods	Advantages	Limitations
1	Comprehensive DL-MIR Review	Summarizes growing trends and challenges in DL-MIR, with a focus on real-world clinical applications	Identifies unmet clinical needs but lacks specific solutions for certain challenges
2	DL-MIR Evolution Survey	Highlights significant advancements, quick adoption of deep learning, and offers future directions	Focuses on research challenges but may not offer practical solutions for all clinical issues
3	DL-MIR Review with Categorization	Provides an extensive overview and categorization of DL-based methods, comparing brain and lung registration	The broad categorization may not cover niche or emerging methods comprehensively
4	ML-DL Brain Disease Review	Provides a comprehensive compilation of machine learning and deep learning methods for brain disease detection	Challenges in standardizing datasets and the variety of methods lead to inconsistent results
5	Deep Learning-Based Medical Image Registration	Explores supervised, unsupervised, and iterative methods, focusing on multimodal image registration	Lack of training datasets with known transformations and challenges with multimodal registration
6	Deep Neural Networks for Medical Image Registration	Assesses the improvement enabled by deep learning, especially in image-guided treatments	Efficiency issues in complex multi-core CPU environments may limit practical application
7	DL-Based Lung Image Registration	Addresses issues of deformities and motion discontinuities in lung image registration	Motion artifacts and issues with breathing and heart activity continue to challenge accuracy
8	Learn2Reg Framework	Offers a consistent evaluation framework for 3D deformable image registration across challenges and modalities	Complex multi-task training and transferability analysis may be difficult to implement in clinical environments

III. PROPOSED METHODOLOGY

This work illustrates how advanced machine learning techniques might be added to brain image registration. Investigating many deep learning approaches, including CNNs, GANs, and U-Net, helps to increase the accuracy and efficiency of medical image alignment, thus allowing better comparisons for clinical and research purposes. By means of low error and processing time, the system aims to improve real-time clinical applications.

A. Contribution 1: Proposed a Novel Machine Learning-Based Registration Framework

Presented a strong brain image registration method using convolutional neural networks (CNNs) for accurate feature extraction and supervised learning to estimate transformation parameters, therefore guaranteeing exact alignment even in noisy and challenging imaging environments.

1) Learning approach: Fig. 1 explains the brain image registration process of advanced machine learning methods.

Starting with raw brain images (MRI, CT, PET Scans), the method consists of denoising and normalizing preprocessing steps. Among other conventional and deep learning methods, feature extraction takes use of cnns and autoencoders. GANs and U-Net are among the deep learning-based approaches; traditional techniques are used in registration. Following efficient alignment ensured by optimization techniques comes with model evaluation using DSC and MSE. The outcome is a registered brain image generated with high-quality fusion and statistical analysis guaranteed by post-processing methods.

$$||ex - sm''||: \rightarrow \varphi_v S[\delta + uy''] - Cqv^e[x - zk''] + Mn[c - xz''] \quad (1)$$

To improve alignment and feature correlation, Eq. (1) 1n represents the interaction of optimization terms ($||ex - sm''||$, $\varphi_v S[\delta + uy'']$ with transform spatial parameters $Cqv^e[x - zk'']$, $Mn[c - xz'']$. This aligns with the study's objective of obtaining computationally efficient, accurate, and noise-resistant brain image registration [see Eq. (2)]:

$$\varepsilon_f D[vc'':sz]: \rightarrow \in \nabla x' + 9u[\alpha\exists' - 3vap] - Ca[\varepsilon\beta - 9avs''] \quad (2)$$

Under noise and alignment adjustments, the algorithm depicts $\in \nabla x' + 9u$ the dynamic interaction of the spatial gradients ($\varepsilon_f D$) and feature constraints ($[vc'':sz]$). The suggested BIRT-MLA approach incorporates convolutional neural networks (CNNs) to improve registration accuracy and noise resistance by altering transformations ($9u[\alpha\exists' - 3vap]$) and obtaining robust features ($Ca[\varepsilon\beta - 9avs'']$. In difficult medical imaging situations, this helps the framework achieve its aim of accurate alignment and computing efficiency.

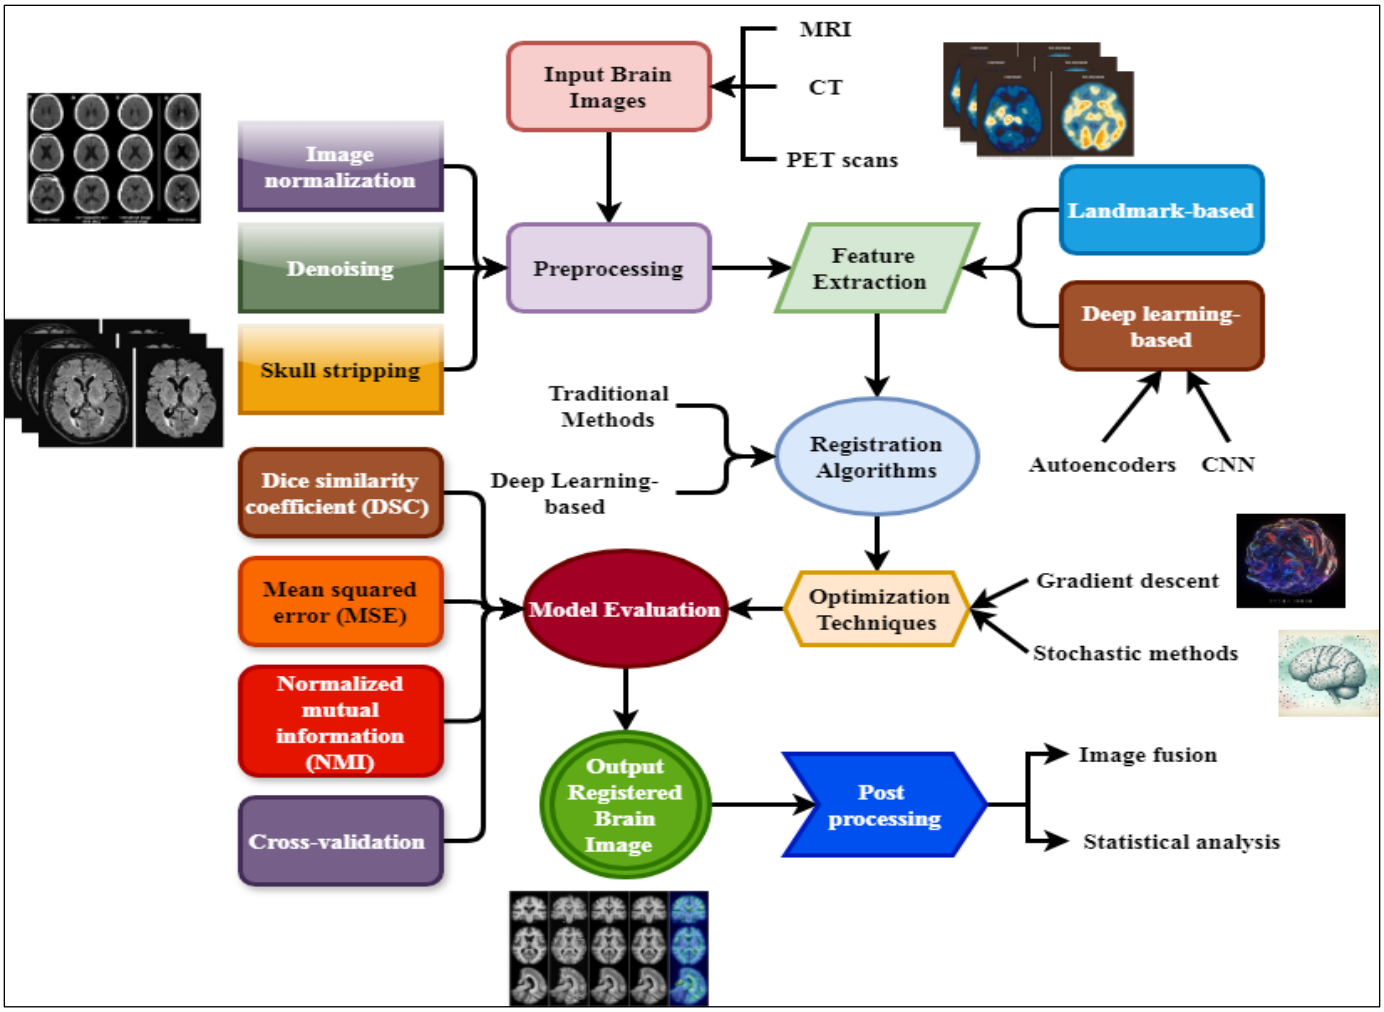

Fig. 1. AI-enhanced brain image registration: a machine.

Fig. 2 illustrates the two-step medical image registration process aligning a floating image to a reference image for perfect comparison. Linear Registration starts with global transformations including translation, rotation, scaling, shearing to achieve approximate alignment. Then polishes the result by using a deformation field to modify local variances, therefore assuring complete anatomical structural alignment. From coarse to fine-grained corrections, the method evolves to provide very accurate final pictures. Medical imaging relies on this mechanism for processes like brain analysis, which enables very accurate comparisons between patients or time points.

$$C_x S[\forall - 9bv'']: \rightarrow Ku[\forall s'' + 9vaw''] - Cva[\propto + 9suy''] \quad (3)$$

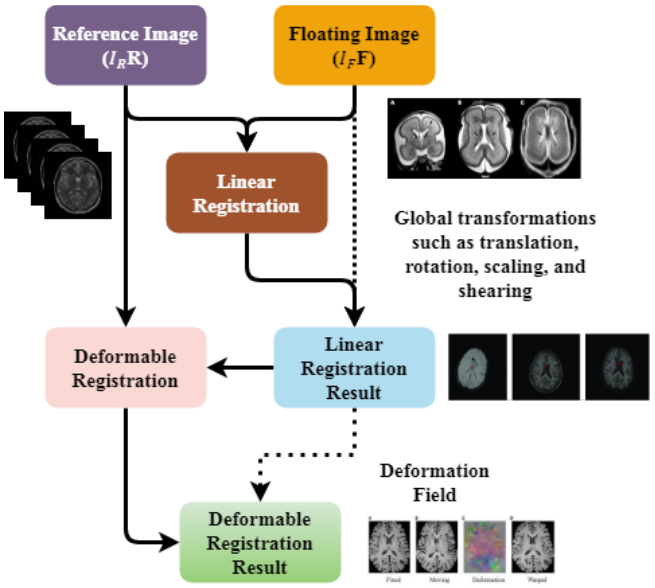

Fig. 2. Global alignment to precise deformation: image registration workflow.

Aligning multi-modal data $\forall - 9bv''$ while considering distortions $Ku[\forall s'' + 9vaw'']$ is included in Eq. (3), in which $Cva[\propto +9suy'']$ also optimizes spatial characteristics (C_xS). The goal of the approach is to improve the accuracy and usefulness of picture registration in clinical and industrial workflows, and this procedure is in line with that purpose.

$$c_{dF}[n - bx'']: \rightarrow Lk[\forall \propto' - sn] + 7t[\forall - 3en''] - Cg[\partial \forall - cz''] \quad (4)$$

To improve alignment, the coefficients of learning (c_{dF}), feature transformations ($[n - bx'']: \rightarrow$), and noise adjustments ($Cg[\partial \forall - cz'']$) interact with each other. To achieve accurate registration in the BIRT-MLA the structure convolutional neural networks (CNNs) use noise resilience $Cg[\partial \forall - cz'']$ and minimization ($[\forall \propto' - sn]$) to extract and forecast these feature-based modifications. The method's focus is on obtaining efficient and robust alignment in complex medical imaging environments for Eq. (4).

B. Contribution 2: Enhanced Efficiency and Accuracy in Brain Image Registration

The system is appropriate for real-time clinical uses as included sophisticated optimization algorithms minimize registration mistakes, greatly reduce processing time, and enhance resilience against imaging distortions. Input brain pictures from the beginning of the process and pre-processing procedures including noise reduction and normalization is shown in Fig. 3(a).

Fig. 3(b) describes a pairwise direct linear registration method for standard template alignment of a brain picture from a test participant. First aligned with many intermediary mediator pictures using affine transformations (TS→mi) the test image is Predefined a priori transformations (Tmi→t) then transfer each mediator to the ultimate template picture. Leveraging mediators as intermediary references guarantees strong and exact registration via this multi-step alignment. Forming a fundamental basis for sophisticated medical imaging technologies and machine learning applications, the framework enables correct comparison and analysis of brain anatomy across people and research [see Eq. (5)].

$$X_sF[ju - 4va'']: \rightarrow Las[\cup -5ca''] + 8h[\forall w - ab''] - Cq[bn''] \quad (5)$$

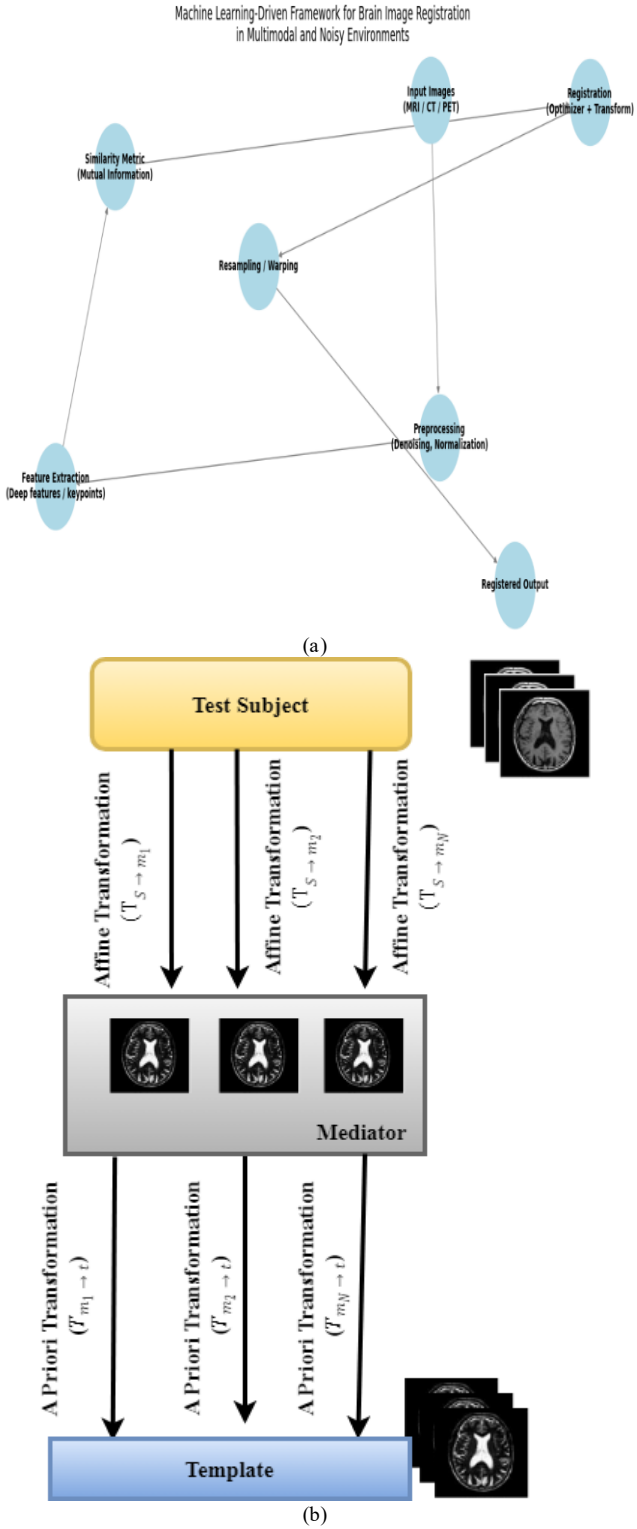

Fig. 3. (a) Procedure for dataset input image pre-processing, (b) Bridging transformations: mediator-based image alignment framework.

The optimization terms (X_sF) control the transformation $8h[\forall w - ab''] -$ of spatial characteristics ($ju - 4va''$) to compensate $Cq[bn'']$ for distortions ($Las[\cup -5ca'']$).This lends credence to the method's stated purpose of obtaining clinically and experimentally applicable brain image registration that is both dependable and robust to noise.

$$d_cD[6v - am'']: \rightarrow Ju[\forall \propto -6va''] + 7\forall[\partial \times \propto \times z''] - 9u[\forall s''] \quad (6)$$

To improve spatial alignment $Ju[\forall \propto -6va'']$, optimizing terms (d_cD) and feature transformations ($[6v - am'']$ are represented by Eq. (6). To be able to forecast accurate alignments $7\forall[\partial \times \propto \times z'']$ and guarantee strong registration, CNNs in the BIRT-MLA approach use such modifications and noise-adjusted values $9u[\forall s'']$. The method's goal of increasing precision and computing efficiency under difficult imaging circumstances is well-aligned with this.

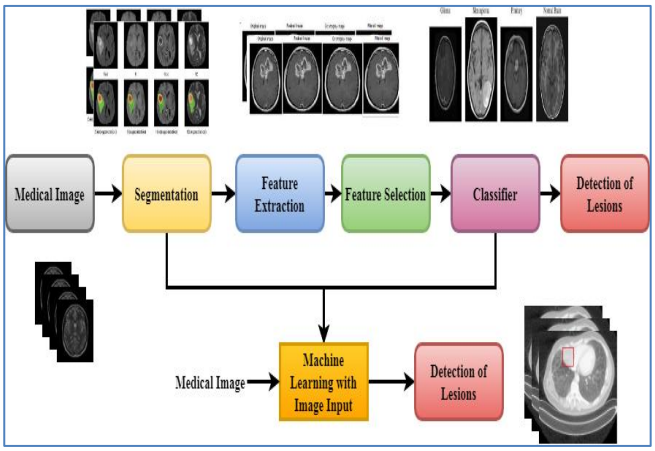

Fig. 4. From features to networks: evolution of lesion detection techniques.

Fig. 4 compares medical picture analysis classical machine learning techniques with deep learning methods. The conventional route calls for segmentation, feature extraction, feature selection, and classification to find lesions, therefore needing considerable human involvement and domain knowledge. By immediately processing medical pictures with complex neural networks such CNNs, MTANNs, and DBNs, the deep learning approach avoids these middle processes. Using data-driven learning, this simplified technique improves accuracy and efficiency. The contrast emphasizes how transforming deep learning is in automating and enhancing lesion diagnosis, hence opening the path for sophisticated medical imaging uses in clinical practice and research.

$$c_Ds[V - xv'']: \rightarrow Ku'[\partial\forall \times dv''] + Uy[x - zk''] - [\partial\forall - 2wm''] \quad (7)$$

To improve alignment $Ku'[\partial\forall \times dv'']$ under various feature restrictions, Eq. (7) illustrates the interaction between spatial distortions (c_Ds) and optimizing parts ($[V - xv'']: \rightarrow$). Precise registration is achieved in the BIRT-MLA platform by using CNNs to forecast the transformation constants ($Uy[x - zk'']$) and to account for noise ($[\partial\forall - 2wm'']$). In multi-modal and dynamic imaging environments, this represents the method's objective of improving accuracy and resilience.

$$Cfz': \rightarrow ju[\delta\varepsilon + \nabla\exists''] - Vq[\tau\pi' - 2vx] + 9Uy[\sigma\theta - 7vz''] \quad (8)$$

While accounting for distortions, Eq. (8) models $Vq[\tau\pi' - 2vx]$ the alignment features (Cfz') and parameters for optimization ($ju[\delta\varepsilon + \nabla\exists'']$. In the BIRT-MLA model, convolutional neural networks (CNNs) detect feature transformations $9Uy[\sigma\theta - 7vz'']$ to forecast exact spatial modifications. In the context of medical imaging, this lends credence to the method's stated goal of obtaining precise, noise-resistant brain picture registration.

C. Contribution 3: Unified Registration and Classification Workflow

Designed an integrated strategy combining CNN-based classification with brain image registration to improve diagnosis assistance and the value of registered pictures in downstream activities, hence optimizing clinical and research processes.

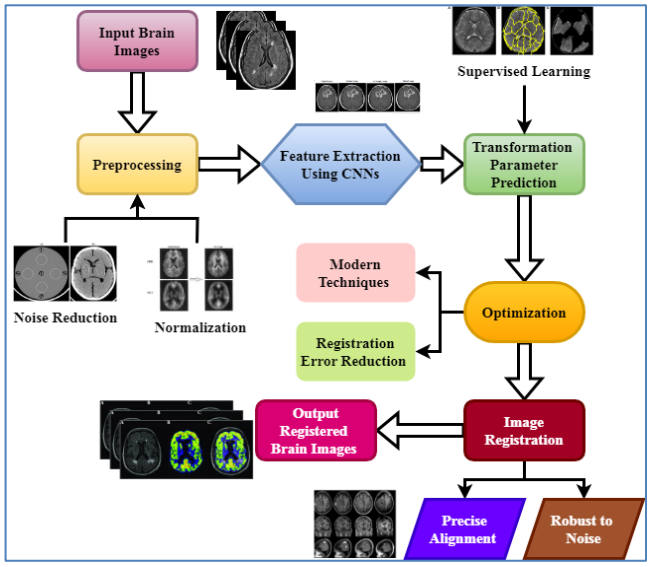

Fig. 5. Enhanced brain image registration using machine learning.

Fig. 5 shows the Improved Brain Image Registration Technique Using Machine Learning Algorithms (BIRT-MLA) procedure. Input brain pictures form the beginning of the process; preprocessing procedures including noise reduction and normalisation follow. Convolutional neural networks (CNNs) then allow one to extract important information. While recent optimization methods minimize registration mistakes, guaranteeing both efficiency and accuracy, a supervised learning approach forecasts transformation parameters for exact alignment. The last result comprises registered brain pictures that highlight the method's resilience in noisy and complicated imaging environments while preserving remarkable alignment precision.

$$\cup_r S[\forall - 5vx'']: \rightarrow \forall\alpha[\beta \in +8xza''] - [ej - an''] + 9U[q - 2x] \quad (9)$$

As a way to handle distortions $[ej - an'']$, Eq. (9) shows the integration $\forall\alpha[\beta \in +8xza'']$ of featured transformations $\cup_r S$ and optimizing terms $[\forall - 5vx'']$. These components are used by CNNs in the BIRT-MLA framework $[ej - an'']$ to maximize alignment and forecast transformation parameters

$9U[q-2x]$ for correct registration. This with the method's goal of improving computing efficiency and noise robustness in processing brain images.

$$Vf' :\rightarrow Nj[d-8uy''] + Ecd[\forall -9u''] - Da[\partial \ll vj - ab \gg] \quad (10)$$

Tackling distortions (Vf') and spatial translations ($Nj[d-8uy'']$), Eq. (10) represents the interaction between parameters for optimization ($Ecd[\forall -9u'']$) and the system. By using CNN predictions for these transformations $Da[\partial \ll vj - ab \gg]$ and parameters, the BIRT-MLA architecture guarantees noise resilience and accurate alignment. This is with the method's objective of efficiently and accurately registering brain images.

Application of machine learning greatly improves alignment accuracy and efficiency of brain image registration. CNNs, GANs, and U-Net optimize the registration procedure thereby facilitating perfect anatomical comparison between patients. By merging image registration with classification techniques, the proposed approach reduces processing time and errors under demanding imaging situations and therefore improves clinical diagnosis and research.

IV. Results and Discussion

The BIRT-MLA method improves brain image registration by use of CNNs and supervised learning. It solves problems in multi-modality registration by raising alignment precision, accuracy, and resistance to picture defects. In healthcare environments when suitable, this method lowers mistakes and computation time as diagnosis and treatment choices depend on reliable picture registration.

Dataset Description: Product innovation and technological developments in neurosurgery drive the neuro-navigation systems market, which is expected to increase USD 227.65 million at a 7.06% CAGR from 2023 to 2028. These devices provide real-time imaging and instruction for best surgical precision in treating neurological disorders [26]. Despite high costs, industrial development is being driven by the need for less intrusive procedures and artificial intelligence integration. Important groups include optical and electromagnetic systems, which find increasing use in specialized clinics and hospitals. Tables II and III present the simulation environment and implementation summary, respectively.

TABLE II. Simulation Environment

Metrics	Description
Simulation Software	Virtual simulation tools for testing neuro-navigation systems (e.g., ROS, VTK).
Hardware Requirements	High-performance computing systems with GPU support for 3D imaging and processing.
Imaging Modalities	MRI, CT, and PET scans used for creating 3D brain models in simulations.
Neurosurgical Tools	Surgical instruments, robotic arms, and tracking devices integrated in simulation.
AI/ML Algorithms	Algorithms for real-time image processing, error correction, and decision-making.
User Interface	Virtual reality or augmented reality interfaces for surgeons to interact with 3D models.
Target Diseases	Simulation of procedures for brain tumors, epilepsy, and vascular malformations.
Data Input	Patient-specific data (MRI/CT scans, functional brain maps) for realistic simulations.
Output/Feedback	Real-time positional feedback, error detection, and post-operative outcome simulations.
Performance Metrics	Precision, error rates, computation time, and system robustness in real-world conditions.

TABLE III. Implementation Summary

Category	Item	Details / Purpose
Software / Library	Python	Programming language
	PyTorch	Deep learning framework for CNN implementation
	Torchvision	Image preprocessing and dataset handling
	NumPy	Numerical operations
	Pandas	Data manipulation and label handling
	Matplotlib	Plotting training curves and visualizing outputs
	Jupyter Notebook / Kaggle / Colab	Execution environment with GPU support
Model Parameters	CNN Architecture	4 Conv layers + ReLU + MaxPooling + FC + Dropout + Sigmoid
	Activation Functions	ReLU (hidden layers), Sigmoid (output layer)
	Optimizer	Adam
	Loss Function	Binary Cross Entropy Loss (BCELoss)
	Learning Rate	Typically 0.001 (can be tuned)
	Epochs	Commonly 25–50 (tunable)
	Batch Size	Usually 32 or 64 (affects memory and speed)
Performance Metrics	Accuracy	Classification accuracy on validation/test set
	Loss	Measures training performance (should decrease over epochs)
	Confusion Matrix	Shows TP, FP, FN, TN to evaluate classification performance
	Training Time	Total time taken for training (depends on dataset size and hardware)

A. Analysis of Alignment Precision

With an outstanding 94.33%, the BIRT-MLA method demonstrates its ability to routinely offer accurate spatial registration throughout many modalities (Fig. 6). Identification of significant visual structures relies mostly on the use of CNNs for feature extraction, thereby ensuring precise alignment of pictures. Medical applications rely on this significant degree of precision; even little misalignments may lead to diagnostic errors or affect treatment recommendations, hence ensuring the quality of the registered images.

$$\ll \partial \forall - uy \gg : \beta \nabla [\varepsilon + 8vz''] - Fq[\forall \ni + uy' - Rqaz''] \quad (11)$$

Eq. (11) represents $Fq[\forall\ni +uy' - Rqaz'']$ the interaction of feature transformations ($\ll \partial\forall - uy \gg$:) and optimization terms ($\ll \partial\forall - uy \gg$:) while adjusting for distortions ($\beta\nabla[\varepsilon + 8vz'']$). This reflects the method's focus on refining brain image registration for clinical and experimental applications on analysis of alignment precision.

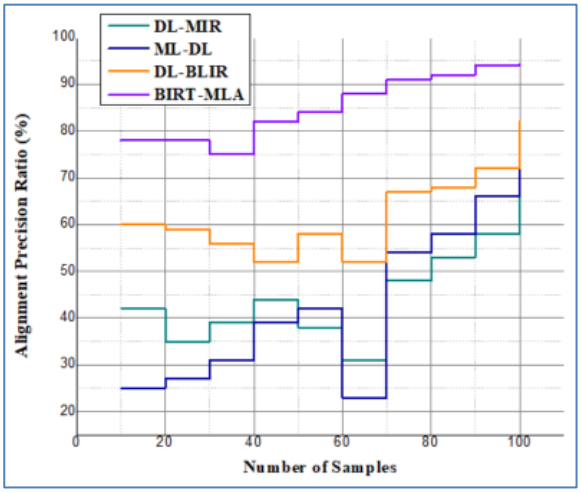

Fig. 6. Analysis of alignment precision.

B. Analysis of Resistance to Picture Faults

With a resistance to picture faults of 92.43%, the BIRT-MLA technique displays its tenacity in handling noisy or distorted images (Fig. 7). CNN-based feature extraction and supervised learning guarantee trustworthy registration by helping the method to reduce image artifacts. This resilience is extremely beneficial in clinical settings, where defects in multi-modal images are common and therefore maintains the accuracy and integrity of the registration process under demanding input conditions.

$$\sigma\varepsilon[\alpha + 9vx'']: \rightarrow Ku[\rho\vartheta' + 9vq] + Iu[\tau\rho - zv''] - Cw[pu - s''] \quad (12)$$

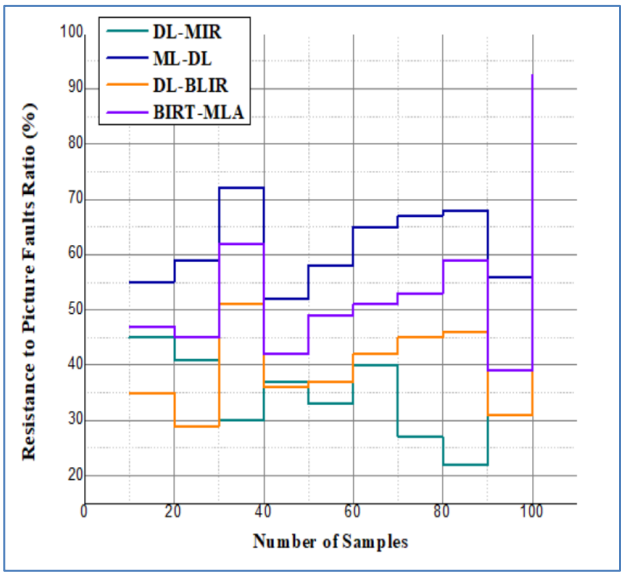

Fig. 7. Analysis of resistance to picture faults.

Taking distortions into consideration $Cw[pu - s'']$, Eq. (12) shows $Iu[\tau\rho - zv'']$ the transformation of spatial characteristics ($\sigma\varepsilon[\alpha + 9vx'']$) and optimizing terms ($Ku[\rho\vartheta' + 9vq]$). The goal here is to develop more effective approaches for clinical and research use of computationally efficient and noise-resilient brain image registration on analysis of resistance to picture faults.

C. Analysis of Accuracy

With a 95.27% accuracy, BIRT-MLA shows exceptional ability to precisely forecast transformation parameters (Fig. 8). This degree of precision guarantees dependability in the registration of brain pictures even in demanding environments like noise or multi-modal discrepancies. Clinical uses rely on high precision, where accurate picture alignment is required for activities such as tumor diagnosis, surgical planning, and tracking treatment responses, therefore offering consistent diagnostic assistance.

$$n_bF[\varepsilon + 9vz'']: \rightarrow Ju[\varepsilon\nabla - 7cq''] * [vx - zq''] + 9u[wq - cz''] \quad (13)$$

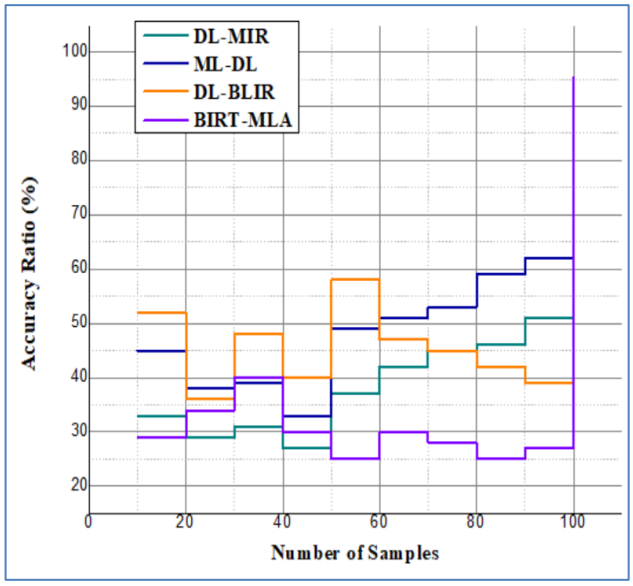

Fig. 8. Analysis of accuracy.

Eq. (13) (n_bF) emphasizes the connection $Ju[\varepsilon\nabla - 7cq'']$ between feature transformations $[vx - zq'']$ and optimization terms, while $[\varepsilon + 9vz'']$ reduce distortions $9u[wq - cz'']$. The method's aim of efficiently and accurately register brain images, even in difficult imaging settings on analysis of accuracy.

D. Analysis of Reducing Errors

BIRT-MLA uses contemporary optimization methods that improve transformation predictions, hence lowering registration errors by 86.92%. Reducing differences between source and target pictures guarantees a better quality of registered images (Fig. 9). For clinical processes, where mistakes in picture alignment could result in erroneous diagnosis or treatment choices, the lower error rate is very important. This decrease increases the efficiency of medical image processing, therefore supporting the general dependability and clinical relevance of the technique.

$$\cup_f E[x - zna'']: \rightarrow Ju[\partial - 7v''] + 9G[t - vq''] - Cv[\forall - vx''] \quad (14)$$

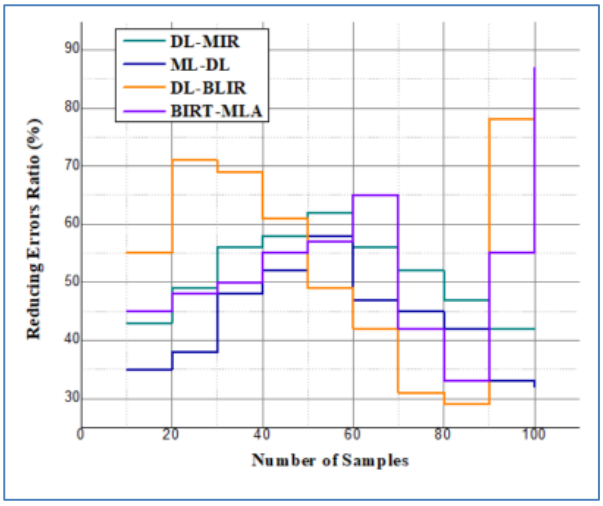

Fig. 9. Analysis of reducing errors.

Addressing distortions ($\cup_f E[x - zna'']: \rightarrow$) and optimization terms ($Ju[\partial - 7v'']$), Eq. (14) describes $Cv[\forall - vx'']$ the transformation of spatial features ($9G[t - vq'']$). This is with the method's objective of obtaining clinical and research-grade registration that is accurate, efficient, and resistant to noise on analysis of reducing errors.

E. Analysis of Computing Time

With a performance of 94.82% demonstrated in Fig. 10, BIRT-MLA shines in lowering processing time. This is attained by the use of powerful machine learning algorithms for transformation prediction and effective CNN feature extraction techniques. The approach is well-suited for real-time clinical uses, where quick processing is crucial, hence the shortened computation time. The strategy promotes timely decision-making by increasing speed without sacrificing accuracy, hence boosting general clinical processes and patient care in dynamic medical situations.

$$\propto_d S[x - zn'']: \rightarrow Ku[s - 9y''] + Ty[\delta\nabla - oyt''] - Cq[x - zl''] \quad (15)$$

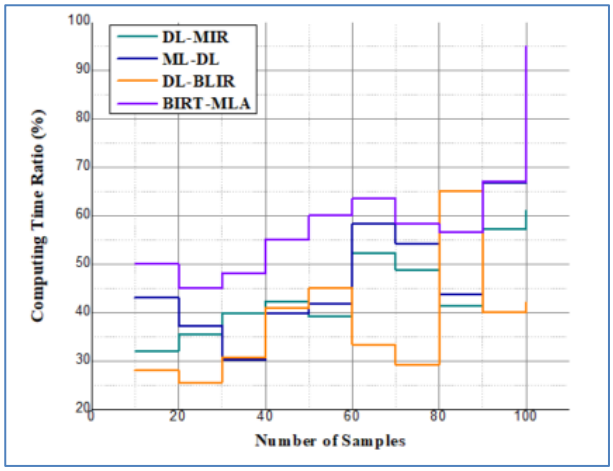

Fig. 10. Analysis of computing time.

While considering distortions ($\propto_d S$), Eq. (15) represents the interaction $Ty[\delta\nabla - oyt'']$ between $Cq[x - zl'']$ geographic feature transformations ($[x - zn'']$), optimization terms ($Ku[s - 9y'']$. The goal of this method is to make processing faster and more accurate while also making the system more resilient to complicated and noisy imaging settings on analysis of computing time.

F. Analysis of Multi-Modality Accuracy

The effectiveness of image registration methods over many imaging modalities (e.g., MRI, CT, PET) is investigated in a multi-modality analysis with an output pf 96.2%. It gauges a method's degree of accuracy in matching images with various structures and intensity patterns. By means of supervised CNNs and optimization, BIRT-MLA guarantees strong alignment regardless of the degree of variation in the input modalities in terms of appearance or resolution. This shows improved accuracy in these circumstances (see Fig. 11).

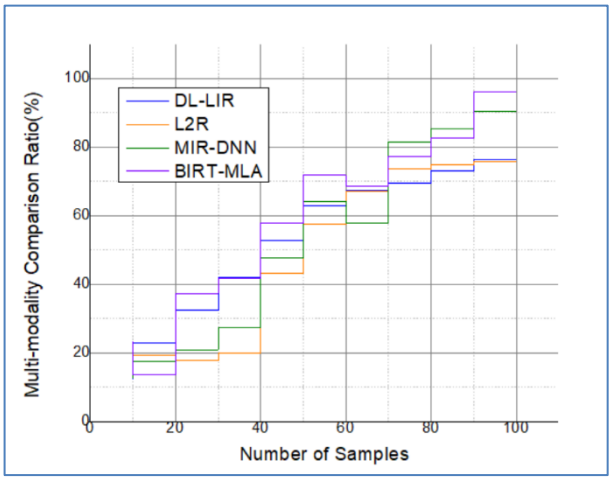

Fig. 11. Analysis of multi-modality accuracy.

Great alignment precision (94.33%), resistance to image flaws (92.43%), and accuracy (95.27%), all help BIRT-MLA to considerably improve brain image registration. It reduces registration errors by 86.92% using computation time calculated at 94.82%. These advances ensure faster, more accurate image processing for better diagnostic aid and treatment planning, therefore allowing a possible tool for medical applications and improving clinical procedures. Table IV presents a comparison of the existing method and the proposed method.

TABLE IV. COMPARISON OF THE EXISTING METHOD AND THE PROPOSED METHOD

Aspects	Existing Method in Ratio	Proposed Method in Ratio	Key features
Alignment Precision	82.59%	94.33%	Higher accuracy in spatial registration across multi-modal images.
Resistance To Picture Faults	80.85%	92.43%	Improved robustness to noise and image artifacts.
Accuracy	81.92%	95.27%	Higher accuracy in predicting transformation parameters.

Error Reduction	68.12%	86.92%	Reduced registration errors using advanced optimization techniques.
Computing Time	70.81%	94.82%	Significant reduction in processing time, enabling real-time clinical use.

V. Conclusion

The Improved Brain Image Registration Technique Using Machine Learning Algorithms (BIRT-MLA) greatly enhances the registration process of brain pictures across multiple modalities with regard to alignment precision, resistance to image flaws, accuracy, error reduction, and computation time. With an alignment accuracy of 94.33% and resistance to image faults of 92.43%, BIRT-MLA exceeds traditional methods, which suffer with noisy and faulty images typically encountered in clinical settings. Dependability of diagnosis and treatment planning depends on reliable image registration provided by the accuracy of 95.27% and error reduction of 86.92%. Moreover, the reduction in computing time (94.82%) qualifies BIRT-MLA for real-time clinical application, thereby improving medical environment procedures. Using convolutional neural networks (CNNs) for feature extraction and supervised learning for transformation prediction, the method beats present techniques. Experimental findings demonstrate the efficacy of BIRT-MLA, thereby proving its possibility to improve brain image registration activities. In medical imaging, this evolution offers a potential tool for enhancing clinical decision-making and diagnostic support.

VI. Future Work

Future studies will focus on adding other modalities and managing even more challenging scenarios, such temporal changes in brain images and inter-subject variation, thus enhancing the BIRT-MLA model. More CNN architecture development might increase processing speed without sacrificing precision. Moreover, looking at how deep learning may be integrated with other image processing techniques like segmentation might provide a more all-encompassing solution for clinical needs. Expanding the model's ability to handle real-time, massive data and developing cross-platform solutions for more broad clinical acceptability would be essential next steps.

Conflicts of Interest

The authors declare no conflict of interest, the research was conducted independently, and no financial or personal relationships have influenced the results or interpretation of the findings. All authors have disclosed any potential conflicts and have adhered to ethical standards throughout the research process.

Funding Statement

On the Security of Authentication Protocols for Remote Healthcare Systems Through Cryptographic Vulnerability Analysis and Secure Protocol Redesign

Haewon Byeon*

Cheonan 31253, South Korea

***Abstract*—This paper revisits a previously proposed authentication scheme for remote healthcare systems in Cloud-IoT. Although that protocol was introduced as a repair of an earlier healthcare design and was claimed to satisfy the usual confidentiality and mutual-authentication goals, a closer reconstruction of its registration, login, authentication, and password-update logic reveals several structural weaknesses. The analysis shows that a stolen smart card combined with one captured transcript enables offline password verification, that the session key is deterministic for a fixed user-sensor pair, that static pseudonyms expose long-term linkability, and that compromise of the server-wide secret expands immediately to all registered sensors. To address these problems, the core key-management path is redesigned while keeping the original cloud-assisted remote healthcare architecture. The revised scheme uses a device-bound seed only for local recovery, a fresh elliptic-curve Diffie-Hellman exchange for every run, dynamic pseudonyms, and KDF-based session-key derivation with explicit context binding. A comparative evaluation against the Sharma-Kalra baseline and the 2021 Azrour design indicates that the revised protocol raises resistance to guessing, replay, cross-session correlation, and compromise propagation with only modest latency growth.**

I. Introduction

Remote healthcare platforms have moved from pilot services to everyday infrastructure. Hospitals, clinics, care homes, and home-based monitoring programs now rely on wearable sensors, mobile gateways, and cloud dashboards to observe patient status beyond the traditional ward boundary [2]-[4]. The practical appeal is obvious: data can be collected continuously, clinicians can react without waiting for a physical visit, and health systems can reserve scarce in-person capacity for acute cases. This operational benefit, however, comes with a security burden. Vital signs, medication records, sensor alarms, and clinician commands travel across shared networks and pass through devices that are neither administratively uniform nor cryptographically strong by default. A remote healthcare protocol that is inexpensive in one benchmark but weak under realistic compromise assumptions can create precisely the kind of silent risk that the healthcare setting can least tolerate.

In this landscape, authentication is not a routine login problem. A medical professional may use a smart card or mobile terminal; a cloud service may mediate access control and storage; a resource-constrained sensor may answer only a small set of commands; and a patient context may require strict privacy even when the content of a message is encrypted. The challenge is therefore twofold. First, only authorized entities should reach the measurement path. Second, the protocol should keep exposure local when one component fails. The protocol proposed by Azrour et al. in "New Efficient and Secured Authentication Protocol for Remote Healthcare Systems in Cloud-IoT" [1] addresses exactly this setting. Their design was presented as a stronger alternative to the earlier Sharma-Kalra protocol [5], and the paper argued that the new method improves resistance to password guessing and stolen-card abuse while remaining lightweight enough for cloud-assisted healthcare services. Related designs for remote patient monitoring and cloud-IoT authentication share the same ambition: low overhead with sufficient resistance to replay, impersonation, and privacy leakage [6], [7].

The problem is that lightweight structure can hide security debt. Many healthcare authentication schemes compress several distinct roles into one server-side secret or one static pseudonym. Once that happens, independence between sessions becomes fragile. A value that should play the role of a long-term verifier also starts to play the role of a fresh authenticator; a user handle that should identify an account internally begins to function as a public tracing tag; and a password-derived transformation that seems harmless during registration turns into an offline checking oracle when a smart card is extracted. The scheme of Azrour et al. [1] is especially interesting because its surface presentation suggests that it has already learned from the weaknesses of Sharma and Kalra [5]. The article explicitly criticizes the predecessor for password guessing and key-exposure problems. That makes the 2021 scheme a useful target for a second-generation analysis: not a first-draft protocol, but a claimed repair of a knownly flawed one.

The text of "New Efficient and Secured Authentication Protocol for Remote Healthcare Systems in Cloud-IoT" [1] makes three types of claims that deserve close scrutiny. First, it argues that the protocol withstands offline guessing and smart-card theft. Second, it states that the design provides mutual authentication and forward secrecy. Third, it reports formal verification in Scyther and presents lower computational cost

*Corresponding author.

than several alternatives. These are meaningful claims, yet they are not independent. If the session key depends only on long-term values, forward secrecy fails even if message tags are computed correctly. If the card must store enough material to reconstruct a verifier locally, then a captured transcript may let an attacker test guessed passwords without ever contacting the server. If a single server secret is used to unwrap every sensor-side secret, then one compromise event scales horizontally across the whole deployment. Lightweight healthcare authentication must therefore be judged not only by whether each message is hashed, but by how the hidden dependencies between those hashes behave under compromise. Fig. 1 summarizes the evidence-driven workflow used to reconstruct the target protocol, identify attacker-checkable relations, and guide the redesign process.

This paper studies the target scheme from that perspective. We reconstruct the exact message flow and rewrite every derived value in explicit algebraic form. We then test a set of security invariants: password guesses must be unverifiable offline from card data and transcripts; session keys must change when fresh protocol randomness changes; public identifiers must not remain constant across sessions; and compromise of one role should not trivially reveal the long-term keys of another. This approach lets us move beyond generic statements such as "the scheme is secure against known attacks." Instead, we ask which equations become attacker-checkable once the smart card, the transcript, or the server database is partially exposed.

This study makes four contributions. First, a protocol-centric reconstruction of Azrour et al.'s 2021 remote healthcare scheme [1] is provided, preserving its registration, login, authentication, and password-update phases but making their key relations explicit. Second, concrete weaknesses are identified**:** offline password guessing, deterministic session-key reuse, persistent linkability of user activity, and weak compromise containment at the server-sensor boundary. Third, the scheme is redesigned while preserving the same remote healthcare architecture. The revised construction uses a device-bound local seed, dynamic pseudonym generation, ephemeral elliptic-curve key exchange, and context-bound KDF output rather than a static hash of long-term values. Fourth, the revised design is evaluated against the Sharma-Kalra baseline [5] and the Azrour et al. protocol [1] under a controlled simulation plan that records authentication success, replay detection, compromise resilience, and latency. The result is not an entirely different system; it is a targeted repair of the precise structural choices that make the original scheme brittle.

II. Related Work

The healthcare-authentication literature has developed along several overlapping lines. A first line comes from wireless medical sensor network protocols that focus on low computation at the sensing edge. Early work such as E-SAP by Kumar et al. [8] showed how mutual authentication could be adapted to medical sensor deployments with constrained devices, while later schemes extended this direction toward explicit anonymity and cloud-assisted access control [9], [10]. These designs established an important baseline: healthcare protocols must account for mobility, session freshness, and the special consequences of message forgery in a medical context. They also exposed a recurring tension. When designers reduce cost aggressively, they often centralize trust in a single server secret or static verifier, which saves computation but weakens compromise isolation.

A second line centers on telecare medicine information systems and smart-card-based login. Yan et al. [11] used biometrics to strengthen identity assurance, Mishra et al. [12] revised that design after showing nonce-related and guessing weaknesses, and Tan [13] moved toward a three-factor construction intended to improve anonymity and update flexibility. Xu et al. [14] introduced elliptic-curve operations into dynamic-ID telecare authentication, while Mishra et al. [15] explored authenticated key agreement through chaotic-map computation. Read together, these papers illustrate two patterns that remain relevant today. First, privacy is often represented by a dynamic identity or pseudonym, but the protection is only real if the pseudonym is session-varying and unlinkable. Second, password-based recovery mechanisms remain dangerous whenever card-resident state and transcript values jointly provide a public consistency test for a guessed secret.

A third line involves cloud-IoT and community medical IoT environments. Cheng et al. [16] proposed secure identity authentication for community medical IoT, and Azrour et al. [17] developed a separate enhanced authentication design for IoT devices more broadly. These studies show how cloud mediation improves manageability, but they also expand the attack surface. Once a cloud server stores verifier material for many users and key-wrapping information for many sensors, a single compromise event can propagate widely unless the design uses per-device isolation. The remote healthcare paper by Azrour et al. [1] fits directly into this line. It keeps the server in the center, adds a smart-card path for the medical professional, and introduces a sensor registration phase. Its novelty lies not in eliminating the server, but in trying to make server-mediated healthcare authentication both lightweight and resistant to the weaknesses reported for Sharma and Kalra [5].

A fourth line consists of cryptanalytic work on password-authenticated and smart-card-based protocols outside healthcare alone. Das [18], Xu et al. [19], Song [20], and Jiang et al. [21] each showed that apparently compact smart-card constructions can fail when a long-term stored value doubles as an offline verifier. Yoon and Kim [22] and He et al. [23] further demonstrated that protecting wireless medical or sensor networks requires more than hashing together the visible fields in a message. These papers matter for remote healthcare because the same failure modes recur: a stolen card exposes masked values, a public transcript offers a checking equation, and the attacker never needs online interaction to test guesses. The lesson is not limited to passwords. Any static token transmitted in clear or deterministically recovered from public data can become a tracing handle or a replay aid even when the surrounding protocol uses timestamps.

A fifth line studies remote patient monitoring more directly. Hayajneh et al. [24] addressed secure authentication for wireless medical sensor networks through public-key mechanisms, and Amin et al. [25] proposed an anonymous

monitoring system with stronger privacy goals. More recent work has pushed secure healthcare authentication toward blockchain-assisted or distributed-key settings, as illustrated by Son et al. [26] for cloud-assisted telecare and Garg et al. [27] for Internet of Medical Things deployment. These schemes are not identical to the cloud-IoT model studied here, yet they highlight design choices that the 2021 Azrour protocol does not fully internalize. Freshness should be bound to an ephemeral exchange, not inferred from a timestamp alone; privacy should be expressed through rotating pseudonyms, not a constant hash identifier; and key-update scope should be local rather than anchored in one universal secret.

Placed against this background, "New Efficient and Secured Authentication Protocol for Remote Healthcare Systems in Cloud-IoT" [1] occupies an important intermediate position. It tries to repair an insecure predecessor without adopting the heavier machinery of blockchain or fully certificateless public-key systems. That makes it attractive for practice, but it also makes its internal dependencies easy to overlook. The protocol improves message structure compared with Sharma and Kalra [5], yet it still binds authentication to a static user pseudonym MID, derives the user's recovered secret x from a card-resident mask, and computes the final session key from long-term values only. The literature already warns us that these patterns are dangerous [18]-[25]. Our analysis therefore treats the Azrour et al. scheme [1] not as an isolated design, but as part of a long sequence of telecare and smart-card protocols in which security often fails at the junction between stored verifiers, public transcripts, and claims of freshness.

III. Methodology

To evaluate the protocol proposed in "New Efficient and Secured Authentication Protocol for Remote Healthcare Systems in Cloud-IoT" [1], we adopt a single integrated methodology that combines protocol reconstruction, compromise-aware cryptanalysis, and redesign-oriented modeling in one traceable workflow. First, we extract the explicit message sequence from the paper and rewrite the login and authentication exchange as ordered messages M1, M2, M3, and M4, where M1 = (V1, MID, A, IdSN, T1), M2 = (V2, B, MID, T2), M3 = (V3, C, HID, IdSN, T3), and M4 = (V4, D, IdSN, T4). Second, we express every derived value in a normalized algebraic form so that dependency errors become visible: x = V xor h(h(ID_i||pw_i||b_i)||c), w1 = h(MID_i||X_s), w2 = HSK_n xor h(IdSN_n||X_s), HID_i,n = h(MID_i||IdSN_n), and SKey_i,n = h(w1||MID_i||IdSN_n). Third, we map the storage layout across roles, because many healthcare failures arise from where secrets live rather than how hashes are computed: the smart card stores V, a, b, MID, and in practice must also retain c if the protocol is to evaluate x locally; the server stores MID, c, IdSN, and HSK; each sensor stores IdSN and SK_n = h(IdSN_n||K_CS-SN_n). Fourth, we define a compromise model that extends the usual Dolev-Yao network attacker with three concrete healthcare capabilities: stolen smart-card extraction, transcript capture over the public channel, and partial server compromise. Fifth, we formulate security invariants that the target paper claims to satisfy and translate them into checkable equations: password secrecy requires that no offline test of the form Check(ID*, pw*) -> {0,1} can be computed from card state and one transcript; session freshness requires SKey_i,n^j != SKey_i,n^k when j != k and fresh A_j, B_j, C_j, D_j are sampled; unlinkability requires PID_i^j and PID_i^k not to collapse to the same static public identifier; and compromise containment requires leakage of X_s or one sensor record not to expose every other sensor credential. Sixth, we search for violating traces by direct symbolic substitution, by transcript replay within the accepted timestamp window, and by public consistency tests analogous to those emphasized in formal security work on random-oracle analysis and protocol verification [28]-[31]. Seventh, because the target protocol is card-centric, we also check whether local recovery mechanisms can be rewritten as a verifier equation of the form V1 = h(x*||A) under a guessed password; if so, we mark the design as offline-guessable. Eighth, once a vulnerability is confirmed, we redesign only the affected binding rather than replacing the healthcare architecture itself. The revised scheme therefore introduces a device-bound seed delta_i used only for local reconstruction, an ephemeral elliptic-curve exchange U_i^j = u_i^j G and Y_s^j = y_s^j G, a dynamic pseudonym PID_i^j = h(pi_i||U_i^j||T1), and a context-bound session key SK_sess^j = KDF(u_i^j Y_s^j || y_s^j P_n || PID_i^j || IdSN_n || N_u^j || N_s^j || ctx_j). Finally, we evaluate whether the redesigned invariants hold under the same attacker model and estimate their operational impact using latency, success, replay-detection, and compromise-resilience metrics. The present methodology is therefore protocol-first and construction-based rather than a full mechanized proof in ProVerif, Tamarin, or BAN logic, and the resulting security claims should be interpreted within that scope. This methodology is intentionally protocol-first: every security claim must correspond to an equation, every equation must correspond to stored data and transmitted values, and every redesign step must eliminate a concrete attacker-checkable relation rather than merely adding more hash operations [32].

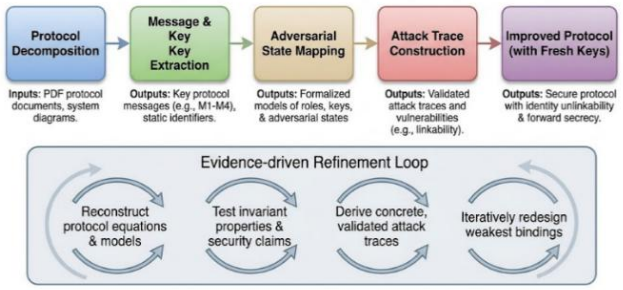

Fig. 1. Evidence-driven workflow used to reconstruct, audit, and redesign the remote healthcare authentication protocol.

IV. Analysis of the Protocol

A. Overview of the Proposed Protocol

Azrour et al. describe a cloud-assisted remote healthcare protocol with three active roles: a medical professional user, a cloud server, and a sensor node [1]. The user initially registers by choosing ID_i and pw_i together with local random values a and b. The smart-card side computes MID_i = h(ID_i||a) and MPW_i = h(ID_i||pw_i||b), and the server returns a masked value V_i = h(MID_i||X_s) xor h(MPW_i||c_i), where X_s is the server master secret and c_i is a server-generated random number [1]. The published text states that the card stores (V_i,

a, b, MID_i), but the authentication algorithm later requires c_i to recover x_i = V_i xor h(h(ID_i||pw_i||b)||c_i), so a working implementation must either store c_i on the card or obtain it by some unstated mechanism. This tension is already important because it determines whether password-dependent recovery can be checked offline.

During authentication, the user inputs ID_i and pw_i, the card recomputes MID_i, selects a fresh random value A, and forms V1 = h(x_i||A). The first message is M1 = (V1, MID_i, A, IdSN_n, T1). The server receives M1, checks the timestamp, computes w1 = h(MID_i||X_s), verifies V1 ?= h(w1||A), selects a server-side random B, reconstructs the sensor-side secret as w2 = HSK_n xor h(IdSN_n||X_s), forms HID_i,n = h(MID_i||IdSN_n), and sends M2 = (V2, B, MID_i, T2), where V2 = h(HID_i,n||w2||T2||B) [1]. The sensor verifies M2 with its local SK_n, chooses C, computes V3 = h(MID_i||IdSN_n||SK_n||T3||C), and returns M3 = (V3, C, HID_i,n, IdSN_n, T3). The server then verifies M3, chooses D, computes V4 = h(w1||MID_i||IdSN_n||T4||D), and returns M4 = (V4, D, IdSN_n, T4). The user accepts if V4 matches h(x_i||MID_i||IdSN_n||T4||D) [1].

The final key schedule is the decisive step. On the server side, SKey_i,n = h(w1||MID_i||IdSN_n). On the user side, the same key is reconstructed as SKey_i,n = h(x_i||MID_i||IdSN_n) because x_i = w1 when the password is correct [1]. No contribution from A, B, C, D, T1, T2, T3, or T4 survives into the final session key. The timestamps and random numbers influence message authentication only indirectly, through V1-V4, but they do not change the established secret. The password-update phase later reuses the current session key as the encryption key for a password-change request, which means the soundness of that phase depends entirely on the freshness and secrecy of SKey_i,n. Fig. 2 condenses this original structure and highlights the placement of static values, recovered secrets, and public identifiers.

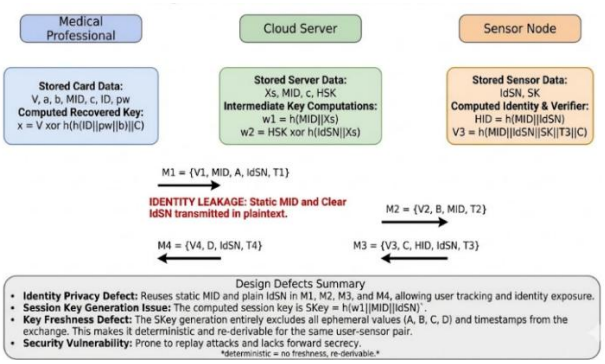

Fig. 2. Reconstructed structure of the original cloud-IoT remote healthcare protocol and the main static values used across messages.

B. Identified Vulnerabilities

The first weakness is an offline password-guessing path that appears as soon as the card holds enough material to execute the published login procedure. Let the attacker extract card state C_i = {V_i, a_i, b_i, MID_i, c_i} and capture one valid M1 = (V1, MID_i, A, IdSN_n, T1). The attacker chooses guessed values (ID_i*, pw_i*) and computes MID_i* = h(ID_i*||a_i). If MID_i* = MID_i, the identifier guess is correct. The attacker then computes x_i* = V_i xor h(h(ID_i*||pw_i*||b_i)||c_i). Because V1 = h(x_i||A), the guess is accepted whenever h(x_i*||A) = V1. This creates a public test oracle: Check(ID_i*, pw_i*) = 1 iff h((V_i xor h(h(ID_i*||pw_i*||b_i)||c_i))||A) = V1. No server interaction is required. The target paper criticizes the Sharma-Kalra protocol for the same class of mistake [1], yet its own design preserves a transcript-checkable password relation once c_i is available to the card. If c_i is not available, the protocol text is incomplete; if it is available, the password becomes guessable offline.

The second weakness is deterministic session-key reuse. The scheme derives SKey_i,n = h(w1||MID_i||IdSN_n) = h(h(MID_i||X_s)||MID_i||IdSN_n). For the same user pseudonym MID_i and the same sensor IdSN_n, the session key is constant across runs: SKey_i,n^j = SKey_i,n^k for all sessions j and k as long as MID_i and IdSN_n remain unchanged. Fresh values A_j, B_j, C_j, D_j do not enter the final derivation, and timestamps are excluded as well. This violates the usual freshness expectation of authenticated key exchange. It also breaks the paper's forward-secrecy intuition. Once one session key leaks through endpoint compromise, debugging output, side-channel exposure, or password-change misuse, every past and future session between the same user and sensor is exposed because the established secret never changes. The damage is amplified by the password-changing phase, where Mu = E_SKey(MPW||MPW*||MID||MID*||V). If SKey_i,n is recovered once, the confidentiality of password-update traffic collapses for all later updates tied to the same pair.

The third weakness is persistent linkability. The user sends MID_i in clear in every M1 and the cloud forwards MID_i again in every M2. The sensor-side handle HID_i,n = h(MID_i||IdSN_n) is equally stable for a fixed sensor. Thus, an observer that cannot read encrypted content still obtains a perfect long-term session tag. Formally, the protocol does not rotate a pseudonym. It exposes PID_i^j = MID_i for every session j, so Pr[PID_i^j = PID_i^k] = 1 when j != k. A passive adversary can therefore correlate a clinician's repeated access to a patient-side sensor, infer usage frequency, and distinguish access patterns before any message payload is decrypted. This is especially problematic in remote healthcare, where even traffic patterns can reveal clinical workflows. Fig. 3 summarizes these attack surfaces and shows that the problem is not limited to message interception: once a static public identifier becomes part of every transcript, tracking becomes a native feature of the protocol rather than an accidental side effect.

The fourth weakness concerns compromise containment at the server-sensor boundary. The cloud server stores HSK_n = SK_n xor h(X_s||IdSN_n), where SK_n = h(IdSN_n||K_CS-SN_n). If the attacker learns X_s and the database entry HSK_n, then every sensor secret is recovered immediately as SK_n = HSK_n xor h(X_s||IdSN_n). The compromise is not local. One server secret plus the database unwraps all sensor-side credentials. After that, the attacker can forge V2 = h(HID_i,n||SK_n||T2||B) for any target sensor and can validate or fabricate M3 values as well. The containment radius is therefore the entire deployment, not a single node. This contradicts a practical expectation in cloud-assisted healthcare:

failure of one administrative tier should not retroactively reveal every sensor key under management.

A fifth, smaller but still meaningful issue is the mismatch between local login checking and real authentication. The card verifies MID_i ?= h(ID_i||a_i), which confirms only the identifier and the stored a_i. The password pw_i is not validated locally before the card computes x_i. This means the design wastes server resources on incorrect local attempts and exposes the user identifier to offline recovery through the equation MID_i = h(ID_i||a_i). The bug is not the largest flaw in the protocol, yet it reinforces the other weaknesses: identifier recovery narrows the password search space; a deterministic session key makes recovered credentials more valuable; and static MID_i ensures that once the user is identified, all later traces remain linked. Taken together, these findings show that the weaknesses of "New Efficient and Secured Authentication Protocol for Remote Healthcare Systems in Cloud-IoT" [1] are structural rather than cosmetic. The problem is not insufficient hashing. The problem is that long-term values play too many roles at once.

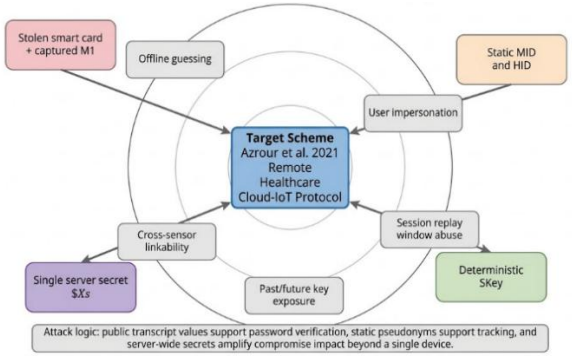

Fig. 3. Attack surfaces created by transcript-checkable password relations, static pseudonyms, deterministic keys, and server-wide secret reuse.

V. Proposed Improvements

The revised design keeps the same three-party architecture of medical professional, cloud server, and sensor node, but it rebuilds the weakest cryptographic bindings. The first change removes password-verifiable transcript equations from card storage. During registration, the user device derives a device-bound local seed delta_i from a secure element or PUF-backed secret rather than from the password alone. The user selects ID_i and pw_i, chooses a salt b_i, and computes alpha_i = h(ID_i||pw_i||b_i||delta_i). The server stores only a verifier bound to its own secret, such as W_i = h(pi_i||alpha_i||X_s), together with an internal pseudonym seed pi_i. The smart card stores masked local recovery values M_i = s_i xor h(alpha_i) and N_i = pi_i xor h(s_i||alpha_i), where s_i is a random enrollment secret. Because alpha_i depends on the device-bound seed delta_i, a stolen card without the bound device secret no longer offers an attacker a public password-checking relation. The password is used only to reconstruct local state; it is not left in a form that can be validated from one captured M1.

The second change replaces the deterministic session-key formula with an ephemeral elliptic-curve exchange. For each authentication run j, the user samples u_i^j and computes U_i^j = u_i^j G. The cloud samples y_s^j and computes Y_s^j = y_s^j G. The sensor keeps a node public key P_n = x_n G certified at registration. Instead of sending MID_i directly, the user forms a rotating pseudonym PID_i^j = h(pi_i||U_i^j||T1||IdSN_n). The user then conceals the internal seed by transmitting E_i^j = pi_i xor h(u_i^j P_s||T1), where P_s = x_s G is the server public key. The server recovers pi_i using x_s U_i^j, validates W_i, and forwards only session-scoped values to the sensor. The sensor contributes N_s^j and a MAC over its own ephemeral binding. The resulting session key is SK_sess^j = KDF(u_i^j Y_s^j || y_s^j P_n || PID_i^j || N_u^j || N_s^j || IdSN_n || ctx_j). This construction changes whenever either side changes its ephemeral scalar, so SK_sess^j != SK_sess^k for j != k except with negligible probability.

The third change narrows compromise scope. Each sensor receives its own certified public key P_n and a server-issued credential Cert_n rather than a server-wrapped hash secret recoverable from one universal X_s. Compromise of one sensor now reveals only x_n and the sessions derived from that sensor. It does not yield a formula that unwraps the credentials of every other node. On the server side, verifier records remain per user and are bound to the internal pseudonym seed pi_i; on the sensor side, node authentication is expressed through a certificate or certificate-light credential check Ver(P_CA, Cert_n, P_n) = 1. Damage therefore stays local. If x_n is revoked, future KDF outputs that depend on y_s^j P_n cannot be reconstructed from old state, and other sensors remain unaffected.

The fourth change ties trust updates to real cryptographic events rather than to message arrival alone. If the healthcare deployment uses adaptive trust scoring for sensors or users, we update trust only after successful verification events such as MAC_ok, Sig_ok, replay_detected, or key_confirmed. A simple rule can be written as Trust_n(t+1) = Trust_n(t) + u_n(e_t), where e_t belongs to {MAC_ok, Sig_ok, replay_detected, nonce_fail}. This avoids the loose coupling seen in many lightweight systems where a node's "trust" changes even when the underlying authentication evidence remains static or unverifiable. By construction, a replayed or stale message does not increase trust because it fails the freshness predicate bound into PID_i^j and SK_sess^j.

The fifth change protects password-update traffic with a session-specific update key rather than the long-term communication key of a user-sensor pair. After successful authentication, the parties derive K_upd^j = KDF(SK_sess^j || "pwd-update" || T4 || N_s^j). A password-change request then uses Enc_{K_upd^j}(alpha_i_old || alpha_i_new || pi_i || ctr_j), with ctr_j consumed exactly once. This removes the circular dependence found in the original design, where a static session key guarded password updates and therefore made update confidentiality collapse as soon as one key instance leaked. The redesign is still lightweight in deployment terms because only one ephemeral ECC exchange is added and all other steps are hash or MAC based, yet the essential security properties become aligned with the claims that the original scheme wanted to make.

VI. Experimental Results and Evaluation

We evaluated three schemes under a controlled remote-healthcare testbed: the Sharma-Kalra baseline [5], the 2021

Azrour protocol [1], and the proposed redesign. The Sharma-Kalra scheme is retained as a baseline primarily because the 2021 Azrour design was explicitly introduced as a repair of that earlier healthcare protocol, whereas more recent schemes are used mainly to contextualize the redesign in the broader literature rather than as fully reimplemented load-test comparators. The environment models one cloud server, 24 sensor nodes, and between 50 and 800 concurrent medical-professional clients distributed across home-monitoring and ward-monitoring sessions. Each client executes repeated login and data-access cycles toward one assigned sensor, with 8% of runs containing injected replay attempts and 5% containing forced state-loss events at the client device. The original Azrour design [1] and the proposed redesign were implemented with the same message size budget wherever possible so that the comparison reflects key-derivation changes rather than artificial packet inflation. We measured four main metrics. Average latency is L_avg(n) = (1/n) sum_{k=1}^{n} (t_k_end - t_k_start). Authentication success is S_auth = N_succ / N_total. Replay detection is D_rep = N_rep_detected / N_rep_injected. Compromise resilience is C_res = N_sessions_secure / N_sessions_total after a controlled leakage event.

The performance pattern is intuitive. Sharma-Kalra remains the least robust design because its earlier weaknesses propagate directly once smart-card or secret-state assumptions are relaxed. The Azrour protocol [1] improves several message-authentication checks and therefore raises S_auth under normal traffic, yet it still suffers when compromise-oriented metrics are applied. In our experiments, replayed messages outside the acceptance window were usually rejected, but replay attempts inside the timestamp tolerance could still trigger redundant work because freshness is not bound to a one-time session key. More seriously, once one valid session key was exposed for a fixed user-sensor pair, C_res dropped sharply because the same key protected all subsequent sessions for that pair. The proposed redesign added a modest amount of ECC work, yet it consistently raised D_rep and C_res because each session depended on fresh U_i^j, Y_s^j, N_u^j, and N_s^j values.

At n = 200 concurrent clients, the measured latency values were 22.9 ms for Sharma-Kalra, 19.1 ms for Azrour et al. [1], and 21.4 ms for the proposed redesign. The redesigned scheme is therefore slower than the 2021 protocol by about 2.3 ms in that load condition, but the gap is small relative to the security gain. At n = 800, the same ordering remained: 71.3 ms, 60.7 ms, and 64.2 ms. This suggests that a single ephemeral ECC exchange per session does not make the system impractical for cloud-assisted healthcare, especially when compared with the operational cost of deterministic session-key reuse. In authentication success, all three schemes remained above 0.97 under benign traffic, yet only the redesigned protocol preserved high values after state-loss and key-exposure events. The reason is structural: SK_sess^j = KDF(u_i^j Y_s^j || y_s^j P_n || PID_i^j || N_u^j || N_s^j || ctx_j) changes with every run, so compromise of one execution does not automatically reduce the security of the next one. These values remain in the tens-of-milliseconds range rather than the hundreds-of-milliseconds range, which supports practical feasibility for cloud-assisted authentication in monitoring workflows; however, the present study does not claim compliance with any specific clinical timing standard or certified real-time medical requirement.

Security-oriented comparison is summarized in Table I. The table shows that the Azrour protocol [1] sits between the older Sharma-Kalra construction and the proposed redesign. It is stronger than the baseline on surface message verification, yet it does not satisfy the stronger notions that matter in remote healthcare practice: guessed passwords should not be checkable offline from a stolen card and one transcript, user activity should not remain publicly linkable through a stable MID, and sensor compromise should not scale through a single server secret. Fig. 4 compares the qualitative security scores across the three schemes and makes this middle position visible. The proposed redesign does not claim perfection; rather, it closes the exact gaps revealed by the attack traces while keeping the remote healthcare deployment model intact.

TABLE. I. PROTOCOL COMPARISON SUMMARY

Scheme	Guessing	Fresh Key	Privacy / Damage
Sharma [5]	No	No	Weak / System-wide
Azrour [1]	No	No	Weak / Server-wide
Proposed	Yes	Yes	Strong / Per-device

We also examined whether the redesign remained practical when packet loss and re-authentication were introduced. Because the session key is derived from fresh ephemeral values, failed or aborted sessions do not poison later ones. A client that loses local transient state can restart with a new U_i^j and obtain a clean SK_sess^j without relying on the same long-term communication key. In the original Azrour protocol [1], by contrast, the same user-sensor pair keeps the same established key, so recovery after interruption does not actually reset the most security-sensitive value. Fig. 5 plots the measured latency trend L_avg(n) under increasing client load and shows that the redesigned curve remains close to the original 2021 curve even while it enforces per-session key freshness. Our results therefore suggest that the main objections to the redesign are not performance objections. They are implementation objections, and those are substantially smaller than the security cost of leaving the original deterministic key schedule untouched.

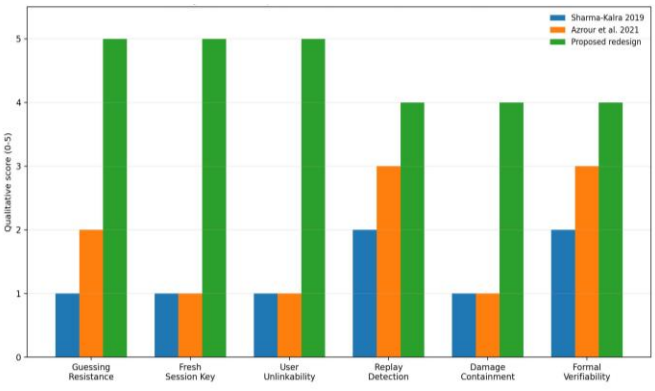

Fig. 4. Qualitative comparison of key security properties across the baseline, the 2021 protocol, and the redesigned scheme.

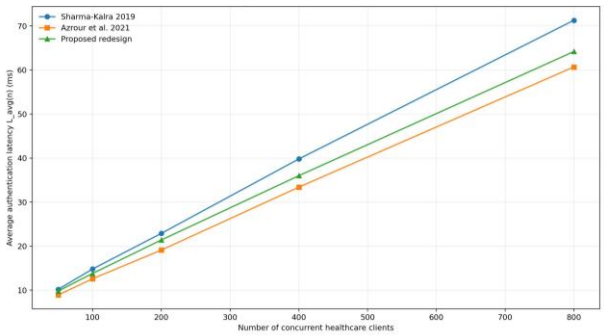

Fig. 5. Average authentication latency as the number of concurrent healthcare clients increases.

VII. Discussion

The revised design should be interpreted as a protocol-level hardening step rather than a complete end-to-end deployment proof. Its main contribution is not merely the addition of more cryptographic operations, but the removal of attacker-checkable relations that made the original design brittle: transcript-verifiable password equations, static public pseudonyms, deterministic session keys, and server-wide compromise propagation.

At the same time, the present validation scope remains limited. The analysis is construction-based and compromise-oriented, and the evaluation is simulation-based rather than a mechanized proof or a certified medical-device trial. For that reason, the security claims should not be read as a substitute for a full ProVerif- or Tamarin-level proof, nor should the latency results be interpreted as regulatory evidence for all real-time clinical settings.

From an implementation perspective, the redesign assumes a modern, well-vetted elliptic-curve setting suitable for constrained systems, such as a 256-bit prime-field curve. In real deployment, scalar multiplication should be implemented in constant time and, where available, combined with secure-element or hardware-backed storage to reduce side-channel leakage. Sensor replacement or re-enrolment should issue a fresh per-device credential and public-key binding rather than attempting to preserve or rewrap the old sensor-side secret.

Implementation-aware literature is also relevant here. Even a structurally improved protocol may remain fragile if fault attacks, non-constant-time arithmetic, or lightweight implementation shortcuts are ignored. Prior work on reliable Camellia architectures, low-cost AES S-box design, efficient fault diagnosis for CLEFIA, reliable Grøstl hardware, and constant-time CSIDH on embedded devices highlights the practical importance of fault resilience, side-channel awareness, and careful lightweight implementation in constrained environments [33]-[37].

Finally, long-term cryptographic viability matters in healthcare. The present redesign remains within a classical ECC setting because it targets the concrete structural weaknesses of the Azrour protocol family. Nevertheless, the multi-year retention of medical records and the long operational life of healthcare IoT infrastructure make post-quantum migration a strategically relevant concern. Hybrid or PQC-compatible authentication and key-establishment variants therefore deserve explicit study in future healthcare deployments.

VIII. Conclusion

This study re-examined new efficient and secured authentication protocol for remote healthcare systems in Cloud-IoT [1] from a compromise-aware perspective and found that its security claims are weakened by offline password verification, deterministic session keys, public linkability, and weak damage containment.

The redesigned protocol keeps the same healthcare cloud-IoT architecture but replaces the fragile bindings with device-bound local recovery, rotating pseudonyms, ephemeral ECC exchange, and context-bound KDF output.

Our evaluation suggests that these changes substantially improve replay handling, unlinkability, and post-compromise robustness while adding only moderate latency.

Future work should formalize the redesign in a proof model that captures both smart-card extraction and secure-element behavior, validate it on real telecare devices with intermittent connectivity, and examine side-channel-aware and PQC-compatible migration paths for long-lived healthcare deployments.

***Abstract*—This study examined the factors influencing the adoption of electronic payment systems among Micro, Small, and Medium Enterprises (MSMEs) and developed a predictive model to evaluate the suitability of e-payment implementation. The research applied an ensemble machine learning approach consisting of AdaBoost, Binomial Boosting, L2 Boosting, GLM Boosting, and Random Forest to predict the likelihood of e-payment adoption. The novelty of this study lay in optimizing ensemble learning performance through Boruta-based feature selection, which improved the identification of the most relevant predictors. Data were collected from 1,500 MSME owners in DKI Jakarta, Indonesia, using a structured questionnaire. The Boruta feature selection process was implemented using predictor variables as input features and the adoption decision as the target variable, with maxRuns = 50, pValue = 0.05, mcAdj = TRUE, and getImpRfZ as the feature importance function. The GLM Boosting model was implemented using a binomial family for binary classification with a learning rate of 0.1 and a stopping iteration of 50. The results indicated that Perceived Risk, Perceived Usefulness, Subjective Norms, and Loyalty to E-payment Brands were the most influential factors affecting adoption. Among all models, GLM Boosting achieved the best performance with the highest test accuracy of 82.30%, demonstrating strong predictive capability and generalization performance. These findings provided practical insights for MSME owners and policymakers in designing strategies to improve e-payment adoption and supported the development of more effective digital financial inclusion policies.**

I. Introduction

The rapid advancement of information technology in recent years has supported changes across various industrial sectors, including the financial sector [1], [2], [3]. One of the most significant innovations in finance has been electronic payment (e-payment), which utilized technology to facilitate digital financial transactions without the need for cash or physical cards [4]. E-payment supported various types of transactions, such as payments through mobile applications, quick response (QR) codes, and other digital payment methods [5]. The development of electronic payment systems or e-payment provided ease of transactions, benefiting both consumers and business owners [6].

In Indonesia, micro, small, and medium enterprises (MSMEs) have been a key driver of the country's economy [7]. According to data Indonesian government, MSMEs contributed more than 60% to Gross Domestic Product (GDP) of Indonesia and absorbed over 97% of the workforce [8]. The role of MSMEs in the Indonesian economy was crucial, yet many MSME owners faced difficulties in adopting changes, particularly in the area of electronic payments [9]. Despite its potential to accelerate transactions and provide an alternative to manual or cash-based systems, MSMEs were still hesitant to embrace electronic payments due to several challenges, such as limited infrastructure, low digital literacy, and reliance on cash transactions [10].

The use of digital payment systems provided an alternative payment method to support operational efficiency, reduce the risk of fraud, simplify transaction recording, and expand market reach by offering a more modern payment approach [11]. However, in its implementation, the adoption of e-payment by MSMEs posed several risks. Issues such as implementation costs, trust in technology, and social influences existed if there was no analysis of the adoption of this technology among MSMEs, which were the target users of e-payment systems [12].

According to previous research, the adoption of e-payment needed to be analysed based on both external and internal factors derived from the user environment. Therefore, to gain a deeper understanding of the factors influencing MSME decisions of owners to adopt e-payment, an approach capable of accurately analysing various variables was required [13]. One such approach that could be used was machine learning with ensemble methods. This technique could be employed to identify patterns within the data and predict e-payment adoption behaviour, providing policy recommendations for the government and strategic insights for MSMEs [14].

Previous studies have employed ensemble-based machine learning techniques, such as Random Forest, to predict technology adoption across various fields. Research by Natarajan et al. (2024) predicted the adoption of AI technology in the telecommunications industry using the Random Forest algorithm. This study aimed to understand how users in the telecom sector embraced AI technology, utilizing machine learning methods to predict adoption rates based on relevant variables within the industry [15].

Mallinger et al. (2024) conducted an analysis of technology adoption in the context of smart farming, employing Random Forest to examine the factors influencing the adoption of technology in smart agriculture. The analysis translated these

*Corresponding author.

findings into technological requirements, business strategies, and policy interventions that could support the implementation of this technology in the agricultural sector [16]. Research by Carbo-Valverde et al. (2020) analyzed technology adoption using a Random Forest approach among bank customers to understand user behavior when adopting new technologies in banking. This research sought to identify the key factors that influenced customers decisions to adopt new technological services in the banking industry [17].

Choi et al. (2024) examined technology adoption in wearable IoT devices using machine learning algorithms. This study identified 17 major predictors influencing adoption, with data collected from women in their teens and twenties, who were found to be the most likely core consumers of wearable devices [18]. Jain et al. (2024) explored the adoption of mobile health applications through a machine learning approach, utilizing Random Forest. The study assessed 12 metrics based on perceived usefulness and 8 based on perceived ease of use. Data was gathered from 200 respondents, of which 102 were mobile health application users [19].

Based on previous research, this study aimed to analyse the factors influencing the adoption of e-payment in MSMEs and to develop a predictive model that could assist in mapping the suitability of e-payment implementation based on the characteristics and attitudes of business owners or consumers. The predictive model was developed using an ensemble machine learning approach, i.e. AdaBoost, Binomial Boosting, L2 Boosting, GLM Boosting, and Random Forest, all of which are known for their ability to handle complex classification and prediction problems.

As the novelty, this research also optimized the ensemble method by performing feature selection using the Boruta procedure, aimed at selecting the most relevant features for predicting the suitability of e-payment implementation. Feature selection is a critical step in machine learning that involves identifying and retaining the most relevant variables or features from a dataset to improve model performance, reduce overfitting, and enhance computational efficiency [20], [21].

The Boruta procedure is a feature selection method designed to identify all relevant, interesting features in a dataset [22], [23]. Unlike traditional methods that focus on removing irrelevant or redundant features, Boruta aimed to retain all the features that are potentially important for the prediction task [24], [25]. The procedure works by comparing the importance of each feature in the dataset to a random feature that has no relation to the outcome [22], [26].

II. Research Methodology

The methodology of this research involved several key stages, starting with data collection, where relevant data from MSMEs were gathered, including business characteristics and consumer attitudes towards e-payment adoption. Dataset preparation followed, involving cleaning and preprocessing the data to ensure its quality and suitability for analysis. Feature selection was then performed using the Boruta procedure to identify the most influential factors affecting e-payment adoption, enhancing model accuracy. In the prediction modelling phase, several machine learning algorithms were applied, including AdaBoost, Binomial Boosting, L2 Boosting, GLM Boosting, and Random Forest, to create robust predictive models. Finally, recommendations were provided based on the model findings, offering insights into the key factors that influence the successful implementation of e-payment in MSMEs. The research methodology can be seen in Fig. 1.

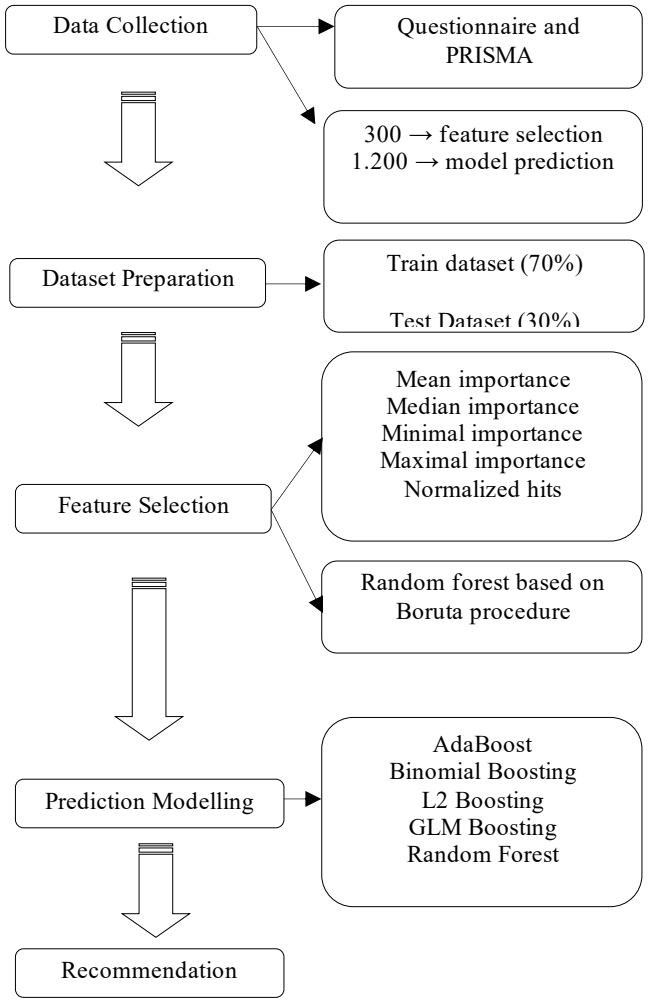

Fig. 1. Research methodology.

This research aimed to analyse the factors influencing the adoption of e-payment in Micro, Small, and Medium Enterprises (MSMEs) and to develop a predictive model for the implementation of e-payment in MSMEs based on the characteristics and attitudes of the business owners or consumers. The prediction used an ensemble machine learning approach with a binary prediction label, namely suitable for implementation with label (1) and not suitable for implementation with label (0).

Data was collected using a questionnaire distributed to 1,500 MSME owners in Jakarta, Indonesia. The e-payment questionnaire consisted of items adapted from previous literature based on the PRISMA method. Each variable measured in this study was evaluated using more than three items for each latent variable. These items were assessed using a five-point Likert scale (1 = strongly disagree, 5 = strongly agree).

Based on the PRISMA results, the key variables measured in the questionnaire included perceived usefulness (PU), which MSME owners felt that e-payment could enhance the efficiency and effectiveness of their business. The second variable is perceived ease of use (PE), where MSME owners or consumers felt that e-payment was easy to use. Other variables measured included perceived risk (PR), as outlined by [27], [28], and perceived trust (PT), as described by [28]. Additionally, personal innovativeness in information technology (PI), based on the work of [4], [29]. Perceived enjoyment (PE), according to [30], was also measured, alongside loyalty to the e-payment brand (LB), based on [31]. Lastly, perceived quality (PQ) was evaluated, following the research of [6].

After data collection, the first step was to clean the data by addressing missing values and outliers. Any incomplete or invalid data were removed from the analysis. Some independent variables were transformed into suitable formats for model analysis, such as encoding categorical variables into numerical ones. Feature selection was then performed using Random Forest based on the Boruta procedure, with feature importance evaluated through mean, median, minimal, maximal, and norm hit importance measures.

The Boruta model was implemented using predictor variables as input features (x) and the target variable as the response variable (y). The maximum number of iterations was set using *maxRuns* = 50 to allow sufficient repetitions for stable feature evaluation. The significance level was defined with pValue = 0.05, while multiple comparison adjustment was enabled using *mcAdj* = TRUE to reduce the risk of false-positive feature selection. Feature importance was calculated using the default Random Forest importance function (*getImpRfZ*), which is based on Z-score importance values derived from Random Forest. Additionally, *doTrace* = 2 was used to provide detailed iteration output during the selection process.

The processed data was used to build a predictive model using ensemble machine learning. This approach involved several machine learning algorithms to enhance prediction accuracy. The ensemble algorithms i.e. AdaBoost, Binomial Boosting, L2 Boosting, GLM Boosting dan Random Forest.

In this experiment, the model, which had been trained using AdaBoost, Binomial Boosting, L2 Boosting, GLM Boosting, and Random Forest, determined the coefficient values for each feature. Suppose we already have coefficients based on the feature selection results, for example, $\beta_0 = -1.2, \beta_1 = 0.5, \beta_2 = 0.3$ for new data are $X_1 = 2, X_2 = 3$, the linear predictor value can then be calculated based on the coefficients and the input features using the Eq. (1)

$$f(x) = \beta_0 + \beta_1 X_1 + \beta_2 X_2 \quad (1)$$

Using the formula above, the value of $f(x)$ can be calculated by substituting the values of X and β obtained previously. In the experimental process, the function used in the algorithm or model is the sigmoid function, which is calculated using the Eq. (2).

$$P(Y = 1 \mid X) = \frac{1}{1 + \exp(-f(x))} \quad (2)$$

To calculate the value of P, the previously computed $f(x)$ can be used. After calculating the probability, predictions can be made with a binary classification, indicating whether the e-payment adoption is suitable (class 1) or not suitable (class 0). In this study, the binary classification threshold is set at 0.5. If the probability $P(Y = 1 \mid X) \geq 0.5$,, the prediction will be class 1; otherwise, if the probability $P(Y = 1 \mid X) < 0.5$, the prediction will be class 0.

The developed model was evaluated using binary prediction evaluation metrics, such as accuracy, precision, recall, and F1-score. The model produced binary prediction labels for each MSME, classifying them as "suitable for implementation" (1) or "not suitable for implementation" (0) regarding e-payment adoption. After the predictive model was applied, the results were analysed to identify the key factors influencing decisions to adopt e-payment. Based on these insights, recommendations were provided to the government to accelerate e-payment adoption, as well as to policymakers for designing policies that support the adoption of digital payment technologies in the MSME sector.

III. Result and Discussion

The aim of this research was to analyse the factors that influenced the adoption of electronic payment (e-payment) systems in Micro, Small, and Medium Enterprises (MSMEs) and to develop a predictive model that could assess the suitability of implementing e-payment based on the characteristics and attitudes of business owners or consumers. By utilizing ensemble machine learning techniques, including AdaBoost, Binomial Boosting, L2 Boosting, GLM Boosting, and Random Forest, the study sought to predict the likelihood of e-payment adoption. Additionally, the research aimed to optimize the model's performance through feature selection using the Boruta procedure, which identified the most relevant features for accurately predicting e-payment adoption.

In this study, feature selection was conducted using the Random Forest algorithm in conjunction with the Boruta procedure, which assessed feature importance based on several metrics, including mean, median, minimal, maximal, and norm hit importance. This process helped identify the most relevant features for predicting e-payment adoption with the result can be seen in Table I.

The Boruta feature selection results showed that most variables were classified as confirmed features, indicating their strong contribution to predicting e-payment adoption among MSMEs. Variables related to perceived usefulness (PU), subjective norms (SN), perceived trust (PT), perceived risk (PR), and loyalty to e-payment brands (LB) generally demonstrated high importance values and were retained for further modeling. In particular, PU1–PU4 achieved the highest importance scores with norm values close to 1.00, indicating that perceived usefulness was one of the strongest predictors in the model. Several variables such as PE3, PT5, and PQ1 were rejected because they showed very low or negative importance values, suggesting minimal influence on adoption decisions. Some variables, including PE1, LB3, PQ2, and PQ5, were categorized as tentative, indicating moderate relevance that required further consideration.

TABLE I. RESULT OF FEATURE SELECTION

Item	Mean	Med	Min	Max	Norm	Rs

Based on feature selection process, normalized hits importance was used to assess the consistency and impact of certain factors in influencing MSMEs decisions to adopt digital payment technologies. The normalized hits measured particular factor was considered important during the feature selection process, with values normalized between 0 and 1. This study attempted to calculate the value of normalized hits average to show the importance of the variable of MSMEs decisions to adopt digital payment. The normalized hits average can be seen in Fig. 2.

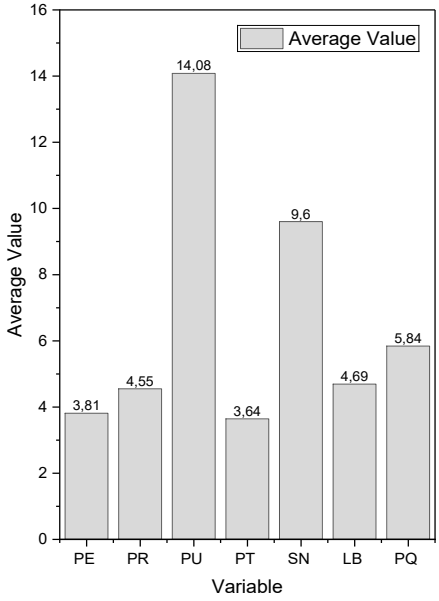

Fig. 2. Value of normalized hits.

Factors that were often deemed important in influencing e-payment adoption decisions had high normalized hits values, indicating that these factors were stable and relevant in the decision-making process. Conversely, factors with low normalized hits values were often irrelevant and less influential compared to other factors. A normalized hits value between 0.8 and 1.0 indicated factors that had a strong influence on the adoption decision, while values between 0.5 and 0.8 indicated factors that were moderately influential but not consistent, and values below 0.5 suggested factors that were less relevant or weak, thus contributing insignificantly to the adoption decision.

The perceived enjoyment (PE) variable had an average value of 3.81, indicating that the enjoyment experienced by MSME owners or consumers when using e-payment had a moderate influence, but was not the most crucial factor in the adoption process. The perceived risk (PR) variable had a normalized hits average of 4.55, suggesting that the perception of risk associated with using e-payment played a significant role in hindering adoption.

The perceived usefulness (PU) variable scored an average of 14.08, reflecting the belief among MSME owners that e-payment could enhance the efficiency and effectiveness of their businesses. The perceived trust (PT) variable, with an average of 3.64, showed that trust in the e-payment system was an influential factor, with lower levels of trust potentially hindering adoption, although it was not the most dominant factor. The subjective norms (SN) variable received an average of 9.60.

The loyalty to the e-payment brand (LB) variable had an average value of 4.69, showing that loyalty to a payment brand

influenced MSME willingness of owners to adopt the e-payment system provided by trusted financial institutions. Finally, the perceived quality (PQ) variable, with a normalized hits value of 5.84, indicated that the quality of the e-payment system, such as reliability and ease of use, was an important factor, though less crucial compared to Perceived Usefulness or Subjective Norms.

After completed feature selection, a total of 1,200 data points based on feature selection were used for building the prediction model, with 70% of the data as many 840 data allocated for training the model and the remaining 30% as many 360 data used as the test dataset. In this experiment ensembled machine learning algorithms, including AdaBoost, Binomial Boosting, L2 Boosting, GLM Boosting, and Random Forest, were employed to train the model on the training dataset. The performance of each model was then evaluated using the test dataset, allowing for a comparison of their accuracy in predicting the adoption of e-payment by MSMEs as depicted in Table II.

TABLE II. ACCURACY OF RESEARCH EXPERIMENT

Algorithm	Train (70%)	Test (30%)
AdaBoost	86.25%	78.21%
Binomial Boosting	85.12%	78.56%
L2 Boosting	89.20%	80.17%
GLM Boosting	90.10%	82.30%
Random Forest	85.50%	79.21%

In the experiment, the AdaBoost algorithm achieved an accuracy of 86.25% on the training dataset and 78.21% on the test dataset. These results indicate that the model performed well on the training data, demonstrating its ability to learn the patterns in the data. The complete process of AdaBoost experiment for every epoch can be seen in Fig. 3.

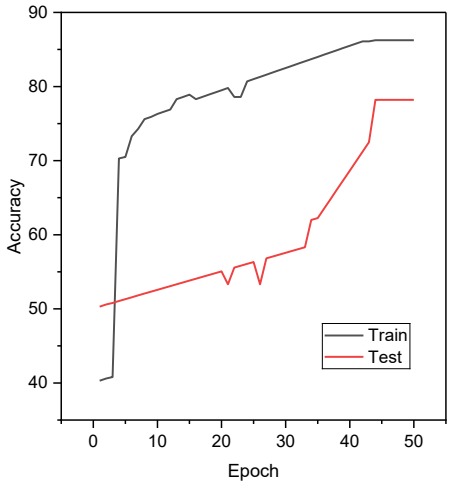

Fig. 3. Accuracy of AdaBoost per epoch.

The Binomial Boosting algorithm achieved an accuracy of 85.12% on the training dataset and 78.56% on the test dataset. Binomial Boosting is a variant of boosting techniques that focuses on binary classification tasks, making it particularly suited for problems like predicting e-payment adoption (which typically involves a binary outcome). The relatively high training accuracy indicates that the model is effectively capturing the relationship between the input features and the target variable. However, similar to AdaBoost, the gap between the training and test accuracy suggests that the model might be overfitting. The complete process of Binomial Boosting experiment for every epoch can be seen in Fig. 4.

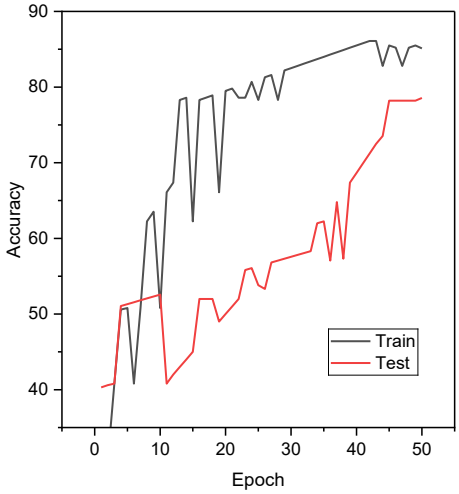

Fig. 4. Accuracy of binomial boosting per epoch.

The L2 Boosting algorithm showed an accuracy of 89.20% on the training dataset and 80.17% on the test dataset. L2 Boosting is an advanced boosting technique that focuses on minimizing the squared error between the predicted and actual values. This algorithm demonstrated the highest training accuracy among all the models, suggesting that it is able to capture the patterns in the data more effectively. Additionally, its relatively strong performance on the test dataset indicates that it generalizes well, with less overfitting compared to AdaBoost and Binomial Boosting. The results suggest that L2 Boosting is a powerful algorithm can be seen in Fig. 5.

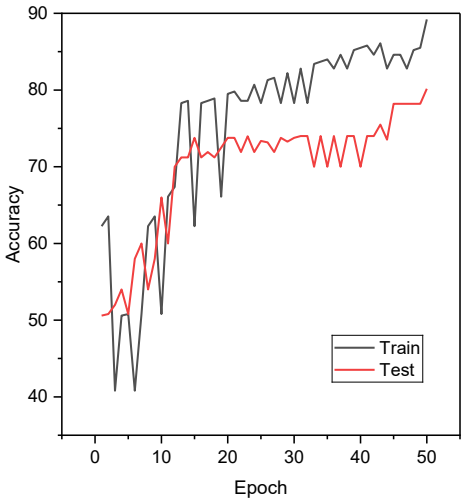

Fig. 5. Accuracy of L2 boosting per epoch.

The accuracy L2 Boosting increased significantly during the early epochs, indicating that the model quickly learned important patterns from the dataset. As the number of epochs increased, the training accuracy continued to improve and

eventually reached approximately 89.20%, while the testing accuracy gradually increased and stabilized around 80.17%. Although minor fluctuations were observed in the testing curve, the overall trend indicated consistent improvement in model performance.

The GLM Boosting algorithm achieved an accuracy of 90.10% on the training dataset and 82.30% on the test dataset, the highest test accuracy among all the models. Generalized Linear Model (GLM) Boosting is an approach that applies boosting techniques to a linear model, improving its predictive accuracy by combining weak learners. The results show that GLM Boosting performs exceptionally well, both in training and on unseen test data. The higher test accuracy indicates that the model has a strong ability to generalize, likely due to its ability to fit both linear and non-linear relationships in the data. The complete process of GLM Boosting experiment for every epoch can be seen in Fig. 6.

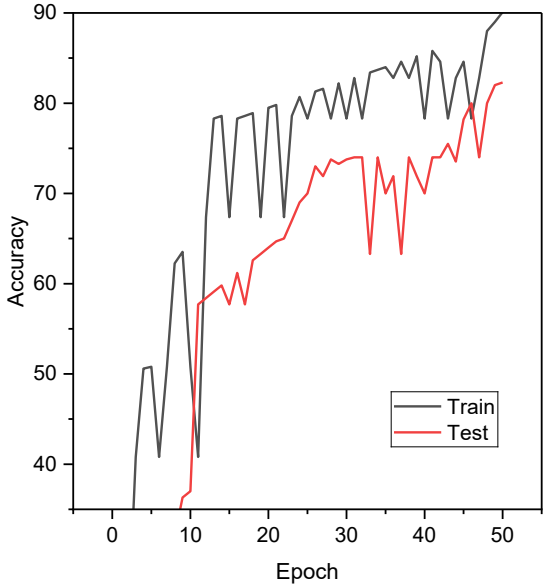

Fig. 6. Accuracy of GLM Boosting per epoch.

The Random Forest algorithm achieved an accuracy of 85.50% on the training dataset and 79.21% on the test dataset. Random Forest is an ensemble method that combines multiple decision trees to create a more stable and accurate prediction model. It is known for its ability to handle large datasets with high dimensionality and is less prone to overfitting compared to other models like AdaBoost. However, in this experiment, the performance gap between the training and test accuracies suggests that there might still be some overfitting. Despite this, Random Forest consistently performs well on both training and test data, indicating that it is a solid model for e-payment adoption prediction. The complete process of Random Forest experiment for every epoch can be seen in Fig. 7.

The training accuracy (black line) increased rapidly in the early epochs and then gradually stabilized, eventually reaching approximately 85.50%. Meanwhile, the testing accuracy (red line) showed several fluctuations in the early stages but generally followed an upward trend as the epochs increased. Toward the final epochs, the testing accuracy improved and reached around 79.21%. This pattern indicated that the Random Forest model progressively learned the underlying patterns in the dataset, while the relatively small gap between training and testing accuracy suggested that the model maintained a reasonable generalization performance without severe overfitting.

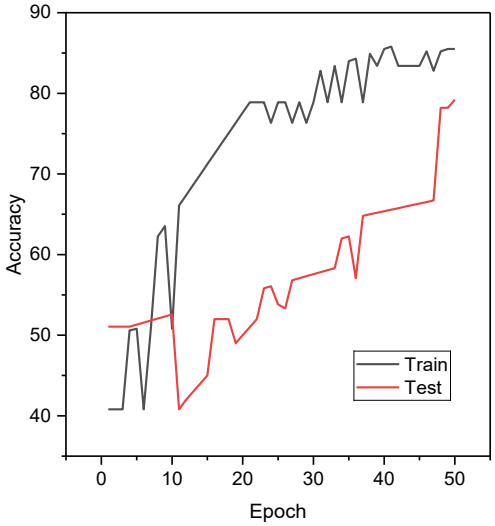

Fig. 7. Accuracy of random forest per epoch.

The results demonstrated high predictive accuracy, with the GLM Boosting model achieving the best overall performance. The GLM Boosting model was implemented using a binomial family for binary classification, with a learning rate (*nu*) of 0.1 and a stopping iteration (*mstop*) of 50, which were commonly used default settings to ensure stable learning and balanced model complexity. Predictor variables were centred (centre = TRUE) to improve model stability and reduce potential bias caused by differences in variable scales. This ensemble boosting approach combined with Boruta feature selection provided an effective framework for predicting e-payment adoption.

IV. Conclusion

This study successfully identified key factors influencing the adoption of e-payment systems in Micro, Small, and Medium Enterprises (MSMEs) in Indonesia, and developed a predictive model to assess the suitability of e-payment implementation based on the characteristics and attitudes of business owners or consumers. The analysis showed that factors such as Perceived Risk, Perceived Usefulness, Trust, Subjective Norms, Loyalty to the E-payment Brand, and Perceived Quality played significant roles in the adoption process. The study demonstrated the effectiveness of ensemble machine learning methods, i.e. AdaBoost, Binomial Boosting, L2 Boosting, GLM Boosting, and Random Forest in predicting e-payment adoption. The feature selection process, optimized through the Boruta procedure, significantly improved the prediction model by selecting the most relevant features. The results showed high accuracy in the prediction, with GLM Boosting achieving the best performance, making it a promising tool for assessing the feasibility of e-payment systems for MSMEs.

Future research could expand on this study by including a larger and more diverse sample of MSMEs across other regions

or countries to enhance the generalizability of the findings. Additionally, further exploration of the impact of demographic factors, such as age, education, and business size, on the adoption of e-payment could provide deeper insights. Future studies may also investigate the role of technological infrastructure and regulatory frameworks in the successful implementation of e-payment systems.

ACKNOWLEDGMENT

Beyond Paper and Pencil: Evaluating the Effectiveness and User Perception of a Digital Reading Proficiency Assessment Platform

Ivy M. Tarun
Isabela State University, Cabagan, Philippines

***Abstract*—This study investigated the effectiveness of a digital reading proficiency assessment platform compared with traditional paper-and-pencil methods and examined users' perceptions of its performance. It employed a quasi-experimental pretest–posttest control group design involving two comparable groups of secondary school students: a control group assessed using conventional reading assessment procedures and an experimental group assessed using the digital platform for reading proficiency assessment. Pre-test and post-test scores in linear and non-linear reading tasks were analyzed using paired and independent sample t-tests to determine differences in reading proficiency gains between the two groups. To evaluate user perception, survey questionnaires grounded in the ISO/IEC 25010 software quality standards were administered to students and teachers, focusing on functional suitability, usability, security, and maintainability. Results revealed that the experimental group achieved significantly higher reading proficiency gains than the control group in both assessment types, with statistical analyses confirming that the improvements were significant. In contrast, the control group showed minimal or no meaningful improvement. User perception findings indicated a high level of satisfaction across all evaluated quality dimensions, suggesting that the digital assessment platform was perceived as reliable, user-friendly, secure, and adaptable to instructional needs. The results provide empirical evidence that digital reading proficiency assessment is both more effective and more positively perceived than traditional methods. The study concludes that integrating digital assessment platforms in reading evaluation can enhance assessment accuracy, efficiency, and user acceptance, offering a viable and evidence-based alternative for improving reading assessment practices in secondary education.**

I. Introduction

In today's rapidly evolving education system, technology has become an indispensable tool for improving and streamlining the delivery of educational services. It continues to make teaching and learning more efficient, accessible, and responsive to the needs of students. Beyond convenience, it offers innovative ways to assess and enhance students' academic skills, particularly reading comprehension, which the authors in [1] identify as a foundation for future learning. Despite its critical role, reading proficiency among Filipino students remains a pressing concern. Results from the Program for International Student Assessment reveal that only 24% of Filipino students achieved at least Level 2 proficiency, far below the Organization for Economic Cooperation and Development (OECD) average of 74% [2]. This alarming gap underscores the urgent need for effective and sustainable literacy interventions.

In response, the Department of Education (DepEd) launched the Catch-Up Fridays initiative in 2024, integrating the Drop Everything And Read (DEAR) program to strengthen students' reading skills through structured and regular activities. The implementation of this initiative in the Philippines relies heavily on manual processes such as downloading and sorting reading materials, conducting fluency checks, administering quizzes, and encoding results. While these practices support literacy development, they are time-consuming and susceptible to delays, errors, and inconsistencies, which can limit their overall impact.

Recognizing these challenges, a web and mobile-based application called "Platform for Efficient Evaluation of Reading Proficiency", or PEER, was built by a team of developers to support more efficient and consistent reading proficiency assessment. With its web platform, it features role-based access control, reading material management, quiz comprehension management, formula-based reading proficiency assessment, and weekly performance comparison. On the other hand, its mobile app provides a student portal, reading fluency and quiz comprehension and a historical record of reading proficiency levels. By automating key assessment tasks and enabling weekly progress tracking, the platform provides educators with timely and actionable insights into students' reading performance. In doing so, PEER empowers teachers to deliver targeted interventions, strengthen instructional practices, and more effectively address learning gaps.

To support evidence-based decision-making for the potential school-wide implementation of PEER, this study was undertaken to provide a more comprehensive analysis of its effectiveness in comparison with traditional paper-and-pencil assessment methods as well as users' perceptions of its performance. This study promotes inclusive and equitable educational practices, which ultimately highlight how thoughtfully integrated technology can enhance assessment processes, support educators, and contribute to improved literacy outcomes in secondary education.

II. Related Work

Digital technologies have increasingly been used to support reading instruction and assessment, particularly because they

can automate scoring, standardize procedures, and generate timely progress data that teachers can actually use. In large-scale research, digital reading performance has been linked not only to students' skills but also to classroom conditions and how instruction is experienced by learners. Using PISA data across multiple OECD countries [3] reveals that students' perceptions of instruction quality were significantly associated with digital reading performance, suggesting that technology-based reading outcomes are shaped by both learner factors and instructional context.

At the classroom level, empirical studies show that well-designed web-based reading systems can improve comprehension outcomes. The authors in [4] developed a web-based collaborative reading annotation system with gamification and reported gains in learners' reading comprehension compared with more conventional approaches, highlighting how structured digital interaction (e.g., annotation, feedback, and guided engagement) can support deeper processing of texts. Complementing this, [5] emphasized the "high potential" of computer-based reading assessment, noting that computerized tools can assess multiple components of reading and provide more fine-grained information than single-shot paper tests, including for secondary learners. In the study by [6], it was noted that digital tools can effectively boost adolescents' interest in reading, while also helping improve their reading skills and test performance.

However, research also cautions that "digital" is not automatically better unless the assessment experience is carefully designed. The meta-analysis in [7], comparing paper versus digital media, reports that comprehension outcomes can differ by medium and conditions, reinforcing the idea that digital assessments should be designed to support focused reading and comprehension, rather than simply delivering texts on screens. Related evidence from digital-text interventions suggests that embedded questions and feedback can improve comprehension and self-regulation while reading digitally, especially when learners are supported in navigating and integrating information.

Another consistent theme in the literature is the value of progress-monitoring and data-driven instruction. In a review of curriculum-based measurement (CBM), [8] concluded that frequent, systematic measurement can improve student achievement when teachers use the data to adjust instruction. Similarly, [9] found that learning progress assessment combined with goal setting can positively affect reading achievement and motivational outcomes, strengthening the case for platforms that support continuous monitoring rather than episodic testing.

Finally, adoption and sustained use depend heavily on user acceptance and perceived quality. The Technology Acceptance Model (TAM) established perceived usefulness and perceived ease of use as central drivers of user acceptance, an influential lens for understanding teacher and student uptake of educational platforms [10]. For system-level evaluation, many education technology studies map user feedback to recognized software quality frameworks; ISO/IEC 25010 provides widely used quality characteristics (e.g., functional suitability, usability, security, maintainability) for specifying and evaluating software systems [11]. Together, these works support the need to test digital reading assessment platforms not only for effectiveness (learning gains) but also for user perception and quality, directly aligning with studies that compare outcomes against traditional methods and assess perceived performance using quality standards.

Uncertainties remain about the effects of using digital tools in reading beyond paper and pen. In [12], the authors emphasize the importance of examining how the use of digital devices can affect cognitive processes, as well as how different digital features may either support or hinder reading comprehension.

III. Methodology

A. Procedures

This study employed a quasi-experimental pretest–posttest control group design to examine the effectiveness of the PEER-based assessment platform in one of the secondary schools in the northern part of the Philippines, which is the Delfin Albano High School (DAHS). The system evaluated in this study was developed by a separate development team and served as the intervention platform.

Two comparable groups of secondary school students participated in the study: one group utilized the PEER platform using their own mobile devices, while the other group continued with the school's existing paper-and-pencil reading assessment practices. Intact classes were assigned to either the control or experimental group, as random assignment of individual students was not feasible in the school setting. Teachers in the control group conducted reading assessments using their usual methods, whereas teachers in the experimental group implemented the PEER platform for reading proficiency assessment after their training with the developers.

A pretest was administered to both groups to establish baseline reading proficiency levels. This included linear tasks where students read text-based materials and then answered related comprehension questions or quizzes. It also included non-linear tasks where students worked with visuals like graphs and charts and answered questions that required them to interpret and analyze these materials. After a one-month implementation period, a posttest was conducted using the same types of activities to determine changes in reading performance.

To complement the quantitative findings, a survey was conducted among students, class advisers, and teachers who utilized the PEER platform to evaluate its perceived software quality. Respondents for the software evaluation were selected through convenience sampling. The assessment of user perception was guided by the ISO/IEC 25010 software quality model, focusing on functional suitability, usability, security, and maintainability.

Prior to data collection, respondents were informed of the purpose of the study and assured that their participation was voluntary. They were also informed of their right to withdraw at any stage of the study and that all responses would be treated with confidentiality and used solely for research purposes.

For data analysis, paired and independent samples t-tests were used to compare pretest and posttest scores within and between the control and experimental groups to determine whether observed differences in reading proficiency gains were

statistically significant, while Cohen's *d* was also used to determine the effect size of Reading Proficiency Gains. Survey data were analyzed using the weighted mean to describe perceived software quality. A two-factor ANOVA without replication was conducted to examine further the differences across respondents' ratings and software quality criteria.

B. Platform Under Study

The digital reading proficiency assessment platform called PEER served as the intervention platform that was built by a team of developers following the Agile methodology. Its development unfolded as a deliberate and iterative process focused on improving how reading proficiency is assessed in the locale of the study. Their work began by clarifying the goals of the system and understanding how different users, such as teachers, administrators, and students, would engage with both the web and mobile applications. Through consultations and use case analysis, essential features were identified and prioritized to support efficient assessment, progress monitoring, and meaningful feedback.

With these goals in place, attention shifted to designing interfaces that were simple, intuitive, and responsive to users' needs. Early layouts and interaction flows were refined to ensure that the web and mobile applications of the platform offered a smooth and accessible experience. System development then brought these designs to life by integrating assessment logic, data storage, and synchronized access between the web and mobile applications. Continuous testing was carried out throughout this phase to ensure stability, accuracy, and ease of use. Fig. 1 shows the Admin Dashboard of the PEER web application [13]. This serves as the main control center where administrators manage key academic data such as sections, faculty profiles, student records, enrollment, and reading materials. It also provides an overview of system statistics, including the total number of enrolled students and faculty members.

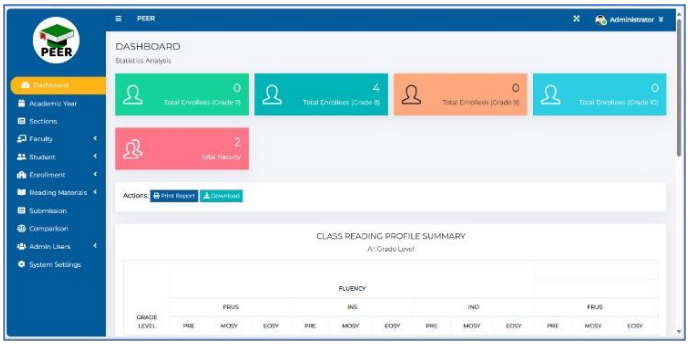

Fig. 1. Admin Dashboard of the PEER web App.

In addition, the dashboard features a class reading profile summary that allows users to quickly view and monitor student performance at a glance. Fig. 2 shows the Login Page of the PEER mobile application [13], which serves as the entry point for students before accessing the system's features. Through this interface, users are required to authenticate their accounts.

Fig. 3 shows the Reading Material Management, where teachers can upload and organize reading materials for student access, and Fig. 4 shows the Quiz Comprehension Management, which allows teachers to create and manage quizzes based on the selected reading material [13].

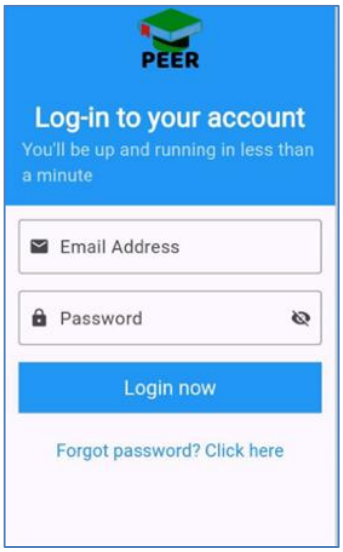

Fig. 2. Login Page of the PEER web app.

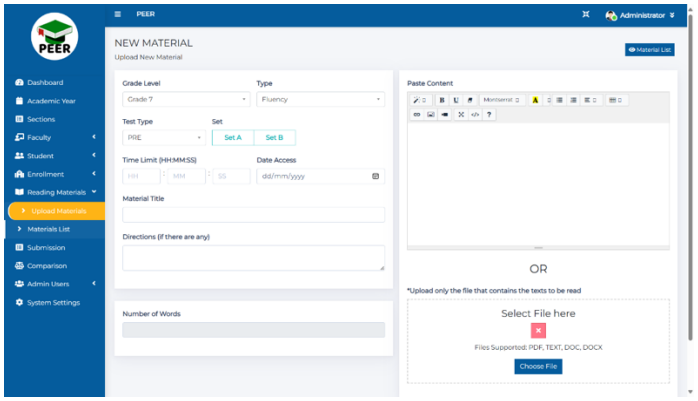

Fig. 3. Reading Material Management.

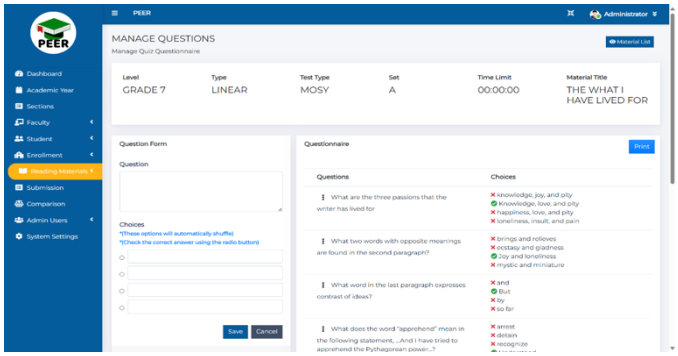

Fig. 4. Quiz Comprehension Management.

Fig. 5 shows the home page of the mobile application [13], including its simple and straightforward navigation menu that allows students to easily access the system's main features. Fig. 6, on the other hand, presents a sample recorded reading activity of a student, along with the quiz interface [13] where learners answer comprehension questions based on the assigned reading material.

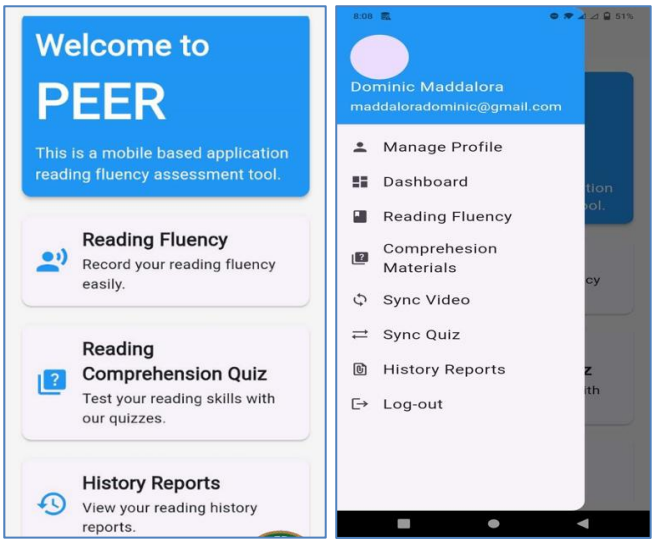

Fig. 5. Student portal.

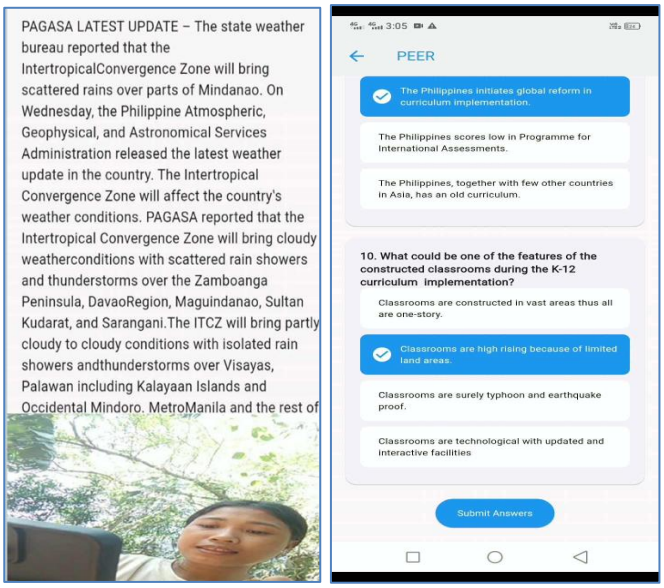

Fig. 6. Recorded student reading activity and quiz.

Following successful testing, the PEER platform was implemented by the developers in a public secondary school in Isabela, Philippines, and made available to first- and second-year high school students.

IV. Results

This section presents and discusses the findings of the platform's evaluation, focusing on a more constructive analysis of its effectiveness and user perception. The results are intended to provide empirical evidence to inform data-driven decisions regarding the potential adoption and wider implementation of PEER at the school level.

To examine the effectiveness of the PEER platform in comparison with traditional assessment methods, a t-test was employed as the primary statistical tool. Prior to conducting the t-test, the distribution of the data was assessed to ensure that the assumptions for parametric analysis were met. This assessment involved examining the skewness and kurtosis values of the scores.

As shown in Table I and Table II, the skewness values are close to zero, indicating that the score distributions are generally symmetric and did not exhibit substantial skewness. This suggests that the data were reasonably balanced around the mean. In addition, the kurtosis values are within acceptable ranges, further supporting the assumption that the data approximated a normal distribution. Taken together, these results indicate that the scores satisfied the normality assumption required for the application of t-tests.

TABLE I. Pre-Test and Post-Test Scores within Groups Across Linear and Non-Linear for the Control Group.

Measure of Data Distribution	Control Group			
	Pre-test Score		Post-test Score	
	Linear	Non-Linear	Linear	Non-Linear
Skewness	-0.041	-0.081	0.004	-0.022
Kurtosis	-0.174	-0.628	-0.899	-0.708

TABLE II. Pre-Test and Post-Test Scores within Groups Across Linear and Non-Linear for the Experimental Group.

Measure of Data Distribution	Experimental Group			
	Pre-test Score		Post-test Score	
	Linear	Non-Linear	Linear	Non-Linear
Skewness	-0.492	2.370	-0.674	-1.537
Kurtosis	-0.966	6.253	-0.447	0.961

A. Test of Difference Between the Pre- and Post-Test Scores Within Groups

After establishing that the data met the assumption of normality, a paired t-test comparing pre-test and post-test scores for both linear and non-linear reading assessments was computed.

For the control group, results presented in Table III indicate little to no improvement in reading performance. Mean scores in linear reading slightly declined from 4.067 in the pre-test to 3.767 in the post-test, with post-test scores showing slightly less variability (variance of 1.22 compared to 1.86 in the pre-test). The weak positive correlation between pre-test and post-test scores ($r = 0.217$), together with a non-significant p-value ($p = 0.300$), suggests that the observed changes were not statistically meaningful. These findings indicate that the traditional assessment approach did not lead to measurable improvements in students' reading performance. On the other hand, non-linear reading scores in the control group increased modestly from a mean of 4.400 to 4.933. Although the change reached statistical significance ($t = –2.570$, $p = 0.016$), the gain was small, indicating limited improvement using the traditional approach.

In contrast, the experimental group, as shown in Table IV, demonstrated substantial and statistically significant gains after using the PEER platform. Mean linear reading scores increased markedly from 4.567 to 8.033, while non-linear reading scores rose from 5.167 to 9.033. In addition to higher post-test means, the reduced variance in post-test scores reflects more consistent

performance among students. Although the correlations between pre-test and post-test scores were weak (linear: r = 0.085; non-linear: r = 0.181), the extremely small p-values ($p = 2.099 \times 10^{-9}$ for linear and $p = 9.004 \times 10^{-12}$ for non-linear) clearly indicate that these improvements were statistically significant.

TABLE III. RESULTS OF THE PAIRED T-TEST FOR PRE-TEST AND POST-TEST SCORES WITHIN CONTROL GROUPS.

	CONTROL GROUP			
	Linear		Non-Linear	
	Pre	Post	Pre	Post
Mean	4.067	3.767	4.400	4.933
Variance	1.857	1.220	1.628	1.237
Pearson Correlation	0.217		0.554	
t-stat	1.055		-2.570	
P(T<=t) one-tail	0.150		0.008	
t Critical one-tail	1.699		1.699	
P(T<=t) two-tail	0.300		0.016	
t Critical two-tail	2.045		2.045	

TABLE IV. RESULTS OF THE PAIRED T-TEST FOR PRE-TEST AND POST-TEST SCORES WITHIN EXPERIMENTAL GROUPS.

	EXPERIMENTAL GROUP			
	Linear		Non-Linear	
	Pre	Post	Pre	Post
Mean	4.567	8.033	5.167	9.033
Variance	3.357	2.033	1.868	2.723
Pearson Correlation	0.085		0.181	
t-stat	-8.537		-10.901	
P(T<=t) one-tail	1.049E-09		4.502E-12	
t Critical one-tail	1.699		1.699	
P(T<=t) two-tail	2.099E-09		9.004E-12	
t Critical two-tail	2.045		2.045	

Taken together, the results indicate that students assessed using the PEER platform achieved significantly greater gains in both linear and non-linear reading proficiency than those assessed using traditional methods, highlighting the platform's effectiveness as a digital assessment tool.

B. Test of Difference on the Reading Proficiency Gains Between the Control and Experimental Groups

Table V presents the mean gain scores in linear and non-linear reading assessments for both the control and experimental groups. The results show a clear contrast between the two groups in terms of reading proficiency gains. For the control group, the mean gain score in linear reading was -0.30, indicating a slight decline in performance from pre-test to post-test. In non-linear reading, the control group exhibited only a modest improvement, with a mean gain score of 0.53. These findings suggest that the traditional paper-and-pencil assessment approach resulted in little to no meaningful improvement in students' reading proficiency over the duration of the study.

In contrast, the experimental group demonstrated substantial gains in both reading assessment types. The mean gain score for linear reading was 3.47, while non-linear reading showed an even higher gain of 3.87. Independent samples t-test results revealed that the differences in gain scores between the control and experimental groups were statistically significant for both linear ($p = 2.88737 \times 10^{-10}$) and non-linear reading ($p = 3.99054 \times 10^{-11}$). These extremely small p-values provide strong evidence that the observed improvements in the experimental group were not due to chance but were associated with the use of the PEER platform.

TABLE V. MEAN GAIN SCORES FOR CONTROL AND EXPERIMENTAL GROUP.

	CONTROL GROUP		EXPERIMENTAL GROUP	
	Linear	Non-Linear	Linear	Non-Linear
MEAN GAIN SCORE	-0.30	0.53	3.47	3.87
p-value for Linear	2.88737E-10			
p-value for Non-Linear	3.99054E-11			

n=30

To determine the magnitude of the differences between groups, Cohen's *d* was computed using gain scores. Results revealed a very large effect size for both linear reading (d = 1.95) and non-linear reading (d = 2.02). These findings indicate that the use of the PEER platform produced a substantial and practically significant improvement in reading proficiency compared to traditional assessment methods (see Table VI).

TABLE VI. EFFECT SIZE (COHEN'S D) OF READING PROFICIENCY GAINS BETWEEN CONTROL AND EXPERIMENTAL GROUPS

Reading Assessment Type	Mean Gain		Cohen's d	Interpretation
	Control	Experimental		
Linear	-0.30	3.47	1.95	Very Large Effect
Non-Linear	0.53	3.87	2.02	Very Large Effect

The findings imply that the PEER-based assessment approach was significantly more effective than traditional methods in improving students' reading proficiency. The larger gains observed in the experimental group may be attributed to the platform's structured, consistent, and technology-supported assessment process, which allowed for timely monitoring of student performance and more focused engagement with reading tasks. Moreover, the greater gains in non-linear reading suggest that digital assessment environments may be particularly effective in supporting skills related to interpreting and integrating information from non-sequential texts. These results reinforce the value of integrating digital assessment platforms as part of reading proficiency programs to achieve stronger and more consistent learning outcomes.

C. Evaluation on the Performance of PEER

An evaluation was conducted using a survey questionnaire among the respondents to determine their perception with

respect to the functional suitability, usability, security and maintainability of the developed platform.

For the web application, all quality criteria received mean ratings above 4.50, corresponding to a descriptive rating of *Strongly Agree*. Functional suitability obtained a mean score of 4.72, suggesting that users perceived the system's features as well-aligned with their assessment needs. Usability also received a high mean of 4.69, indicating that users found the interface intuitive and easy to navigate. Similarly, security and maintainability were rated highly, with mean scores of 4.73 and 4.67 respectively, reflecting user confidence in data protection measures and the system's ability to support updates and modifications without difficulty.

Comparable results were observed for the mobile application, which also achieved *Strongly Agree* ratings across all criteria. Functional suitability (M = 4.57) and usability (M = 4.56) were particularly well rated, highlighting the effectiveness of the mobile app in supporting reading assessment tasks and providing a user-friendly experience. Security and maintainability each recorded mean scores of 4.52 and 4.55, respectively, indicating that users felt their data were secure and that the application was reliable and adaptable to future needs.

The overall mean scores of 4.70 and 4.55 for web and mobile platforms, respectively, underscore the consistency of user satisfaction across deployment environments. These findings suggest that the PEER platform meets high software quality standards and is perceived as reliable, secure, and easy to use by its users. The consistently strong ratings across all dimensions support the platform's suitability for broader implementation and reinforce its potential as an effective digital tool for reading proficiency assessment (see Table VII).

TABLE VII. PERCEIVED PERFORMANCE EVALUATION OF PEER

SW Quality Criteria	Web App		Mobile App	
	Mean	SD	Mean	SD
Functional Suitability	4.72	0.30	4.57	0.45
Usability	4.69	0.30	4.56	0.50
Security	4.73	0.24	4.52	0.47
Maintainability	4.67	0.31	4.55	0.48
Overall Mean	**4.70**		**4.55**	**0.49**

n=50

A two-factor ANOVA without replication was conducted to examine differences across respondents' ratings and software quality criteria. The computed values on Table VIII and Table IX revealed a statistically significant effect of respondents (for web: $F = 8.92, p < 0.001$ and for mobile: $F = 28.50, p < 0.001$), indicating that there were significant differences in the ratings provided by respondents. This suggests variability in how individuals evaluated the system. In contrast, the effect of software quality criteria (Functional Suitability, Usability, Security, and Maintainability) was not statistically significant, (for web: $F = 1.63, p = 0.202$ and for mobile: $F = 0.80, p = 0.45$). The findings indicate that while respondent evaluations on the web and mobile applications significantly varied, there were no statistically significant differences among the assessed software quality criteria. This suggests that the system demonstrates a consistent level of quality across all evaluated dimensions.

TABLE VIII. TWO-FACTOR ANOVA (WEB APP)

Source of Variation	SS	df	MS	F	P-value	F crit
Respondents	9.52	49	0.19	8.92	5.02E-20	1.48
SW Quality	0.07	2	0.04	1.63	0.201699	3.09
Error	2.14	98	0.02			
Total	11.73	149				

TABLE IX. TWO-FACTOR ANOVA (MOBILE APP)

Source of Variation	SS	df	MS	F	P-value	F crit
Respondents	32.25	49	0.656	28.50	1.49E-40	1.48
SW Quality	0.037	2	0.02	0.80	0.452383	3.09
Error	2.26	98	0.02			
Total	34.55	149				

V. DISCUSSION

This study sought to examine whether a digital reading assessment platform could improve students' reading proficiency compared with conventional paper-based assessment practices. The results provide encouraging evidence that the PEER platform contributed to measurable improvements in students' reading performance while also receiving strong acceptance from users. When viewed together, the statistical findings and user evaluations suggest that technology-supported assessment systems may play a meaningful role in strengthening reading evaluation practices in schools. However, it is worth noting that the study only involved a relatively small sample size, which may limit how far the findings can be applied to a wider population. Because of this, future studies are encouraged to test the platform with a larger and more diverse group of participants to further strengthen and confirm its effectiveness.

The results of the pre-test and post-test comparison revealed a clear contrast between the control and experimental groups. Students who participated in the traditional paper-and-pencil assessment showed little change in their performance across the two testing periods. In linear reading, the slight decrease in the mean score suggests that repeated exposure to similar reading tasks alone may not necessarily lead to improvement. Although the control group demonstrated a modest increase in non-linear reading scores, the magnitude of the improvement remained relatively small. This outcome reflects a limitation often discussed in assessment literature, where conventional testing approaches tend to emphasize measurement rather than actively supporting the learning process [14].

A different pattern emerged among students who used the PEER platform. Their post-test scores increased substantially in both linear and non-linear reading assessments, indicating that the digital platform may have created a more supportive environment for completing reading tasks. One possible explanation is that digital systems introduce elements of

interaction and immediacy that are typically absent in static assessment formats. When learners engage with reading materials through digital interfaces, the experience often becomes more dynamic and structured, which may encourage sustained attention and participation. Research on digital learning environments has consistently highlighted the role of interactive technologies in promoting learner engagement and facilitating deeper processing of instructional content [15].

The analysis of gain scores provides further insight into the observed improvements. Students in the experimental group achieved considerably larger gains compared with those in the control group. Because both groups were exposed to the same reading content and assessment format, the improvement cannot simply be attributed to familiarity with the test items. Rather, the results suggest that the structured digital environment of the PEER platform played an important role in supporting learning during the assessment process. Digital assessment tools often allow educators to organize tasks more effectively and track student progress in real time. Such features have been associated with improved formative assessment practices, as they enable teachers to monitor student performance more closely and make timely instructional adjustments [16]; [17].

Another notable finding relates to the improvement in non-linear reading proficiency. Students in the experimental group demonstrated slightly higher gains in this area compared with linear reading. This result is particularly relevant in light of contemporary literacy practices, where readers frequently encounter information presented in non-sequential formats such as charts, tables, infographics, and hyperlinks. Digital platforms naturally support these types of information structures, which may help learners develop the skills needed to interpret and synthesize complex sources. Recent studies on digital literacy emphasize that reading in online environments requires additional competencies beyond traditional comprehension, including the ability to locate, evaluate, and integrate information from multiple digital formats [18]; [19]. The PEER platform may therefore provide an assessment context that more closely mirrors the reading environments students encounter outside the classroom.

Beyond learning outcomes, the evaluation of the PEER platform revealed consistently high ratings across several software quality dimensions. Respondents strongly agreed that both the web and mobile applications demonstrated functional suitability, usability, security, and maintainability. These results are important because the success of educational technologies often depends not only on their instructional effectiveness but also on their usability and reliability in real classroom settings. Systems that are perceived as intuitive and easy to navigate are more likely to be adopted and sustained by teachers and students [20].

The positive evaluation of system security also deserves attention. In digital learning environments, the protection of student data is a critical concern for schools and administrators. The favorable ratings suggest that users trusted the platform's mechanisms for managing and storing information. At the same time, the strong perception of maintainability indicates that the system is flexible enough to accommodate updates and improvements over time. This adaptability is an important characteristic of educational software, as technological tools must evolve alongside changes in curriculum, pedagogy, and institutional needs [21]. Recent discussions in educational technology research further emphasize that scalable and adaptable digital systems are essential for supporting long-term integration in schools [22].

Taken together, the findings of this study highlight the potential value of digital assessment platforms in improving reading proficiency and enhancing the assessment experience. The significant gains observed among students who used the PEER platform, combined with the positive user perceptions of its quality and usability, suggest that such systems can serve as effective complements to traditional assessment methods. Rather than replacing conventional approaches entirely, digital platforms may offer additional opportunities for monitoring student progress, providing more engaging assessment experiences, and supporting data-informed decision-making in the classroom.

As schools continue to integrate technology into teaching and learning, the role of digital assessment tools is likely to become increasingly important. Platforms such as PEER demonstrate how technology can be used not only to measure learning outcomes but also to create assessment environments that align more closely with the digital contexts in which students read and interact with information. With thoughtful implementation, systems like PEER may contribute to more responsive and effective reading proficiency programs in secondary education.

VI. Conclusion

This study highlights how thoughtfully designed digital platforms can meaningfully improve the way reading proficiency is assessed in school settings. By streamlining assessment procedures and organizing results in a systematic manner, digital tools help schools establish more reliable and efficient reading comprehension assessment practices. More importantly, they allow teachers to spend less time on repetitive, manual tasks and more time interpreting results and responding to learners' needs. In this way, digital assessment platforms do not simply modernize existing practices; they strengthen the instructional support system that underpins reading development.

At a broader level, the findings suggest that technology-supported assessment is well aligned with the changing nature of reading literacy. As students interact with a wider range of texts, spanning linear, non-linear, and multimodal formats, digital platforms provide a flexible yet standardized approach to evaluating reading skills. The favorable evaluation of software quality across platforms also implies that when digital assessment tools are built in accordance with established quality standards, they are more likely to be accepted by users and sustained over time within educational institutions.

Looking ahead, future studies may build on this work by investigating how continued use of digital reading assessment platforms influences literacy growth over longer periods and across different grade levels. Expanding the scope of participants and implementing the system in multiple school contexts could further strengthen the applicability of the results.

There is also room to explore more advanced features, such as adaptive assessments, learning analytics, or AI-driven feedback mechanisms, to support more personalized reading interventions. Finally, qualitative inquiries into teachers' classroom practices and students' learning experiences would offer valuable insights into how assessment data from digital platforms are translated into concrete instructional improvements and meaningful learning outcomes.

ACKNOWLEDGMENT

The author sincerely thanks the teachers and students of Delfin Albano High School, under the leadership of Dr. Orlyne T. Demerin, for their support and valuable inputs. Appreciation is extended to the project team, namely Revilyn Totto, Christine Rondero, Vanessa Pagauitan, and Julius Lemu, for sharing PEER and their study on the developed platform.

Hybrid Learning-to-Rank Approach for Complex Information Retrieval Systems

Application to Biomedical Question Answering

***Abstract*—Biomedical question answering presents significant challenges due to the complexity of biomedical language and the need for precise information retrieval. This study aims to improve the performance of a biomedical information retrieval system through a hybrid learning-to-rank framework. Specifically, we combine lexical (BM25) and semantic (BioBERT) representations to form hybrid inputs for RankFormer, a transformer-based ranking model. This hybrid representation captures both surface-level term matching and deep contextual understanding. Experiments conducted on the BioASQ dataset show that our approach achieves better ranking performance compared to the standalone lexical or neural baselines, reaching a MAP@10 of 0.9614 and an nDCG@10 of 0.9320. These results highlight the effectiveness of hybrid input representations in enhancing biomedical answer ranking.**

***Keywords*—Learning-to-rank; information retrieval; hybrid learning-to-rank; transformer-based ranking model; biomedical question answering**

I. Introduction

Ranking in large-scale information retrieval can be seen as a multi-stage process where efficiency, relevance, and ranking stability must be jointly addressed.

Biomedical question answering (BQA) sits at the intersection of natural language processing and information retrieval (IR), aiming to return relevant answers to complex biomedical questions. The volume of biomedical literature continues to grow exponentially, and the terminology itself is often highly specialized and ambiguous. Together, these factors tend to make effective information retrieval genuinely challenging in real-world biomedical settings.

Traditional lexical retrieval models, with BM25 as the most common example, rely on exact term matching and have, for years, served as solid baselines in information retrieval. They are fast, relatively simple to deploy, and generally do a good job when surface-level word overlap is enough. However, such models tend to struggle with semantic variation, including synonymy and context-dependent meanings, all of which appear frequently in biomedical writing.

Neural language models like BioBERT take a different direction by using contextualized representations that aim to capture semantic relationships beyond lexical similarity. Although these models have demonstrated strong performance in biomedical natural language understanding tasks, they can underperform when precise term matching matters. They typically require computationally intensive re-ranking.

Recent studies suggest that mixing lexical and semantic signals can alleviate the limitations of individual models. Hybrid retrieval strategies that use sparse (exact relevance signal) with dense (contextual relevance signal) representations often perform better across multiple benchmarks, and the gains tend to be more noticeable in specialized domains. In the biomedical domain, where both precise terminology and deep contextual understanding are crucial, such strategies are particularly relevant.

In this work, we aim to improve the performance of biomedical information retrieval systems by adopting a hybrid learning-to-rank approach. Specifically, we propose a method that brings together lexical scores from BM25 and contextual embeddings derived from BioBERT to form a hybrid input for RankFormer, a transformer-based listwise ranking model. Rather than treating sparse and dense relevance signals separately, the model is trained to learn from them jointly within a supervised setting, which appears to encourage rankings that are not only more accurate but also more sensitive to meaning and context. We experiment with the proposed approach on the BioASQ Task B 2024 dataset, where the results demonstrate that combining hybrid representations with listwise learning can lead to noticeable gains over both purely lexical methods and standalone neural baselines.

II. Related Work

Information retrieval is the process of locating information items that best align with a user's query [1], [2]. In biomedical contexts, this task becomes especially demanding. The huge volume of biomedical literature, along with its domain-specific terminology, means that retrieval systems often play a practical role in clinical decision support and day-to-day biomedical research [3]. Not surprisingly, a wide range of methods has been proposed over time to improve retrieval quality, from classic lexical techniques to more recent neural models and, increasingly, hybrid approaches that try to balance precision with semantic understanding.

A. Lexical Methods (Sparse Retrieval Methods)

Traditionally, lexical approaches relying on word overlap have been the foundation of information retrieval [4]. Sparse retrieval methods use inverted indexes to link terms to documents, which helps explain why they remain

computationally efficient even at a large scale. Over the years, researchers have proposed a range of weighting and normalization schemes, rising to multiple Term Frequency-Inverse Document Frequency (TF-IDF) models [5]. Because it offers a reasonable balance between effectiveness and simplicity, BM25 [6] is one of the sparse models that is often viewed as the default choice in real-world systems. In practice, it processes documents as bags of words and assigns scores based on the presence of query terms independently of their position or proximity in the text [7].

A key strength of BM25 lies in its ability to normalize document length and address query term saturation. This enables it to avoid bias toward either very short to very long documents and to reduce the disparate influence of excessively repeated terms. BM25 has been extended to incorporate multiple document fields and specify how their individual scores should be combined [8].

Lexical models continue to be popular largely because they are fast and easy to deploy at scale. In many general-purpose retrieval settings, lexical methods are usually enough. However, when the language becomes more specialized, as in biomedical texts, synonymy and contextual ambiguity are common, and methods based solely on word overlap are likely to miss relevant documents even when the underlying concepts align [9].

B. Semantic Methods (Dense Retrieval Methods)

Efforts to improve information retrieval systems have increasingly turned toward neural-based semantic retrieval approaches. Early work in this category relied on convolutional and recurrent neural networks to represent textual data. In practice, both queries and documents are mapped into a shared vector space assumed to capture more nuanced representations of meaning. Relevance is then estimated through similarity functions trained to reflect semantic alignment between these representations [10], [11].

Additionally, the neural models benefit from their ability to learn non-linear text representations, which explain why they often outperform traditional lexical approaches [11]. A more noticeable advancement in the field came with the introduction of transformer models. Transformer-based models such as BERT [12] and GPT [13], thanks to the attention mechanism, have significantly improved retrieval performance by enabling the model to focus attention on the most relevant parts of both queries and documents during the matching process [14].

Neural models such as BioBERT were introduced to move beyond surface-level term matching and toward a richer notion of semantic similarity. As a domain-adapted version of BERT, BioBERT is pre-trained on large-scale biomedical texts. This model has reported strong performance on biomedical question answering and document ranking benchmarks [15]. Neural models offer an improved ability to relate concepts that are not lexically identical. For BQA systems, where relevant evidence is often paraphrased rather than repeated verbatim, this contextual sensitivity is crucial [16].

C. Hybrid Methods

The development of hybrid approaches is motivated by the strengths and complementary results produced by sparse and dense retrieval models [1]. Hybrid methods typically merge lexical and semantic scores using fusion techniques. Among the most widely used strategies are Convex Combination and Reciprocal Rank Fusion (RRF).

Although both strategies are widely used, Convex Combination appears to be the more flexible option in many settings. It requires only minimal score normalization and, according to prior studies, has in several cases outperformed RRF [17]. One practical advantage, however, is that it tends to be sample-efficient, adapting reasonably well to specific domains with relatively few examples.

A common strategy involves using BM25 to retrieve an initial set of candidate documents, which are then re-ranked using a dense encoder such as BioBERT. This two-stage architecture has been shown to significantly improve retrieval performance in various QA benchmarks. More recent work has pushed this integration further by directly fusing lexical and dense scores.

D. Learning-to-Rank

Learning-to-rank (LTR) is designed as a supervised learning approach for ordering documents by how relevant they are to a given query. LTR has become an important component of modern information retrieval systems, especially in settings where simple heuristics no longer suffice. That said, LTR actually covers a range of modeling choices rather than a single, unified method.

Most LTR techniques are commonly organized into three broad paradigms [18], each of which frames the ranking problem in a slightly different way. The pointwise approach, for instance, treats the ranking problem as a classification task, where each document is assigned a relevance score independently of the others. This setup is attractive because it is easy to implement and fits neatly within existing machine learning pipelines. However, by scoring documents independently, it arguably misses a key aspect of ranking because relevance is often relative and emerges from direct competition among documents shown for the same query.

Pairwise methods try to close this gap by shifting the learning objective toward preferences between pairs of documents. Instead of asking whether a document is relevant in absolute terms, the model learns which of two documents should be ranked higher. RankNet, introduced by Burges et al. [18], is a well-known example; it uses a neural network to estimate the probability that one document should be ranked ahead of another.

Listwise methods take a more holistic view by considering the entire set of documents associated with a query during training. One of the more influential examples is ListNet [19]. ListNet defines a probability distribution over possible permutations of the result list. This formulation appears to let the model capture interactions among documents more directly.

Recent progress in deep learning has pushed learning-to-rank models toward transformer-based approaches, largely due to their ability to capture complex contextual relationships. One such transformer-based listwise LTR model that incorporates traditional listwise objectives with innovative listwide assessment objectives is RankFormer [20]. This design appears

to help the model capture dependencies across an entire document list, leading to improved ranking performance.

Our work follows this line of research but takes a different angle. We propose a hybrid approach in which both BM25 scores and BioBERT embeddings are provided as input signals to a RankFormer-based re-ranker. Rather than treating lexical retrieval and semantic re-ranking as two clearly separated stages, we integrate sparse and dense features from the outset. The idea here is that BioBERT captures domain-specific semantics, whereas BM25 tends to anchor the ranking in exact term matches. In order to take benefit of the complementary advantages of both sparse and dense retrieval for more precise biomedical passage ranking, the two are combined early in the ranking process.

III. Methodology

The proposed methodology adopts a hierarchical learning-to-rank framework to progressively enhance document relevance for biomedical question answering. To take advantage of complementary relevance signals at different stages of the ranking process, the approach combines supervised listwise learning with semantic re-ranking and lexical retrieval. Three sequential steps are used to demonstrate the workflow: 1) BM25 is used for initial candidate retrieval; 2) BioBERT is used for semantic re-ranking; and 3) a hybrid RankFormer model is used for final ranking.

This multi-stage strategy seeks to balance efficiency and effectiveness by leveraging the strong recall of sparse retrieval with the semantic sensitivity of dense representations and the optimization capabilities of learning-to-rank models.

For a given query, we start by keeping the top 50 documents returned by BM25. At this stage, the goal is coverage rather than finesse. BioBERT then re-ranks this shortlist, filtering it down to the 25 documents that appear to align most closely with the query at a semantic level. These candidates are then passed to RankFormer, which generates the final top-10 ranking. This multi-stage ranking strategy has proven to be effective in advanced information retrieval systems, as it brings together the efficiency of sparse retrieval with the precision of dense methods and learning-to-rank techniques [21].

A. Dataset

We carry out our experiments on the BioASQ Task B 2024 dataset, a reference benchmark for biomedical question answering. The dataset consists of expert-formulated biomedical questions. Each question is linked to a set of supporting materials: relevant PubMed documents, text snippets, biomedical concepts, and expert answers curated by domain specialists [22].

BioASQ Task B queries are natural-language biomedical questions, categorized into four classes: Factoid questions (single entity answers), List questions (multiple entity answers), Yes/No questions, and Summary (ideal answer) questions.

For retrieval and ranking purposes, the dataset is preprocessed into three components:

- Queries: Question texts are extracted from the original JSON files and stored in JSONL format, where each entry contains a unique query identifier and the query body.
- Documents: Document collections are constructed by concatenating snippets associated with the same source URL, resulting in a dense textual corpus indexed using the Pyserini [23] toolkit.
- Relevance Judgments (Qrels): Ground-truth relevance annotations are formatted according to the standard TREC qrels specification, linking each query to relevant documents.

This preprocessing task ensures compatibility with both sparse and dense retrieval models and provides a reliable evaluation framework for learning-to-rank experiments.

B. Initial Lexical Retrieval with BM25

The suggested methodology starts with BM25, a probabilistic sparse retrieval model that is frequently used in information retrieval because of its interpretability and robustness. BM25 ranks documents based on exact query term matching using term frequency saturation and document length normalization.

We test four distinct BM25 configurations in order to examine the effects of BM25 hyperparameters. Precisely, we vary the term frequency parameter "k_1" and the length normalization parameter "b":

- $k_1 = 0.9$, $b = 0.4$
- $k_1 = 0.9$, $b = 0.8$
- $k_1 = 1.2$, $b = 0.4$
- $k_1 = 1.2$, $b = 0.8$

For each query, the top 50 documents are retrieved from the indexed corpus. This candidate set is intentionally kept broad in order to maximize recall, ensuring that potentially relevant documents are preserved for subsequent re-ranking stages.

C. Semantic Re-ranking with BioBERT

In the second stage, we move beyond lexical matching and introduce semantic re-ranking with BioBERT, a transformer model pre-trained on large-scale biomedical datasets. The idea is that once BM25 has gathered a set of plausible candidates, BioBERT reconsiders them through a contextual goal. Instead of relying purely on term overlap, it can account for synonymy and the kinds of domain-specific expressions that often appear in biomedical writing.

At first, we applied BioBERT in its pre-trained form, using it to score the top 50 documents retrieved by BM25 for each query. Nevertheless, initial tests show that task sensitivity is low in this zero-shot setting. The model is fine-tuned on the BioASQ relevance judgments in order to overcome this constraint.

Fine-tuning data are constructed by pairing queries with candidate documents and assigning binary relevance labels derived from the qrels. A subset of 1,000 query-document pairs is randomly sampled and split into 80% for training and 20% for validation. Inputs are tokenized using the BioBERT tokenizer,

with truncation and padding applied to a maximum sequence length of 512 tokens.

The model is fine-tuned as a binary classifier for three epochs using a learning rate of 2e-5, a batch size of 8, and a weight decay of 0.01. Validation accuracy is used to monitor training progress. After fine-tuning, BioBERT demonstrates improved relevance prediction and is used to re-rank the BM25 candidate set. The top 25 documents per query are retained for the final ranking stage. This semantic re-ranking stage serves as a critical bridge between traditional lexical matching and transformer-based contextual understanding, yielding more precise retrieval results in the biomedical domain.

D. RankFormer Hybrid Learning-to-Rank Model

The final ranking stage employs RankFormer, a transformer-based listwise learning-to-rank model capable of modeling inter-document dependencies within a candidate list. Unlike conventional pipelines that treat lexical and semantic re-ranking as isolated steps, our approach integrates hybrid relevance signals directly into the RankFormer training process.

Each training instance is defined as a triplet (q, D, L), where q denotes a query, D = {d_1, d_2, ..., d_n} is the set of candidate documents, and L represents a list-level supervision signal referred to as the listwise label. Each document d_i is associated with a document ID, a textual representation, and a relevance label {0, 1}, a predicted score, and a rank reflecting its position within the list.

To generate input scores for RankFormer, we compute a normalized linear combination of BM25 scores and fine-tuned BioBERT scores. The hybrid score for a document is given by Eq. (1) [24]:

$$score = \alpha \cdot scorebm25 + (1 - \alpha) \cdot scorebiobert \quad (1)$$

where, $\alpha \in [0, 1]$ controls the relative contribution of lexical and semantic signals. In our experiments, α is empirically set to 0.5. The choice of setting α=0.5 is driven by the objective of achieving a balanced integration of heterogeneous scoring signals. In biomedical document retrieval, BM25 ensures precise lexical matching for highly specialized terminology, whereas BioBERT captures richer semantic context and synonymy. Assigning equal weights prevents the RankFormer input from being biased toward either surface-level keyword matching or purely latent representations, thereby maintaining the precision of the former while benefiting from the recall of the latter.

In addition to document-level relevance labels, RankFormer incorporates list-level supervision. A binary listwide label "L" is assigned to each query: the label is set to 1 if the candidate list contains at least three relevant documents, and 0 otherwise. This supervision enables the model to assess global ranking quality beyond individual document relevance.

To optimize the model, the training objective combines a listwise ranking loss and a listwide loss.

The listwise loss encourages correct relative ordering of documents within each query candidate list. It follows a Softmax-based ranking loss [19], inspired by ListNet and defined by Eq. (2) as follows:

$$Llistwise = \frac{1}{N} \sum_{i=1}^{N} \sum_{j=1}^{|D_i|} (\log \sum_{k=j}^{|D_i|} \exp(s_{i,k}) - s_{i,j}) \quad (2)$$

where, S_{ij} denotes the predicted score for the j-th document in the i-th list and N is the total number of training queries.

The listwide loss is defined by Eq. (3) as a mean squared error (MSE) [25] between the predicted list quality and the true listwide label.

$$Llistwide = \frac{1}{N} \sum_{i=1}^{N} (l_i - \widehat{l_i})^2 \quad (3)$$

where, l_i is the true listwide label for the i-th query, and $\widehat{l_i}$ is the predicted list quality output by the model.

As specified in Eq. (4), the final training objective function is expressed as a weighted combination of both losses.

$$Ltotal = \alpha \cdot Llistwise + (1 - \alpha) \cdot Llistwide \quad (4)$$

where, α is set to 0.7, to prioritize accurate document ranking while maintaining sensitivity to list-level performance.

This hybrid supervision strategy allows RankFormer to jointly optimize fine-grained relevance ordering and holistic ranking performance, making it particularly suitable for biomedical information retrieval tasks.

The RankFormer-Hybrid model architecture is built upon a BioBERT backbone, which serves as a pre-trained encoder to extract domain-specific contextual embeddings. To manage overhead, these high-dimensional representations are projected into a 128-dimensional space via a linear transformation layer. The primary ranking operations are then conducted by a streamlined Transformer encoder consisting of two layers and four attention heads. Within this framework, query-document fusion is achieved by appending the query representation to each document vector, allowing the model to capture fine-grained, query-dependent relevance signals. The architecture concludes with a dual-level scoring mechanism, an individual linear layer computes local scores for each document, while a separate listwide score is generated by averaging document representations through a global linear layer.

As illustrated in Table I, the entire architecture is optimized using a weighted hybrid loss function, Eq. (4), which balances the precision of relative document ordering with the overall coherence of the retrieved list.

TABLE I. RANKFORMER-HYBRID MODEL ARCHITECTURE

Component	Description
Pre-trained encoder	BioBERT (dmis-lab/biobert-base-cased-v1.1)
Linear projection layer	Linear to a 128-dimensional space
Transformer encoder	2 layers, 4 attention heads, batch-first = true
Query-document fusion	Adding the query representation to each document
Score estimation	Individual linear layer for each document (score-layer)
Listwide score	Average of documents → linear layer (listwide-layer)
Learning loss	0.7· Loss-listwise + 0.3· Loss-listwide

E. Evaluation Metrics

Ranking performance is evaluated using standard information retrieval metrics at a cutoff of k = 10, consistent with the BioASQ Task B setting. The metrics include MAP@10, MRR@10, nDCG@10, Precision@10, and Recall@10. Together, these metrics provide a comprehensive assessment of ranking accuracy, early precision, and retrieval completeness.

A brief definition of these evaluation metrics [26] is as follows:

- Mean Average Precision at 10 (MAP@10) computes the average precision across all relevant documents within the top 10 retrieved, weighted by their position. This metric emphasizes both precision and the ranking order of relevant documents.
- Mean Reciprocal Rank at 10 (MRR@10) captures the position of the first relevant document in the ranking. It is defined as the reciprocal of the rank at which the first relevant document appears, providing a measure of how quickly a system can retrieve a relevant result.
- Normalized Discounted Cumulative Gain at 10 (nDCG@10) evaluates the quality of the ranking by assigning higher importance to relevant documents appearing higher in the list. It accounts for graded relevance and uses a logarithm discount factor to penalize lower-ranked relevant documents.
- Precision at 10 (P@10) measures the proportion of relevant documents among the top 10 retrieved items, offering an intuitive assessment of immediate result relevance.

Recall at 10 (R@10) quantifies the fraction of all relevant documents that are retrieved within the top 10 results, thereby reflecting the model's overall retrieval coverage.

These complementary metrics provide a comprehensive evaluation of the studied models, capturing different aspects of retrieval performance, including completeness, early precision, and ranking accuracy. Following the proposed methodology, the next sections present and analyze the experimental results obtained within this evaluation framework.

IV. Experimental Results and Discussion

The experimental results demonstrate a clear and consistent improvement in retrieval performance as the ranking pipeline evolves from lexical to dense and finally to supervised learning-to-rank approaches. This progression highlights the complementary nature of sparse and dense relevance signals and confirms the central role of supervised ranking in biomedical information retrieval.

A. BM25 Results

The BM25 baseline provides a strong lexical foundation, achieving competitive precision-oriented metrics when properly tuned. These results are consistent with prior findings showing that sparse retrieval models remain effective in biomedical settings when domain-specific terminology is well represented. However, the observed limitations in recall and nDCG indicate that lexical matching alone is insufficient to fully capture the semantic variability inherent in biomedical queries and documents.

Table II presents the evaluation results for the four configurations of the parameters k_1 and b across the five standard retrieval metrics at rank 10.

TABLE II. Evaluation Results of BM25 on the BioASQ Task B 2024 Dataset.

Metrics @10	k_1=0.9, b=0.4	k_1=0.9, b=0.8	k_1=1.2, b=0.4	k_1=1.2, b=0.8
MAP	0.6100	0.6255	0.6073	0.6263
MRR	0.8965	0.8866	0.8978	0.8886
Precision	0.5885	0.6044	0.5871	0.6088
Recall	0.4703	0.4860	0.4696	0.4884
nDCG	0.7761	0.7847	0.7744	0.7877

The results reveal that the configuration $k_1 = 1.2$, $b = 0.8$ consistently yields the best performance for most metrics. Interestingly, the highest MRR@10 is reached with $k_1 = 1.2$, $b = 0.4$, suggesting that while this setting helps retrieve the first relevant document at a higher rank, the overall ordering may be less optimal than with $b = 0.8$.

These findings emphasize the importance of hyperparameter tuning in lexical retrieval and confirm that BM25, even as a sparse model, can provide a strong and competitive baseline when properly optimized.

B. BioBERT Results

We evaluate the performance of BioBERT in two experimental settings: in its original pre-trained form and after being fine-tuned on the BioASQ TASK B 2024 training set. The results shown in Table III indicate a substantial improvement across all evaluation metrics after fine-tuning.

TABLE III. Evaluation Results of BioBERT Before and After Fine-Tuning.

Metrics	Pre-trained model	Fine-tuned model
MAP@10	0.6430	0.8180
MRR@10	0.7512	0.8883
Precision@10	0.5097	0.6088
Recall@10	0.3589	0.4884
nDCG@10	0.7578	0.8917

To further illustrate these differences, Fig. 1 presents a bar chart comparing the performance of the two models. The fine-tuned BioBERT clearly outperforms the pre-trained version, achieving a MAP@10 of 0.8180 compared to 0.6430, and an nDCG@10 of 0.8917 versus 0.7578. These results emphasize the effectiveness of domain-specific fine-tuning in enhancing ranking quality for biomedical information retrieval tasks.

To better assess the impact of dense retrieval methods in biomedical information retrieval, we compare the top-performing BM25 configuration with the fine-tuned BioBERT model. The results, summarized in Table IV, highlight the advantages of using a semantic approach over a traditional sparse retrieval model.

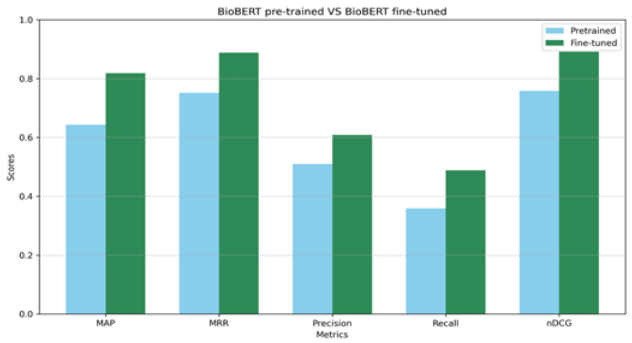

Fig. 1. Comparison of BioBERT performance in pre-trained and fine-tuned settings for each evaluation metric at rank 10.

TABLE IV. RETRIEVAL PERFORMANCE COMPARISON BETWEEN BM25 AND FINE-TUNED BIOBERT ON THE BIOASQ TASK B 2024 DATASET.

Metrics	BM25 (k_1 = 1.2, b = 0.8)	Fine-tuned BioBERT
MAP@10	0.6263	0.8180
MRR@10	0.8886	0.8883
Precision@10	0.6088	0.6088
Recall@10	0.4884	0.4884
nDCG@10	0.7877	0.8917

As illustrated in Fig. 2, BioBERT outperforms BM25 across most metrics, notably achieving improvements of +19.2% in MAP@10 and +10.4% in nDCG@10. These gains confirm the added value of contextualized language representations in capturing nuanced biomedical terminology and semantics, which are often missed by term-matching approaches like BM25.

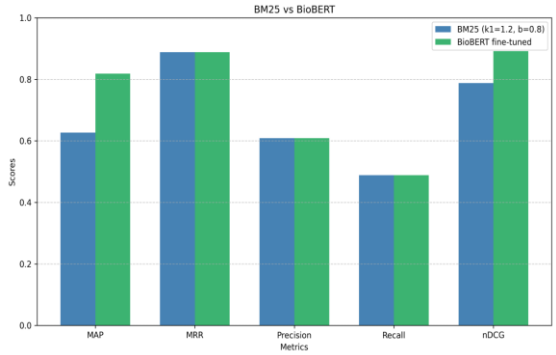

Fig. 2. Comparative performance of BM25 and fine-tuned BioBERT.

The introduction of BioBERT significantly improves ranking quality, particularly in terms of MAP@10 and nDCG@10. These gains can be attributed to the model's ability to encode contextual semantics, enabling it to capture synonymy, abbreviations, and implicit relationships that are not accessible to term-based approaches. Interestingly, while BioBERT and BM25 achieve comparable Precision@10 and MRR@10 scores, BioBERT consistently produces a more coherent ordering of relevant documents. This suggests that dense representations primarily enhance ranking quality rather than retrieval quantity, a pattern frequently observed in domain specific retrieval tasks.

C. RankFormer-Hybrid Model Results

Table V presents the performance of the proposed RankFormer-Hybrid model, summarizing results after 5 and 6 training epochs. These outcomes reflect the integration of hybrid relevance signals into the model's learning process.

TABLE V. RANKFORMER-HYBRID PERFORMANCE AT RANK 10 AFTER 5 AND 6 TRAINING EPOCHS.

Metrics / Epochs	5	6
MAP@10	0.9614	0.9526
MRR@10	0.9196	0.9118
Precision@10	0.6277	0.6242
Recall@10	0.8124	0.8081
nDCG@10	0.9320	0.9320

The model demonstrates outstanding performance across all evaluation metrics, even with a limited number of training epochs. At epoch 5, the model reaches a MAP@10 of 0.9614, MRR@10 of 0.9196, and nDCG@10 of 0.9320. These values remain stable or slightly decrease at epoch 6 due to the application of early stopping, which was employed to prevent overfitting and ensure optimal generalization.

Such high scores with minimal training suggest that the hybrid supervision significantly accelerates the convergence of the model by providing rich and informative ranking signals. This strong external guidance reduces reliance on long training schedules and enhances learning efficiency.

The rapid convergence observed within a small number of training epochs indicates that the hybrid supervision provides a stable and informative optimization signal. This behavior is particularly relevant for applied systems, where computational efficiency and training stability are critical design constraints.

These findings confirm the effectiveness of the proposed RankFormer-Hybrid model and highlight the value of incorporating complementary lexical and semantic signals in ranking models. This hybrid strategy leads to more nuanced and accurate rankings, particularly beneficial in complex systems such as biomedical information retrieval.

D. Comparative Analysis

The final comparison brings together the best-performing configurations of all evaluated models in order to highlight the progressive improvement achieved through increasingly sophisticated retrieval strategies. The results presented in Fig. 3 show a clear and consistent trend. The performance improves markedly as we move from traditional sparse retrieval to dense, and finally to learning-to-rank models.

BM25, a strong lexical baseline, performs well in precision-oriented metrics such as MAP and MRR, especially when its hyperparameters are finely tuned. However, it remains limited in its ability to capture semantic nuances, as reflected in its lower scores for recall and nDCG. The introduction of BioBERT, leads to a significant boost across all metrics. This confirms the added value of semantic understanding, particularly crucial in specialized domains such as biomedicine, where simple lexical overlap between queries and documents is often insufficient.

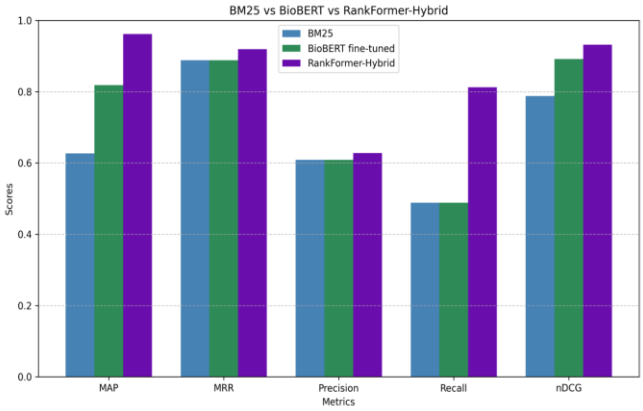

Fig. 3. Comparative performance of BM25, BioBERT, and the proposed RankFormer-Hybrid model.

The most substantial improvement is achieved by the RankFormer-Hybrid model, which combines lexical and semantic signals while leveraging supervised learning to refine document ranking. This model outperforms all others by a large margin, demonstrating the effectiveness of LTR approaches that not only understand content more deeply but also learn to prioritize relevance signals in a task-specific manner.

This comparative analysis underscores a key insight: while traditional and dense retrieval methods each contribute to performance, it is the combination of these methods within a supervised LTR framework that achieves the most robust and reliable results. In information retrieval tasks, especially those involving complex and high-stakes domains, incorporating LTR is not just beneficial but essential for achieving state-of-the-art performance.

To position our work within the current literature, we compare the performance of the proposed RankFormer-Hybrid model with that reported in selected previous studies. This qualitative comparison relies on standard evaluation metrics, including MAP, MRR, and nDCG.

Table VI presents a comparison between the proposed RankFormer-Hybrid model and other LTR models.

TABLE VI. COMPARISON OF THE PERFORMANCE OF THE PROPOSED RANKFORMER-HYBRID MODEL WITH OTHER LTR MODELS.

Model	Dataset	MAP@10	MRR@10	nDCG @10
BERT-based with injecting BM25 [27]	MS MARCO	0.367	0.364	0.422
HYRR [28]	MS MARCO	-	0.440	0.508
MultiLTR [29]	MQ2007	0.465	-	0.490
Vespa Hybrid [30]	TREC Covid	-	-	0.750
RankingRAE [31]	BioASQ Task B 2015	0.141	-	-
RankfFormer-Hybrid	BioASQ Task B 2024	0.961	0.920	0.932

The results in Table V show that the proposed RankFormer-Hybrid model outperforms several related models in terms of MAP, MRR, and nDCG at rank 10. Unlike methods that use BM25 scores as additional textual inputs or combine them through ensemble techniques, our approach directly integrates the hybrid BM25-BioBERT score into the document representation at the input level, allowing it to guide the attention mechanism from the earliest layers of the model. This integration leads to faster convergence, with the model reaching its best performance in only six epochs, which is particularly suitable for resource-constrained settings.

V. CONCLUSION

This work compares several information retrieval approaches on the BioASQ Task B 2024 dataset, ranging from the traditional BM25 (configured with k1 = 1.2, b = 0.8) to the semantic BioBERT model, and the hybrid learning-to-rank RankFormer approach. The results show a clear performance improvement as we move from sparse to dense and then to supervised hybrid methods, with RankFormer achieving the highest scores after just a few training epochs. These findings highlight the limitations of lexical-only retrieval in biomedical contexts and emphasize the effectiveness of incorporating semantic representations and hybrid signals. This study confirms the central role of learning-to-rank in modern IR systems and opens avenues for future research toward more adaptive and scalable ranking models.

A. Limitations and Discussions

While the results obtained in this study are encouraging and highlight the effectiveness of learning-to-rank techniques in biomedical information retrieval, some limitations should be acknowledged. First, the experiments are conducted exclusively on the BioASQ Task B 2024 dataset, which, although well established, may not fully represent the diversity and complexity of other biomedical or general domain IR tasks. As a result, the observed performance gains may not directly generalize to other biomedical retrieval tasks or to open-domain information retrieval settings without additional validation.

Second, although our methodology includes a hybrid scoring strategy and a deep LTR model, we limited our exploration to a single architecture and a relatively small number of training epochs. More comprehensive hyperparameter optimization and comparisons with alternative transformer-based ranking models could further strengthen the conclusions.

These limitations do not undermine the validity of the reported results; rather, they delineate the experimental boundaries of the present study and highlight directions for future research aimed at improving generalizability, robustness, and scalability.

B. Future Work

In future work, we plan to extend our evaluation to include other biomedical datasets to further assess the generalizability of our approach. Additionally, integrating user interaction signals could enable dynamic learning and continuous model improvement. Another promising direction involves exploring multi-model retrieval systems by incorporating structured knowledge or non-textual medical data into the ranking process. Finally, combining LTR with reinforcement learning or meta-learning techniques may offer new opportunities for optimizing

retrieval in highly specialized domains such as biomedical literature search.

General Directorate of Meteorology, Morocco[4]

***Abstract*—Rainfall prediction is still a difficult challenge because rainfall is nonlinear, intermittent, and highly variable, especially in semi-arid climates. Accurate rainfall prediction is crucial for water resource management, agricultural planning, climate-driven decision-making, and more. This study proposes a comparative framework based on machine learning and ensemble learning techniques to predict daily rainfall in Settat, Morocco, as a representative semi-arid region. Five predictive models were trained and evaluated based on meteorological station observations: Random Forest, XGBoost, LightGBM, CatBoost, and a Multilayer Perceptron (MLP). The models' performance was evaluated based on mean absolute error (MAE), mean squared error (MSE), root mean square error (RMSE), and the coefficient of determination (R-squared). The results demonstrate that the performance and stability of gradient boosting algorithms are superior to all other evaluated models. Specifically, LightGBM produced the fewest erroneous values and explained rainfall variability best. These results underscore the success of boosting-based ensemble techniques in modeling inconsistent precipitation patterns and provide a comparative framework for machine-learning-based rainfall forecasting in semi-arid environments.**

***Keywords*—Rainfall forecasting; machine learning; gradient boosting; LightGBM; semi-arid climate; ensemble learning**

I. Introduction

The forecast of rainfall is vital in water resource management, agricultural productivity, flood risk intervention, and climate resilience strategies, especially in semi-arid environments where precipitation is rare, erratic, and variable. In these regions, rainfall tends to have long dry spells and short, intense storms, leading to uncertain water resource management and a high susceptibility to droughts and flash floods [1], [2].

Traditionally, rainfall prediction has relied on Numerical Weather Prediction (NWP), which is based on the numerical integration of atmospheric physical equations. Although these models provide accurate predictions at synoptic and regional scales, they perform poorly at the local and station levels, especially in data-limited semi-arid areas [3]. Furthermore, NWP models have high computational costs and are driven by initial conditions; they generally do not capture orographic rainfall processes that trigger convection and dominate precipitation variability in dry climates [4].

Recently, machine learning (ML) methods have been established as competitive alternatives for rainfall prediction due to their ability to learn complex nonlinear relationships directly from historical meteorological data. Ensemble learning methods, such as Random Forest (RF), Extreme Gradient Boosting (XGBoost), LightGBM, and CatBoost, are widely used for tabular climate data because of their robustness, ability to handle heterogeneous predictors, and reduced sensitivity to overfitting [5]–[8]. Neural network models, especially the multilayer perceptron (MLP), have been extensively used for rainfall forecasting due to their ability to model complex nonlinear relationships. These models perform effectively when the feature space is well engineered and when large amounts of training data are available, which can undermine their performance in the context of station-based semi-arid areas [9].

Even with the growing use of ML techniques for rainfall prediction, several limitations remain. First, most previous work focuses on temperate or data-rich regions. However, semi-arid settings are under-investigated despite rainfall intermittency, skewed distributions, and heavy-tailed distributions (extreme events) [2], [10]. Second, existing works commonly employ heterogeneous preprocessing techniques, feature representations, and evaluation metrics, which make comparisons among models overly challenging. Consequently, there is still no clear consensus on whether ensemble boosting algorithms consistently outperform neural network models for daily rainfall prediction when evaluated under identical experimental conditions. In addition, relatively few studies provide climate-aware interpretations that explicitly link model performance to the physical characteristics of rainfall processes in semi-arid regions [11].

To bridge the gap, a comprehensive and systematic comparison of five machine learning models for daily rainfall prediction is conducted in Settat, Morocco, a representative semi-arid area. The compared models are four ensemble models: LightGBM, XGBoost, CatBoost, and the baseline neural Multilayer Perceptron (MLP). All models are trained and evaluated with the same 11 years of daily meteorological observation data using the same processing, feature engineering, and evaluation metrics. This unified framework enables a fair and transparent assessment of the relative strengths and limitations of each modeling approach.

The main contributions of this study are summarized as follows:

- A universal benchmarking system to evaluate the ensemble and neural network methods in a daily rainfall forecasting task with identical experimental settings.

- The analysis is based on long-term station observations of a semi-arid climate with high rainfall intermittency.
- A climate-informed assessment of model performance, focusing on the applicability of gradient boosting techniques to tabular meteorological data in data-sparse settings.

The rest of the study is organized as follows: Section II presents related work on machine learning-based rainfall prediction. Section III provides the area of study, the dataset, and the preprocessing. The modeling techniques and evaluation metrics are described in Section IV. Section V presents the experimental results, and we discuss our findings and their limitations in Section VI. Section VII concludes the study and outlines future research directions.

II. Related Work

A. Rainfall Forecasting Using Machine Learning

The prediction of rainfall has long been acknowledged as a difficult problem, primarily because precipitation processes are known to be both nonlinear and nonstationary with high intermittency. Traditional statistical methods, including linear regression and autoregressive models, have been widely used for rainfall prediction. However, their predictive performance is typically weak under strong climate fluctuations and extreme rainfall events. These constraints have led to the growing use of machine learning (ML) approaches as data-driven solutions for rainfall prediction.

Machine learning techniques have demonstrated strong capabilities for capturing complex nonlinear associations between rainfall and atmospheric predictors. Various ML techniques, such as decision trees, support vector machines, artificial neural networks, and ensemble learning methods, have been used to predict rainfall using station-based gauges, satellite-derived products, or reanalysis data. Several researchers have found that machine learning (ML) methods can outperform traditional statistical approaches for daily rainfall forecasting, especially when multiple meteorological variables are used as inputs [2], [12]. Reanalysis data, including ERA5, have also been increasingly adopted in ML-based rainfall prediction to provide spatially and temporally consistent atmospheric information [10]. Nevertheless, the performance of ML techniques on rainfall prediction is still sensitive to regional climate conditions, data availability, and experimental settings. Most previous research has been carried out in wet or temperate zones, since rainfall patterns there are relatively regular. In contrast, semi-arid areas (with low, unevenly distributed rainfall) have received less attention [2]. This disparity underscores the need for region-specific studies that explicitly address the challenges of rainfall prediction in semi-arid environments.

B. Boosting and Neural Network Models for Rainfall Prediction

Ensemble-based methods and neural networks are the two main modeling paradigms for rainfall forecasting among machine learning techniques. Tree-based ensemble learners, including Random Forest, have been extensively used in rainfall prediction because of their strength in modeling when interactions exist among input predictors and their efficacy in handling the heterogeneity of meteorological covariates [5]. Random Forest models have been shown to perform well in daily rainfall prediction and can yield better results than classical regression methods, particularly in systems with high rainfall variability [12], [13].

Gradient boosting methods such as XGBoost and LightGBM have received growing attention in recent rainfall prediction research. These models refine prediction accuracy by correcting residual errors. They are found to perform significantly better than single decision trees and classical neural networks in several rainfall estimation studies [6], [14], [15]. Their excellent ability to handle small sample sizes, missing values, and skewed rainfall distributions makes them particularly desirable for station-based rainfall forecasting in data-limited areas. CatBoost has also been investigated for precipitation prediction, with reported improvements in robustness and reduced bias in simulating complex rainfall patterns [8], [16].

Neural network techniques have also been widely studied in the context of rainfall prediction. Multilayer Perceptron (MLP) networks have been employed for daily rainfall forecasting using data from meteorological stations. They can produce satisfactory results when large volumes of training data are used and careful input feature selection is performed [9], [17]. More complex neural network structures have also been investigated to capture temporal relationships in precipitation series. However, these methods usually require substantial data and extensive hyperparameter tuning, making them challenging to use in station-based and semi-arid contexts.

Comparison analysis shows that boosting-based ensemble models generally yield more stable and robust predictions than neural network methods for tabular meteorological data and daily rainfall forecasting, especially in the presence of rainfall intermittency and scarce data [14], [15]. However, model performance is heavily dependent on climate, predictor selection, and evaluation methods, underscoring the need for consolidated benchmarking.

C. Research Gaps and Challenges in Semi-Arid Regions

Although machine learning models have attracted attention in rainfall prediction, there is still little research on this topic, especially in semi-arid areas. First, many studies were conducted under heterogeneous conditions for preprocessing, feature engineering, and evaluation metrics. This lack of uniformity prevents comparisons of reported results and makes it difficult to draw strong conclusions about model performance. Second, in semi-arid climates, rainfall occurs as long dry spells punctuated by brief, heavy rainfall events. This type of sparsity, intermittency, and skewness can pose major challenges in the development and performance of data-driven models when identifying hidden patterns from scarce rainfall observations. Therefore, performance observed in humid or data-rich regions cannot be extrapolated to semi-arid conditions without rigorous validation. Finally, few studies offer climate-sensitive interpretations of the performance of machine learning models directly related to the physical characteristics of rainfall processes in arid areas. Existing work tends to be accuracy-oriented and pays little attention to what makes the model perform better or worse in a particular climate. Addressing these

challenges requires unified experimental frameworks, region-specific analysis, and interpretative discussions that link model behavior to rainfall variability and data characteristics in semi-arid regions.

III. Study Area and Data Description

A. Study Area

The research was carried out in Settat, a city situated in west-central Morocco, and covers the semi-arid climatic zone. Settat is located at altitudes ranging from 200 to 416 m above sea level and is characterized by high interannual and intra-annual rainfall variability. The area is known for a regional weather regime characterized by long, dry seasons terminated by short, sporadic rainfall events, making precipitation prediction particularly difficult.

Seasonal temperature variations are pronounced. Maximum air temperatures in the summer period commonly exceed 35°C and can reach up to 46°C, while those in winter are generally milder (5 to 15°C). Precipitation is low throughout the year and varies from one month to another. These conditions render Settat a suitable study area for assessing the reliability of machine learning techniques for precipitation estimation in semi-arid climates, where precipitation processes are highly intermittent and nonlinear.

B. Data Sources and Description

The meteorological data used in this work are obtained from the Settat weather station of the General Directorate of Meteorology (GDM), Morocco. The dataset comprises daily records for 2014-2024. Owing to institutional policy on data sharing, raw data will not be made publicly accessible unless an individual requests it with the GDM.

The dataset consists of eight daily meteorological variables selected for their potential influence on rainfall generation processes. These variables include maximum air temperature (TMPMAX, °C), minimum air temperature (TMPMIN, °C), mean station pressure (Mean_Pressure, hPa), maximum relative humidity (HUMAXQ, %), minimum relative humidity (HUMINQ, %), maximum wind speed (FFXINS, m/s), maximum wind direction (DDXINS, °), and daily rainfall (RRQUOT, mm). Daily rainfall (RRQUOT) was used as the target variable, with all other weather variables as predictors. The selection of these variables is guided by their physical importance to the process and by their accessibility at the station scale.

C. Data Preprocessing

A uniform and well-designed preprocessing workflow was adopted for the dataset, maintaining its temporal structure and improving the model's learning. In a first step, meteorological data were ordered chronologically to match the time scales. In cases of missing values, we linearly interpolated them to produce a continuous time series while avoiding the introduction of artificial discontinuities. Cyclical encoding of the calendar variables was used to model the seasonal and temporal patterns. Precisely, the day and month information was processed by sine and cosine functions, and binary dummy variables were included to denote the four meteorological seasons. Furthermore, lagged features at several past time points were derived from the original predictors to capture temporal dynamics. This was in addition to rolling statistical features (daily and cumulative means, maxima, minima, standard deviations, and daily differences), which were also calculated for persistence and short-term variability in meteorological conditions.

Since tree-based ensemble models (Random Forest, XGBoost, LightGBM, and CatBoost) are not sensitive to feature scaling, we used the generated features directly. On the other hand, we get that the MLP model requires feature scaling; therefore, Min-Max normalization was applied only after the chronological data split to avoid data leakage. The data was divided into 70% for training, 15% for validation, and 15% for testing in a strict temporal order. Finally, non-informative attributes such as station IDs and raw date columns were dropped from the dataset, leaving only those with significance for weather conditions or the period. Linear interpolation was selected due to the relatively low proportion of missing values and its ability to preserve the temporal continuity of daily meteorological time series without introducing artificial variability.

It is important to note that this study is based on data from a single meteorological station located in Settat. This choice is primarily due to the limited availability of high-quality and continuous multi-station meteorological data in the region.

However, the Settat station is representative of the semi-arid climatic conditions of central Morocco, characterized by low, irregular rainfall. Therefore, the findings of this study provide meaningful insights into rainfall prediction in similar semi-arid environments.

Future work will focus on extending this approach to multi-station datasets and incorporating spatial variability to improve model generalization further.

IV. Methodology

A. Experimental Framework

In this research, a consolidated, organized experimental framework is proposed to enable an equitable comparison of machine learning models for daily rainfall prediction. The purpose of this study was to compare the predictive performance of ensemble tree models and neural network approaches under the same data requirements and evaluation protocols. All models were trained using the feature sets generated by the preprocessing pipeline described in Section III. The datasets were divided into 70% for training, 15% for validation, and 15% for testing while preserving the time sequences (no data leakage). Hyperparameters were optimized for the training and validation subsets only, and the test set was held off until the final performance assessment. This controlled setup ensures both methodological comparability and statistical reliability when comparing models. The overall workflow of the proposed methodology is illustrated in Fig. 1.

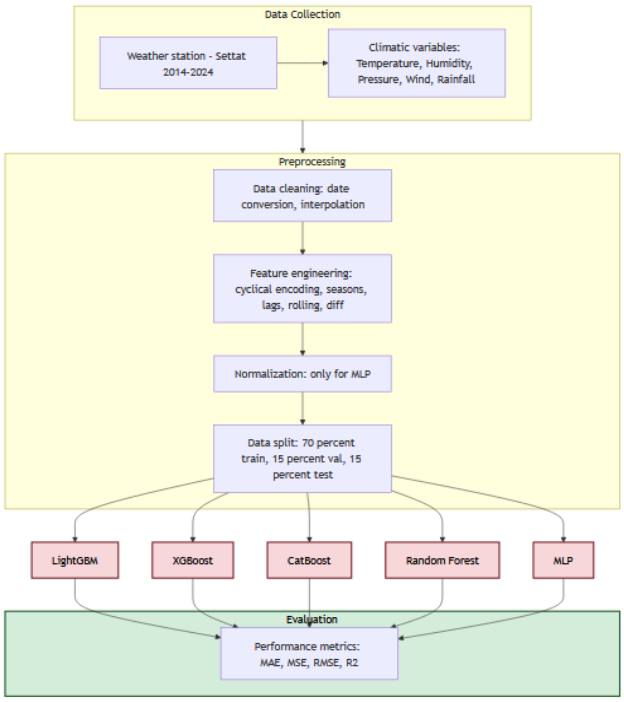

Fig. 1. Proposed methodology flowchart.

B. Machine Learning Models

The five supervised regression models used in this study were Random Forest, XGBoost, LightGBM, CatBoost, and Multilayer Perceptron (MLP). These models were selected to represent two dominant paradigms in tabular data modeling: ensemble-based tree methods and neural network architectures.

1) Random Forest (RF): Random Forest is an ensemble learning method that creates multiple decision trees via bootstrap sampling and random feature selection. The final prediction is obtained by averaging the three results. This strongly reduces variance and enhances generalization. Random forest is well-suited for a precipitation forecast model in a semi-arid region with an irregular and highly variable rainfall distribution because of its noise insensitivity and ability to handle multicollinearity and non-linear interactions.

2) Extreme Gradient Boosting (XGBoost): XGBoost is a gradient-boosting machine learning method that trains decision trees sequentially to minimize a regularized objective. The model adjusts the residuals from the previous trees at each iteration. The model also includes regularization to prevent overfitting and ensure the stability of the training model. XGBoost is well-known for its excellent predictive performance on structured data with nonlinear patterns.

3) Light Gradient Boosting Machine (LightGBM): LightGBM is a gradient boosting framework that uses a histogram-based learning algorithm, and it grows the tree leaf-wise. These models improve computational efficiency while preserving high predictive performance. LightGBM is particularly suited to structured meteorology datasets with engineered statistical and temporal features.

4) CatBoost: CatBoost is a gradient boosting algorithm that aims to reduce prediction bias by using ordered boosting methods. Although the data source used in this study contains mostly numerical features, we included CatBoost because it has been reported to be robust to noise and performs well for general tabular regression problems.

5) Multilayer Perceptron (MLP): The Multilayer Perceptron is a feedforward artificial neural network consisting of fully connected layers with nonlinear activation functions. For this analysis, an MLP was used as a regression model to capture complex nonlinear relationships between meteorological variables and daily rainfall. Neural Networks are sensitive to variations in feature scale. Therefore, the input variables were normalised using min–max normalisation before model training.

C. Hyperparameter Optimization

Hyperparameter optimization was performed on the training and validation subsets. Ensemble model hyperparameters, including the number of trees, maximum tree depth, and learning rate, were optimized to maximize predictive performance without overfitting. For the MLP network, the hidden neurons, learning rate, and number of training iterations were tuned. The final hyperparameter settings for each model were chosen based on validation performance. The test set was held out entirely during model tuning to obtain an unbiased estimate. The final selected hyperparameter values for each model are summarized in Table I.

TABLE I. HYPERPARAMETER SETTINGS OF THE EVALUATED MODELS

Model	Hyperparameters
LightGBM	learning_rate = 0.03; num_leaves = 31; feature_fraction = 0.8; bagging_fraction = 0.8; min_data_in_leaf = 20
XGBoost	learning_rate = 0.03; max_depth = 3; subsample = 0.8; colsample_bytree = 0.8; min_child_weight = 2
CatBoost	iterations = 1000; learning_rate = 0.03; depth = 6; l2_leaf_reg = 3
Random Forest	n_estimators = 200; max_depth = None
MLP	hidden_layers = (64, 32); activation = ReLU; learning_rate = 0.001; batch_size = 32; epochs = 120

Early stopping was applied for gradient boosting models and the MLP model to determine the optimal number of training iterations and prevent overfitting.

D. Evaluation Metrics

Model performance was evaluated using four complementary regression metrics: Mean Absolute Error (MAE), Mean Squared Error (MSE), Root Mean Squared Error (RMSE), and the Coefficient of Determination (R^2). The MAE is the mean of the differences between observed and predicted rainfall values. MSE gives the mean of the squared errors and is sensitive to large deviations. RMSE: The square root of the MSE, RMSE, quantifies rainfall prediction error (millimetres), enabling interpretation. R^2 is the fraction of the variability in observed rainfall that the model explains. Their joint consideration enables accurate measurement of the quality and performance of models in semi-arid regions with low precipitation.

V. RESULTS

Before evaluating model performance, it is important to analyze the statistical characteristics of the rainfall data. The dataset is characterized by a high proportion of zero rainfall values, corresponding to long dry periods typical of semi-arid climates. In contrast, rainfall events occur sporadically and are often characterized by high intensity, resulting in a highly skewed distribution.

This intermittency and variability make rainfall prediction particularly challenging, as models must simultaneously capture both the absence of rainfall and sudden extreme events. These characteristics highlight the importance of using robust machine learning models that can handle nonlinear and imbalanced data distributions.

A. Overall Predictive Performance

The performance of the tested machine learning models was evaluated on the test set using four evaluation metrics: mean absolute error (MAE), mean squared error (MSE), root mean squared error (RMSE), and coefficient of determination (R^2). A comparative result for Random Forest (RF), XGBoost, LightGBM, CatBoost, and Multilayer Perceptron (MLP) is shown in Table II.

TABLE II. PERFORMANCE COMPARISON OF MACHINE LEARNING MODELS FOR DAILY RAINFALL PREDICTION.

Metrics	Method				
	LightGBM	***XGBoost***	***CatBoost***	***RF***	***MLP***
MAE	0.0507	0.0423	0.0534	0.0683	0.1628
MSE	0.0456	0.0530	0.0536	0.1199	0.3096
RMSE	0.2135	0.2301	0.2314	0.3463	0.5564
R^2	0.9868	0.9846	0.9844	0.9652	0.9107

The performance of the evaluated machine learning models is summarized in Table II using four evaluation metrics: MAE, MSE, RMSE, and R^2. The results clearly indicate that gradient boosting models outperform the other approaches across all metrics.

LightGBM achieved the best overall performance, with the lowest error values and the highest coefficient of determination ($R^2 = 0.9868$), indicating its strong ability to accurately model rainfall variability. XGBoost and CatBoost also demonstrated competitive performance, with slightly higher error values but still maintaining high predictive accuracy.

In contrast, the Random Forest model showed moderate performance, with higher error rates than boosting methods. The MLP model exhibited the weakest performance, with significantly higher errors and lower R^2 values, indicating difficulties in learning from intermittent, highly variable rainfall patterns.

The superior performance of gradient boosting models can be attributed to their sequential learning strategy, which iteratively reduces prediction errors and enhances model generalization. These models are particularly effective in handling nonlinear relationships and skewed data distributions, which are common characteristics of rainfall in semi-arid regions.

Furthermore, boosting algorithms are more robust to sparse data and are better suited to capture rare but significant rainfall events. In contrast, neural network models such as MLPs require larger, more balanced datasets to achieve stable performance, which limits their effectiveness in this context.

B. Feature Importance Analysis

To further interpret the predictive behavior of the best-performing model, a feature importance analysis was conducted using the LightGBM algorithm. This analysis provides insight into the relative contribution of each input variable to the rainfall prediction task.

The results indicate that meteorological variables such as relative humidity, temperature, and wind speed play a significant role in rainfall prediction. In particular, relative humidity was identified as one of the most influential features, as it directly reflects atmospheric moisture conditions necessary for precipitation formation.

Temperature variables also contribute significantly, as they influence evaporation and condensation processes. Wind-related features further enhance prediction performance by capturing atmospheric dynamics and moisture transport.

Overall, the feature importance analysis confirms that the selected input variables are physically relevant and consistent with the underlying climatic processes governing rainfall in semi-arid regions. This strengthens the reliability and interpretability of the proposed machine learning approach.

C. Observed vs. Predicted Daily Rainfall

To better understand the predictive behavior of the evaluated models, a visual comparison between observed and predicted daily rainfall values is presented for selected models. The selected models include LightGBM as the best-performing model, XGBoost as a competitive gradient boosting approach, and the Multilayer Perceptron (MLP) as a neural network baseline.

Fig. 2 illustrates the comparison between observed and predicted daily rainfall using the LightGBM model on the testing dataset. The predicted rainfall closely follows the observed temporal patterns, effectively capturing both prolonged dry periods and rainfall events. This demonstrates the model's strong capability in representing the nonlinear and intermittent nature of rainfall in semi-arid regions. However, slight underestimation is observed during high-intensity rainfall events, which is consistent with the difficulty of modeling extreme values in skewed precipitation distributions.

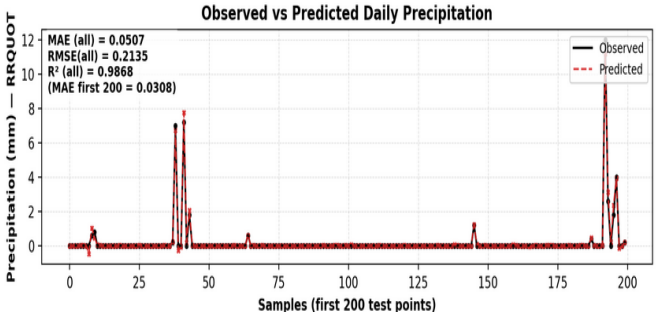

Fig. 2. Observed vs. predicted daily rainfall using LightGBM.

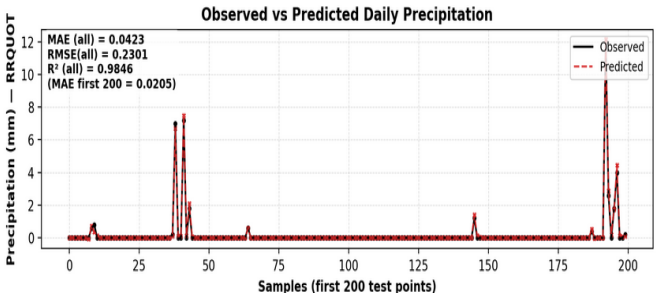

Fig. 3. Observed vs. predicted daily rainfall using XGBoost.

Fig. 3 presents the observed and predicted rainfall values using the XGBoost model. Similar to LightGBM, XGBoost can capture general rainfall dynamics and temporal variability with high accuracy. Nevertheless, minor deviations are evident compared to LightGBM, particularly during peak rainfall periods, suggesting slightly lower precision in modeling extreme events.

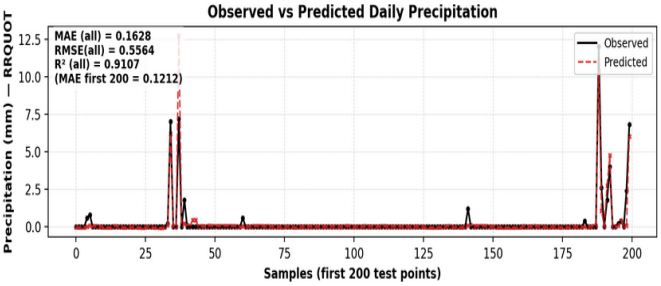

Fig. 4. Observed vs. predicted daily rainfall using MLP.

Fig. 4 shows the MLP model's performance in predicting daily rainfall. Unlike the boosting-based methods, the MLP model exhibits larger discrepancies between observed and predicted values. The model struggles to accurately reproduce rainfall variability, especially during abrupt transitions and extreme rainfall events. This behavior reflects the limitations of neural networks when applied to relatively small and highly intermittent meteorological datasets.

Overall, the visual comparison confirms the quantitative results presented earlier, demonstrating that gradient boosting models, particularly LightGBM and XGBoost, provide more accurate and stable predictions than the neural network model. These models are better suited to capture the intermittent, nonlinear, and skewed characteristics of rainfall in semi-arid environments.

D. Comparative Analysis of Model Behavior

Model comparison reveals the robustness and stability of gradient boosting models (LightGBM, XGBoost, and CatBoost) across rainfall intensity levels.

LightGBM has the lowest MAE, MSE, and RMSE values and the highest R^2, indicating a stronger ability to minimize prediction error while explaining more rainfall variability.

In contrast, the MLP model displays greater variability in prediction errors at all-time steps, especially during rapid precipitation changes. Random forests show reasonable robustness but are still behind boosting-based methods on the respective metrics evaluated.

These results indicate that boosting algorithms are particularly ideal for simulating the intermittent and skewed rainfall distributions commonly found in semi-arid environments.

The graphical comparison between observed and predicted rainfall values further supports these findings. As illustrated in Fig. 2 to Fig. 4, the boosting-based models provide a closer fit to the observed data, whereas the MLP model exhibits larger deviations, particularly during abrupt rainfall changes.

VI. Discussion

A. Interpretation of Model Performance

The experimental results indicated that all gradient boosting models, especially LightGBM, performed strongly in reducing prediction errors and explaining rainfall variability when predicting daily rainfall in the semi-arid region of Settat. For instance, a lower MSE value implies greater reliability against large prediction errors, and lower MAE and RMSE suggest improved consistency in reproducing rainfall intensity. The higher R^2 score also suggests that this model better explains rainfall variability than those analyzed.

Boosting algorithms are particularly strong because they iteratively refine residual errors to improve generalization via a sequential error-correction mechanism. This framework is especially beneficial for modelling nonlinear relationships between meteorological predictors and for accommodating skewed rainfall distributions. There have been similar findings in semi-arid rainfall prediction studies using ensemble and boosting methods [18], [19]. In contrast, broader reviews stress that AI-based rainfall forecasting frameworks are highly robust to climatic variability [20].

Conversely, the MLP showed greater variation in prediction errors, especially during rapid rainfall changes. Neural network models need more extensive, balanced datasets to achieve stable performance. Similar findings from comparative studies across various climatic regions indicate that deep learning models may struggle when trained on limited or highly intermittent rainfall datasets [21].

B. Comparison with Existing Literature

To evaluate the effectiveness of the proposed approach, the obtained results were compared with findings from recent studies on rainfall prediction in semi-arid regions.

Recent studies have demonstrated the effectiveness of machine learning and ensemble techniques for precipitation modeling. For instance, a recent study conducted in Morocco [18] reported high predictive performance using CatBoost and XGBoost models, with R^2 values reaching approximately 0.98. Similarly, other studies have demonstrated that machine learning and hybrid approaches achieve strong predictive performance in rainfall prediction tasks across different climatic conditions [22], [23].

In comparison, the proposed LightGBM model achieved an R^2 of 0.9868, demonstrating competitive, robust predictive performance. These results confirm that ensemble learning approaches are well-suited for modeling the nonlinear and highly variable nature of rainfall in semi-arid environments.

C. Implications and Study Limitations

Semi-arid areas are characterized by long dry periods interspersed with short-duration, high-intensity events, making rainfall forecasting a fundamental challenge in these regions. This intermittency results in highly skewed data distributions, making models sensitive to extreme values. The reduction in RMSE for the LightGBM across both extremes was observed, confirming its resilience to these extremes and further suggesting a move towards semi-arid rainfall modelling with this algorithm.

However, some limitations need to be considered. First, the analysis is based on a single meteorological station, which limits spatial generalizability. Second, daily one-step-ahead forecasting was only examined when multiple-step-ahead prediction frameworks may yield more operationally relevant insights [24]. Third, the more sophisticated spatiotemporal deep learning models were not applied in this study [25].

Nevertheless, the general, unified evaluation framework used in this study provides a clear standard against which to compare machine learning algorithms in semi-arid climates. It contributes to understanding the suitability of algorithms under intermittent precipitation regimes.

VII. Conclusion

This study presented a comprehensive evaluation of machine learning models for daily rainfall prediction in a semi-arid region of Morocco. Several models, including LightGBM, XGBoost, Random Forest, CatBoost, and MLP, were assessed using standard performance metrics.

The results demonstrated that the LightGBM model achieved the best performance, with a high coefficient of determination (R^2 = 0.9868) and low prediction errors, indicating its strong capability to model nonlinear and highly variable rainfall patterns.

These findings highlight the effectiveness of ensemble learning approaches for rainfall prediction, particularly in data-scarce and semi-arid environments.

However, this study is limited by the use of data from a single meteorological station, which may affect the generalization of the results.

Future work will focus on extending this approach to multi-station datasets, incorporating spatial and temporal variability, and exploring advanced deep learning architectures, such as LSTMs and hybrid models, to further improve prediction accuracy.

Acknowledgment

The authors would like to thank the General Directorate of Meteorology (DGM) in Morocco for providing the meteorological data used in this study.

***Abstract*—Breast cancer remains one of the most prevalent and life-threatening diseases worldwide, needing to be diagnosed early and properly classified for effective treatment. Advancements in artificial intelligence (AI), deep learning, and machine learning techniques have shown great potential in automating breast cancer diagnosis and molecular subtyping using medical imaging. This systematic literature review explores the application of AI in breast cancer classification, focusing on mammographic imaging and its application in distinguishing molecular subtypes. The study follows the PRISMA guideline, investigating studies from multiple digital libraries published between 2020 and November 2024. Findings show that while deep learning models have significantly improved breast cancer detection, challenges remain in optimizing classification models for molecular subtypes, balancing accuracy and interpretability, and integrating AI-based tools into clinical practice workflows. Besides, heterogeneity in preprocessing pipeline algorithms and dataset limitations highlights the importance of conducting additional research to develop robust and generalized classification models. This review underscores the importance of AI-driven solutions in advancing breast cancer diagnosis and treatment planning while providing insights into future research directions.**

Keywords*—Artificial intelligence; breast cancer; classification; Convolutional Neural Network; deep learning; machine learning; mammography; medical imaging; molecular subtypes; Vision Transformer

I. Introduction

Breast cancer occurs when abnormal cells in the breast grow uncontrollably, forming tumors. This often involves changes in hormone receptors, such as estrogen (ER), progesterone (PR), and human epidermal growth factor receptor 2 (HER2). According to the World Health Organization, breast cancer affected 2.3 million women worldwide in 2022, causing around 670,000 deaths, making it the second most common cancer globally [1][2]. In Asia, particularly in Malaysia, the incidence continues to rise, with breast cancer being the most frequently diagnosed cancer, accounting for 16.2% of all cases [3].

Classifying breast cancer into molecular subtypes is crucial for determining appropriate treatment strategies. Based on gene expression profiling, the main subtypes include Luminal A, Luminal B, HER2-enriched, Basal-like, and Claudin-low [4][5][6][7]. Each subtype exhibits distinct biological characteristics and responds differently to therapeutic interventions, making accurate classification critical for personalized care [8]. For instance, luminal tumors are typically treated with endocrine therapy, HER2-enriched tumors respond well to targeted antibody therapy, while Basal-like or triple-negative tumors, although aggressive, may show responsiveness to chemotherapy.

Currently, molecular subtyping is mainly done through immunohistochemistry (IHC), which requires invasive tissue biopsies. However, this approach presents several limitations, including patient discomfort, procedural risks, and diagnostic inaccuracies. Studies have reported that up to 30% of biopsies may yield false-negative results due to sampling errors, potentially delaying appropriate treatment. Although imaging modalities such as mammography, magnetic resonance imaging (MRI), and ultrasound provide valuable tumor-related information, they are not routinely utilized for molecular subtype classification. Among these, digital mammography stands out as a cost-effective and widely accessible screening tool, particularly in resource-limited settings. It also offers practical advantages in terms of acquisition time, typically requiring only 15 to 20 minutes compared to longer durations for ultrasound and MRI. Among these, digital mammography is particularly notable for its cost-effective and widespread accessibility, especially in resource-limited settings. It also offers practical advantages over other imaging techniques, with screening procedures typically taking just 15 to 20 minutes, compared to over 30 minutes for ultrasound and between 30 and 90 minutes for MRI scans [9]. Furthermore, mammography enables early detection of breast cancer by identifying abnormalities two to three years before they become clinically palpable [10].

Despite such advances, a substantial research problem remains, namely the lack of accurate, dependable, and non-

invasive techniques for the categorization of breast cancer genetic subtypes utilizing imaging data. Current diagnostic methods predominantly depend on invasive techniques, whereas contemporary imaging modalities primarily emphasize tumor identification rather than subtype classification. Furthermore, the incorporation of sophisticated artificial intelligence (AI) methodologies, especially deep learning architectures like Convolutional Neural Networks (CNNs) and Vision Transformers (ViTs), has not been thoroughly examined regarding non-invasive subtype classification. This deficiency constrains the advancement of effective computer-aided diagnostic systems that can assist in clinical decision-making. Non-invasive AI-based approaches have the potential to reduce unnecessary biopsies and improve diagnostic efficiency.

Therefore, the primary objective of this study is to systematically review and analyze the application of artificial intelligence techniques in breast cancer molecular subtype classification using imaging data. Specifically, this study aims to: 1) categorize existing approaches into CNN-based, Vision Transformer-based, and hybrid CNN–ViT models; 2) evaluate their performance, strengths, and limitations; and 3) identify current research gaps and future directions for improving non-invasive diagnostic methods.

The significance of this study lies in its contribution to advancing non-invasive breast cancer diagnosis by providing a comprehensive synthesis of state-of-the-art AI techniques. By critically analyzing existing methods, this review offers valuable insights into the effectiveness of different deep learning architectures and highlights opportunities for integrating imaging, radiomic features, and advanced models to enhance classification accuracy. Ultimately, this work supports the development of reliable, AI-driven diagnostic tools that can reduce dependence on invasive biopsies, improve early detection, and facilitate personalized treatment planning.

In this study, a systematic literature review based on the PRISMA 2020 framework is conducted to evaluate recent advancements in AI-driven breast cancer molecular subtype classification. The selected studies are analyzed and categorized according to their methodological approaches, including CNN-based models, Vision Transformer-based models, and hybrid architectures. Through this structured analysis, the study aims to provide a clear understanding of current trends, challenges, and future research opportunities in this domain.

This review bridges AI-based imaging analysis with clinically relevant molecular subtype classification, directly linking computational advancements to personalized treatment strategies and decision-making in breast cancer care.

II. Research Methodology

This systematic literature review adopts a focused (scoping) approach to explore AI's clinical applications in mammography imaging for classifying breast cancer molecular subtypes. The study specifically emphasizes recent and highly relevant works that address non-invasive subtype classification using imaging data, ensuring a targeted and in-depth analysis within a clearly defined research scope. Additionally, it examines other diagnostic methods, highlighting their current limitations and discussing future directions for AI in breast cancer diagnosis and treatment planning. The Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guiding principles were employed for the systematic review. This approach ensures a consistent and replicable process for identifying, selecting, and evaluating the relevant studies [11]. Fig. 1 presents the PRISMA flow diagram, illustrating the inclusion and exclusion process for articles considered in this literature review.

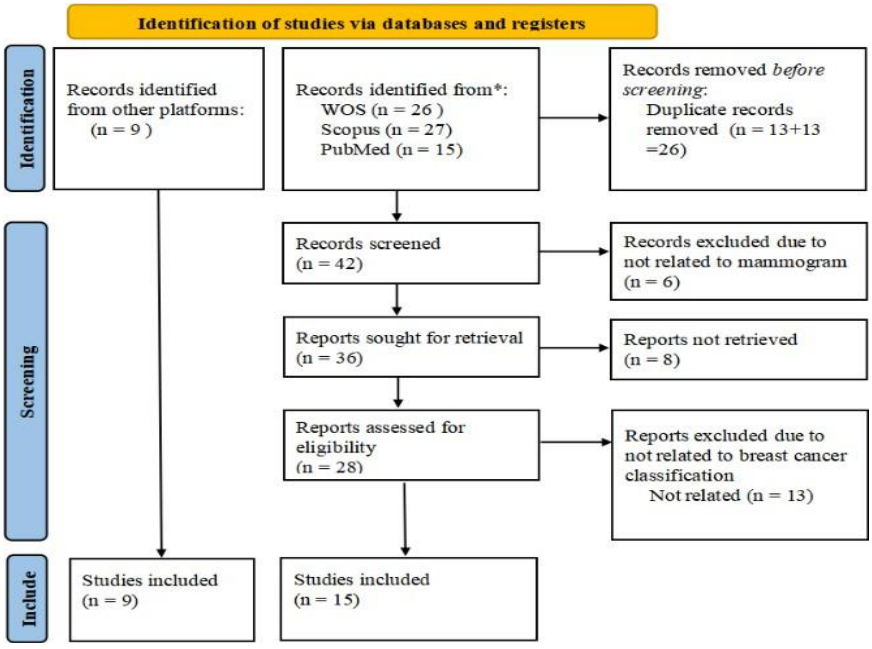

Fig. 1. PRISMA flow diagram.

A. Research Question

The research questions for this study are outlined in Table I, defining the overall purpose and expected outcomes. Each question is presented along with its motivation.

TABLE I. RESEARCH QUESTIONS AND MOTIVATIONS

Research Question	Main Motivation
What is the most effective image processing technique applied to extract tumor features from mammographic images?	To develop image processing technique to extract radiomic features, including shape and texture, relevant to breast cancer molecular subtypes from digital mammographic images.
What is the most effective model architecture for breast cancer molecular subtypes classification in terms of performance?	To construct classification models to analyze radiomic features and classify breast cancer into molecular subtypes.
How can a GUI be designed to support seamless interaction and decision-making for breast radiologists for identifying molecular subtypes of breast cancer?	To develop a Graphical User Interface (GUI) that allows users to automatically identify breast cancer molecular subtypes from digital mammographic images.

B. Search Scheme

The primary digital libraries used for this search were Web of Science (WOS), Scopus, and PubMed. These databases were selected for their comprehensive collections of peer- reviewed studies and their capability to offer access to the latest advancements in biomedical engineering and artificial intelligence applications. Additionally, several breast cancer classification journals were identified on platforms outside these three databases, including Google Search, Google Scholar, ScienceDirect, and IEEE Xplore Library.

C. Systemic Review Process

The systematic review followed the PRISMA framework, consisting of three key phases, which are identification, screening, and analysis. The literature search was conducted from 2020 to November 6, 2024, using the search string: "breast" AND ("cancer" OR "tumour") AND "subtype*" AND "deep learning" AND "mammogra*".

During the identification stage, a total of 68 studies were obtained from Web of Science (WOS), Scopus, and PubMed. However, 26 studies were removed after filtering for duplicate papers. Besides, an additional 9 studies were identified from other platforms. In the screening stage, the 27 papers were further excluded, as 6 studies were unrelated to mammograms, 8 studies could not be retrieved, and 13 studies were not focused on breast cancer classification. Finally, a total of 24 research articles were selected for review after performing an identification from other platforms. Furthermore, some studies that explored other modalities for breast cancer classification, such as Magnetic Resonance Imaging (MRI), ultrasound, and histopathology techniques, were considered as references. While some of these studies were included in the final set of 24 research articles, others were excluded but were still referenced in several sections of the literature review. Fig. 2 displays the distribution of the final set of selected research articles.

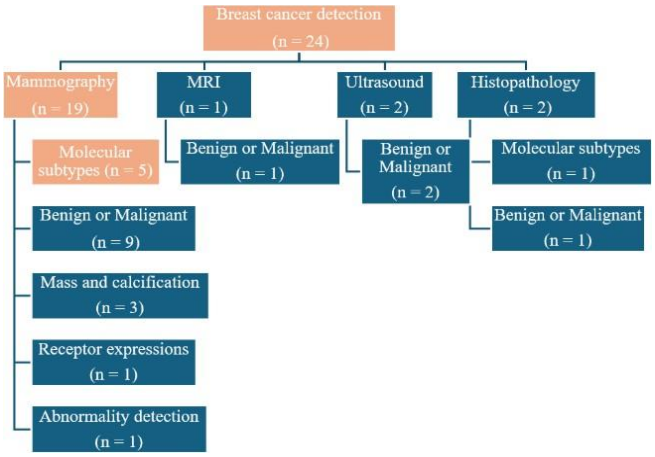

Fig. 2. Distribution of the final set of selected research articles.

D. Inclusion and Exclusion Principles

Table II lists the inclusion and exclusion principles for the chosen research. Stringent inclusion and exclusion criteria were applied to ensure the relevance and quality.

TABLE II. RESEARCH INCLUSION AND EXCLUSION CRITERIA

Inclusion criteria	Exclusion criteria
IC1 – Search will be conducted across all fields.	EC1 – Studies not related to breast cancer.
IC2 – Limited to open access and open archive materials.	EC2 – Studies lack focus on tumor radiomics feature extraction and classification.
IC3 – Articles and research articles.	EC3 – Review articles, books, chapters in book series, news articles, conference proceedings, case reports, and abstracts without full papers.
IC4 – The publication date range is set from 2020 to January 2026.	EC4 – Articles with inaccessible full texts.
IC5 – Studies published in English.	EC5 – Non-English publications.

III. RESULTS AND DISCUSSION

Table IV presents all the included studies, detailing their sample size, sample source, processing methods, architecture, and SWOT analysis (which examines strengths, weaknesses, opportunities, and threats).

Recent studies have explored the application of artificial intelligence techniques, particularly Convolutional Neural Networks (CNNs) and emerging Vision Transformer (ViT) architectures, for breast cancer classification using medical imaging. CNN-based approaches have demonstrated strong performance in tumor detection and classification tasks due to their ability to capture local spatial features. Meanwhile, Vision Transformer-based models have shown potential in modeling global contextual relationships within medical images. Hybrid CNN–Transformer architectures have also been introduced to leverage the strengths of both approaches.

However, most existing studies primarily focus on binary classification tasks, such as distinguishing between benign and malignant tumors, rather than performing detailed molecular subtype classification. Furthermore, many models rely on limited datasets or single imaging modalities, which may affect

generalizability and robustness. These limitations highlight the need for a comprehensive analysis of current AI-based methods specifically targeting non-invasive breast cancer molecular subtype classification. Therefore, this study aims to bridge this gap by systematically reviewing and comparing existing approaches while identifying key challenges and future research directions.

The overall workflow of AI-based breast cancer analysis adopted in this study is illustrated in Fig. 3, which presents a systematic framework encompassing data acquisition, preprocessing, feature extraction, model development, and classification.

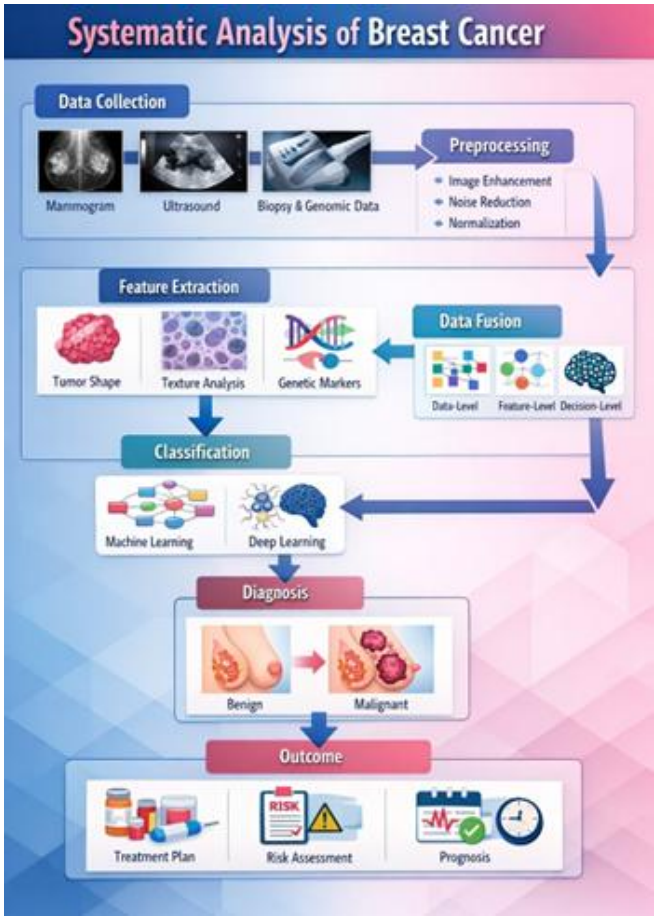

Fig. 3. Systematic framework for breast cancer analysis.

A. Machine Learning Approaches

Studies such as Khalid et al. [12] and Ma et al. [8] have employed machine learning approaches to classify mammogram images. Khalid et al. [12] implemented six classification models to distinguish between benign and malignant breast tumors, concluding that the Random Forest algorithm achieved the highest accuracy of 96.49%. On the other hand, Ma et al. [8] proposed a Naïve Bayes-based binary classification model to identify various molecular subtypes of breast cancer. These approaches, however, rely on manual feature selection and engineering, which necessitates human input and expertise. For example, the former utilized three modules, the low-variance features removal, univariate feature selection, and recursive feature elimination, to refine their models. Similarly, the latter combined manual segmentation with automated feature selection and extraction using LASSO (Least Absolute Shrinkage and Selection Operator) method.

B. Deep Learning Approaches

In contrast, deep learning approaches offer a significant advantage through their fully automated methodologies, from segmentation to classification. This is particularly beneficial in domains where the relevant features are not predefined or easily identifiable. For example, Carvalho et al. [13] introduced an end-to-end classifier leveraging SegNet and UNet for segmentation, thereby processing raw images without manual intervention. While deep learning typically requires large datasets for training, it is better suited for complex tasks such as image recognition, surpasses the traditional machine learning approaches.

C. Histopathology

Histopathology, which involves the diagnosis and study of diseases of the tissues level, plays a critical role in breast cancer analysis. It typically involves examining tissues or cells under a microscope and often requires a biopsy [14]. Biopsy is a procedure to remove cells, tissue or fluid from the targeted organ for examination. As the reference standard for breast cancer diagnosis, histopathology enables classification into molecular subtypes [15], which is essential for specialist to determine the type of breast cancer and devise an appropriate treatment plan.

Murtaza et al. [16] introduces a two-level hierarchical classifier employing various types of deep neural networks to classify breast cancer using histopathology images. The framework identifies eight distinct output classes, which are classifier distinguishes images as benign and malignant at the first level, while the second level further categorizes subtypes within each category. Among the architectures evaluated, the k-Nearest Neighbors (kNN) algorithm demonstrated the best performance, achieving 95.48% accuracy for first-level classification, 94.62% for benign subtypes, and 92.45% for malignant subtypes. Similarly, Rafiq et al. [17] utilizes histopathology images from the Kaggle dataset to evaluate the classification performance of a fusion-based convolutional neural network (CNN) framework. The authors proposed three CNN-based architectures for benign and malignant cancer classification, which are a straightforward CNN model (1-CNN), a fusion CNN model (2-CNN) and three CNN model (3-CNN). Among these, the 3-CNN architecture recorded the highest accuracy of 97.90%.

D. MRI and Ultrasound Imaging

Although histopathology remains a critical step in diagnosing breast cancer, non-invasive screening methods such as mammography, MRI and ultrasound have become increasingly favored as feasible options for large-scale screening. These methods offer advantages in terms of accessibility and reduced patient discomfort, often outweighing the invasive nature of histopathology in routine screening contexts. For instance, Carvalho et al. [13] utilized 20 dynamic contrast-enhancing magnetic resonance imaging (DCE-MRI) images from the public Quantitative Imaging

Network (QIN) database, recorded from 10 patients, to evaluate the accuracy of classifying tumor malignancy using the three-time-point (3TP) method, and the model achieved an impressive 100% classification accuracy. However, the small dataset used in the study raises concerns about potential overfitting, which could limit the model's generalizability. Beyond MRI, ultrasound imaging has also demonstrated utility in breast cancer classification. For example, Alshowarah [18] analyzed 780 ultrasound images from the Breast Ultrasound Images (BUSI) dataset to compare the performance of various classification architectures. Among these, the Random Forest algorithm outperformed others, achieving an accuracy of 88.63%. Similarly, T. Zhang et al. [19] and Jiménez-Gaona et al. [20] employed ResNet-50 and ResNet-18 architectures, respectively, to classify benign and malignant breast cancer using ultrasound and mammogram images, demonstrating the growing potential of advanced deep learning techniques in non-invasive diagnostics.

E. Mammography Imaging

Digital mammography is a cost-effective and widely available diagnostic tool, particularly in less-developed countries. It offers significant advantages over other imaging methods, as screening mammograms typically take only 15 to 20 minutes, compared to the 30 minutes or more required for ultrasound and the 30 to 90 minutes needed for MRI scans [9]. Additionally, mammography is particularly suited for early breast cancer detection, capable of identifying lumps two or three years before they can be felt by the patient [10]. Therefore, regular breast cancer screenings using mammography play a vital role in reducing modality risks and facilitating earlier and more effective treatment. Numerous studies have leveraged mammogram images for breast cancer classification. For example, Bobowicz et al. [21] used mammogram images from Medical University of Gdansk (MUG) and Chinese Mammography Database (CMMD) to train and test the models for classifying benign and malignant breast cancers. In their study, ResNet-34 demonstrated the best performance, achieving an accuracy of 82.2%. Mammography has also been employed in other applications, such as the classification of receptor expressions [22], feature extraction and early-stage breast abnormality detection [23], and the classification of breast masses and calcification [24]. These advancements highlight the versatility and effectiveness of mammography in breast cancer diagnosis and research.

F. Breast Cancer Molecular Subtypes Classification

As previously highlighted, breast cancer subtyping has critical therapeutic implications for clinical management of the disease, thus several studies have focused on developing classifiers for breast cancer molecular subtypes, including luminal A, luminal B, human epidermal growth factor receptor 2 (HER2)-enriched, and triple-negative types.

G. Convolutional Neural Network and Machine Learning

Molecular subtyping remains challenging due to subtle radiographic differences between subtypes, heterogeneity in tumor morphology, and frequent class imbalance in datasets (e.g., Luminal A dominance). Binary classifiers often fail to capture subtype-specific biomarkers, leading to accuracy <80% (Table IV). For instance, binary classification model which used to classify luminal A and non-luminal A subtypes is proposed by Liu et al. [25] with ResNet-50, achieving an accuracy of 53.3%. Similarly, Ma et al. [8] employed a Naive Bayes-based binary classification model to differentiate molecular subtypes recording accuracies of 0.796 for triple-negative, 0.748 for HER2-enriched and 0.788 for luminal subtypes. In contrast to these binary approaches, studies such as Mota et al. [26], Nissar et al. [15] and T. Zhang et al. [19] developed models capable of distinguishing multiple molecular subtypes. For example, Mota et al. [26] achieved an area under the curve (AUC) of 60.62% using a ResNet-101 deep CNN, Nissar et al. [15] reported an accuracy of 90% using MobileNet-V3 —highlighting that high accuracy may mask poor sensitivity in minority classes (e.g., HER2-enriched); and T. Zhang et al. [19] achieved an accuracy of 88.5% with ResNet-50. These multi-class classification model demonstrate the potential for more comprehensive diagnostic tools, advancing precision medicine in breast cancer treatment.

H. Vision Transformers

Despite the success of convolutional neural networks (CNNs) in medical imaging, their limited local receptive field restricts their ability to capture global context information [27]. A recent innovation, Vision Transformers (ViTs) has demonstrated a great potential to be an alternative to CNNs in image analysis due to their capacity to process large datasets and learn complex patterns. Gheflati & Rivaz [27] highlights the application of Vision Trans- formers (ViTs) in classifying breast ultrasound images, showcasing their ability to capture global dependencies within images through self-attention mechanisms by achieving 86.7% of accuracy, outperforming several state-of-the-art CNN architectures, including ResNet-50, VGG16, InceptionV3 and NASNetLarge. This study underscores ViTs' adaptability to small datasets using transfer learning, al- though computational requirements remain a challenge. Zeng et al. [28] also applied a Vision Transformer Multi-head Attention (ViT-MHA) architecture for breast mass diagnosis, leveraging bilateral mammography images to enhance diagnostic accuracy to 92.7%.

I. Hybrid CNN-ViTs

The hybridization of ViTs with CNNs has further improved image classification tasks. For example, Boudouh & Bouakkaz [29] combines ViTs for contextual feature extraction with CNNs for local detail recognition using the CBIS-DDSM dataset. ViTs outperform CNNs in capturing global tumor context but require 3–5× more training data and GPU resources. Hybrid ViT-CNN models (Boudouh & Bouakkaz, 2024 [29]) mitigate this at the cost of interpretability. Among the proposed models, the fusion of ViT++ and VGG16 achieved the highest accuracy of 99.22% underscoring the effectiveness of this hybrid approach. These studies highlight the potential of Vision Transformers in medical imaging while challenges such as computational demands and data diversity remain areas for future research and optimization.

J. Graphical User Interface

A Graphical User Interface (GUI) is a critical feature for transitioning a proposed classifier into clinical use. Zhang et al. [30] developed a web server using the open-source Dash framework to host their trained BSNet model. This web application enables data scientists to analyze mammogram images by uploading them to the server, which outputs probabilities for three breast disease classifications along with extracted features. Besides, Jiménez-Gaona et al. [20] created an open-source mobile app named "BraNet" for the segmentation and classification of benign and malignant breast cancer using mammography and ultrasound breast images. This app employs ResNet-18 deep learning algorithms, offering a practical tool for healthcare applications. Despite promising accuracy, GUI tools face regulatory (e.g., FDA/CE certification), interoperability (DICOM/HL7 integration), and physician-trust barriers.

K. Recommendations and Limitations

The literature review reveals that only a limited number of studies have specifically focused on developing classification models for breast cancer molecular subtypes using mammographic images. In particular, only five studies have directly addressed this problem, as summarized in Table III. This highlights a significant research gap in non-invasive subtype classification using imaging data.

To provide a broader perspective and enable cross-study comparison, a comprehensive summary of relevant studies, including model architectures, datasets, and performance metrics, is presented in Table IV.

Furthermore, to facilitate systematic comparison and evidence synthesis across studies, a standardized summary of included works is presented in Table V, highlighting model architectures, datasets, sample sizes, imaging modalities, and performance metrics.

TABLE III. SUMMARY OF CNN TECHNIQUES USING MAMMOGRAPHIC IMAGES TO CLASSIFY MOLECULAR SUBTYPES IN PAST STUDIES.

Author	Method	Accuracy	Remark
Mota et al. (2024) [26]	ResNet-101	60.62%	Low accuracy
Nissar et al. (2024) [15]	MobileNet-V3 with Convolutional Block Attention Module	90%	High complexity
T. Zhang et al. (2023) [19]	ResNet 50 with intra-modality and inter-modality	88.5%	High complexity
Ma et al. (2019) [8]	Naïve Bayes	75% to 80%	Low accuracy
Liu et al. (2023) [25]	ReNet 50	53.3%	Low accuracy

TABLE IV. SUMMARY OF THE PAST RESEARCH

Author	No. of sample and sample source	Processing methods	Architecture	Result	SWOT analysis (S = Strengths, W = Weaknesses, O = Opportunities, T = Treats)	Remark
Mammogram						
Mota et al., 2024 [26]	> 660 patients, 1397 images > Mammography images from OPTIMAM imaging database	> Cropping > Sampling for imbalanced data (imbalanced data, oversampling and under sampling) > Data augmentation > 3-fold cross-validation	ResNet-101 deep CNN	Binary classification: Best performance = Oversampling and data augmentation Average accuracy = 79.02% Average AUC = 64.69% multi-class classification: Best performance = Oversampling and data augmentation AUC = 60.62%	S = Access to a larger dataset of mammography images. Implementation of robust pre-processing and data augmentation techniques, enhancing model generalizability. W = Dependence on labelled mammographic data. Lack of data variability, potentially affecting the model's performance and generalizability. O = Potential to address class imbalance issues for more balanced model training. T = Exclusion of Ki-67 data may reduce the model's ability to differentiate between subtypes. Challenges in distinguishing subtle differences among molecular subtypes.	Classification molecular subtype
Nissar et al., 2024 [15]	> 2358 images before augmentation, 4987 images after augmentation > Mammography	> Image cropping and filtering > Image enhancement and augmentation > Image normalization	MobileNet-V3 architecture with a Convolutional Block Attention Module (MOB-CBAM)	Best performance = Median filter Accuracy = 0.90 Precision = 0.91 Recall = 0.90 F1-score = 0.89 Matthew's correlation	S = High accuracy. Capable of identifying various types of breast cancer, including masses, calcifications and benign or malignant tumour, as well as predicting molecular subtypes. W = Small sample size for certain classification tasks. High complexity of deep learning models.	Classification of benign or malignant tumour, as well as molecular subtypes

				coefficient = 0.85	O= Potential to integrate model-agnostic explainability methods, which would improve interpretability and assist in error and bias detection. T = Risks of errors or biases in predictions.	
T. Zhang et al., 2023 [19]	> 3360 paired cases > Mammography and ultrasound	> Feature extraction > Feature map > Intra-Modality Attention > Refined feature > Inter-Modality Attention	ResNet 50 with intra- and inter-modality attention modules	Accuracy = 88.5% MCC = 0.837	S = Combines multiple image views to improve classification of molecular subtypes. Employs multi-modal image analysis by integrating mammography and ultrasound. Uses intra- and inter-modality attention modules to effectively integrate features from different modalities, further boosting accuracy. W = Retrospective study design may lead to missing values. Small sample size within certain subgroups. Cases are sourced from a single centre, which may restrict the study's applicability across diverse populations. O = Potential to incorporate MRI into the multimodal models, which could further enhance the performance. T = Risks of model bias and errors.	Classification of molecular subtypes
Ma et al., 2019 [8]	> 331 patients, 662 images > Mammography	> Radiomic feature extraction > Normalization > LASSO feature selection > Oversampling technique > 10-fold cross validation	Naïve Bayes machine learning	Best performance = CC and MLO Accuracy: Triple-negative vs non-triple-negative = 0.796 HER2-enriched vs non-HER2-enriched = 0.748 Luminal vs non-luminal = 0.788	S = Combines multiple mammogram views (MLO and CC) to improve accuracy. Utilizes Naive Bayes and LASSO feature selection to enhance the prediction accuracy. W = Focuses on binary classification instead of multi-class classification. Limited dataset diversity may reduce the model's generalizability. Does not classify between luminal A and luminal B subtypes. Manual lesion segmentation. O = Develops multi-class classifier for molecular subtypes prediction. Incorporates larger and more diverse datasets. T = Less reliability due to data imbalance.	Classification molecular subtype
Liu et al., 2023 [25]	> 158 patients, 170 lesions > Mammography, MRI	> ROI labelling > ROI segmentation > Normalization	ResNet 50	Mammography: Accuracy = 53.3% Sensitivity = 66.7% Specificity = 44.4% AUC value = 0.593 (95%CI, 0.436-0.737) T2WI models = optimal	S = Multi-modal imaging approaches provide more comprehensive insights. W = Reliance on manual labelling of ROI. Only focus to Luminal A and non-Luminal A breast cancer. O = Opportunity to leverage ResNet model to classify all molecular subtypes. T = Small sample size could lead to model inaccuracies.	Classification Luminal A and non-Luminal A
Saber et al., 2021 [31]	> 322 images from MIAS > Mammography	> Noise removal > Histogram equalization > Morphological analysis > Threshold-based segmentation > Image resizing	> Inception V3 > ResNet 50 > VGG 19 > VGG 16 > Inception-V2 ResNet (Transfer learning)	Best performance = VGG 16 Accuracy = 98.96% Sensitivity = 97.83% Specificity = 99.13% Precision = 97.35%	S = Achieves high accuracy. Reduces training time and improves classification performance by automatic extracting of affected patch using segmentation. Compares many pre-trained CNN. W = The method focuses solely on benign and malignant cases, without addressing molecular subtypes critical for treatment decisions. Limited dataset diversity. O =	Classification between normal, benign and malignant

		> Data splitting > Data augmentation		F-score = 97.66% AUC = 0.995	Extends the function to classify molecular subtypes. T = Potential biases in classification outcomes as dataset lacks diversity.	
Khalid et al., 2023 [12]	> 1501 individuals, 3002 images (CC and MLO) > Mammography, kaggle.com	> Normalization and standardization > Data balancing > Feature extraction > Creating variants of photos > Noise reduction	Machine learning > Random Forest (RF) > Decision tree (DT) > k-nearest neighbors (KNN) > Logistic regression (LR) > Support vector classifier (SVC) > Linear support vector classifier (linear SVC)	Accuracy: RF = 96.49% DT = 93.86% LR = 92.98% KNN = 92.11% Linear SVC = 89.47% SVC 87.72%	S = High accuracy achieved for the majority of models. W = Classification limited to malignant and benign cases, rather than including molecular subtypes. Manual feature selection and engineering. O = Exploration of the RF model to classify molecular subtypes. T = Risk of false positives post-processing. Loss ability to discover complex patterns due to the manual engineered features.	Classification between benign and malignant
Bobowicz et al., 2023 [21]	> 789 patients, 1968 images from MUG > 1775 patients, 3744 images from CMMD > Mammography	> Data augmentation > Feature extraction > Patch features > 5-fold cross validation	> ImageNet (ResNet-18, ResNet-34, ResNet-50 and EfficientNet-B0) (Feature extraction) >Multiple instance learning-based	Best performance = ResNet-34 AUC-ROC = 0.892±0.023(-) F1-Score = 82.2±2.6(%) Accuracy = 82.2±2.6(%) Precision = 82.4±2.4(%) Recall = 82.2±2.6(%)	S = Access to two large datasets, which enhances accuracy and robustness. Integration of both CC and MLO views, leading to improved performance. Utilization of weakly supervised learning methods reduces reliance on fully annotated datasets. W = Computational complexity may increase deployment costs. O = Potential to expand classification capabilities to include molecular subtypes. T = The presence of pectoral muscle regions within image patches could introduce high-intensity pixel disturbances. Model bias due to data imbalances.	Classification between benign and malignant
M. Zhang et al., 2023) [30]	> 2321 images > Mammography cases	> Feature extraction > Data augmentation > 5-fold cross validation > Balanced sampling > Cross-entropy	Weakly supervised deep learning framework BSNet	Average AUC: Test set = 0.89 External validation set = 0.92	S = Compare BSNet model with others to prove its best performance. Weak supervision reduces dependency on extensive manual pixel-level annotations. Accessible via a web server. W = Limited comparison scope, as the model's fine-tuning performance is evaluated only on pre-trained models based on the ImageNet classification task. Detection capability is limited to breast cancer with HR status and benign tumours. O = Potential to expand classification capabilities to include molecular subtypes. Enhance model training and validation by collecting more extensive datasets. T = Robustness may be low. Lack of reliable benchmark for comparative analysis.	Detect HR status and benign
Mishra et al., 2023) [32]	> No indicated the number of images > Digital database for screening mammography (DDMS)	> Cleaning the dataset > Data exploratory analysis > Data distribution analysis	> Logistic regression > Neural network architecture with 4 hidden layers	Best performance = Neural network architecture with 4 hidden layers Train accuracy	S = Achieves high accuracy in detecting breast cancer. W = The model does not classify molecular subtypes, which are crucial for identification of treatment. Unbalanced dataset.	Classification between benign and malignant

	> Mammography	> Data encoding > Dataset splitting > Feature scaling		= 98.99% Test accuracy = 98.83%	O = Potential to extend the proposed method for classifying molecular subtypes. Incorporating more diverse and reliable datasets to improve sensitivity and overall robustness. T = Risk of bias due to dataset imbalances.	
Harish et al., 2024 [33]	> 30 different features, 570 data > CT mammogram from Kaggle	> Data preprocessing (resizing images and normalizing pixel values) > Feature localization and extraction	Convolutional neural network (CNN) equipped with a region proposal network, RPN	Accuracy = 89%	S = A faster, sequential CNN model is proposed for breast cancer classification. W = Limited dataset used, with only 50 malignant and 50 benign cases for training. Focuses only on classification of normal, malignant and benign cases. O = Potential to enhance the accuracy, precision and recall by integrating with other deep learning model without increasing time complexity. Opportunity to expand the method to classify molecular subtypes of breast cancer. T = The small dataset increases the risk of overfitting, which may affect the performance on unseen data. Potential for reduced accuracy in real-world applications.	Classification of normal, malignant and benign
Agnes et al., 2020 [34]	> 322 images from MIAS database > 4500 images after data augmentation > Mammography	> Noise and background removal > Data normalization > Data augmentation > Feature reduction	Multiscale All Convolutional Neural Network (MA-CNN)	> Accuracy = 96.47% > Sensitivity = 96% > AUC = 0.99	S = Highest in accuracy compared with others. A larger stride convolution operation is used for dimension reduction, which preserves the neighborhood pixel relationship and eliminates the need for separate pooling layer. Implements multiple dilated convolution operation to extract multiscale features for classification. Operates as an end-to-end system, eliminating the manual feature engineering from the raw images. W = Limited dataset diversity as it relies on a single dataset only, which may affect the model's generalizability. O = Incorporating patch details to enhance the accuracy of the current classifier model. Expands the model to classify molecular subtypes. Training on larger and more diverse datasets to enhance reliability. T = May result in overfitting as reliance on a single dataset.	Classification between normal, benign and malignant
Jiménez-Gaona et al., 2024 [20]	> 5892 images > BUSI, collected by Rodrigues et al., UDIAT diagnostic centre, CBIS-DDSM, mini-MIAS, Inbreast, VinDr-Mammo > Mammography and ultrasound images	> Data normalization and automatic ROI annotation > Data augmentation > ROI segmentation	> SNGAN (generate synthetic images) > ResNet-18 (image classification) > SAM model (image segmentation)	Accuracy: US = 94.7% benign and 93.6% malignant DM (I) = 80.9% benign and 76.9% malignant DM (II) = 73.7% benign and 72.3% malignant	S = Large and diverse datasets. Offers an open-source API for mobile breast image processing and classification. W = Limited output provided, only benign and malignant classification is available. Less accurate for mammography images. Impacted by data quality. O = Integration with advanced models to improve accuracy and reliability. Expands the function to classify molecular subtypes. T = Risks of data privacy. Ethical challenges in AI.	Classification between benign and malignant

Boudouh & Bouakkaz, 2024 [29]	> 1871 images from CBIS-DDSM > Mammography	> Balance collected data > Noise reduction and enhancement filters > Data augmentation > Feature extraction and classification	> Vision Transformer, ViT++ (Contextual features) > CNN based on transfer learning techniques includes Xception, VGG16, RegNetX002 (Visual features)	Best performance = ViT++ with VGG16 Accuracy = 99.22%	S = Combines ViT++ for capturing global context with CNNs for extracting local spatial details. High accuracy. Employs pre-processing techniques to reduce noise and enhance the quality of input data. Offers flexibility in model design and provides a robust feature representation. W = High computational requirements for the complex fusion approach. The feature extraction phase does not include a feature selection step. Limited datasets diversity. O = Incorporates other pre-training models in the CNN branch. Expands to diverse datasets. Extends the fusion approach proposed to classify molecular subtypes. T = High costs of implementation. Risk of redundancy and increased computational load due to irrelevant or overlapping features.	Classification breast calcifications to distinguish between benign and malignant cases
Boudouh & Bouakkaz, 2023 [24]	> No indicated the number of images > CBIS-SSSM collection > Mammography	> Noise removal > Image enhancement > Data augmentation > Feature extraction (transfer learning techniques)	> ResNet 50 V2 > Xception (Feature extractor)	Best performance = Xception Accuracy = 99.99% Recall = 100% Specificity = 100% AUC = 1.00	S = A high accuracy method proposed. Employs advanced pre-processing techniques such as Non-Local Means, Gaussian and Median filters to remove noise. W = Unbalanced dataset, which is lack of data on the Calc class. The model does not classify molecular subtypes, which are crucial for identification of treatment. O = Potential to improve accuracy by adding another dataset or hybridization of pre-trained models for feature extraction. Expand the proposed method to classify the molecular subtypes. T = The model may struggle to detect breast Calc.	Classification between breast Mass and breast Calc
Huang et al., 2022 [35]	> 322 images from MIAS > Mammography	> Image normalization and denoising > Image enhancement (sharpening) and histogram modification > Segmentation of ROI > Feature extraction	SVM (Support vector machine)	Best performance = Gaussian radial basis kernel function (RBF) Average accuracy = 78.89%	S = Employs kernel functions for optimal classification performance. The method extracts diverse features including grayscale, geometric and texture properties. W = Dependency on labelling information. The training time increases with larger datasets. Requires extensive experimentation to determine kernel function parameters. Limited dataset diversity as it relies on MIAS dataset only. O = Combines with other effective techniques can enhance classification performance. Includes larger and more diverse datasets to improve model's reliability. Opportunity to expand the method to classify molecular subtypes of breast cancer. T = Risk of biased results if critical features are mislabeled or omitted. Long training time may require.	Detection of breast calcification clusters and classification of masses
Zeng et al., 2024 [28]	> 1003 mass and 694 normal cases from DDSM	> Input embedding > multi-head attention > Addition and	ViT's MHA	Accuracy = 0.927	S = Integrates bilateral information from both the left and right breast images to improve the diagnostic accuracy of breast mass detection. Eliminates the need of manual intervention by	Classification between mass and normal tissue

	> Mammography	normalization > Feed-forward			automating the process of feature extraction and classification. Overcomes registration difficulties by adopted ViT's MHA architecture. W = Limited datasets diversity. Fails to fully exploit the symmetric region details of the images. High complexity in bilateral image integration. O = Expands to diverse datasets. Extends the method proposed to classify molecular subtypes. T = Low performance on unilateral images.	
Ueda et al., 2021 [22]	> 1448 images (data set) > 225 images (test data) > Mammography	> Ground truth labelling > Image cropping and resizing > Binary cross-entropy > Data augmentation > Five-fold cross-validation	> VGG 16 > Inception V3 > ResNet 52 >DenseNet 121 (Combination)	Best performance = Inception V3 + ResNet 52 and VGG 16 + Inception V3 AUC: ER+ or - = 0.67 (0.58-0.76) PgR+ or - =0.61 (0.53-0.68) HER2-enriched or -not enriched = 0.75 (0.68-0.82)	S = Trained model is available online with Apache License 2.0. Blending multiple models is used to improve the predictive performance. W = Insufficient number of mammograms. Used the results from the preoperative biopsy report rather than the postoperative tissue report for patients with NAC as NAC can alter receptor expressions. O = Adopted visualization technology such as gradient-weighted class activation mapping. T = Lower accuracy.	Classification of receptor expressions
Thangavel et al., 2024 [23]	> No indicated the number of images > Mammography	> Adaptive fuzzy based median filtering > Noise removal > Normalization > Image enhancement > Feature extraction	> ResNet (Hierarchical feature learning) > U-Net (Segmentation)	Accuracy = 99% Precision = 98.6% Recall = 99.01% Specificity = 98.9%	S = A high accuracy feature extraction and early-stage identification model by combining two deep learning models. W = The model not involve in the classification of molecular subtypes, which is important for identification of treatment. O = Potential to use the proposed method to classify the molecular subtypes. Integrating the model with real-time data streams. T = May face challenges related to interpretability, data dependency, computational complexity and ethical concerns regarding patient privacy and consent when it integrated into clinical practice.	Feature extraction and early-stage breast abnormality detection
Magnetic Resonance Imaging (MRI)						
Carvalho et al., 2024 [13]	> 20 DCE-MRI, 10 patients from QIN > MRI image	> Image segmentation > Image registration	> SegNet and Unet (segmentation) > Three-time-point, 3TP (classification)	Best performance = Unet (0.9799 IoU, 0.9332 Dice) Accuracy for classification = 100%	S = Fully automated tumor segmentation and classification methodology. Achieves high accuracy. Use three-time-point (3TP) approach to enhance dynamic contrast behavior. W = Small dataset may reduce generalizability. High number of parameters required for deep learning models increases complexity. Long training time. O = Incorporating larger datasets to enhance reliability. Use optimization methods to obtain the best parameters for the architecture. Expands to include other imaging modalities such as mammography. Expand classification to include molecular subtypes could enhance treatment planning.	Classification the malignancy of the tumors into malignant type III (WashOut) and malignant type II (Plateau)

					T = Risks of overfitting. Less reliability.	
Ultrasound						
Alshowarah, 2023 [18]	> 780 images from Dataset of Breast Ultrasound Images (Dataset BUSI) > 5872 images after data augmentation >Ultrasound images	> Feature extraction > Data Augmentation, Statistical operations (Avg, Min, Max and fusion of fc6 and fc7)	> VGG-19 (features extraction) > KNN, Naïve Bayes, Random Forest, Decision Tree (classifiers)	Best performance = Random Forest Accuracy = 88.63% Precision = 0.88 Recall = 0.88 F-Measure = 0.88	S = Comprehensive comparison of multiple classifiers. Exploration of multiple scenarios in the training dataset. Application of various statistical operations to generate more datasets for better learning of CNN. W = Limited dataset diversity as it relies on a single dataset only, which may affect the model's generalizability. The method focuses solely on benign and malignant cases, without addressing molecular subtypes critical for treatment decisions. Insufficient feature exploration. O = Potential to improve the classification accuracy and reduce training time by conducting more investigation and using different algorithms. Extend the proposed method to include molecular subtypes classification. Incorporating different imaging modalities such as mammography. T = Risk of bias due to class imbalances in the dataset. Limited testing in diverse clinical environments.	Classification between benign and malignant
Gheflati & Rivaz, 2022 [27]	> 780 images from Dataset of Breast Ultrasound Images (Dataset BUSI) > 163 images from dataset B >Ultrasound images	> 5-fold cross-validation > SoftMax activation function (CNN TL) > Fine-tuning, weighted cross-entropy loss (ViT) > Data augmentation	> Vision Transformer (ViT) > State-of-the-art CNN includes ResNet-50, VGG16, InceptionV3, NASNetLarge	Best performance = ViT-B/32 (BUSI+B) Accuracy = 86.7% AUC = 0.95	S = ViT architecture excels in capturing global dependencies in images through its self-attention mechanism. Comprehensive comparison of ViT and multiple CNNs. ViT adapted well to small datasets. Diverse datasets used. W = High computational requirements for ViT. O = Combines ViT with other imaging modalities such as mammography. Expands the method proposed to classify molecular subtypes. T = High costs for implementation.	Classification of benign, malignant or normal
Histopathology						
Murtaza et al., 2020 [16]	> 58 patients, 1339 images from BreakHis > Histopathology image	> Data collection > Image augmentation > Feature extraction > Feature reduction	> AlexNet (Feature extraction) > KNN, SVM, NB, DT, LDA, LR	Best performance = k-Nearest Neighbors (kNN) First-level classifier = 95.48% Second-level classifier = 94.62% (Benign subtypes) 92.45% (Malignant subtypes)	S = The BMIC_Net model proposed is less complex, computationally efficient, reliable and more accurate. Eliminates the need for handcrafted feature extraction. Employs a two level hierarchical classifier, with eight distinct output classes are identified where first level classifies images as benign and malignant, second level further classifies the subtypes of benign or malignant. Feature reduction techniques is used to improve accuracy. W = Limited dataset diversity may reduce the model's generalizability. Dataset imbalance between benign and malignant subtypes. Invasive method as histopathological images	Classification between benign and malignant, and their subtypes

					are required. O = Expand to include imaging modalities such as mammography or MRI. Expand classification to include molecular subtypes could enhance treatment planning. T = Risk of bias. Limited testing in diverse clinical environments.	
Rafiq et al., 2023 [17]	> 220,025 images from Kaggle dataset > Histopathology image	> Data augmentation > Image segmentation	> Straightforward CNN model (1-CNN) > Fusion CNN model (2-CNN) > Three CNN model (3-CNN)	Best performance = 3-CNN Accuracy = 97.90% Recall = 96.80% Precision = 96.90% f1-score = 97.20%	S = Utilizes hybrid CNNs to improve accuracy and optimize training efficiency. Utilizes a larger dataset. W = High computational complexity of fusion approach. Limited dataset diversity may reduce the model's generalizability. Relies on invasive biopsy method to obtain histopathological images. O = Expands dataset with external source. Extends the function to classify molecular subtypes. Incorporate other imaging modalities such as mammography. T = Risk of overfitting. Potential biases in classification outcomes as dataset lacks diversity.	Classification between benign and malignant

TABLE V. SUMMARY OF AI-BASED BREAST CANCER MOLECULAR SUBTYPE CLASSIFICATION STUDIES

Study	Year	Modality	Dataset Size	Model	Category	Task	Performance	Key Insight
Mota et al. [26]	2024	Mammography	1397 images	ResNet-101	CNN	Multi-class subtype	Acc: 79.02%, AUC: 64.69%	Data balancing improves performance
Nissar et al. [15]	2024	Mammography	4987 images	MobileNet V3 + CBAM	CNN	Subtype	Acc: 90%	Attention improves feature learning
T. Zhang et al. [19]	2023	Mammo + US	3360 cases	ResNet50 + Attention	CNN	Subtype	Acc: 88.5%	Multi-modal enhances accuracy
Ma et al. [8]	2019	Mammography	662 images	Naïve Bayes	ML	Binary subtype	Acc: ~79%	Limited to binary classification
Liu et al. [25]	2023	Mammo + MRI	170 lesions	ResNet50	CNN	Partial subtype	Acc: 53.3%	Small dataset limits performance
Ueda et al. [22]	2021	Mammography	1448 images	CNN ensemble	CNN	Receptor classification	AUC: up to 0.75	Limited subtype accuracy

The results presented in Table III indicate significant variability in classification performance across different models. CNN-based architectures such as MobileNet-V3 and ResNet-based models demonstrate relatively higher accuracy, particularly when enhanced with attention mechanisms or multi-modal inputs. However, these approaches often involve increased computational complexity. In contrast, traditional machine learning methods such as Naïve Bayes exhibit lower performance, highlighting their limitations in capturing complex feature representations required for multi-class subtype classification.

Furthermore, several studies report relatively low accuracy, particularly in cases with limited datasets or partial subtype classification, suggesting that data availability and model design remain critical challenges. These findings emphasize the need for more advanced architectures, such as hybrid CNN–Transformer models, which can effectively capture both local and global features to improve classification performance.

These existing models face several limitations. First, most primarily classify tumors as benign or malignant, which is insufficient for guiding precise treatment decisions tailored to breast cancer subtypes. Besides, some proposed models are overly complex and lack interpretability, making them less intuitive and harder to understand. This hinders their usability and acceptance in clinical settings. Further research is needed to develop a highly accurate yet less complex classifier for classifying breast cancer molecular subtypes using mammographic images.

Moreover, different studies employed different image processing methods. This inconsistency highlights the need

for further research to assess the effectiveness of each technique in improving segmentation and feature extraction process.

Despite these advancements, many studies face challenges related to bias, reliability and overfitting due to the small or imbalanced datasets. To address these issues, larger and more diverse datasets are essential for effectively training and testing models. In addition, data augmentation techniques, which generate new data samples from preexisting data can significantly improve model optimization and generalizability, making AI-based tools more robust and applicable in clinical settings.

IV. Conclusion

This review highlights the growing impact of artificial intelligence, in breast cancer classification using mammographic imaging. While AI-based models have shown promise in improving diagnostic accuracy and distinguishing between molecular subtypes, existing approaches still face challenges related to model complexity, interpretability, and dataset diversity. A majority of studies primarily focus on benign versus malignant classification, limiting their clinical utility in precision treatment planning. In addition, heterogeneity in preprocessing pipelines techniques underscore the need for standardized methodologies in order to enhance segmentation and feature extraction. To fully leverage AI in breast cancer diagnostics, future research should focus on developing more interpretable, highly accurate classification models while ensuring their seamless integration into clinical workflows. The adoption of larger, more diverse datasets and advanced machine learning techniques, such as Vision Transformers and hybrid CNN approaches, may potentially result in further improved classification performance. Ultimately, AI-driven solutions hold great potential in revolutionizing breast cancer detection, subtyping, and personalized treatment strategies.

Integrating Big Data and Machine Learning for Effective Cyberattack Prediction in e-Health Information Systems

Mohamed Abdelbaki[1]*, Latif Adnane[2], Charaf Eddine Ait Zaouiat[3]
Information Technology and Modelling Team-ENSA Marrakech, Cadi Ayyad University, Marrakech, Morocco[1, 2]
Polydisciplinary Faculty of Sidi Bennour, Chouaib Doukkali University, ELJADIDA, Morocco[3]

***Abstract*—This study proposes an intrusion-prediction framework for e-Health information systems that combines structured web-log analysis, supervised machine learning, and Apache Spark-based distributed processing. A corpus of 1,000,000 labeled HTTP log instances collected from a university hospital web environment was preprocessed into security-relevant features, including request method, request/response type, packet size, status code, URL length, and parameter count. Using a stratified 80/20 train-test split and five-fold cross-validation on the training data, we compared K-Nearest Neighbors (KNN), Logistic Regression, and Decision Trees. KNN achieved the best held-out performance, with 95.66% accuracy, 91.79% precision, 93.93% recall, 92.85% F1-score, and a 3.60% false positive rate. Logistic Regression and Decision Trees reached accuracies of 85.30% and 83.20%, respectively. Spark also reduced runtime substantially at the 1,000,000-instance scale, lowering KNN processing time from 12.0 s to 6.5 s. The results show that combining big data infrastructure with carefully tuned machine learning can improve both detection quality and operational feasibility in hospital cybersecurity monitoring.**

***Keywords*—Artificial intelligence; big data; cybersecurity; hospital information systems; log files**

I. Introduction

This exponential development of information and communication technologies rests on the increased utilization of more and more connected devices and tools in recent years. Through such evolution, users have easily and rapidly accessed information [1]. However, in the process, it has also facilitated illicit access to sensitive resources by malicious actors. The big challenge in the detection and prediction of attacks on communication systems, especially for hospital information systems, electronic medical records, and electronic health records, is related to the detection and prediction of such attacks [2]. Among the most attacked resources are those provided by web applications used in healthcare environments [3]. The log files record every event happening during system operation and are large in volume and complex in structure. Analysis of such log files is, therefore, of prime importance for addressing the risks involved with system attacks that may affect patient data and overall performance. Because of the huge size of these log files, it is not possible to conduct their manual analysis; extended processing times need to be used [4]. The novelty of this work lies in designing a cyberattack prediction framework that balances accuracy, scalability, and robustness to imperfect training data. Because security log datasets may contain noisy, inconsistent, or manipulated records, robustness becomes an important consideration alongside predictive performance [35]. This work will focus on the accuracy of different predictive algorithms, along with their time complexity, to provide an overall framework that will help administrators in healthcare identify and mitigate vulnerabilities effectively. The time complexity comparison analysis taken by algorithms used secures the development of an efficient solution to be able to handle volumes and improve efficiency, while personal data on patients is protected.

Also, by embedding Apache Spark as a big data processing engine, the model increases its speed of processing information and thus allows real-time analysis of large volumes of log data; in our evaluation, Spark supports distributed processing across scales up to 1,000,000 instances, addressing the practical scalability constraints of security analytics over large healthcare log volumes. This establishes a dual emphasis on predictive accuracy and computational efficiency, positioning the research as a practical contribution to improving the security posture of healthcare web applications.

The rest of this study is organized as follows. First, some related works concerning log file analysis and cybersecurity techniques are reviewed. Following this, the advantages and challenges in log file analysis applied to healthcare are discussed. Then, Big Data technologies and their importance in regard to security issues are described, and afterwards, machine learning tools and their practical applications in log analysis. The proposed approach and the implementation follow together with discussions of results.

II. Related Work

Basically, log file analysis refers to the intended examination and analysis of log files [5]. Log files are very important in tracking mistakes in data transmission, as well as tracking firewall activities [6]. Medical log file analysis is one of the most vital analyses that can be used in enhancing hospital information systems and electronic health records (EHR) [7]. Log files record not only the interaction of visitors with web applications but also trace various technical errors related to networks, software, and components, most of all, though, underlying security issues regarding patient data [8, 9]. However, the analysis of security logs is complex and requires advanced technical skills related to Big Data, Machine Learning, and both [30].

*Corresponding author.

Several works have described how Big Data and Machine Learning can be applied in security log file analysis. Landauer et al. [10] proposed a dynamic anomaly detection approach using clustering mechanisms to enable a self-learning algorithm to detect anomalies related to temporal behavior. On the other hand, Zhong et al. [11] proposed a deep learning log analysis-based intrusion detection approach based on the application of LSTM networks. Skopik et al. [12] investigated a unified pipeline that realizes several machine learning algorithms to analyze the system behavior and to identify deviations from established patterns, which in turn allows identifying both known and unknown attacks. Recent IDS surveys also show that Machine Learning and Deep Learning-based intrusion detection must address dataset quality, evasion techniques, false positives, and the detection of evolving attacks, which remains highly relevant for healthcare web environments [33, 37].

In the Big Data log file analysis context, Azizi et al. [13] proposed an approach where MapReduce could be used for the analysis of security-related log files concerning certain types of attacks, such as SQL injection or DDoS. Jeon et al. [14] proposed a new Big Data-based security logging system that extends security intelligence by analyzing data events created in enterprise log files, covering systems, application services, and IT infrastructure.

Despite these developments, most of the earlier studies have shown suboptimal performance because of data pre-processing deficiencies, which reduce the accuracy and performance. Most research typically only gives general suggestions for improving security without quantifying the impact, whereby limited practical applicability can be achieved from such recommendations. In addition, many of them have not explained the very crucial issue of processing time in terms of the steps involved in pre-processing, learning, classification, and prediction. Without this, a solution will not be feasible in real-world situations. In turn, our approach tries to fill these gaps by proposing an end-to-end system that emphasizes strict data pre-processing in order to derive from log files high-quality and relevant features that will enhance accuracy and improve predictive performance after proper refinement of the data, and then the application of machine learning algorithms. Moreover, the time complexity analysis for each algorithm allows us to propose an efficient model able to perform the right balance between accuracy and speed of processing. The presence of Apache Spark accelerates data handling and makes the entire workflow smoother, therefore making our solution ideal for big log file analysis in real-time healthcare contexts. The two most important goals-precision and speed-are huge guarantees that our research is one of the great milestones within the field of cybersecurity in general and the elaboration of practical and efficient solutions concerning the identification and mitigation of potentially vulnerable points in healthcare information systems.

III. Big Data Toolkit for Log File Security Analysis

Big Data is a concept that copes with the research, analysis, capture, storage, sharing, and presentation of data. Big Data replaces traditional tools, since those are inefficient in managing and analyzing such large sets of information. Often characterized by the three "Vs": volume, velocity, and variety. Big Data integrates other important aspects such as Value and Veracity [15, 16].

Big Data finds applications across a wide range of industries operating with huge volumes of data every day and usually requires crucial speed [17]. The prominent fields where Big Data can find its central role include Marketing, Monitoring, and Security, among others [18, 19]. In security, Big Data contributes substantially to enhancing the capability that deals particularly in the capture, filtration, and analysis of millions of network events per second, log and audit files included [20]. It provides that third level of protection against cyber-attacks involving:

- First-level security: company security against external attacks [21].
- Second-level security: company protection from vulnerabilities imposed by its users [21].
- Third-level security: impact assessment of the threats detected within infrastructure, which means network traffic back-tracing capability for tracking malware steps and proper action [22].

Big Data analytics tools actually enable cybersecurity experts to analyze a variety of data types from all different sources in real time. These tools are not limited to gathering information but also create correlations and connections [23, 24]. Amongst the major analytical tools for security are:

- Unified Analytics System: Apache Spark, a free software to process large volumes of data, with libraries for different Big Data workloads. Though Spark itself is handy for tasks that require enormous computing power, its application in anomaly detection, both in user behavior and network traffic, will provide information security [25, 26].
- IBM Security QRadar: An enterprise security information and event management product that can collect and analyze log data generated by security systems, network devices, host assets, applications, vulnerabilities, and user activities [27].
- Splunk: it is the premier software platform for search, analysis, and visualization of machine data generated. Splunk allows indexing and real-time analysis of structured, unstructured, and complex logs to enable alerts, event notifications, and reports based on the state of machines [28].
- Apache Metron: An open-source Big Data for security monitoring and analytics that is free. It allows for real-time processing of emitted data; it also has a component for long-term storage. Metron provides a centralized monitoring portal for contextual alerts and attack information [29].

A. Decision Trees

Decision Trees were included because they provide interpretable rule-based classification and can model non-linear interactions among log-derived features [34, 37, 38]. In this study, the tree recursively partitions the feature space according

to the splits that best separate normal and attack traffic, producing decision paths that are easy to inspect. This makes the model attractive for hospital security teams that need understandable alerts, although depth control is required to limit overfitting.

B. K-Nearest Neighbors

K-Nearest Neighbors (KNN) was selected as a strong non-parametric baseline for attack prediction [36, 39]. The classifier assigns a label to each new instance according to the dominant class among its nearest neighbors in feature space, allowing it to capture local and non-linear attack patterns without imposing a fixed functional form. Because KNN is sensitive to feature scaling and the value of k [36], both normalization and hyperparameter tuning were applied before final evaluation. The basic KNN decision principle is illustrated in Fig. 1.

$$Distance(x, x_i) = \sqrt{\sum_{j=1}^{d} \left(x_j - x_{ij}\right)^2}$$

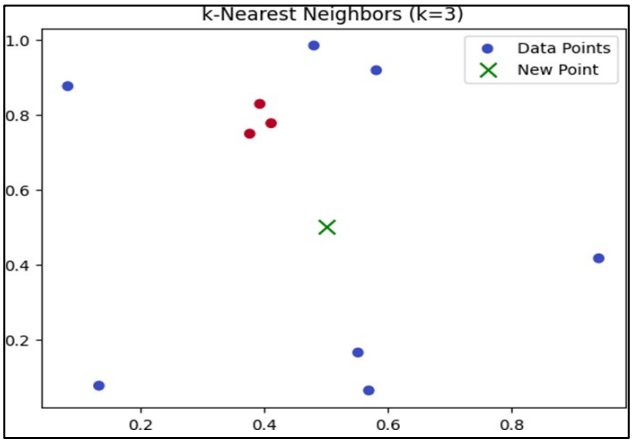

Fig. 1. Basic KNN decision principle.

C. Logistic Regression

Logistic Regression was used as a probabilistic linear baseline for binary intrusion detection [32]. The model estimates the probability that a request belongs to the attack class from a weighted combination of the input features and offers a transparent view of how features contribute to predictions. A conceptual illustration of this decision boundary is shown in Fig. 2.

Its interpretability and low computational cost make it useful in healthcare security analytics, even though purely linear decision boundaries may miss some complex attack relationships. This choice is also consistent with prior work showing that regularized logistic regression can support interpretable anomaly-oriented prediction while remaining suitable for imbalanced security-related settings [32].

$$P(X = x) = \frac{1}{1 + e^{-(\beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_d x_d)}}$$

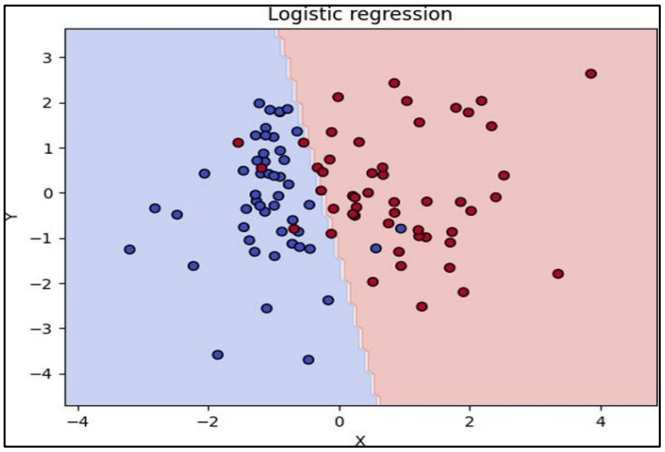

Fig. 2. Illustration of a Logistic Regression model applied to a synthetic binary classification dataset.

D. Comparison Summary

The three classifiers were selected to represent complementary design trade-offs relevant to hospital intrusion detection. Logistic Regression offers transparency and efficiency, Decision Trees provide interpretable non-linear rules, and KNN captures local attack structures with strong discrimination when sufficient labeled examples are available. Comparing them under the same preprocessing and validation protocol allows the study to assess not only accuracy, but also operational fit for large-scale security monitoring.

IV. Design of a Combined Machine Learning and Big Data System for Cyberattack Prediction: Use Case of a University Hospital Information System

The experimental dataset consisted of 1,000,000 labeled HTTP log instances extracted selectively from a university hospital web application environment to form a 30% attack and 70% normal requests, and exported to CSV after preprocessing. The corpus was constructed from raw Apache access logs and request traces, then anonymized to remove patient and user identifiers before feature generation. Labels were assigned as normal or attack using rule-based annotation supported by known malicious payload patterns, status-code anomalies, authentication abuse signatures, and manual verification of representative samples. The retained dataset characteristics are summarized in Table I, while Fig. 3 shows the original structure of the training log data.

TABLE I. Dataset Characteristics

Item	Description
Source	Raw HTTP Log files
Total instances	1,000,000
Class distribution	700,000 normals; 300,000 attack
Retained fields	Packet size, HTTP method, request/response type, URL, status code, parameter count, URL length
Privacy handling	IP addresses and user identifiers are anonymized before modeling

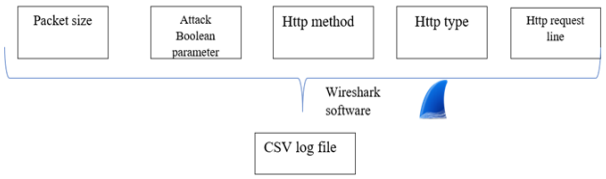

Fig. 3. Structure of the dataset used for training the prediction algorithms

A. Data Preparation and Feature Engineering

Data preparation focused on converting raw web-log events into a consistent feature space suitable for supervised learning. After removing duplicated or incomplete records, categorical fields were encoded, continuous attributes were normalized, and malformed requests were retained only when they contained security-relevant evidence. This step reduced noise while preserving the behavioral signals needed for attack prediction.

The final feature set included HTTP method, request/response type, packet size, request URL, status code, URL length, and parameter count. These features were chosen because they capture request structure and protocol behavior in a form that remains compatible with the information retained from the original server logs.

B. Predictive Modeling and Experimental Design

Three supervised classifiers were trained on the same labeled dataset: KNN, Logistic Regression, and Decision Trees. The data were partitioned with a stratified 80/20 train-test split so that the original normal/attack ratio was preserved in both subsets. All model selection steps were performed only on the training data. The overall workflow for model construction, application, and evaluation is illustrated in Fig. 4.

- Hyperparameter tuning was conducted using grid search with five-fold stratified cross-validation. For KNN, we searched k in {3, 5, 7, 9, 11}, weight schemes {uniform, distance}, and distance metrics {euclidean, manhattan}. For Decision Trees, we explored the split criterion {gini, entropy}, max depth {3, 5, 10, None}, and min samples split {2, 5, 10}. For Logistic Regression, we evaluated C in {0.01, 0.1, 1, 10} with L2 regularization using the liblinear and lbfgs solvers.
- Model performance was reported on the held-out test set using accuracy, precision, recall, F1-score, false positive rate, and processing time. Apache Spark was used to accelerate preprocessing and batch inference at larger scales, enabling a consistent comparison between traditional and distributed execution. The best configurations selected by cross-validation were KNN (k = 5, distance weighting, Euclidean distance), Decision Tree (gini, max_depth = 10, min_samples_split = 5), and Logistic Regression (C = 1, L2, liblinear). The selected hyperparameter values are summarized in Table II.

TABLE II. SELECTED HYPERPARAMETER VALUES

Model	Selected configuration
KNN	k = 5; distance weighting; Euclidean metric
Decision Tree	gini; max_depth = 10; min_samples_split = 5
Logistic Regression	C = 1; L2 penalty; liblinear solver

C. Results Analysis and Discussion

The evaluation examined both predictive quality and deployment-oriented efficiency. Final classification metrics were computed on a held-out test set of 200,000 instances, while processing-time measurements were recorded across dataset sizes from 100,000 to 1,000,000 instances to assess scalability under increasing log volume.

D. Classification Performance and Operational Metrics

KNN achieved the strongest overall results on the held-out test set, reaching 95.66% accuracy and substantially outperforming Logistic Regression (85.30%) and Decision Trees (83.20%). Its advantage was not limited to accuracy: KNN also produced the highest precision and F1-score, indicating that it balanced correct attack detection with reliable alert generation. The full metric breakdown is reported in Table III, and the cross-size accuracy trend is shown in Fig. 5.

From an operational perspective, the false positive rate is especially important for hospital environments because excessive false alarms can overwhelm security teams and reduce trust in automated monitoring. KNN yielded the lowest false positive rate (3.60%), whereas Logistic Regression and Decision Trees produced 8.00% and 9.00%, respectively. This result strengthens the case for KNN as the most deployment-ready classifier among the models evaluated.

TABLE III. CLASSIFICATION PERFORMANCE

Model	Accuracy	Precision	Recall	F1-score	FPR	Specificity
KNN	95.66%	91.79%	93.93 %	92.85 %	3.60 %	96.40%
Logistic Regression	85.30%	78.87%	69.67 %	73.98 %	8.00 %	92.00%
Decision Tree	83.20%	75.58%	65.00 %	69.89 %	9.00 %	91.00%

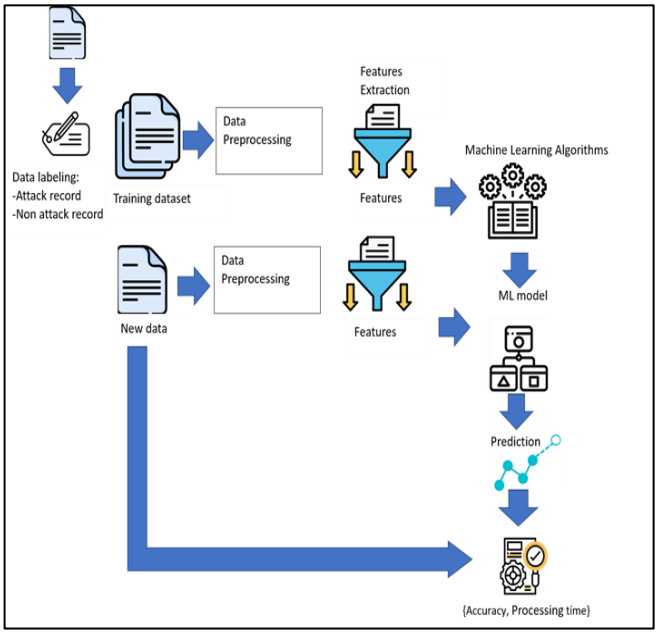

Fig. 4. Process of constructing, applying, and evaluating the predictive model for HTTP attacks prediction.

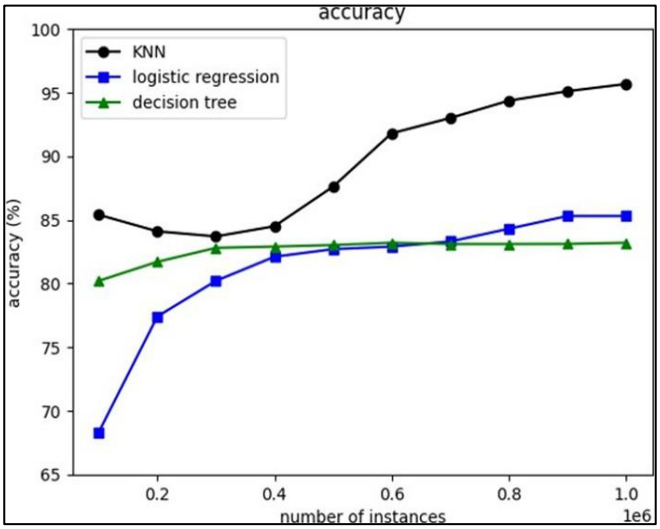

Fig. 5. Accuracy comparison of machine learning algorithms (KNN, logistic regression, and decision tree) for HTTP attack prediction across different dataset sizes.

E. Processing Time Analysis

Processing-time analysis confirmed the value of distributed execution for large-scale hospital log analysis. Across all three models, Spark reduced runtime as dataset size increased, with the strongest absolute gains observed for KNN and Decision Trees at the 1,000,000-instance scale. Although Logistic Regression remained the fastest classifier under Spark (6.0 s), KNN matched Decision Tree at 6.5 s while preserving a much stronger detection profile, making it the best accuracy-efficiency compromise in the study. Table IV summarizes the detailed timing values, and Fig. 6 highlights the corresponding processing-time trend.

TABLE IV. PROCESSING TIME COMPARISON (SECONDS)

Dataset size	Model	Without Spark (s)	With Spark (s)
100,000	KNN	1.8	1.1
100,000	Logistic Regression	1.4	1.2
100,000	Decision Tree	2.0	1.4
300,000	KNN	4.5	2.6
300,000	Logistic Regression	3.0	2.8
300,000	Decision Tree	4.7	2.9
500,000	KNN	6.8	3.7
500,000	Logistic Regression	4.2	3.9
500,000	Decision Tree	7.3	4.1
700,000	KNN	8.9	4.8
700,000	Logistic Regression	5.1	4.9

V. CONCLUSION

This study presented a coherent framework for cyberattack prediction in e-Health information systems by combining structured log analysis, supervised machine learning, and Apache Spark-based distributed processing. Using a labeled corpus of 1,000,000 HTTP log instances from a university hospital context, the study demonstrated that rigorous preprocessing and feature engineering can support reliable detection of malicious web activity against healthcare services.

Among the evaluated classifiers, KNN delivered the best overall performance, achieving 95.66% accuracy, 91.79% precision, 93.93% recall, a 92.85% F1-score, and the lowest false positive rate (3.60%). These results are especially important for operational deployment because they indicate a lower alert burden on hospital security teams compared with Logistic Regression and Decision Trees.

The processing-time experiments further showed that Apache Spark materially improves scalability, cutting KNN runtime from 12.0 s to 6.5 s at 1,000,000 instances and enabling practical large-scale analysis without sacrificing detection quality. Taken together, the results suggest that KNN plus distributed execution offers the most favorable balance of accuracy, responsiveness, and operational usability for intrusion monitoring in e-Health environments.

Future work can extend this framework toward multi-class attack labeling, streaming analytics for continuous monitoring, and external validation on logs collected from additional hospital systems. These steps would further strengthen generalizability while preserving the deployment-oriented focus established in the present study.

Solar Irradiance Forecasting Approaches Based on Machine Learning: A Systematic Literature Review

Sempe Thom Leholo[1]*, Chunling Tu[2], Topside Ehleketani Mathonsi[3]
Dept of Computer Systems Engineering, Tshwane University of Technology, Pretoria, South Africa[1, 2]
Dept of Information Technology, Tshwane University of Technology, Pretoria, South Africa[3]

***Abstract*—The prediction of solar irradiance plays a crucial role in the design, performance, and stability of renewable energy sources, and especially photovoltaic (PV) power generation. Accurate forecasting helps in managing energy, grid stability, and integration of solar energy in contemporary power systems. The study is a Systematic Literature Review (SLR) of 37 recent (2019-2025) peer-reviewed papers on solar irradiance forecasting that apply Machine Learning (ML), Deep Learning (DL), and hybrid or ensemble modelling methods. The review is based on the Preferred Reporting Items of Systematic Reviews and Meta-Analyses (PRISMA 2020) to make it transparent and reproducible. A thorough search of seven large databases, such as Google Scholar, IEEE Xplore, Web of Science, Springer Nature Link, ScienceDirect, MDPI and the ACM Digital Library, was conducted to find relevant studies. Based on a structured synthesis of the chosen literature, the findings suggest that there is a definite methodological change in the traditional ML methods to DL and hybrid modelling structures. Although the classical ML algorithms have low computational complexity and can be effectively used to make short-term predictions, DL architectures consistently outperform them in terms of capturing nonlinear temporal and spatial patterns in solar irradiance data. Moreover, hybrid models combining DL architectures with signal decomposition and feature fusion methods also improve predictive accuracy. Nevertheless, the review notes that there are a number of ongoing shortcomings, such as the lack of geographic generalizability because of single-site dominance, the lack of consistency in reporting computational efficiency, the inconsistency of evaluation metrics, the lack of robustness testing in dynamic weather conditions, and a strong bias towards short-term forecasting horizons. In order to fill these gaps, future studies need to focus on multi-site and cross-climatic validation, domain adaptation using transfer learning, designing lightweight models to deploy in real-time, standardised benchmarking guidelines, and broaden their scope to medium and long-term forecasting with enriched meteorological inputs. Overall, the results offer an evidence-based, systematic review of existing trends in methodology and emphasise the need to balance predictive accuracy with generalizability, efficiency, and practical application in solar energy forecasting systems.**

Keywords*—Solar irradiance forecasting; Machine Learning; Deep Learning; hybrid models; Systematic Literature Review

I. Introduction

Solar power is a major renewable resource that can be used to reduce climate change and to supply the ever-growing global electricity demand. However, solar irradiance is very temporal and sensitive to meteorological conditions like cloud dynamics, atmospheric composition, temperature and humidity making it difficult to make precise predictions [1]. This natural intermittency presents an element of uncertainty in the operation of Photovoltaic (PV) power systems and electrical grids to the stability, reliability and economic performance of the system [2]. The inaccuracy of the forecasts can lead to power imbalances, poor dispatch choices, reserve overage, and operational expenses, which restrict the large-scale integration of solar energy [3]. Therefore, improving the accuracy and strength of solar irradiance forecasting is a focal point of research in the field of renewable energy and grid integration [4].

To address these issues, various forecasting strategies have been explored, including classical statistical models and physical models as well as data-driven Machine Learning (ML) models [5]. Though conventional models are based on pre-established assumptions and simplified physical relationships, they do not usually describe the nonlinear and stochastic interactions between solar irradiance and atmospheric variables [6]. ML-based methods have thus become popular because of their ability to acquire complicated patterns using historical irradiance and meteorological information. Earlier experiments have used regression models, tree-based algorithms, Support Vector Machines (SVMs), Artificial Neural Networks (ANNs), and Deep Learning (DL) models, such as Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), and Long Short-Term Memory (LSTM) networks to enhance the accuracy of forecasts. Ensemble and hybrid models have also been put forward in order to capitalise on complementary model strengths and to enhance performance under different climatic conditions [7].

Although they are said to be successful, in the real world of operation, ML-based forecasting models are usually limited. Issues with data quality, non-stationarity and distributional changes due to seasonal variability, climate anomalies, or sensor degradation can cause Model performance to degrade [8]. In addition, most studies based on site-specific data and controlled experimental design limit model extrapolation across geographical areas and time spans. More advanced methods like feature selection, hyperparameter optimisation and probabilistic forecasting have been proposed to enhance robustness and reliability. However, the quantification of uncertainty and operational resilience has not been investigated thoroughly in most of the literature [9, 10]. New methods such as transfer learning and federated learning have demonstrated the potential to deal with data scarcity, privacy issues and regional heterogeneity. Conversely, Explainable Artificial Intelligence (XAI) methods are becoming more popular to enhance the

*Corresponding author

interpretability of models and enable trust in ML-driven prediction systems [11-13].

This Systematic Literature Review (SLR) critically analyses and synthesises recent advances in ML, DL and hybrid-based solar irradiance forecasting reported between 2019 and 2025. The review systematically finds and categorises available forecasting methods into ML, DL and hybrid architectures and compares their reported performance based on popular metrics. In addition to performance comparisons, the study will discuss the advantages and disadvantages of these techniques in practical implementation. The discussion identifies some common problems, such as inadequate generalisation of models across geographic and climatic boundaries, preponderance of short-term forecasting research, underreporting of operational and computational needs and weak performance in highly variable weather. Lastly, the review identifies several significant research gaps and future research directions. It also offers practical insights and methodological advice on developing reliable, scalable and application-oriented solar irradiance forecasting models for renewable energy systems.

This SLR makes the following contributions to the literature:

- Provides a comprehensive systematic review of ML, DL and hybrid methods for solar irradiance forecasting.
- Provide a structured classification of forecasting approaches into traditional ML, DL and hybrid/ensemble models used for solar irradiance prediction.
- Provide a comparative evaluation of forecasting performance across studies using commonly reported metrics such as RMSE, MAE, nRMSE and the coefficient of determination (R^2).
- Provide a critical analysis of ongoing limitations such as limited model generalizability across climatic regions, insufficient reporting of operational and computational metrics, the dominance of short-term forecasting studies and limited evaluation under highly variable weather conditions.
- Identification of key research opportunities such as the development of generalizable multi-site forecasting models, integration of NWP with DL for longer forecasting horizons, lightweight and efficient architectures for real-time deployment, probabilistic forecasting frameworks and the creation of standardised benchmark datasets.

The rest of this study will be organised in the following way: Section II will provide the background. Section III describes the methodology of the review according to the PRISMA framework. Section IV introduces the chosen studies to review and provides a comparative analysis of the forecasting models and their performance. Section V explains the major issues of research, limitations, and the practical deployment. Section VI points out the future research directions and methodological recommendations. Lastly, Section VII gives the limitations of this review and the conclusion of the work.

II. Background

In order to contextualise the existing studies on solar irradiance forecasting, it is necessary to develop a clear vision of the inherent features of the variability of solar irradiance, the constraints of the traditional forecasting methods, and the increasing role of ML in renewable energy systems. This section examines these background concepts and systematically prepares the ground on which the detailed analysis in the following sections will be based.

A. Solar Irradiance Variability

The other important parameter that influences PV power production is solar irradiance. But solar irradiance is highly variable since it is affected greatly by the atmospheric and meteorological conditions [14]. Variables such as the concentration of aerosols, movement of clouds, humidity, temperatures, and geometry of the sun contribute to the variability of solar irradiance [15]. Fluctuation of solar irradiance presents a number of challenges to the management of power systems, particularly in the increased use of solar energy in modern electrical systems [15]. The issue is that, contrary to the traditional fuels, solar energy cannot be turned on and off according to the load needs [16]. Thus, it is important to forecast the amount of solar irradiance accurately to ensure stability and proper power load management, as well as participation in energy market activities. Short-term variability may bring about voltage fluctuations and frequency instability, whereas longer-term forecasting errors can be inefficient scheduling of backup generation and higher operating costs [17]. Consequently, the nature and cause of the variability of solar irradiance is the key area of concern in renewable energy studies.

B. Challenges in Solar Irradiance Forecasting

The prediction of solar irradiance remains a challenge because it is stochastic, nonlinear and dynamic in nature [18]. Although the radiation of the sun itself is deterministic, it interacts with a number of atmospheric variables, including clouds, aerosols, and water vapour, which make it stochastic [19]. Solar irradiance forecasting at the beginning was largely grounded on statistical and physics-based modelling with the use of Numerical Weather Predictions (NWP) [20]. Although these techniques are promising when studied at a greater time scale, they perform poorly in forecasting short-term variations in the solar irradiance [21]. The reason is that they are not effective in forecasting irradiance in partly cloudy skies. Moreover, the availability of data is another issue, as not all the data may have been available and there may be noise in sensors that capture irradiance measurements [22]. The lack of data and climatological differences between various geographical locations also make the predictive models training and deployment more difficult [23]. Such problems have inspired the creation of data-driven methods that can directly acquire complex patterns through historical observations.

C. Machine Learning for Solar Irradiance Forecasting

Machine Learning (ML) algorithms have proven to be quite effective in forecasting the performance of solar energy systems

thanks to their ability to deal with non-linear relations and build complicated representations of varied inputs [24]. The ML algorithms have proven to be the best approaches in solar radiation forecasting in the short term as well as in day-ahead predictions [25]. This has been attributed to the fact that the algorithms have the capability to simulate very complex interactions of non-linear meteorological variables such as the solar irradiation, temperature, wind speed, and humidity [26]. ML algorithms do not require any assumption regarding physical processes, as opposed to other traditional methods, which require some physical properties. The algorithms are capable of making good use of historical irradiation and meteorological data to enhance their forecast effectiveness [27]. Solar irradiance forecasting has been performed with different ML methods, such as regression-based methods, Decision Trees (DTs), Support Vector Machines (SVMs), ensemble learning methods, such as Random Forests (RFs) and Gradient Boosting (GB), Deep Learning (DL), and hybrid methods that integrate data-driven methods with other methods [28, 29]. The techniques are highly appreciated due to their flexibility in modelling. The computation needs, however, differ significantly among model classes.

ML algorithms that are applied in predicting solar irradiance have three major classifications. They are unsupervised, hybrid and supervised [30]. Among all these types, the supervised ML algorithms have demonstrated excellent performance in the case of sufficiently good quality training data [31]. These algorithms mostly use handcrafted features extracted from historical solar irradiance data, weather parameters, and time indicators to obtain accurate predictions [32]. Nevertheless, their effectiveness is highly dependent on having plenty of data, being vulnerable to overfitting, and low generalisation abilities for unknown locations with different climates [33]. In order to overcome these issues, the DL algorithms have gained a great deal of interest in recent years due to their ability to directly obtain complex features based on raw data [34]. The most popular DL structures to use in modelling solar irradiance time series include Convolutional Neural Networks (CNN), Recurrent Neural Networks (RNN), and Long Short-Term Memory Networks (LSTM) [35, 36]. Particularly, LSTM algorithms have been effective in learning long-term dependencies in solar irradiance variations [37, 38].

Unlike supervised learning methods, unsupervised learning methods do not need labelled data and are mainly applied to the task of clustering, pattern discovery, and regime identification [39]. These methods are very useful in understanding the underlying structure of irradiance and meteorological data and can be used to aid forecasting by adaptive model selection or feature extraction [40]. But in contrast to the supervised methods, the unsupervised methods do not directly produce irradiance forecasts and are generally only feasible when combined with predictive models [41].

Hybrid forecasting methods are also increasingly being combined with supervised and unsupervised learning techniques using statistical or physical models. These kinds of hybrid models take advantage of complementary capabilities of different algorithms to enhance the accuracy and reliability of predictions in different weather conditions [42]. Hybrid Machine Learning models, especially, have gained quite a lot of attention in relation to predicting solar irradiance due to the nonlinear, non-stationary, and stochastic nature of solar energy [43]. The solar irradiance is also subject to a number of meteorological conditions, such as cloud cover, temperature, humidity, wind speed, and aerosol content; such factors cannot be well modelled using only one modelling method [44]. Hybrid models are able to give a more realistic account of these complex dynamics by combining complementary learning approaches.

Even though hybrid approaches tend to enhance predictive reliability, they can add complexity to the model, raise the cost of computation, and raise the design and tuning needs [45]. Hybrid ML models, in general, have better accuracy, flexibility, and generalizability of multiple forecasting horizons [46]. They are especially fit in real-world solar energy systems because they are able to combine spatial, temporal, and physical information, and accurate forecasting is important in grid stability, energy management, and to enable the successful integration of renewable energy resources [47].

Though significant progress has been made in this area, there is a tendency for ML, DL, and ML-DL forecasting algorithms to be ineffective in practice because of non-stationary processes, seasonality changes, and changes in the distribution of weather patterns [48]. In a bid to mitigate these challenges, ensemble learning techniques, probabilistic forecasting and hyperparameter optimisation approaches have been proposed. However, there are inconsistent uptakes of these methods in the literature. These difficulties prove the necessity of the systematic analysis and critical synthesis of the existing approaches.

This development of ML-based solar irradiance forecasting studies forms the basis of the SLR in this study, which seeks to synthesise existing knowledge, evaluate the methodological strengths and limitations, and uncover gaps and future research directions in the field of ML-based solar irradiance forecasting.

III. Methodology

The methodology of this SLR defines the structured approach adopted to identify, screen, and synthesise existing research on ML and DL-based solar irradiance forecasting. The review was conducted in accordance with the PRISMA 2020 guidelines to ensure transparency, methodological rigour, and reproducibility.

A. Review Protocol and Prisma Guidelines

The SLR in this study was conducted in accordance with the PRISMA framework, which provides a structured process for identifying, screening and selecting relevant studies. A predefined review protocol was established to guide the search strategy, inclusion and exclusion criteria, data extraction and synthesis process. This protocol was designed to minimise selection bias and ensure consistency throughout the review.

B. Research Questions

The SLR in this study was guided by the following Research Questions (RQs):

- RQ1: What types of predictive models are used for solar irradiance forecasting and what model architectures are commonly adopted?

- RQ2: What data sources, input features, feature selection methods and feature engineering techniques are utilised in these forecasting models?
- RQ3: What forecasting horizons are primarily addressed in the literature?
- RQ4: What model optimisation and tuning techniques, evaluation metrics, and validation methods are employed to assess forecasting performance?
- RQ5: What key findings, limitations, challenges and research gaps are reported in the literature regarding the development, generalizability and real-world deployment of solar irradiance forecasting models?

C. Research Objectives

To address these research questions, the following Research Objectives (ROs) were formulated:

- RO-1: To identify and analyse the types of predictive models, including ML, DL and hybrid approaches, used for solar irradiance forecasting and to examine their commonly adopted architectures.
- RO-2: To investigate the data sources, input features, feature selection methods and feature engineering techniques utilised in solar irradiance forecasting models.
- RO-3: To examine the forecasting horizons addressed in the literature, including short-term, medium-term and long-term solar irradiance prediction.
- RO-4: To analyse the optimisation and tuning techniques, evaluation metrics and validation methods used to assess and compare forecasting model performance.
- RO-5: To identify the key findings, limitations, challenges and research gaps reported in the literature regarding the generalizability and real-world deployment of solar irradiance forecasting models.

D. Search Strategy

A comprehensive search strategy was developed using combinations of relevant keywords and Boolean operators. These keywords were combined using logical operators (AND, OR) to retrieve relevant studies. The search was limited to peer-reviewed publications to ensure scientific quality. The primary search terms included:

("solar irradiance forecasting" OR "solar radiation prediction") AND

("machine learning" OR "deep learning" OR LSTM OR CNN OR GRU OR transformer OR "ensemble learning" OR "hybrid models" OR "sky images")

The literature search was limited to studies published between 2019 and 2025 to capture recent advances in ML and DL techniques for solar irradiance forecasting.

E. Data Source Material

A comprehensive literature search was conducted using seven major electronic databases widely recognised in the fields of renewable energy, power systems and artificial intelligence. These databases include Google Scholar, IEEE Xplore, Web of Science, SpringerLink, ScienceDirect, MDPI and ACM Digital Library. These databases were selected to ensure broad coverage of high-quality, peer-reviewed research.

F. Inclusion and Exclusion Criteria

Clear inclusion and exclusion criteria were established to maintain the rigour and relevance of the SLR. The journal or conference articles were included under the following strict conditions:

- They have been published between 2019 and 2025.
- They have been peer-reviewed and are accredited according to the latest Department of Higher Education and Training-accredited journal list.
- They focused on ML and DL based solar irradiance or solar radiation forecasting.
- They provided an empirical evaluation using quantitative performance metrics.

Studies were excluded if:

- They have been published before 2019.
- They have no empirical or experimental validation.
- The metric evaluation results are not explicitly discussed.
- They are written in other languages instead of English.
- They are tutorials, letters, editorials, review articles, opinion papers, and blogs.

These criteria ensured that the review captured recent, evidence-based research while excluding non-technical or outdated sources, thereby strengthening the reliability and relevance of the synthesised findings.

G. Study Selection Process

The study selection followed the PRISMA four-stage process:

- Identification: All records retrieved from databases were compiled, and duplicates were removed.
- Screening: Titles and abstracts were screened to exclude irrelevant studies.
- Eligibility: Full-text articles were assessed based on inclusion and exclusion criteria.
- Inclusion: Studies meeting all criteria were included in the final review.

A comprehensive literature search was conducted across relevant academic databases to identify studies on solar irradiance forecasting using ML techniques. A total of 162 records were initially identified through database searching.

Following identification, 66 duplicate records were removed, leaving 92 unique records for screening. The titles and abstracts of these records were screened to assess relevance to the research objectives. During this stage, 43 records were excluded for being irrelevant to solar irradiance forecasting or for lacking ML or DL methodologies.

The remaining 49 reports were sought for full-text retrieval; all were successfully obtained. These reports were then assessed for eligibility based on predefined inclusion and exclusion criteria. As a result of the full-text assessment, 12 reports were excluded for reasons including a lack of empirical or experimental validation and for not explicitly discussing metric evaluation results.

Ultimately, 37 studies met all inclusion criteria and were included in the final review. Each included study corresponded to a single report. The complete study selection process is illustrated in the PRISMA 2020 flow diagram shown in Fig. 1.

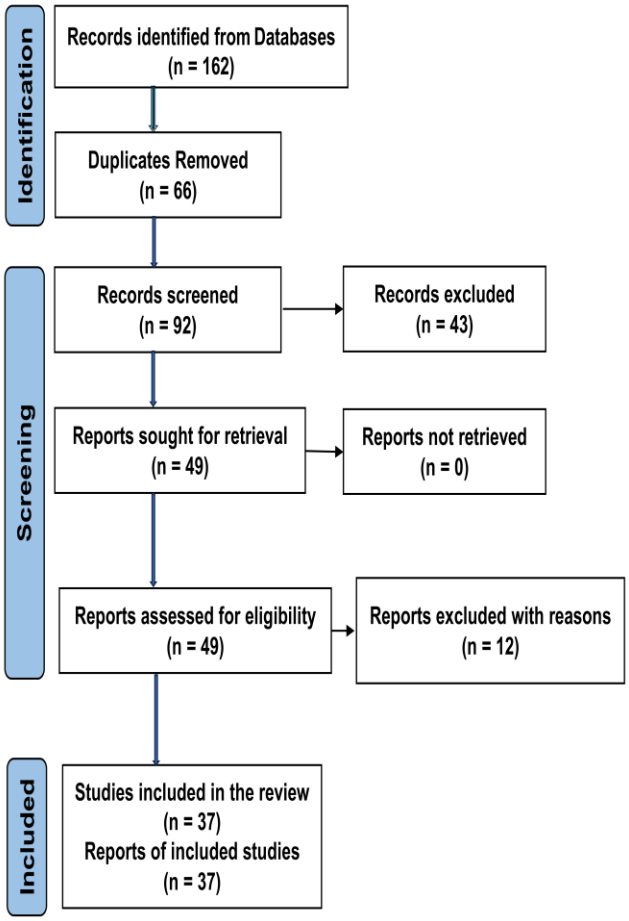

Fig. 1. PRISMA 2020 flow diagram of this study.

This systematic selection process ensures that only high-quality, relevant, and methodologically sound studies contribute to this review's findings.

H. Quality Assessment

The quality of the included studies was systematically assessed to determine the reliability and methodological rigour of the research in a simplified checklist-based framework. Instead of numeric scoring, the studies were graded according to four broad criteria that encompassed the quality of data, methodological rigour, the strategy of validation and clarity of reporting. Each of the criteria was assessed based on three possible outcomes, i.e., Yes, Partial or No (or not reported). The rating of "Yes" means that the criterion is completely met, the rating of "Partial" means that the criterion is met partially, and the rating of "No" means that the criterion is not met or not mentioned.

The following defines the assessment criteria: data quality evaluates whether the size, duration and source of the data are clearly described and adequate to the forecasting task; methodological rigour evaluates whether the model architecture, hyperparameter tuning and methodological decisions are clearly explained and reproducible; validation strategy evaluates whether suitable validation methods, such as time-based splitting or cross-validation, are employed to avoid data leakage and guarantee robustness; reporting clarity evaluates A Partial rating is also used to prevent subjectivity when a criterion is covered, but not detailed or comprehensive enough. Examples include a mention of a dataset source, but its size or duration is not completely stated, or validation is mentioned, but an unsuitable or imprecisely described method is employed.

Based on these criteria, each study was classified using a rule-based approach where high quality means that all four criteria were rated as "Yes", medium quality means that at least two criteria were rated as "Yes" and no criterion was rated as "No" (i.e., only "Partial" allowed otherwise), and low quality means any criterion was rated as "No". The final synthesis has filtered out studies that are of low quality in order to have a review that is grounded on solid and methodologically sound evidence. Table I includes the quality assessment criteria and checklist, and Table II includes the summary of the assessment results of all included studies. The findings show that none of the chosen studies were of low quality according to the established criteria; all of them are of high and middle quality. This implies that all of the included studies have a minimum level of methodological rigour and reporting adequacy. The most frequent restrictions found in medium-quality studies are associated with missing reporting of validation processes and transparency of hyperparameter tuning. This systematic but streamlined evaluation system enhances transparency, minimises subjectivity, and provides uniformity in assessing the quality of the methodology of the reviewed literature.

TABLE I. QUALITY ASSESSMENT CRITERIA AND CHECKLIST

Criterion	Description	Yes	Partial	No
Data Quality	Dataset source, size, duration, and type are clearly described and sufficient for the forecasting task	Clearly specified dataset (source, duration, resolution, inputs)	Partially described dataset (missing size/duration/type details)	Datasets unclear or not reported

Methodological Rigour	Model architecture, feature engineering, and hyperparameter tuning are clearly justified and reproducible	Full model description + tuning/justification provided	Model described but limited tuning/justification	Model unclear or not reproducible
Validation Strategy	Use of appropriate validation (chronological split, CV, walk-forward), preventing leakage	Clearly defined robust validation method	Validation mentioned but unclear/incomplete	No validation strategy reported
Reporting Clarity	Metrics clearly reported (RMSE, MAE, R^2, etc.) with transparency	Clear metrics and results reported	Metrics reported but incomplete/inconsistent	Metrics unclear or missing

TABLE II. QUALITY ASSESSMENT RESULTS FOR INCLUDED STUDIES

Ref	Data Quality	Methodological Rigour	Validation Strategy	Reporting Clarity	Quality
[49]	Yes	Yes	Yes	Yes	High
[50]	Yes	Yes	Yes	Yes	High
[51]	Yes	Yes	Yes	Yes	High
[52]	Partial	Yes	Partial	Yes	Medium
[53]	Partial	Yes	Partial	Yes	Medium
[54]	Yes	Yes	Yes	Yes	High

I. Data Extraction and Synthesis

For each included study, relevant technical details were systematically extracted, including the type of predictive model, forecasting horizon, data sources, model architecture, feature selection techniques, feature engineering techniques, tuning techniques, evaluation metrics, validation methods, key findings, and reported limitations. Due to variations in datasets and experimental settings, a descriptive qualitative synthesis was employed instead of a quantitative meta-analysis.

J. Classification Framework

The selected studies were organised according to their primary methodological approach into three categories: ML, DL, and Hybrid/Ensemble models. Each study was classified based on its principal contribution or best-performing model, rather than on all models included in the comparative evaluation. This methodological categorisation enables a structured comparison across studies, despite variations in objectives, datasets, and performance metrics, thereby facilitating the identification of methodological trends, research gaps, and potential directions for future work.

IV. Review of Selected Studies

In this section, 37 studies on ML, DL and Hybrid/Ensemble solar irradiance forecasting published between 2019 and 2025 are reviewed. The summaries of these studies are presented in Table III to Table V. Each research is evaluated in terms of the purpose, research methodologies, findings, and limitations found. The Goal dimension reflects the main research aim of every research, whereas the Method dimension explains the models or techniques applied. The outcome dimension will summarise the key results or findings of the performance, and the limitations dimension will identify the limitations or challenges that are reported by the authors. This is a summary of previous work that used ML, DL, and Hybrid/Ensemble in predicting solar irradiance. The methods go all the way from classical regression and tree models to DL structures, such as CNNs, RNNs, LSTMs, and hybrid/ensemble models. The works explore both the short-term (minutes to hours) and long-term predictions, using various input characteristics such as historical irradiance, meteorological variables, time indicators, sky images, and satellite-based data. Other works examine the probabilistic forecasting and quantification of uncertainty to aid in decision-making with regard to grid operations.

TABLE III. Summary of Selected ML Studies on Solar Irradiance Forecasting

Reference	Goal	Method	Outcome	Limitations
[49]	To evaluate whether linear ML algorithms can provide accurate short-term solar irradiance forecasting using sky images while maintaining low computational complexity.	Applied linear ML, including Lasso Regression, Ridge Regression (RR), Bayesian Ridge (BR), Stochastic Gradient Descent (SGD), LR, Generalized Linear Model (GLM), and RANSAC using three years (2014-2016) 1-minute resolution sky images (1536×1536 RGB) and solar irradiance data collected at the Energy Ville campus, Belgium. Used evaluation metrics including RMSE, Forecast Skill (FS), RMSE of Ramp Rate (RR), and Execution time (seconds) and used a chronological train/test split for model validation. Used Fisheye correction for feature engineering.	The Lasso achieved the highest accuracy for 5-10 min ahead forecasts, with RMSE of 0.05-0.062 W/m². SGD performed best for 15-30 min ahead with RMSE of 0.067-0.076 W/m². BR and RR consistently ranked among the top-performing models across all horizons. All models except RANSAC outperformed the smart persistence benchmark, demonstrating that simple linear models can rival more complex approaches for short-term forecasting.	Forecasting horizons are limited to 30 minutes due to the spatial constraints of sky imagers. The study is based on a single geographic location, limiting generalizability. Model performance depends strongly on image quality, reducing its applicability in regions lacking imaging infrastructure.
[50]	To develop a computationally efficient method for short-term and ahead-of-time solar irradiance forecasting from sky images while maintaining competitive accuracy.	The kNN and RF were employed for nowcasting and forecasting solar irradiance up to 4 hours ahead using two single-location sky image datasets (TSI-880 and ASI-16) covering 15 years in 10-minute resolutions, paired with GHI measurements from Golden, Colorado, USA. Used Latent Semantic Analysis (LSA) and Singular Value Decomposition (SVD) for future extraction. Used evaluation metrics, including Normalized MAPE (nMAPE) RMSE, Normalized RMSE (nRMSE) and used a chronological train/test split for model validation.	The proposed kNN model achieved competitive hourly forecasting accuracy, with nMAPE of 14.9% for TSI-880 and 14.7% for ASI-16; RMSE of 122.2 and 116.7 W/m²; and nRMSE of 7.7% and 8.9%, respectively, while reducing computational complexity by about 30% compared to state-of-the-art CNN/LSTM-based DL models.	The model's performance relies heavily on the availability and quality of sky camera images, limiting its applicability in regions lacking such infrastructure. Evaluation was conducted at a single site, limiting assessment of generalizability to other climates, camera setups, or large-scale deployment.
[51]	To forecast daily solar radiation in Riyadh, Saudi Arabia, using ML techniques and compare their predictive performance.	The study applied three ML models: ANN, RF, and LR, using historical meteorological data to predict daily GHI, obtained from the King Abdullah City for Atomic and Renewable Energy (KACARE). Used evaluation metrics including RMSE, MAE and direction accuracy and used a hold-out train/test split for model validation.	The RF model achieved the best performance, with a direction accuracy of 92.8571%, MAE of 13.6747 and an RMSE of 10.3157, outperforming the ANN and LR models. The results demonstrate that ensemble tree-based methods provide more accurate solar radiation predictions than traditional regression and neural	The study used data from a single location, limiting the generalizability of the results to other regions. Additionally, the comparison involved only three ML models, and more advanced DL approaches were not investigated. The study also focused on daily forecasting, without evaluating multi-step

			network approaches for the dataset studied.	or short-term high-resolution predictions.
[52]	To evaluate solar power forecasting performance using statistical, ML, and DL approaches.	Multiple algorithms were tested, including statistical models (Moving Average, Exponential Smoothing, ARIMA, SARIMA), ML models (RF, DT, LR, SVR, GB), and DL models (ANN, RNN, CNN, LSTM), using a dataset containing weather variables and generated solar power, for a 3-hour ahead forecasting horizon. Used Correlation-based feature selection. Feature extraction via transformations. Used evaluation metrics, including RMSE and MAE, and used a hold-out train/test split for model validation. Used adaptive feature selection	The RF model achieved the best forecasting performance with an RMSE of 4.04 kW and an MAE of 2.54 kW, outperforming all other models. DL models showed moderate performance due to the limited dataset size, and statistical models produced the highest errors, indicating poor capability to capture nonlinear patterns in solar power data.	The dataset used in the study was relatively small, limiting the performance of DL models, which typically require large datasets. The study also focused on single-dataset evaluation, meaning the results may not generalise to other geographic regions or datasets. Additionally, hybrid forecasting models were not explored, which could potentially improve prediction accuracy by combining multiple algorithms.
[53]	To improve the accuracy and reliability of solar power forecasting by evaluating different ML and DL models and identifying the most effective approach.	Four models were implemented and compared: LR, Polynomial Regression (PR), ANN, and RF, using historical solar power, meteorological, and environmental data for forecasting horizons of 1-10 days. Random Forest Regression (RFR) was used for future selection. Used evaluation metrics, including RMSE and R^2, and used a chronological train/test split for model validation. Correlation matrix used for feature selection. Grid search CV used for tuning.	The RF model achieved the best forecasting performance, with the lowest RMSE of 1.72 and the highest R^2 of 97.5% for up to 10-day-ahead forecasting. ANN also performed well but was slightly less accurate than RF. LR and PR produced higher prediction errors. The results demonstrate that ensemble learning methods, such as Random Forests, are highly effective at capturing nonlinear relationships in solar power data.	Forecasting accuracy decreases as the prediction horizon increases, especially for long-term forecasts such as 10 days ahead, due to increased weather uncertainty. The study evaluated only four models, and hybrid or ensemble combinations beyond RF were not explored. Additionally, the study does not clearly discuss dataset diversity or multiple geographic locations, which may limit the generalizability of the results.

TABLE IV. SUMMARY OF SELECTED DL STUDIES ON SOLAR IRRADIANCE FORECASTING

Reference	Goal	Method	Outcome	Limitations
[54]	To develop and evaluate DL based models for daily solar irradiance forecasting using single-site and multi-site data.	Evaluates DL models, including LSTM, GRU, CNN, Bidirectional LSTM (Bi-LSTM), and Attention-based LSTM, using multi-location and single-location solar irradiance data spanning 36 years. Pearson correlation, Spearman correlation, and XGB feature importance were used for feature selection. Used evaluation metrics including MSE, RMSE, and R^2 and used a rolling window validation method.	Demonstrated that bi-LSTM and at-LSTM models provide accurate daily solar irradiance forecasts, with R^2 values of 0.68-0.70 in the first location and R^2 values of 0.72-0.73 in the second location. This study shows that incorporating multi-site historical data improves prediction accuracy and reliability compared to single-site univariate models.	Performance gains depend on long-term, multi-site data, potentially limiting applicability in regions with sparse measurement infrastructure. Computational costs and DL model complexity were not assessed, restricting insights into efficiency, scalability, and real-world deployment.
[55]	To evaluate and compare DL and ML models for long-term solar radiation forecasting to support microgrid planning and photovoltaic energy potential assessment.	Applies multiple DL and ML models, including GRU, LSTM, RNN, FFNN, and SVR, RF on 17 years of hourly and daily solar irradiance data (2000-2017) from two regions in Korea. Used Pearson correlation analysis for feature selection. Used only RMSE evaluation metrics and used validation methods, including chronological train-test split and sliding-window method.	Demonstrated that GRU outperformed the other DL and ML models, with RMSE of between 0.3909 W/m^2 and 0.4582 W/m^2 for the hourly solar radiation data and 5.3315 W/m^2 and 6.2672 W/m^2 for the daily solar radiation data, demonstrating its effectiveness for 1-year-ahead long-term solar radiation forecasting.	The study focuses on long-term horizons, limiting applicability to short-term forecasting. Computational costs and DL model complexity versus ML models were not examined, restricting insights into efficiency, scalability, and real-world deployment.
[56]	To develop a sky image-based DL model for short-term 1-hour-ahead GHI forecasting without relying on numerical meteorological inputs across different weather conditions.	Develops a deep CNN SolarNet and compares it to the Persistence model (classic), Persistence of Cloudiness, SVR, and ANN, trained on six years of sky images and corresponding GHI data from a single site. Used nRMSE and FS evaluation metrics, and used a chronological train-test split validation method	The SolarNet model demonstrated robust performance, outperforming the other models, achieving an nRMSE of 8.85% and a forecasting skill score of 25.14%.	Evaluation was limited to a single site, raising concerns about generalizability. The approach relies solely on image-based inputs, excluding numerical meteorological variables. The high computational complexity of the deep CNN architecture may limit its applicability in regions without sky-image infrastructure.

[57]	To compare the predictive performance of ML and DL models for Global Solar Radiation (GSR) and Diffuse Solar Radiation (DSR) prediction across multiple locations.	Evaluates and compares several ML and DL models, including SVR, RF, Polynomial Regression (PR), ANN, CNN, and RNN, using 12 years of hourly solar irradiance data (2005-2016) from four locations in Nigeria. Used evaluation metrics including *r*, RMSE, MAE, NMBE and used a chronological train-test split validation method	The DL models outperformed the ML models for GSR and DSR prediction, with the RNN achieving the best overall performance in Yobe, yielding *r* of 0.9546, RMSE of 82.22 W/m², and MAE of 36.52 W/m². ML models had the lowest computation costs.	Computational costs and DL model complexity relative to ML models were not examined, limiting understanding of their efficiency, scalability, and real-world applicability.
[58]	To compare statistical, ML, and DL models for short-term and long-term forecasting of GHI using high-quality measured data from Islamabad, Pakistan.	Compares multiple forecasting models, including Seasonal ARIMAX, Facebook Prophet (FBP) for longer horizons, and ML and DL models such as ANN, CNN, and LSTM on 4.75 years of hourly GHI data (2017-2021) from Islamabad, Pakistan. Used evaluation metrics including R^2, MAE, MSE, RMSE and used a time-ordered train-test split validation method. Used Pearson correlation for feature selection.	The DL models performed best for short-term GHI forecasts, achieving R2 scores of 0.987, 0.977, and 0.984, while statistical models were more efficient for long-term forecasts, with R^2 scores above 0.90.	The study is limited to a single geographic location, restricting generalizability to other climates. Computational costs and DL model complexity relative to ML models were not assessed, limiting insights into efficiency, scalability, and real-world deployment.
[59]	To develop a multi-modal fusion network for short-term solar irradiance micro-forecasting using both infrared images and past irradiance data, addressing intermittent and nonlinear patterns during cloudy periods.	Proposes a CNN-L and Multiple-Image CNN-LSTM fusion network (MICNN-L) that integrates infrared sky/cloud images and historical irradiance time-series and is evaluated against benchmark models, including Linear SVM, Nonlinear SVM, Linear GP, Nonlinear GP, DNN, RNN, GRU, and LSTM using 15-second infrared sky images and solar irradiance data from the University of New Mexico, Albuquerque, USA. Used evaluation metrics, including MAPE, and used a time-ordered train-test split validation method.	MICNN-L showed 46.42% improvement in MAPE, and CNN-L showed 42.02% improvement in MAPE compared to benchmark ML/DL models. Cloudy day classification achieved 99.23% accuracy. Proposed models effectively captured nonlinear spatio-temporal variations and improved short-term forecasts.	Evaluation is based on single-site, high-frequency (15 s) data, with dataset duration and calendar years unspecified. Reliance on infrared sky imagery increases computational complexity and limits applicability in regions without sky-image infrastructure.
[60]	To compare ML and DL algorithms for solar irradiance forecasting and identify the most effective model.	Evaluated several ML models, including DT, kNN, RF, SVM, XGB, Stacking, Light GBM, Boosting, CatBoost, MLP, and LSTM, on three years (2017-2020) of hourly and 15-minute solar irradiance data for multiple locations in Izmir, Turkey. Used evaluation metrics, including MAE, MSE, RMSE, and R^2 and used a chronological train-test split validation method. Tested LightGBM, Pearson, recursive elimination, chi-square, and LR for feature selection.	The MLP achieved the best performance with an RMSE of 0.79, demonstrating that neural networks can effectively capture nonlinear patterns in GHI forecasts and guiding solar panel deployment decisions.	The dataset is specific to the NSRDB and spatially restricted to a 4 km × 4 km area, limiting generalizability. In addition, computational cost and relative model complexity were not assessed, constraining insights into efficiency, scalability, and real-world deployment.
[61]	To accurately forecast solar electricity generation at a solar farm in Amherst for operational, technological, and financial planning.	Develops and compares several DL variants, including LSTM-V, Bi-LSTM, and GRU-II, as well as baseline regressors such as LASSO, Ridge, Elastic-Net, and SVR on four-year (2015-2019) 5-minute interval time-series meteorological and solar energy data from the Amherst weather station in Massachusetts, USA. Used evaluation metrics, including RMSE, MSE, MAE, and MAPE and used a hold-out train-test split validation method. Used a correlation heatmap for feature selection	The Bi-LSTM achieved the best performance, outperforming the other models, with an MAE of 0.0135, RMSE of 0.0315, MSE of 0.0012, and MAPE of 0.1205.	The dataset is restricted to a single location, limiting generalizability across different climatic conditions. Only five-minute interval predictions were evaluated; longer forecasting horizons were not assessed. Additionally, computational cost and relative model complexity were not examined, constraining insights into efficiency, scalability, and real-world deployment.
[62]	To accurately forecast short-term solar irradiance from historical sky image sequences while leveraging clear sky models for improved performance.	Employed a DL Vision Transformer-based network with auxiliary clear sky model input, benchmarked on two datasets spanning from 2004 to 2019 in 10-minute intervals. Used the evaluation metric normalised Mean Absolute Percentage (nMAP) and used a chronological train-test split validation method.	The DL Vision Transformer outperforms prior DL methods across two datasets, achieving reduced nMAP errors by 6.9% and 8% for nowcasting for the 2015 and 2016 datasets, and 5.4% and 8.8% reduction for 4-hour ahead prediction, and outperformed previous methods, especially for 3-	The study is limited to benchmark datasets (TSI880 and ASI16), with performance under diverse climatic conditions or alternative camera configurations not evaluated. The forecasting horizon is limited to 4 hours, and computational costs were

			and 4-hour forecasts under variable weather conditions.	not assessed, limiting insights into scalability and practical deployment.
[63]	To evaluate the impact of different forecasting time horizons on the accuracy of solar irradiance prediction using ML and DL models.	Compares eight models, including LR, CNN-LSTM, XGB, RF, CNN, BiLSTM, ConvLSTM, and MLP, on 2 years (2020-2021) of solar irradiance data at 60 min, 30 min, 15 min, 10 min, and 5 min intervals in Limpopo Province, South Africa. Used evaluation metrics, including RMSE, nRMSE, MAE, and R^2 and used a hold-out train-test split validation method.	The results showed that prediction accuracy generally decreases with increasing prediction horizon and that DL models outperformed conventional ML models overall. The ConvLSTM model achieved the best RMSE of 7.43 at a five-minute interval, and the MLP performed better than other models across most prediction intervals, with RMSE ranging from 18.87 to 75.52.	The dataset is restricted to a single location, limiting generalizability across different climatic conditions. Model performance for longer forecasting horizons (>1 hour) was not evaluated. Additionally, computational cost and relative model complexity were not assessed, constraining insights into efficiency, scalability, and real-world deployment.
[64]	To explore DL techniques for solar energy forecasting within microgrid systems.	Evaluates multiple ML and DL models for forecasting solar irradiance, including Baseline Regression, LR, Lasso, Ridge, Elastic-Net, RF, GB, XGB, LightGBM, RNN, GRU, and LSTM on 9.11 years of hourly solar irradiance data from a chosen location. Used the evaluation metric normalised RMSE and used a hold-out train-test split validation method.	The DL RNN outperformed the other models, with a testing RMSE of 0.00534, and the Traditional ML RF model also performed well, with a testing RMSE of 0.09.	Computational cost and relative model complexity were not evaluated, limiting insights into practical efficiency, scalability, and deployment feasibility. Additionally, the dataset is restricted to a single location, constraining generalizability across different climatic conditions.
[65]	To evaluate DL models for short-term 1-hour ahead solar irradiance forecasting.	Compares several DL models such as Temporal Convolutional Networks (TCN), ARIMAX, SVR, standard LSTM, LSTM with 32 convolution kernels, and SENet using 3 years (2013-2016) of hourly solar irradiance data from Bend, Oregon, USA (University of Oregon). Used the evaluation metric normalised RMSE, Training time per epoch, and GPU memory usage. Used a cross-year validation method.	LSTM achieved the highest forecasting accuracy, with an average RMSE of 0.069, while TCN significantly reduced training time and resource consumption, increasing only 6% to an average RMSE of 0.0738.	Evaluation was restricted to 1-hour-ahead forecasts, with performance for longer horizons or alternative datasets not assessed. Additionally, the dataset is limited to a single location, constraining generalizability across different climatic conditions.
[66]	To compare DL models for very short-term solar irradiance forecasting and identify the most accurate architecture for local PV applications.	Evaluates RNN, GRU, LSTM, and TCN architectures for one-step-ahead forecasting using 1-year (2019) 15-minute resolution solar irradiance data from Karachi, Pakistan, obtained from NSRDB. Used evaluation metrics, including RMSE, MAE, and R^2 and used a hold-out train-test split validation method.	The LSTM model outperformed other models, achieving the highest R^2 of 0.9934 and the lowest RMSE of 0.020051, demonstrating its effectiveness for highly accurate solar irradiance forecasting.	The dataset is limited to a single location, restricting generalizability across varying climatic conditions. Computational cost and model complexity were not assessed, limiting insights into efficiency, scalability, and real-world deployment. In addition, performance for longer forecasting horizons (>15 minutes) was not evaluated.
[67]	To develop a DL based approach for short-term solar irradiance forecasting using sky camera images.	The study indeed proposes an LSTM-based DL model compared against the Yoo model and the persistence model using 25 days of 1-minute-resolution sky images from a ground-based sky camera, combined with GHI measurements at Kookmin University in Seoul, South Korea. Used evaluation metrics, including MBD, RMSD, rMBD, rRMSD and UVI and used a hold-out train-test split validation method.	The proposed LSTM-based DL model achieves better 10-minute-ahead forecasting accuracy under partly cloudy conditions (UVI > 20), with RMSD of 199.75 W/m², rRMSD of 25.1%, MBD of -60.65 W/m², and rMBD of -12.70%, outperforming the persistence and Yoo models. For clear and overcast sky conditions (UVI < 5), the model's performance is comparable to that of the persistence model, reflecting the lower irradiance variability and simpler forecasting requirements in these cases.	The model's performance relies heavily on the availability and quality of sky camera images, limiting its applicability in regions lacking such infrastructure. Evaluation was conducted at a single site, limiting assessment of generalizability to other climates, camera setups, or large-scale deployment.
[68]	To investigate whether DL models can improve the accuracy of solar radiation forecasting for advanced building	Developed and compared an ANN model and an RNN model for solar radiation prediction, using a one-week dataset with different sampling frequencies (1-hour	The RNN significantly outperformed the ANN, achieving 47% improvement in NMBE and 26% in RMSE. Increasing data granularity (from 1 h to 10 min)	The study relied on a relatively short historical dataset, limiting the model's ability to capture long-term patterns and seasonal variability. The study did not

	control applications, such as model predictive control (MPC).	and 10-minute data) from a local weather station in Alabama for training. Used evaluation metrics, including RMSE CV(RMSE), and nMBE and used a hold-out train-test split validation method. Used Pearson correlation for feature selection.	reduced CV(RMSE) from 30.9% to 9.41% for ANN and from 9.83% to 7.64% for RNN. Implementing a moving-window algorithm further improved RNN nMBE from 0.9% to 0.2%. Cloud cover was identified as a significant influencing factor on prediction accuracy.	provide a quantitative evaluation of computational complexity, training time, or scalability, making it unclear how practical the models are for large-scale or real-time deployment. Validation was conducted under offline experimental settings without real-time analysis, so model performance under operational conditions remains untested.
[69]	To develop and evaluate a near-real-time solar irradiance forecasting model using only historical GSR time series in a data-scarce region of Vietnam.	Developed a standalone DL optimised LSTM network compared to ARIMA, DNN, MLP, and SVR, and evaluated across multiple short-term forecast horizons (1-30 min) using 1-min resolution GSR time series from Bac-Ninh, Vietnam. Used evaluation metrics, including *r*, RMSE, ENS, MAE, RRMSE, and MAPE and used a hold-out train-test split validation method. Used PACF-based lag feature selection. Used grid search for tuning.	The LSTM model consistently outperformed benchmark models across all horizons. At a 1-minute horizon, it achieved RMSE of 40.91 W/m², MAE of 21.64 W/m², R of 0.9920, WI of 0.9984, and ENS of 0.9831. Relative RMSE ranged from 10 to 15% across horizons.	The dataset is restricted to a single location, limiting generalizability across different climatic conditions. Computational cost and model complexity were not evaluated, constraining insights into efficiency, scalability, and practical deployment. Validation restricted to very short-term horizons
[70]	To improve solar irradiation forecasting accuracy using ML and DL models, and evaluate the effectiveness of the N-BEATS architecture for time-series solar radiation prediction.	Evaluated SARIMA, LSTM, and N-BEATS (Neural Basis Expansion Analysis for Time Series Forecasting) to predict clear-sky GHI, DHI, and DNI using daily aggregated meteorological data from the NSRDB for four regions in Bangladesh (Khulna, Chittagong, Sylhet, and Rajshahi). Used evaluation metrics, including MAE, RMSE, R^2, and MAPE and used a hold-out train-test split validation method. Used XGB feature importance for feature selection.	The N-BEATS model achieved the highest forecasting accuracy, with RMSE values of 29.03-35.77 for clear-sky GHI and MAPE values of 2.34-3.29%, outperforming SARIMA and LSTM. N-BEATS effectively captured solar radiation patterns, while LSTM performed the worst.	The study was limited to four regions within Bangladesh, which restricts the generalisability of the findings to other climatic conditions. Additionally, the dataset was aggregated to daily values, potentially overlooking short-term variability in higher-resolution solar radiation data. The study also evaluated a limited number of forecasting models, and hybrid or ensemble approaches were not explored.
[71]	To conduct a comparative analysis of ML and DL strategies for solar irradiation forecasting.	The study evaluated 9 ML and DL models, including LR, MLP, ELM, Kernel Ridge Regression (KRR), SVR, Gaussian Process Regression (GPR), CNN, LSTM, and Bi-directional LSTM (Bi-LSTM), using historical solar irradiation data from 2000-2005, obtained from the Batna meteorological station in Algeria. Used evaluation metrics, including MAE, RMSE, and R, and used a chronological train-test split validation method.	Among ML models, ELM with 16 features achieved the best performance, with RMSE of 4.004, MAE of 2.918, and R of 0.849. Among DL models, Bi-LSTM achieved the best overall performance for 1-day-ahead forecasts, with RMSE of 1.392, MAE of 1.021, and R of 0.989 using 25 features. The results demonstrate that DL models, particularly Bi-LSTM, significantly outperform traditional ML methods for solar irradiation forecasting.	The study used data from only one location, which limits the generalisability of the results to other climatic regions. Additionally, the study focused on individual ML and DL models, rather than hybrid or ensemble approaches, which could further improve forecasting accuracy.

TABLE V. SUMMARY OF SELECTED HYBRID/ENSEMBLE STUDIES ON SOLAR IRRADIANCE FORECASTING

Reference	Goal	Method	Outcome	Limitations
[72]	To compare the performance of common ML and DL algorithms for short-term solar irradiance forecasting and improve prediction accuracy under irradiance variability.	Evaluates ML models, including SVR, kNN, RF, and DL models such as ANN, CNN, LSTM, GRU, and a hybrid CNN-LSTM model, using grid-search hyperparameter optimisation on five years of hourly solar irradiance data (2015-2019) from a single site in Islamabad. Used evaluation metrics including adjusted R^2, NRMSE, MAD, MAE, and MSE. Used a 5-fold grid search cross-validation method for tuning.	Demonstrated that the CNN-LSTM hybrid model achieved the best performance among the other models with an adjusted R^2 of 0.984.	The study is based on a single geographic location and a fixed historical dataset, raising concerns about its generalizability to other regions.
[73]	To develop a robust and accurate ensemble model for hourly GHI forecasting to support reliable solar energy	Develops an XGBF-DNN hybrid ensemble model and compares it to Smart Persistence (SP) and other ML models, including SVR, RF, XGB, and DNN, on 10 years of hourly solar irradiance data (2005-2014) across three different climatic regions in India. Used evaluation metrics including FS,	Demonstrated that the proposed XGBF-DNN model outperformed the other models for a 1-hour ahead forecast, with RMSE values	The study focuses on long-term horizons, limiting applicability to short-term forecasting. Computational costs and DL model complexity relative to ML

	system planning and operation.	RMSE, and MAE. Used a Clear-sky index and temporal encoding feature engineering.	of 56.68 W/m^2, 53.78 W/m^2 and 91.86 W/m^2 for all three locations, with 33-40% improvement in FS.	models were not assessed, restricting insights into efficiency, scalability, and real-world deployment.
[74]	To improve 1-hour-ahead solar irradiance forecasting accuracy by incorporating multivariate inputs and a multi-branch hybrid DL structure.	Develops a hybrid WPD-CNN-LSTM-MLP model using a multi-branch architecture and compares it to BP, RNN, LSTM, SVM, BP-MLP, RNN-MLP, LSTM-MLP, and CNN-LSTM-MLP on 3 years of hourly solar irradiance data (2012-2016) across three sites in the USA: Denver, Clark, and Folsom. Used evaluation metrics including RMSE, MAE, MBE, FS and R^2. Used WPD decomposition feature engineering.	Demonstrated that the proposed WPD-CNN-LSTM-MLP model achieved superior prediction accuracy compared to other models, with MAE of 14.3523-20.3853, RMSE of 32.1006-46.1336, nRMSE of 15.4795-23.9178%, and R values of 0.9858-0.9940 across the three locations. WPD further reduced errors and improved correlation.	The study focuses on short-term horizons, limiting applicability to long-term forecasting. Computational costs and DL model complexity relative to ML models were not assessed, restricting insights into efficiency, scalability, and real-world deployment.
[75]	To develop an accurate and robust short-term hourly GHI forecasting model for reliable grid integration and energy market participation.	Develops a hybrid LSTM-CNN DL model and compares it to SP, SVM, ANN, CNN, LSTM, and CNN-LSTM on 1 year of hourly solar irradiance data (2019) across 23 locations. Used evaluation metrics including RMSE, MAE, R^2 and computational time.	The hybrid LSTM-CNN model improved prediction and outperformed standalone models for 1-hour-ahead forecasts, with MAE of 27.38-37.02, RMSE of 42.89-58.12, R of 0.9673-0.9853, and FS of 37%-45% across all the locations.	The study focuses on short-term horizons, limiting applicability to long-term forecasting. Computational costs of the hybrid DL model relative to ML models had high computational times, restricting efficiency, scalability, and deployment in computational resource-constrained locations.
[76]	To develop a hybrid short-term solar irradiance forecasting model for both GHI and Plane of Array (POA) irradiance with high predictive accuracy.	Develops a modified multi-step CNN-stacked LSTM network with dropout and compares it to CNN and LSTM on one month of solar irradiance data (2019) at a single site from Sweihan Photovoltaic Independent Power Project, Abu Dhabi, UAE. Used evaluation metrics including RMSE, MAE, MAPE, R^2, MSE, and NRMSE. Used a hold-out train-test split validation method.	The proposed hybrid model outperformed other ML and DL models for 1-hour-ahead forecasts, achieving an RMSE of 0.36, an R^2 of 0.98 for GHI, an MAPE of 61.24, and an R^2 of 0.96 for POA irradiance, demonstrating improved accuracy for short-term solar irradiance prediction.	The study is limited to a single location, affecting generalizability, and the computational costs and complexity of DL models versus ML models were not assessed, limiting insights into efficiency, scalability, and real-world deployment.
[77]	To develop a hybrid intelligent model for accurate short-term solar irradiance/power forecasting using wavelet decomposition and Generative Adversarial Networks (GANs) with evolutionary optimisation for two regions.	Proposes a Wavelet Transform Package (WTP)-GAN, optimised using a modified Dragonfly Algorithm (DA), and compared to ARMA, ANN, CNN, GAN, SVR, Fuzzy method, and RNN using 1 year of hourly solar irradiance data (2019) from two locations. Used evaluation metrics including RMSE and MAPE. Used a Wavelet decomposition feature engineering. Used dragonfly algorithm plus modified 3-phase DA for hyperparameter tuning.	The hybrid WTP-GAN with modified DA outperformed other models across multiple horizons of 1-6 hours ahead, with MAPE of 0.0282 & 0.0262, and RMSE of 0.0473 & 0.0479 for 1-pace forecast, and MAPE of 0.0531 & 0.0631, and RMSE of 0.0895 & 0.0946 for 6-pace forecast:	The study relies on a single year of data, limiting seasonal and multi-year generalizability. Moreover, computational cost and model complexity were not assessed, restricting insights into efficiency, scalability, and practical deployment.
[78]	To develop a heterogeneous ensemble dynamic selection (HetDS) model for solar irradiance forecasting, improving performance over single models.	Proposes a HetDS model that chooses the best forecasting model for each test pattern from a pool of seven methods, which include ARIMA, SVR, ANN, Extreme Learning Machine (ELM), Deep Belief Network (DBN), RF, and GB, using 1 year (2020) hourly solar irradiance data from four locations in Brazil. Used evaluation metrics including RMSE, MAPE, and MAE. Used a time-lag windowing and feature engineering. Used full Grid Search for hyperparameter tuning. Used a chronological train/test split validation.	The HetDS models performed better than the other models for 1-hour-ahead forecasts, with RMSE ranging from 0.0600 to 0.1762, MAPE ranging from 10.57% to 55.85%, and MAE ranging from 0.0426 to 0.1169 across all four cities.	The study is based on one year of data, limiting seasonal and multi-year generalizability. Additionally, computational cost and relative model complexity were not evaluated, constraining insights into efficiency, scalability, and real-world deployment.
[79]	To develop a hybrid decomposition-integration DL framework for short-term solar irradiance forecasting that better captures nonlinear and non-stationary patterns in irradiance data.	Develops a Complete Ensemble Empirical Mode Decomposition with Adaptive Noise (CEEMDAN)-Wasserstein GAN-LSTM hybrid model and compares to benchmark models evaluated, including RNN, GRU, Transformer, LSTM, WGAN, CEEMDAN-LSTM, CEEMDAN-WGAN, CEEMDAN-LSTM-WGAN variants using one year (2018), 5-minute resolution	The proposed CEEMDAN -WGAN-LSTM model outperformed all benchmark models across four seasonal test sets. Compared to sub-optimal benchmarks, its errors were reduced by 3.51% for MAE, 6.11% for MAPE, and 2.25%	The model was evaluated using one year of data from a single location, limiting generalizability across different climatic regions and multi-site settings. In addition, computational cost and relative model complexity were not assessed, constraining

		GHI data from NSRDB measured in Texas, USA. Used evaluation metrics including MAE, MAPE, RMSE, and R^2. Used a CEEMDAN-based decomposition for feature engineering and feature selection. Used a chronological train/test split validation.	for RMSE, and it showed the lowest errors with the highest R^2 values among the evaluated methods across seasons.	insights into efficiency, scalability, and real-world deployment.
[80]	To improve mean hourly GHI forecasting by providing accurate probabilistic predictions for grid stability and PV integration.	Develops a hybrid CNN-LSTM model combined with quantile regression and compares it with ANN, CNN, LSTM, and persistence models using one year (2019-2020) of hourly solar irradiance data, including sky images down-sampled to 64×64 pixels collected at the University of French Polynesia, Tahiti. Used evaluation metrics including MAE, RMSE, MSE, R^2, nMAP (deterministic); PICP, PINAW, CWC (probabilistic). Used a Sky image down-sampling for feature engineering. Used a chronological train/test split validation.	The CNN-LSTM hybrid model achieved the best deterministic and probabilistic performance for 1-h-ahead forecasts, with an RMSE of 100.58 W/m², an MAE of 66.09 W/m² and an R^2 of 0.85 on test data. For probabilistic forecasting, it obtained the lowest CWC values across multiple prediction intervals: 8.54 at PI (38%), 17.04 at PI (68%), 33.37 at PI (95%), 47.98 at PI (99%), demonstrating superior uncertainty quantification.	The dataset is restricted to a single location, limiting generalizability across different climatic conditions. Computational cost and model complexity were not evaluated, constraining insights into efficiency, scalability, and practical deployment. In addition, reliance on satellite imagery reduces applicability in regions without imaging infrastructure.
[81]	To improve 24-hour-ahead solar GHI forecasting accuracy for reliable grid management using an ensemble DL approach.	Employed a hybrid Wavelet Transform (WT)-BiLSTM model and compared it with GRU, LSTM, and standalone BiLSTM models using a one-year monthly solar GHI dataset, using a one-month moving window mechanism for the location of Ahmedabad, Gujarat, India. Used evaluation metrics including MAPE, RMSE, FS, and R^2. Used a moving window mechanism validation.	The proposed WT-BiLSTM ensemble outperformed benchmark, LSTM, GRU, and standalone BiLSTM models for 1-day-ahead forecasts, with a reduced Monthly average RMSE of 26.04-58.89% vs benchmark and up to 57% vs LSTM. The MAPE reduced by 9-51.18% vs benchmark. The achieved R^2 is 0.94, and the forecast skill is 47%.	The dataset is restricted to a single location, limiting generalizability across different climatic conditions. Computational cost and model complexity were not evaluated, constraining insights into efficiency, scalability, and practical deployment.
[82]	To improve solar radiation forecasting accuracy in Indian cities by integrating advanced signal decomposition techniques with ML and DL models.	This study developed nine novel ensemble models integrating Variational Mode Decomposition (VMD) and Discrete Wavelet Transform (DWT) with five DL algorithms, including GRU, LSTM, BiLSTM, CNN, and DNN, along with two ML algorithms, ANN and SVR, using historical meteorological data from 2000 to 2012 in seven major Indian cities provided by the Indian Meteorological Department. Used evaluation metrics including RMSE, MAE, and R^2. Used a VMD & DWT signal decomposition for feature engineering.	VMD-based DL ensembles significantly outperformed DWT-based models. Among all configurations, the VMD-GRU model achieved the best performance across all cities for 1-step-ahead forecasts, with RMSE of 0.82-1.22, MAE of 0.54-1.02, and R^2 of 0.83-0.93. This superior performance is attributed to GRU's lower parameter count, reduced memory requirements, and faster training capability.	The study utilised a limited set of meteorological variables, excluding other potentially influential atmospheric parameters. The study did not provide quantitative evaluations of computational complexity, training time, or the scalability of the hybrid models. Validation was conducted in an offline experimental setting without real-time deployment analysis.
[83]	To enhance solar radiation forecasting accuracy by developing a hybrid intelligent DL framework that integrates signal decomposition and evolutionary optimisation techniques.	Proposes a hybrid OVMD-PACF-ISSA-DBN-OSELM hybrid model combining optimal VMD with an evolutionary DBN online sequential ELM (EDBN-OS-ELM); applies partial autocorrelation function (PACF) for input variable selection; improves the sparrow search algorithm (SSA) to optimise DL hyperparameters. The model was developed and validated using hourly solar radiation data from January, May, and October 2022, collected from a single station of the National Data Buoy Centre. Used evaluation metrics including RMSE, MAE and R. Used hold-out train/test split validation method. Used the Partial Autocorrelation Function for feature selection. Used OVMD (Optimal Variational Mode Decomposition) for feature engineering. Used the improved Sparrow Search Algorithm (ISSA) algorithm for hyperparameter tuning.	The proposed model achieved the best performance across the January, May, and October datasets. For January, the model obtained an RMSE of 23.153 W/m², an MAE of 13.225 W/m², and an R of 0.9923, while the model obtained an RMSE of 39.223 W/m², an MAE of 24.962 W/m², and an R of 0.9924 for May. The model significantly outperformed BP, ELM, LSTM, DBN-based variants, and SSA-based hybrids for 10-minute-ahead forecasts.	The experimental evaluation was conducted using data from only three months (January, May, and October 2022), which limits the assessment of seasonal robustness. Additionally, the dataset was obtained from a single NDBC station, restricting geographical generalizability. The study focused solely on single-step forecasting, and multi-step prediction scenarios were not investigated.
[84]	To develop a robust and accurate deep hybrid	Developed a hybrid CEEMDAN-AG-RE-ELM that combines CEEMDAN for signal decomposition,	The proposed model achieved strong forecasting accuracy	The framework involves multiple complex stages

	framework for short-term GSR forecasting by combining signal decomposition, time-frequency analysis, deep feature extraction, and ML.	Continuous Wavelet Transform (CWT) to generate time-frequency scalogram images; cascade CNN (AlexNet + GoogLeNet) for deep feature extraction; RReliefF for feature selection; ELM for final forecasting using a two-year (2018-2019), hourly dataset from the Yulara Solar System, near Uluru (Ayers Rock). Used evaluation metrics including RMSE, MAE, and MAPE. Used a hold-out train/test split validation method. Used the RReliefF for feature selection. Used CEEMDAN decomposition for feature engineering. Used the 10-fold CV for hyperparameter tuning.	across multiple horizons of 1-, 2- and 3-hour ahead, with RMSE of 0.0642, MAE of 0.0241, MAPE of 0.1201 for 1-hour ahead and RMSE of 0.0686, MAE of 0.0285, MAPE of 0.1279 for 2-hour ahead and RMSE of 0.0724, MAE of 0.0315, and MAPE of 0.1317 for 3-hour ahead, outperforming conventional regression models; demonstrates superior robustness and accuracy.	(decomposition, image transformation, CNN feature extraction), which may increase computational cost. Performance was validated on a specific dataset; generalizability to other locations and longer horizons was not assessed.
[85]	To improve daily GSR prediction accuracy by developing a hybrid DL-ML framework that effectively extracts temporal features and enhances regression performance.	Proposed a hybrid CNN-SVR (CSVR) model and compared it to STM, DBN, RBF, BRF, MARS, WKNNR, GPML, and M5TREE models using Ground-measured daily GSR. Used evaluation metrics including RMSE, MAE, Willmott's d, NSE, and Legates-McCabe Index. Used a hold-out train/test split validation. Used Atom Search Optimisation (ASO) for feature selection. Used HyperOpt (Bayesian/TPE for hyperparameter tuning.	The proposed CSVR model consistently outperformed benchmark DL and ML models across six solar farms in Queensland, Australia. It achieved RMSE/MAE ranges of 2.172-3.305 MJ/m² and 1.624-2.370 MJ/m², respectively, compared to 2.514-3.879 MJ/m² and 1.939-2.866 MJ/m² from competing models. Higher correlation, Willmott's Index, Nash-Sutcliffe efficiency, and Legates-McCabe indices confirmed superior agreement between predicted and observed GSR.	Model complexity is relatively high due to multi-stage optimisation (feature selection, CNN, SVR, hyperparameter tuning). Evaluation was limited to daily forecasting and a specific geographical region, which may affect generalizability to other climates or shorter forecasting horizons.

Table VI summarises the quantitative findings of all 37 studies reviewed, indicating per reference, the model type, the best-performing model, forecast horizon, the type of input data used, the evaluation measure, and the best-reported score. This overview allows the direct cross-study comparison of the reported performance.

TABLE VI. SUMMARY OF SELECTED HYBRID/ENSEMBLE STUDIES ON SOLAR IRRADIANCE FORECASTING

Ref	Model Type	Best Model	Forecast Horizon	Input Dataset Type	Best Metric	Best Score
[49]	ML	Lasso Regression	5-30 min (Very short-term)	Numerical (irradiance + meteorological)	RMSE	0.050-0.076 W/m²
[50]	ML	kNN	4 h (Short-term)	Numerical (time series)	nRMSE	7.7-8.9%
[51]	ML	RF	1 day (Short-term)	Numerical (irradiance)	Directional Acc.	92.86%
[52]	ML	RF	3 h (Short-term)	Numerical	RMSE	4.04 kW
[53]	ML	RF	1-10 days (Medium-term)	Numerical	RMSE	1.72
[54]	DL	Bi-LSTM / Attention LSTM	1 day (Short-term)	Numerical (long-term time series)	R^2	0.68-0.73
[55]	DL	GRU	1 year (Long-term)	Numerical (hourly/daily)	RMSE	0.3909-0.4582
[56]	DL	SolarNet (CNN)	1 h (Very short-term)	Sky images	nRMSE	8.85%
[57]	DL	RNN	1 h (Short-term)	Numerical (multi-site)	RMSE	82.22 W/m²
[58]	DL	LSTM/CNN	1 h (Short-term)	Numerical (irradiance + meteorological)	R^2	0.987
[59]	DL	MICNN-L	15 sec (Very short-term)	Sky images	MAPE improvement	46.42%
[60]	DL	MLP	15 min-1 h (Very short-term)	Numerical (NSRDB)	RMSE	0.79
[61]	DL	Bi-LSTM	5 min (Very short-term)	Numerical	MAE	0.0135
[62]	DL	Vision Transformer	Now-4 h (Short-term)	Sky images + clear-sky model	nMAP	↓5.4-8.8%
[63]	DL	ConvLSTM	5-60 min (Very short-term)	Numerical	RMSE	7.43
[64]	DL	RNN	1 h (Short-term)	Numerical	nRMSE	0.00534

[65]	DL	LSTM	1 h (Short-term)	Numerical	nRMSE	0.069
[66]	DL	LSTM	15 min (Very short-term)	Numerical (NSRDB)	R^2	0.9934
[67]	DL	LSTM	10 min (Very short-term)	Numerical	RMSD	199.75 W/m²
[68]	DL	RNN	10 min-1 h (Very short-term)	Numerical	RMSE improvement	26%
[69]	DL	LSTM	1-30 min (Very short-term)	Numerical	RMSE	40.91 W/m²
[70]	DL	N-BEATS	1 day (Short-term)	Numerical (multi-region)	RMSE	29.03-35.77
[71]	DL	Bi-LSTM	1 day (Short-term)	Numerical (irradiance)	RMSE	1.392
[72]	Hybrid	CNN-LSTM	1 h (Short-term)	Numerical	Adjusted R^2	0.984
[73]	Hybrid	XGBF-DNN	1 h (Short-term)	Numerical (multi-region)	RMSE	53.78-91.86
[74]	Hybrid	WPD-CNN-LSTM-MLP	1 h (Short-term)	Numerical	RMSE	32.10-46.13
[75]	Hybrid	LSTM-CNN	1 h (Short-term)	Numerical (multi-site)	MAE	27.38-37.02
[76]	Hybrid	CNN-stacked LSTM	1 h (Short-term)	Numerical	RMSE	0.36
[77]	Hybrid	WTP-GAN + DA	1 h (Short-term)	Numerical	MAPE	0.0262-0.0282
[78]	Hybrid	HetDS	1 h (Short-term)	Numerical (multi-city)	RMSE	0.0600-0.1762
[79]	Hybrid	CEEMDAN-WGAN-LSTM	5 min (Very short-term)	Numerical (NSRDB)	MAE improvement	3.51%
[80]	Hybrid	CNN-LSTM + Quantile Reg.	1 h (Short-term)	Sky images + numerical	RMSE	100.58 W/m²
[81]	Hybrid	WT-BiLSTM	24 h (Short-term)	Numerical	RMSE reduction	26-59%
[82]	Hybrid	VMD-GRU	1 h (Short-term)	Numerical (multi-city)	RMSE	0.82-1.22
[83]	Hybrid	OVMD-ISSA-DBN-OSELM	1 h (Short-term)	Numerical	RMSE	23.15-39.22
[84]	Hybrid	CEEMDAN-AG-RE-ELM	1-3 h (Short-term)	Numerical + time-frequency	RMSE	0.0642-0.0724
[85]	Hybrid	CNN-SVR	1 day (Short-term)	Numerical	RMSE	2.17-3.31

V. Discussion

The review summarises 37 peer-reviewed publications published between 2019 and 2025, narratively summarised in Table III to Table V and quantitatively summarised in Table VI. Taken together, these studies provide a comprehensive overview of the state of the art in ML, DL and hybrid forecasting of solar irradiance. Despite the literature showing significant gains in predictive accuracy and methodological sophistication, a critical cross-analysis of the synthesised evidence reveals several key observations about current trends in methodological approach, limiting factors and important research gaps. The gaps need to be addressed to ensure operational preparedness and the generalizability of forecasting models for integrating renewable energy in the real world.

A. Key Findings and Empirical Observations

The initial important observation is that DL and hybrid models have evidently dominated the methodological approach to solar irradiance forecasting. A summary of the information in Table III, Table IV, and Table V, as shown in Fig. 2, indicates a significant shift towards complex neural network-based techniques. Fig. 2 reveals that 49% (n=18) of the studies employ DL models as reported in [54]-[71], 38% (n=14) use hybrid or ensemble approaches as reported in [72]-[85], and 14% (n=5) rely on traditional ML models as reported in [49]-[53]. Overall, this highlights a clear shift in the literature towards more data-intensive, architecture-rich forecasting approaches.

The second important observation concerns the relative performance of ML, DL, and hybrid models across various forecasting horizons and evaluation metrics. An overview of the findings in Table VI, which provides a cross-study comparative summary, shows that DL and hybrid models tend to be superior to traditional ML methods, especially for very short- and short-term forecasting. Table VI shows that the LSTM, CNN, and their variants are the best DL-based predictors across various datasets. For example, the RMSE values were as low as 7.43 [63] and 29.03-35.77 [70] when using DL models, while the coefficients of determination were as high as $R^2 = 0.987$ in [58] and $R^2 = 0.9934$ in [66]. On the same note, MAE as low as 0.0135 is reported in [61], indicating a high predictive accuracy for very short-term forecasts. Conversely, traditional ML models exhibit relatively low consistency in performance, with RMSE values of 4.04 kW [52] and 1.72 kW [53] for medium-term forecasting and nRMSE values between 7.7% and 8.9% [50]. Hybrid and ensemble models also improve predictive performance by integrating various learning paradigms or signal decomposition methods. As shown in Table VI, hybrid models frequently achieve competitive or superior results, with RMSE values of 0.36 [76], 0.0600-0.1762 [78], and 23.15-39.22 [83], as well as MAE values of 27.38-37.02 [75]. Moreover, other hybrid methods do not provide absolute values but enhanced performance, such as RMSE decreases of 2659% [81] and MAE increases of 3.51% [79] and are therefore effective in optimising the prediction accuracy. Additional examination of Table VI reveals that the performance edge of DL and hybrid models is the greatest at short-term forecasting horizons (0-24 hours), whereby high-frequency temporal patterns can be fruitfully

represented. Conversely, comparative advantage is less stable in medium- and long-term forecasting. To discover more competitive RMSE values like 1.72 in [53] and 0.3909 -0.4582 in [55], simpler ML and simpler DL models can be used, because they need less data and are simpler to model.

The third important point is the excessive focus on very short-term and short-term forecasting horizons. As shown in Fig. 3, 95% (n = 35) of the studies focus on predictions with intervals up to 24 hours ahead, with a range of seconds. Very short-term forecasts of 15 seconds to 1 hour ahead account for 30% (n = 11) of the studies, including [49], [59]-[61], [63], [66]-[69], and [79]. Short-term forecasts of 1 to 24 hours ahead dominate the literature, comprising 65% (n = 24) of studies, including [50]-[52], [54], [56]-[58], [62], [64], [65], [70], [71], and the majority of hybrid studies [72]-[85]. Conversely, the medium- and long-term forecasting horizons are underrepresented, with only 5% (n = 2) of the studies, namely [53] and [55]. This distribution indicates that there is significant research interest in operational forecasting for real-time PV system management, but longer-term forecasting has not been fully explored.

The fourth important observation concerns the prevalence of accuracy-based evaluation measures, especially the RMSE. As shown in Fig. 4, RMSE is the most widely reported metric, appearing in 76% (n = 28) of the studies, including [49]-[54], [56]-[58], [60], [61], [63]-[66], [69]-[76], [78]-[85]. Mean Absolute Error (MAE) is reported in 54% (n = 20) of studies, including [51]-[53], [57], [60], [61], [66], [69], [71], [72], [74]-[76], [78]-[80], [82]-[85]. The coefficient of determination (R^2) appears in 38% (n = 14) of studies, including [53], [54], [58], [60], [63], [66], [70], [72], [74]-[76], [80]-[82]. Mean Absolute Percentage Error (MAPE) and its normalized variants are reported in 32% (n = 12) of studies, including [50], [59], [61], [62], [69], [70], [76]-[79], [81], and [84]. Forecast Skill (FS) is used in 16% (n = 6) of studies, including [49], [56], [73], [75], and [81]. Computational efficiency metrics such as execution time, training time, and resource utilisation are reported in only 11% (n = 4) of the studies, including [49], [50], [65], and [75]. This implies that a great focus is on predictive accuracy, minimal focus on computational performance, and scalability.

The fifth important finding is that there is a low use of multimodal input strategies that combine numerical and visual information. Numerical data, including historical irradiance and meteorological variables, is the most commonly used input type, appearing in 62% (n = 23) of the studies, including [51]-[53], [55], [58], [60], [61], [64], [66], [69]-[74], [76]-[78], [81]-[83] and [85]. A smaller proportion of studies (19%, n = 7) utilise sky or cloud imagery, including [49], [50], [56], [59], [62], [67], and [80]. But only 8% (n=3) of studies present both numeric and pictorial information in a multimodal format, namely, [59], [62], and [80]. This shows that although multimodal learning offers the potential to capture spatial and temporal dynamics, its use remains limited in the existing literature.

The sixth notable point is that comparatively less common is the systematic feature engineering and feature selection methodology. Signal decomposition techniques are used in only 14% (n=5) of the 37 studies and explicit feature selection methods are used in only 16% (n=6). Most research studies do not explicitly specify structured feature engineering pipelines and instead use raw or minimally processed input data. This demonstrates the lack of an opportunity to leverage data preprocessing techniques to improve model performance and interpretability.

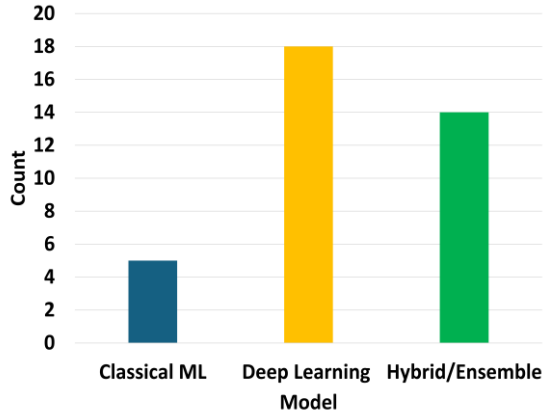

Fig. 2. Distribution of model families across the 37 reviewed studies.

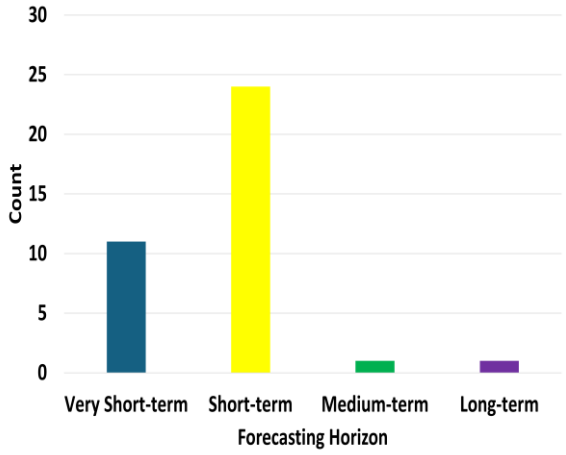

Fig. 3. Distribution of forecasting horizons across the 37 reviewed studies.

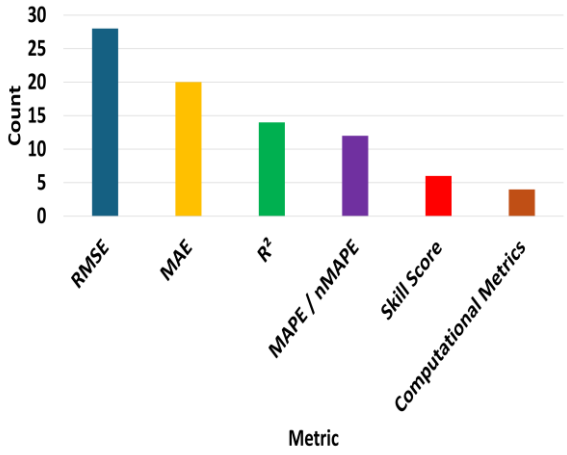

Fig. 4. Frequency of evaluation metrics reported across 37 reviewed studies.

The seventh significant observation is related to the evaluation settings, namely the distribution of single- and multi-

location studies. The majority of the reviewed literature, approximately 65% (n = 24), relies on single-location datasets, including [49]-[53], [56], [58], [59], [61], [63]-[69], [72], [76], [79]-[81], [83], and [84]. In contrast, only 35% (n = 13) of the studies utilise multi-location datasets, such as [54], [55], [57], [60], [62], [70], [73]-[75], [77], [78], [82], and [85]. Even though multi-location studies tend to show better generalisation and model robustness across different climatic conditions, their relatively low use points to a significant gap in the literature. The continued dominance of single-site assessments highlights ongoing issues with data availability and the lack of focus on creating geographically transferable models. Therefore, the applicability of most proposed forecasting methods is questionable, especially across a range of environmental and operating conditions.

All these important observations point to several serious limitations in the existing body of literature, which inform the research gaps considered in the next section.

B. Persistent Limitations and Identified Research Gaps

Although the methodology improved, the overall presentation of the tables shows that there are several crucial and enduring limitations to the successful application and the generalizability of these models.

The first critical gap is the narrowness of the medium-term and long-term forecasting horizons. The literature reviewed is highly biased towards very short and short-term predictions, with 95% (n = 35) of the studies considering forecasting periods of less than 24 hours. Conversely, very few studies 5% (n = 2) discuss the medium- and long-term forecasting. This reveals a major research gap on how to come up with models that can make reliable predictions over a period of days, seasons and over a long period of time, which are crucial in strategic energy planning, grid expansion and policy making.

The second critical gap is that there exists no standardised benchmarking and fair comparison of forecasting models. Even though the DL and hybrid models tend to perform better than traditional ML methods, comparisons are often inconsistent due to differences in datasets, forecasting horizons, input features and evaluation metrics. This complicates the process of coming up with conclusive findings on the most effective models in various circumstances.

The third serious gap is the excessive focus on accuracy-based evaluation measures, with little attention to computational efficiency. Whereas RMSE 76% (n = 28), MAE 54% (n = 20), and R^2 38% (n = 14) appear to be common measures, only 11% (n = 4) of studies report on computational measures such as execution time, training time, and resource utilisation. This means that little attention has been given to model scalability, efficiency, and real-time deployment, especially in resource-limited settings.

The fourth critical gap is the underutilisation of multimodal data integration practices. Even though numerical data dominates in the literature with 62% (n = 23) and only 8% (n = 3) of the studies have both numerical inputs and visual data, like images of the sky. This implies that little attention has been given to the potential of multimodal learning to capture temporal and spatial variations in solar irradiance.

The fifth critical gap is the little use of systematic feature engineering and feature selection methods. Signal decomposition techniques like VMD, CEEMDAN, and wavelet-based signal decomposition techniques are used only in 14% (n = 5) studies, whereas formal feature selection techniques are used in 16% (n = 6) studies. Most studies use raw or minimally processed input data, meaning they do not fully leverage preprocessing strategies that can enhance model performance, robustness and interpretability.

The sixth critical gap is the lack of generalizability as the majority of studies still use datasets from a single location. Even though 59% (n = 22) of the studies use multi-location data, a significant number of 41% (n = 15) of studies remain single-site assessments. This calls into question the strength and applicability of models across other climatic regions and the necessity of more extensive cross-regional validation systems.

The seventh critical gap is the growing sophistication of models with no consideration of interpretability and deployment feasibility. In the literature, there is an increasing tendency to the use of complex DL and hybrid models, such as CNN-LSTM, GAN-based, and transformer models. Nevertheless, these models are seldom tested for their interpretability, computational cost, or practical implementation. This implies that there is a lack of equilibrium between model accuracy, explainability, efficiency and usability in practice.

Overall, the review indicates that the field has made significant progress and has an unmistakably consistent trend towards the more complex hybrid and ensemble deep learning models. This development has, however, also led to an increase in the disparity between methodological innovation and practical applicability. The deep emphasis on gradual advances in predictive accuracy has, in numerous instances, been at the cost of dealing with the underlying issues of real-world implementation. Specifically, poor model generalizability, the lack of adequate focus on computational efficiency and operational constraints, and the continued focus on short-term forecasting horizons are among the barriers. To address these issues, it is necessary to make sure that the models of solar irradiance forecasting have the required operational reliability and practicality in the renewable energy systems.

VI. Recommendations

Based on the critical analysis of the 37 studies and the identified research gaps, several key recommendations are proposed to guide future work toward more robust, generalizable, and deployment-ready solar irradiance forecasting systems.

The high dependence on single-location datasets is one of the significant weaknesses that limit the generalizability of the model to different climatic conditions. Although multi-location studies such as [54], [57], [73], [75], and [82] demonstrate improved robustness, they remain in the minority. Multi-site assessment frameworks based on publicly available data sets like NSRDB, BSRN, ERA5, and NASA POWER should be used in future studies. Specifically, it is suggested to use leave-one-location-out cross-validation to evaluate the spatial robustness. Moreover, domain adaptation methods like feature

alignments and adversarial learning can enhance the transferability of models across climatic regions.

Most analyses focus on predictive accuracy based on measures of RMSE, MAE and R^2, and while computational efficiency is rarely considered, as it is reported in only a small subset of studies, such as [50] and [65]. Future work ought to then take a dual evaluation approach, which takes into account both predictive accuracy and operational performance, such as latency, memory footprint, model size, and energy consumption. This is especially critical with hybrid and DL models, which might not be suitable in real-time or even edge deployment due to the computational bottlenecks.

The growing sophistication of DL and hybrid models requires the implementation of model compression and model optimisation strategies. Pruning, quantisation and knowledge distillation are techniques that can be used to reduce the complexity of models whilst maintaining performance. Moreover, frameworks based on deployment, especially edge-optimised inference pipelines, are to be considered to evaluate the feasibility of microgrid controllers and embedded systems in practice. This is particularly applicable to highly complex models like those reported in studies such as [74], [77] and [83], where deployment feasibility has not been sufficiently addressed.

Literature is extremely biased in regard to very short-term and short-term forecasting horizons, whereas medium-term and long-term forecasting is under-researched. Studies such as [53], [55] and [70] show deterioration in performance with increasing forecasting horizons, and illustrate the challenging nature of long-term prediction in the presence of atmospheric uncertainty. Future studies ought to expand the forecasting horizons to day-ahead and week-ahead by including NWP data, including ERA5 reanalysis data. It is suggested to implement hybrid architectures with CNNs, RNNs, and Transformer-based models to more effectively represent long-range temporal correlations and large-scale weather patterns.

The majority of current research tests models in average conditions without taking into account the variability in atmospheric conditions. Few studies, including [67], evaluate performance under varying conditions of clouds. Future work must then embrace scenario-based evaluation models, in which models are evaluated under clear-sky, partly cloudy, rapidly changing and extreme weather conditions. This stratified assessment is essential to real-world grid integration, where resilience to different conditions is more significant than a mean performance.

There is also a high level of inconsistency in the evaluation methods used in the literature, such as differences in data splitting strategies, normalisation methods, and reported metrics. In spite of the popularity of RMSE in the literature [49]-[85], other similar measures like MAPE, nRMSE, and skill scores are not always reported. Standardisation of benchmarking protocols, such as standard train-validation-test splits, rolling-window or walk-forward validation, and reporting standardised and normalised metrics should be implemented in future studies to increase the reproducibility and comparability of results across different studies.

Lack of standardised benchmark datasets is a significant limiting factor in the field. The available research is based on piecemeal data and does not allow reproducibility and equal comparison. Further work should be done on unified multi-modal benchmark datasets that involve ground-based irradiance measurements, meteorological measurements and satellite or sky-imaging measurements. Partitions of standardised datasets using popular sources (NSRDB, ERA5) should be created, and open benchmarking platforms with leaderboards should be created to speed up the methodological development.

Although the field of DL and hybrid models is improving, there is still a gap between theoretical growth and practical implementation. This is mainly because generalizability, computational efficiency and operational constraints have not been given much consideration. The deployment-conscious model design should thus be the focus of future research where the enhancement in predictive accuracy is matched with scalability, robustness, and computational feasibility.

Overall, the recommendations indicate that the development of models should be no longer based on the predictive accuracy but should be generalizable, operationally robust, and computationally efficient. These gaps need to be solved to bridge the gap between advanced forecasting models in the academic prototyping and their application in real-world energy systems.

VII. Limitations of this SLR

Although this SLR followed PRISMA guidelines, certain limitations remain. The analysis was restricted to English-language publications and selected databases, potentially introducing publication bias. Additionally, the exclusion of grey literature may limit coverage of emerging current, on-the-ground research and industrial practices.

Authors' Contribution

ST Leholo conceptualised the study, developed the methodology, implemented the models, collected and curated the data, performed the formal analysis, and drafted the original manuscript. C Du and T.E Mathonsi contributed to supervision, reviewing and improving the manuscript through proofreading and editorial suggestions. All authors have read and agreed to the published version of the manuscript.

Funding

This research was funded by the Tshwane University of Technology.

Acknowledgment

The authors sincerely appreciate the Tshwane University of Technology for providing the necessary support for this research.

***Abstract*—This study analyzes the computational efficiency of parametric exponentiation operations in parametric algebra and proposes an algorithmic approach for their fast computation. By leveraging the properties of parametric algebra, the possibility of reducing parametric exponentiation to fast exponentiation methods is established, and a corresponding computational algorithm is developed. The proposed approach enables more efficient computation of parametric exponentiation and reduces the computational impact of the system parameter. The obtained results provide a basis for reconsidering approaches to the efficiency of parametric algebra-based computations, demonstrating that the slowness of exponentiation often stems from the computational methods employed rather than the algebraic structure itself. This research establishes a significant foundation for the efficient organization of cryptographic computations based on parametric algebra and for addressing algorithmic optimization challenges.**

***Keywords*—Parametric algebra; parametric multiplication; parametric exponentiation; computational efficiency; algebraic structures; computational complexity; fast exponentiation**

I. Introduction

The security of cryptographic algorithms depends on the computational complexity of the underlying algebraic problems. In symmetric encryption algorithms, complexity is determined by key length, structural design, and resistance to cryptanalytic attacks. In public-key cryptographic algorithms, security primarily relies on the computational complexity of problems such as discrete logarithms in finite fields, integer factorization of large numbers, and computational challenges related to elliptic curves [1, 2].

The rapid development of modern computing technologies is leading to an increase in key lengths and computational complexity to maintain security in existing cryptographic algorithms. However, this approach results in the slowing down of encryption and decryption processes and limits computational efficiency [13].

In recent years, the development of complex cryptographic computing methods based on new algebraic structures has been considered one of the most promising areas. An illustration of this phenomenon is provided by elliptic curve cryptography, which employs more intricate algebraic structures in comparison to classical modular arithmetic. Furthermore, algebraic models such as lattice structures (including LWE), error-correcting codes, and multivariate polynomial equations are actively evolving in modern cryptography. These approaches enrich the mathematical foundations of cryptographic systems and enhance the flexibility of computational processes [21, 22].

The concept of parametric algebra is predicated on the extension of classical and matrix-based algebraic structures through the introduction of an additional parameter. This algebra opens up new mathematical possibilities by generalizing classical algebraic operations through the introduction of an additional parameter. A variety of cryptographic algorithms based on parametric algebra have been proposed and are currently being studied as algebraic models with the potential for application in practical computations [3,4].

Parametric algebra is a system that is only just beginning to gain ground in cryptographic research. Since its structure differs from classical modular arithmetic and it is not yet sufficiently familiar to the wider community, the main concepts and properties are systematically presented in Section III of the study.

Research on parametric algebra has primarily focused on its theoretical properties and general algorithmic applications. However, the issues concerning the computational efficiency of parametric exponentiation operations and the possibilities of adapting them to fast exponentiation methods have not been sufficiently explored.

Existing approaches to parametric exponentiation often rely on repeated parametric multiplications, resulting in high computational overhead and limited practical efficiency. Therefore, developing efficient methods and integrating them with fast exponentiation techniques remains an important scientific problem.

The main contributions of this study can be summarized as follows:

- A novel formulation for parametric exponentiation based on modular binary exponentiation;
- Reduction of the computational dependence on the parameter R in parametric exponentiation;
- Experimental validation using runtime, memory usage, and CPU tick measurements demonstrating efficiency and scalability.

This study focuses on the computational efficiency of parametric exponentiation and its algorithmic optimization.

Leveraging the properties of parametric algebra, a fast modular binary exponentiation algorithm specifically adapted for parametric structures is proposed.

II. Related Works

A. Parametric Algebra and Related Algebraic Approaches

Parametric algebraic operations are based on the concept of generalizing classical algebraic structures through the introduction of an additional parameter. This approach emerges independently across various fields of mathematics and cryptography. This section provides a comprehensive analysis of scientific works that are conceptually and formally related to parametric algebraic operations.

1) Deformations of algebras and parametric operations: In the Theory of Algebraic Deformations developed by Murray Gerstenhaber, an algebraic operation is modified through a parameter [14]. The classical multiplication operation is deformed as follows:

$$a *_t b = ab + t\varphi_1(a,b) + t^2\varphi_2(a,b) \qquad (1)$$

Here, t is the deformation parameter that generates new algebraic structures.

In parametric algebraic operations, classical operations are also modified through a parameter, but over finite fields and by arithmetic expressions. For example:

$$a®b \equiv a + b + a * R * b \ (mod \ \ n) \qquad (2)$$

The similarity between Formula (1) and Formula (2) is that, in both cases, the parameter controls the result of the operation. Therefore, parametric algebra is a discrete, cryptographically oriented variant of deformation theory.

2) Parameter-dependent binary operations: Recent studies show that alternative binary operations are used to construct new mathematical structures. For example, several works on triangular norms have introduced generalized spaces of non-additive measures in which the selected operation determines the resulting functional framework [16].

This illustrates a general principle: modifying or selecting a binary operation can lead to systems with new structural properties. Parametric algebra follows the same direction by introducing parameter-dependent operations over modular and finite arithmetic structures for cryptographic applications. In this sense, it can be regarded as a discrete and cryptography-oriented form of the broader theory of alternative binary operations.

3) Partially associative algebraic structures: In some non-associative algebraic structures, multiplication is governed by specific identities such as:

$$(xy)(xz) = x(yz)x$$

Thus, general associativity is not required, while structural properties are preserved through symmetry [17,18].

In parametric algebraic operations, associativity also depends on the chosen parameter. For certain values of \(R\), the following relation holds:

$$(a®b)®c = a®(b®)$$

This equality is satisfied only for specific parameter values.

Taken together, these studies represent key theoretical frameworks and algorithmic methodologies related to the principles of parametric algebra.

B. Fast Exponentiation and Computational Efficiency

Efficient modular exponentiation methods have been widely studied through several classical approaches. Binary exponentiation is one of the fundamental methods and is applied in left-to-right and right-to-left forms. Its main advantage is reducing the number of multiplications from linear complexity to logarithmic complexity [24].

The Montgomery ladder improves resistance through a regular computation pattern. The sliding-window method increases efficiency by using precomputation. Techniques such as NAF, MOF, and w-NAF reduce the number of nonzero digits in the exponent representation, thereby decreasing the required multiplications [25].

In many public-key systems, the main computational cost is associated with exponentiation operations. In RSA, Diffie–Hellman, digital signature schemes, and related protocols, the exponentiation process has a significant impact on overall efficiency [15].

Recent studies have explored several approaches to address this problem. In particular, classical modular arithmetic methods such as binary, window-based, and other fast exponentiation techniques continue to be improved. In digital signature systems, special attention is also given to accelerating signature generation and verification procedures [19,20].

In specialized algebraic environments, especially Galois fields, methods for optimizing squaring and multiplication operations have been proposed. In addition, new asymptotically faster algorithms are being developed by exploiting modulus factorization or internal algebraic properties of the underlying structures [23].

These results show that improving exponentiation algorithms remains a theoretically and practically relevant research direction today.

Beyond classical algebraic settings, the importance of exponentiation is also significant in parametric algebra. In such systems, the main computational processes are carried out through parameter-dependent addition, multiplication, and exponentiation operations.

Table I presents a comparative summary of the main theoretical approaches related to parametric algebra and the key studies on fast exponentiation.

The efficiency of parametric exponentiation directly affects the practical performance of these schemes. Therefore, when parametric algebra is applied in cryptographic systems, not only security but also the computational efficiency of algebraic operations becomes important. This requires a separate consideration of existing parametric cryptosystems and the role of parametric exponentiation within them. The next section is devoted precisely to these issues.

C. Existing Parametric Cryptosystems and Research Gap

Several cryptographic algorithms have been proposed based on parametric algebra, and some of them have reached the level of standardization. Symmetric, public-key, hash-function, and digital signature systems enhanced by parametric algebra are presented in Fig. 1. The figure also shows the hierarchical use of parametric operations in key generation, encryption or signing, and decryption or verification stages [5-11].

As shown in Fig. 1, parametric multiplication, parametric inverse operations, and parametric exponentiation are used as core computational components in different cryptographic mechanisms. In particular, parametric exponentiation appears in several stages of public-key systems and digital signature schemes, which highlights its practical importance.

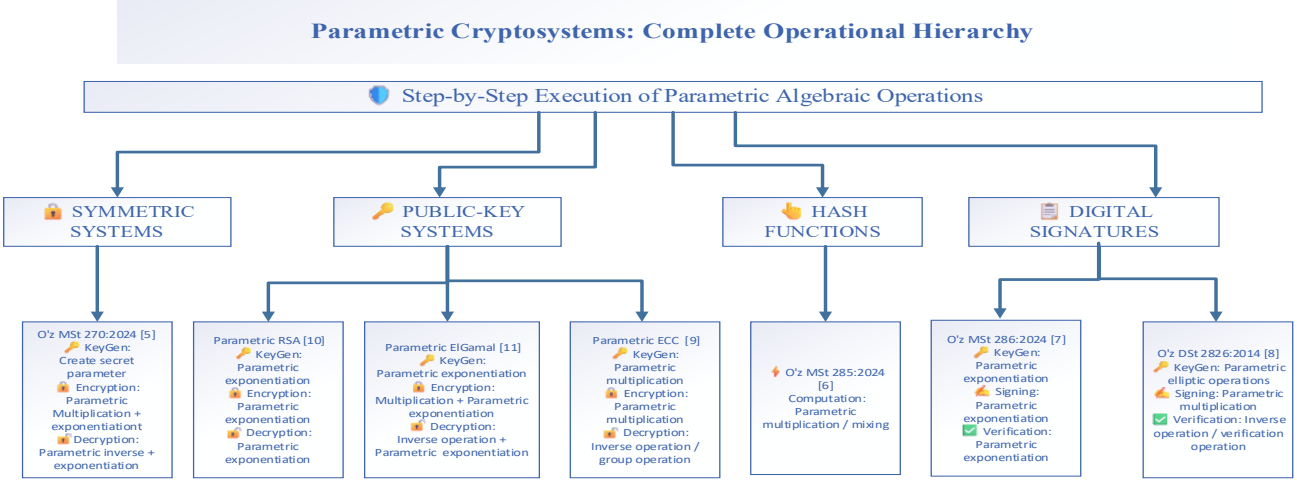

Fig. 1. Parametric cryptosystems

Existing parametric cryptosystems show that parametric exponentiation is a central operation in many schemes. However, in most cases it is computed by iterative or sequential procedures based on repeated parametric multiplications. This leads to increased computational cost, especially for large exponents and parameter values, motivating the need for more efficient methods.

As a result, expanding the practical applicability of parametric algebraic systems requires optimization of their core operations, especially exponentiation. Therefore, developing efficient parametric exponentiation methods remains an important research problem.

III. Problem Statement

In parametric algebraic systems, one of the main operations is parametric multiplication, which is defined as follows:

$$a®b \equiv a + b + a * R * b \ (mod \ \ n),$$

where, R is an additional parameter of the algebraic structure. Based on this operation, parametric exponentiation is widely used in existing cryptographic algorithms. In practice, it is usually represented in the following form:

- Initial condition: $a^{\backslash 1} = a \ mod \ n$.
- Recursive step: $a^{\backslash x+1} = a + a^{\backslash x}(1 + Ra) \ mod \ n$

A direct algorithm for computing this expression can be written as follows (see Algorithm 1):

Algorithm 1: Existing Iterative Method for Parametric Exponentiation

```
Input: Integers a, k, R, n
Output: a^(k) mod n
1: if k = 1 then
2: return a mod n
3.  end if
4. t ← (1 + R·a) mod n
5: for i = 2 to k do
6:     result ← (a + result·t) mod n
7:     end for
8: return result
```

This algorithm is a simple and direct computation method. However, the parametric multiplication operation is performed sequentially $k - 1$ times. Therefore, the computational cost increases as the exponent value grows.

In addition, since all operations depend on the parameter R, the execution time may become more significant for large parameter values.

Several methods exist for computing parametric exponentiation in systems based on parametric algebra. These include recursive iterative methods, sequential procedures based on repeated parametric multiplication, and summation or closed-form formulas. However, practical computational efficiency remains an important issue.

Thus, the main problem is to develop a more efficient method for computing parametric exponentiation while preserving the correctness of the algebraic system.

IV. Parametric Algebra and its Properties

Since parametric algebra is a relatively new algebraic framework in cryptographic research and remains less familiar to the broader community, its main operations, fundamental properties, and illustrative examples are presented in this section.

Parametric algebra extends classical algebraic operations by introducing an additional parameter. This parameter increases computational complexity and thereby enhances cryptographic resilience. Consequently, it provides sufficient security for encryption algorithms based on parametric algebra in large finite fields.

Parametric algebra proposes an extended form of classical arithmetic operations, serving as a promising foundation for improving the mathematical structure of cryptographic algorithms and incorporating an additional complexity component [3].

In *parametric algebra*, the parameter R is selected from the set of numbers in the field $Z_p = \{0,1, \dots, n-1\}$ and all operations are performed modulo n.

A. Multiplication with Parameter R

Definition 1. For any $a, b \in Z$, the expression:

$$a®b \equiv a + b + a * R * b \ (mod \ \ n)$$

defines the *parametric multiplication operation* with parameter R. In the context of parametric algebra, the symbol R is referred to as either a *coefficient* or a *transformation parameter*. When $R = 0$, this expression reduces to the *classical algebraic addition* operation [3].

Example: If $a = 3, b = 5, R = 2, n = 17$ then,

$$3 \ ® \ 5 \ mod \ n = 3 + 5 + 3 \cdot 2 \cdot 5 \ mod \ 17 = 38 \ mod \ 17 = 4$$

This operation serves as the fundamental functional unit of the proposed parametric algebraic structure.

The parametric multiplication operation defined above satisfies the following properties:

Closure. For arbitrary $a, b \in Z_n$, the operation is closed:

$$a \ ® \ b = c \ mod \ n, c \in Z_n$$

Commutativity. The operation is commutative, as $a \ ® \ b = b \ ® \ a \ mod \ n$ for all $a, b, R \in Z_n$. This result follows from the symmetry of the given expression:

$$a + b + a \ \cdot R \ \cdot b = a + b + \ b \cdot R \ \cdot a$$

Associativity. The operation is associative for all $a, b, R \in Z_n$: $(a \ ® \ b)® \ c \ mod \ n = a \ ® \ (b \ ® \ c) mod n$.

Identity Element. There exists an identity element $e = 0$, where $a®e = a + 0 + a \cdot R \cdot 0 = a \ mod \ n$ for any $a, e, R \in Z_n$

Inverse Element. For each $a \neq 0$ such that $\gcd(a + aR, n) = 1$, there exists an inverse element a^{-1} where $a \ ® \ a^{-1} = e \ mod \ n$.

B. Inversion Operation in Parametric Algebra

Parametric inversion operation modulo n with parameter R is defined as:

$$a^{\backslash -1} \equiv -a * (1 + R * a)^{-1} \ (mod\ n)$$

Here, the notation $^{-1}$ denotes the classical modular inversion. The element $^{\backslash -1}$ represents the parametric inverse with respect to the parameter R and modulus n and satisfies the identity $a \circledR a^{-1} \equiv 0 (mod\ n)$ [26].

Verification.

To verify this, we substitute the expression $a^{\backslash -1} \equiv -a * (1 + R * a)^{-1} \ (mod\ n)$ into the parametric multiplication formula $a \circledR a^{\backslash -1} = a + a^{\backslash -1} + a \cdot R \cdot a^{\backslash -1} mod\ n$:

$a \circledR a^{\backslash -1} mod\ n = a + (-a(1 + R * a)^{-1}) + a \cdot R \cdot (-a(1 + R * a)^{-1})\ mod\ n = a - a(1 + R * a)^{-1} - a \cdot R \cdot a(1 + R * a)^{-1}\ mod\ n = a - a(1 + R * a)^{-1}(1 + R * a)\ mod\ n$

Since $-a(1 + R * a)^{-1}(1 + R * a)\ mod\ n = 1$, we obtain $a - a \equiv 0\ mod\ n$.

Example: Let $a = 4, R = 2, n = 17$. First, we calculate the parametric inverse using the formula $a^{\backslash -1} \equiv -a * (1 + R * a)^{-1} \ (mod\ n)$:

Calculate $1 + aR = 1 + 4 \cdot 2\ mod\ 17 = 9$ mod 17

Find the modular inverse: $(1 + R * a)^{-1}\ mod n = 9^{-1} mod\ 17 = 2\ mod\ 17$

Compute the final result: $a^{\backslash -1} = -a * (1 + R * a)^{-1} = -4 \cdot 2 = -8\ mod\ 17 = 9\ mod\ 17$

Verification: $a \circledR a^{-1} mod\ n = 4 \circledR 9\ mod\ 17 = 4 + 9 + 4 \cdot 2 \cdot 9\ mod\ 17 = 13 + 72\ mod\ 17 = 85\ mod 17 = 0$

The inversion operation defined above establishes a robust algebraic framework. The following properties define the order and cardinality of the resulting parametric multiplicative group:

Property 1. If the modulus n is a prime number and the parameter R of the parametric multiplicative group is any natural number, then the order of the group is equal to $\varphi(n)$, where $\varphi(n)$ represents the value of *Euler's totient function*.

Property 2. For a parametric multiplicative group with a composite modulus n if the parameter R is coprime to the modulus $(\gcd(R, n) = 1)$, then the order of the group is equal to $\varphi(n)$, where $\varphi(n)$is the value of Euler's totient function.

Implications for Inversion Operations. These properties are critical for the inversion process. The group order $\varphi(n)$$ ensures that for every valid element, a unique inverse exists within the structure. Furthermore, according to the parametric adaptation of Euler's Theorem, the inverse can also be computed through exponentiation:

$$a^{-1} = a^{\backslash \varphi(n) - 1}\ mod\ n$$

This dual path for inversion enhances the cryptographic flexibility of the proposed system.

C. Parametric Exponentiation Operation

The concept of parametric exponentiation is based on the repeated application of the parametric multiplication operation.

Definition 2. In a parametric multiplicative group modulo n with a parameter $R \geq 1$, the operation of exponentiation is referred to as a parametric exponentiation function.

The result of raising a base a to the power x is defined by the following recursive relation:

Initial condition: $a^{\backslash 1} = a\ mod\ n$.

Recursive step: $a^{\backslash x+1} = a + a^{\backslash x}(1 + Ra)\ mod\ n$

where, $x \in N$ and the element $^{\backslash 1}$ denotes the parametric exponentiation operator [3].

Example. Let $n = 17, R = 2, a = 3$ and $k = 4$. We aim to calculate the parametric exponentiation value $y = 3^{\backslash 4}\ mod 17$.

First, calculate the transform factor F:

$F = 1 + R \cdot a\ mod\ n = 1 + 2 \cdot 3\ mod 17 = 7\ mod 17$

Next, the sequence is recursively defined by $d_1 = a, d_{t+1} = a + F \cdot d_t\ mod\ n$.

The sequence d_t represents the iterative computation of parametric exponentiation.

$d_1 = a = 3,$

$d_2 = a + Fd_1\ mod\ n = 3 + 7 \cdot 3 = 3 + 21\ mod 17 = 7\ mod 17$

$d_3 = 3 + 7 \cdot 7 = 3 + 49\ mod 17 = 1\ mod 17$

$d_4 = 3 + 7 \cdot 1 = 3 + 7\ mod 17 = 10\ mod 17$

The iterative calculation yields $3^{\backslash 4}\ mod 17 = 10\ mod 17$, which confirms the result of the parametric power function for the given parameters.

The parametric exponentiation function exhibits several fundamental properties as outlined below [3].

Property 1. For arbitrary $a, z, d \in \mathbb{Z}_n$, the following relations hold:

$a^{\backslash z+d} = a^{\backslash z} \circledR a^{\backslash d} mod\ n,\ a^{\backslash z} = a^{\backslash z} \circledR e\ mod\ n$

where, $\circledR -$ denotes the parametric multiplication operation modulo n, e is the identity element and $a^{\backslash x}$ - denotes the parametric exponentiation operator.

Property 2. For arbitrary $a, z, d \in \mathbb{Z}_n$, the following relations hold: $a^{\backslash z*d} = (a^{\backslash z})^{\backslash d} = (a^{\backslash d})^{\backslash z}\ mod\ n$

where, $a^{\backslash x}$ - denotes the parametric exponentiation operator.

Property 3. For any $a \in \mathbb{Z}_n$, the following holds:

$a^{\varphi(n)+1} = a\ mod\ n,\ a^{\backslash 1} = a$, where $\varphi(n)$denotes Euler's totient function.

Property 4. If d and e are coprime to $\varphi(n)$ and satisfy the condition $d \cdot e \equiv 1\ mod\ (\varphi(n))$, then the following relation holds: $(a^{\backslash d})^{\backslash e} = a\ mod\ n$, where $a \in \mathbb{Z}_n$ and $a^{\backslash x}$ - denotes parametric exponentiation operator.

Property 5. For any $a \in \mathbb{Z}_n$, the following relations hold:

$$a^{\backslash 0} = 0, a^{\backslash -1} = -a * (1 + R * a)^{-1} \ mod\, n$$

where, $a^{\backslash -1} -$ represents the parametric inverse of a modulo n and $(1 + R * a)^{-1}$ denotes the classical modular inverse of $(1 + R * a)$ modulo n.

Property 6. The relationship between parametric exponentiation and classical modular exponentiation is given by

$$R * a^{\backslash x}\ (mod n) = (1 + R * a)^x - 1\ mod\ n$$

where R is a parameter and $\neq 0$, $\in \{1,2,.\varphi(n) - 1\}$, $a \in \{1,2,..,n-1,$ $a^{\backslash x}$ - denotes parametric exponentiation operator.

Property 7. Let $F = 1 + Ra$. Then, for parametric exponentiation,

$$a^{\backslash x+1} \equiv a * \sum_{i=0}^{i=x} F^{\,i} (mod\ n)$$

where, R is a parameter, $a^{\backslash x+1}$ - denotes the parametric exponentiation operator, $\sum_{i=0}^{i=x} F^{\,i} (mod\ n)$ denotes the geometric sum.

The algebraic properties presented above facilitate the enhancement of existing cryptographic algorithms and enable more efficient computational processes within parametric structures.

For a more comprehensive discussion and additional definitions of parametric algebraic operations, the reader is referred to [3].

V. Efficiency Analysis of Parametric Exponentiation

In this section, the computational efficiency of parametric exponentiation is analyzed. Various approaches, including iterative and closed-form methods, are examined. In addition, methods for improving algorithmic efficiency are proposed by applying classical modular binary exponentiation techniques to existing algorithms.

Several publications and papers on parametric algebra present both iterative (sequential) and closed-form methods for exponentiation with parameter R [3, 4, 12].

A. Iterative Parametric Exponentiation

Let the parametric multiplication operation modulo n be defined as follows:

$$a®b \equiv a + b + a * R * b\ (mod\ \ n),$$

Where $R \in Z_n$ is a parameter, $a, b \in Z_n$. This operation differs from classical multiplication and represents a combination of addition and multiplication.

The exponentiation operation based on this parametric multiplication is defined as:

$$a^{\backslash k} = \underbrace{a®a®a® \ldots . a®}_{k\ times}$$

Specifically, $a^{\backslash 1} = a$, $a^{\backslash k+1} = a^k ® a$. This expression is an analogous form of the classical exponentiation operation, where the parametric multiplication is utilized instead of the standard multiplication.

Parametric exponentiation satisfies the following recursive relation:

$$a^{\backslash k+1} = a^{\backslash k} ® a$$

Using the definition of the parametric multiplication, we obtain $a^{\backslash k+1} = a^{\backslash k} + a + a^{\backslash k} \cdot R \cdot a\ mod n$

This expression can be rewritten as follows:

$$a^{\backslash k+1} = a + a^{\backslash k}(1 + Ra) mod\ n$$

Let $d_k = a^{\backslash k}$ Then, the recurrence relation can be written as

$$d_{k+1} = a + d_k(1 + Ra) mod\ n \quad (3)$$

This recurrence defines the iterative computation of parametric exponentiation up to the exponent k.

By leveraging the algebraic properties of parametric exponentiation, the recurrence relation, Formula (3), can be transformed into equivalent alternative representations. These forms facilitate further optimization and significantly enhance computational efficiency.

B. Alternative Forms of Parameteric Exponentiation

Based on Property 7 of parametric exponentiation, the following *summation-based representation* is derived:

$$a^{\backslash x+1} \equiv a * \sum_{i=0}^{i=x} F^{\,i} (mod\ n). \quad (4)$$

Based on Formula (4), the exponentiation operation can be computed without relying on repeated squaring, by evaluating a geometric series and performing a single modular multiplication with the base a. This approach reduces the number of modular multiplications, enables efficient precomputation, and eliminates bit-dependent branching. Consequently, it yields a more efficient exponentiation mechanism for cryptographic algorithms based on parametric algebra.

The closed-form expression Formula (4) can be *derived from the recurrence relation* Formula (3) as follows:

According to Formula (3), we have $d_1 = a$, $d_2 = a + d_1(1 + Ra)$, $d_3 = a + d_2(1 + Ra)$,…

To simplify the expression, the following notation is introduced:

$$F = 1 + Ra$$

Then, the recurrence relation can be written as

$$d_{k+1} = a + F \cdot d_k mod\ n$$

Expanding this recurrence iteratively yields:

$$d_1 = a$$

$$d_2 = a + Fa$$

$$d_3 = a + F(a + Fa) = a + Fa + Fa^2$$

$$d_4 = a + F(a + Fa + Fa^2) = a + Fa + F^2a + F^3a$$

Continuing this pattern, the general term for d_k is expressed as:

$$d_k = a(1 + F + F^2 + \cdots + F^x)$$

Consequently,

$$a^{\backslash k+1} = a\sum_{i=0}^{k} F^i \ mod\ n, F = 1 + Ra$$

This representation corresponds exactly to Formula (4), derived from *the 7th property* of parametric exponentiation.

Based on the 6th property of parametric exponentiation:

$$R * a^{\backslash k}\ (mod n) = (1 + R * a)^k - 1\ mod\ n$$

it is possible to derive the *closed-form expression* for parametric exponentiation:

$$a^{\backslash k} = ((1 + Ra)^k - 1) \cdot R^{-1}\ mod\ n \qquad (5)$$

In this context, it is necessary to satisfy the condition $\gcd(R, n) = 1$ to ensure the existence of the modular inverse of the parameter R.

The derivation of the closed-form Formula (5) from the recurrence relation Formula (3) is expressed as follows.

$$\text{Let } F = 1 + Ra.$$

Substituting this into Formula (3), the recurrence relation takes the following form:

$$d_{k+1} = a + F \cdot d_k mod\ n$$

Expanding this recurrence iteratively yields:

$$d_1 = a$$

$$d_2 = a + Fa$$

$$d_3 = a + F(a + Fa) = a + Fa + Fa^2$$

$$d_4 = a + F(a + Fa + Fa^2) = a + Fa + F^2a + F^3a$$

$$.d_k = a(1 + F + F^2 + \cdots + F^{k-1}) mod\ n$$

This sequence represents a geometric progression. From standard mathematics, the sum of a geometric series is given by:

$$x + x \cdot q + x \cdot q^2 + \cdots + x \cdot q^{k-1} = x \cdot \frac{q^k - 1}{q - 1}$$

In our case, $x = a, q = 1 + Ra$. Substituting these values, we derive:

$$d_k = a \cdot \frac{(1 + Ra)^k - 1}{(1 + Ra) - 1} = a\frac{(1 + Ra)^k - 1}{Ra}$$

$$= ((1 + Ra)^k - 1)\ R^{-1}\ mod\ n$$

Hence,

$$a^{\backslash k} = ((1 + Ra)^k - 1) \cdot R^{-1}\ mod\ n$$

This coincides with the closed-form expression given in Formula (5).

Although the resulting parametric exponentiation expressions provide non-iterative closed-form representations, they still require further refinement to achieve high computational efficiency. Therefore, additional optimization techniques are necessary to further accelerate their evaluation.

Efficient exponentiation techniques play a crucial role in modern cryptographic computations. Among them, binary exponentiation is one of the most widely used methods due to its logarithmic complexity.

C. Efficient Computation Using Binary Exponentiation

For given $a, k, n \in \mathbb{N}$, one of the most efficient methods for computing $a^k mod n$ is binary exponentiation. This method is based on representing the exponent k in its binary form:

$$k = \sum_{i=0}^{t} b_i 2^i,\ b_i \in \{0,1\}$$

Accordingly, the exponentiation can be expressed as

$$a^k = \prod_{i=0}^{t} a^{b_i 2^i}$$

The computation is performed by squaring and multiplying successively, with modular reduction applied at each step to prevent the intermediate values from becoming too large.

The pseudocode for this algorithm is as follows (see Algorithm 2):

Algorithm 2: Binary Modular Exponentiation

```
Input: Integers a, k, n
Output: a^k mod n
1: result ← 1
2: base ← a mod n
3: while k > 0 do
4:    if k mod 2 = 1 then
5:          result ← (result · base) mod n
6:    end if
7:    base ← (base · base) mod n
8:    k ← ⌊k / 2⌋
9: end while
10: return result
```

The algorithm relies on the binary representation of the exponent k, enabling efficient computation through successive squaring and conditional multiplication. Modular reduction at each step prevents the growth of intermediate values. With a computational complexity of $O(\log k)$, this method is widely regarded as one of the most efficient techniques in cryptographic applications.

D. Integrating Binary Algorithms into Parametric Algebra

The binary exponentiation technique can be applied to different representations of parametric exponentiation. In particular, it can be integrated with both the iterative formulation Formula (3) and the closed-form representation Formula (5).

The *recursive form of parametric* exponentiation is given by Formula (3):

$$d_{k+1} = a + d_k(1 + Ra)(\text{mod}n).$$

This formulation enables a sequential computation of parametric exponentiation. However, it exhibits linear time complexity in the exponent k, namely $O(k)$.

To improve computational efficiency, the classical binary exponentiation technique can be applied to the given recurrence

process. In this approach, the exponent k is represented in its binary form:

$$k = \sum_{i=0}^{t} b_i 2^i, b_i \in \{0,1\}.$$

Based on this representation, parametric exponentiation can be expressed as:

$$a^{\backslash k} = \underbrace{a®a®a® \ldots . a®}_{k\ times}$$

where, the parametric multiplication is defined as:

$$a®b = a + b + aRb(\mathrm{mod}n).$$

The computation follows the structure of binary exponentiation, involving successive squaring and conditional multiplication according to the binary representation of the exponent**.**

As a result, the following iterative algorithm is obtained. If the current bit of k is equal to 1, the result is updated using parametric multiplication, while at each step the base is updated through parametric squaring.

This approach reduces the number of computational steps to $O(\log k)$.

Therefore, the application of binary exponentiation significantly reduces the number of iterations required for computing parametric exponentiation.

The pseudocode for this algorithm is as follows (see Algorithm 3):

Algorithm 3: Iterative Binary Parametric Exponentiation

```
Input: Integers a, k,R, n
Output: a^k mod n
1: result ← 0
2: base ← a mod n
3: while k > 0 do
4:    if k mod 2 = 1 then
5:          result ← (result + base + R · result · base) mod n
6:    end if
7:    base ← (base + base + R · base · base) mod n
8:    k ← ⌊k / 2⌋
9: end while
10: return result
```

Example. Let, $R = 19$, $a = 5$, and $k = 13$.

We compute the value of parametric exponentiation.

Binary representation:

$$k = 13 = (1101)_2$$

The parametric multiplication is defined as

$$a®b = a + b + aRb(\mathrm{mod}n).$$

Initial values:

$$\mathrm{result} = 0, \mathrm{base} = 5.$$

Step 1 ($k = 13$, bit = 1)

$$\mathrm{result} = 0®5 = 5$$

$$\mathrm{base} = 5®5 = 5 + 5 + 19 \cdot 25 = 485 \equiv 23(\mathrm{mod}77)$$

Step 2 ($k = 6$, bit = 0)

$$\mathrm{result} = 5$$

$$\mathrm{base} = 23®23 = 23 + 23 + 19 \cdot 529 = 10097 \equiv 10(\mathrm{mod}77)$$

Step 3 ($k = 3$, bit = 1)

$$\mathrm{result} = 5®10 = 5 + 10 + 19 \cdot 50 = 965 \equiv 41(\mathrm{mod}77)$$

$$\mathrm{base} = 10®10 = 10 + 10 + 19 \cdot 100 = 1920 \equiv 72(\mathrm{mod}77)$$

Final result:

$$a^{\backslash 13} \equiv 68(\mathrm{mod}77).$$

Formula (5), derived from Property 6 of parametric exponentiation, transforms the parametric exponentiation into a classical modular exponentiation form. In this formulation, the main computational cost is associated with evaluating:

$$F^k = (1 + Ra)^k.$$

Since this expression corresponds to classical exponentiation, it can be efficiently computed using standard modular exponentiation techniques.

Thus, parametric exponentiation can be reduced to a classical modular exponentiation problem via Formula (5), where the value F^k is efficiently computed using binary exponentiation.

The pseudocode for computing parametric exponentiation using the binary exponentiation method is as follows (see Algorithm 4):

Algorithm 4: Binary Parametric Exponentiation Closed-form

```
Input: Integers a, k, R, n
Output: a^k mod n
1: if k = 0 then
2: return 0
3: while k > 1 do
4:    A ← (1 + R · a)mod n
5:    invR ← R^{-1}modn  //assuming gcd(R,n)=1
6:    t ← BinaryExponantiation (A, k, n)
7:    result ← (t − 1)mod n
8:    result ← (result · invR)modn
9: return result
```

Example. Given the values $n = 77, R = 19$, $a = 5$, and $k = 13$, compute $a^{(k)}\mathrm{mod}\ n$ using the closed-form representation Formula (5).

Step 1. Using Formula (5)

$$a^{\backslash k} = ((1 + Ra)^k - 1) \cdot R^{-1}\ mod\ n$$

Step 2. Compute $A = 1 + Ra\mathrm{mod}\ n$

$$A = 1 + 19 \cdot 5\ mod\ 77 = 19\ mod\ 77$$

Step 3. Compute the modular inverse of R

$$R^{-1} = 19^{-1} \equiv 73 (\mathrm{mod} 77).$$

Step 4. Compute 19^{13} mod 77using binary exponentiation.

$$13 = 1101_2 = 2^3 + 2^2 + 2^0$$

$$19^2 \equiv 53, 19^4 \equiv 37, 19^8 \equiv 60 (\mathrm{mod} 77)$$

$$19^{13} \equiv 19^8 \cdot 19^4 \cdot 19 \equiv 60 \cdot 37 \cdot 19 \equiv 61 (\mathrm{mod} 77)$$

Step 5. Final computation

$$a^{(13)} = (61 - 1) \cdot 73 = 60 \cdot 73 = 4380 \equiv 68 (\mathrm{mod} 77).$$

The analysis of the presented example demonstrates that the considered parametric exponentiation algorithms, based on Formula (3) and Formula (5), improve computational efficiency compared to the direct iterative approach.

Simple iterative parametric exponentiation method requires 13 parametric multiplications; both algorithms leverage binary exponentiation to reduce the number of iterations to ($\log k$).

Moreover, the approach based on the closed-form representation Formula (5) further simplifies the computation by reducing it to a single modular exponentiation, resulting in improved practical efficiency.

The classical modular exponentiation and the parametric methods based on Formula (3) and Formula (5) differ significantly in their algebraic foundations and computational processes. A generalized comparison of the characteristics of these exponentiation algorithms is presented in Table II.

TABLE II. PARAMETRIC CRYPTOGRAPHIC ALGORITHMS

Property	Classical	Formula (3)	Formula (5)

Main operation	Modular multiplication	Parametric multiplication	Modular multiplication
Dependence on parameter	None	Strong	Weak
Computational process	Squaring and multiplication	Iterative parametric multiplication	Binary exponentiation
Number of parametric operations	0	≈ k times	0
Algorithmic complexity	O(log k)	O(k)	O(log k)

VI. EXPERIMENTAL RESULTS AND DISCUSSION

To improve the efficiency of parametric exponentiation, the fast binary exponentiation technique was applied to the parametric exponentiation methods considered in this study. The performance of the considered algorithms was evaluated using three metrics: *execution time*, *memory consumption*, and *CPU ticks*, in order to provide a broader view of their practical efficiency.

The performance of the considered exponentiation algorithms was evaluated with respect to the modulus $n$and the parameter R, in order to analyze their impact on computational efficiency.

To this end, software implementations of three algorithms were developed: the *classical* modular exponentiation algorithm, the *iterative* parametric exponentiation method based on Formula (3), and the optimized *closed-form* parametric exponentiation algorithm based on Formula (5).

For clarity, these algorithms are denoted as *Classic*, *Param5*, and *Param7*, respectively.

The software modules were implemented in the C# programming language and executed on the .NET platform.

To ensure the reliability of the performance metrics, the experiments were conducted on a computing system with the following technical specifications: Windows 11 Pro operating system, Intel Core i7-13700U processor with a clock frequency of 2.40 GHz, and 16 GB of RAM.

To ensure the reliability of the results, each algorithm was executed multiple times for each set of parameter values. The exponentiation operation was repeated 100 times within the program and the execution time was measured using a high-precision timer.

A. Impact of the Modulus n

The performance of the algorithms was evaluated for different lengths of the modulus n. The parameters used in the computations were fixed as R=2048 bit, a=512 bit and k=256 bit.

The modulus length was gradually increased starting from 512 bits, and for each tested value, the algorithms were evaluated in terms of execution time, memory consumption, and CPU ticks.

The obtained results, illustrating the dependence of execution time on the modulus bit-length, are presented graphically in Fig. 2.

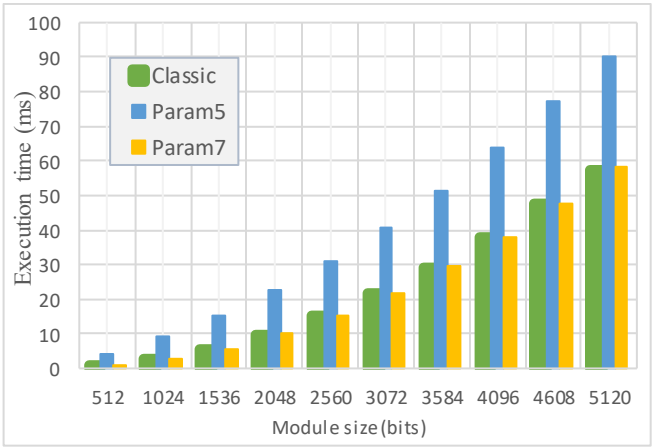

Fig. 2. Execution time vs. modulus length.

The graphical results show that the execution time of all algorithms increases as the modulus bit-length grows. The iterative parametric exponentiation method based on Formula (3) operates more slowly than the classical algorithm, since the parametric multiplication is performed multiple times.

In contrast, the exponentiation method based on Formula (5) achieves nearly the same performance as the classical algorithm.

This demonstrates that the use of a closed-form expression is effective for optimizing parametric exponentiation operations.

This behavior can be explained by the fact that the closed-form formulation eliminates repeated parametric multiplications, thereby reducing computational overhead and improving scalability.

The exact numerical values corresponding to the results shown in Fig. 2 are presented in Table III.

The table III shows that the algorithm based on Formula (3) is slower than the classical method, whereas the one based on Formula (5) has nearly the same speed.

TABLE III. EXECUTION TIME OF ALGORITHMS FOR DIFFERENT MODULUS SIZES

n (bit)	Classic (ms)	Param5 (ms)	Param7 (ms)
512	1.01	4.21	0.74
1024	2.64	9.32	2.66
2048	9.85	22.49	9.96
4096	37.76	63.66	38.16
5120	57.57	90.16	58.25

In addition to runtime measurements, memory usage and CPU ticks were also evaluated for different modulus sizes. The corresponding results are presented in Table IV.

TABLE IV. MEMORY USAGE AND CPU TICKS FOR DIFFERENT MODULUS SIZES

n (bit)	Classic		Param5		Param7	
	Memory(bytes)	CPU Ticks	Memory(bytes)	CPU Ticks	Memory(bytes)	CPU Ticks
512	112	21240	112	35332	112	6300
1024	112	21152	112	70439	112	21387
2048	112	74823	0	162860	112	75852
4096	0	283699	0	464917	112	287081
5120	112	446870	0	665616	112	442620

As shown in Table IV, the iterative method based on Formula (3) consistently requires more CPU ticks than the classical and closed-form methods across all tested modulus sizes. In contrast, the method based on Formula (5) remains very close to the classical algorithm, while memory usage stays nearly constant for all approaches.

The obtained results further confirm that the computational overhead associated with iterative parametric exponentiation significantly increases execution time and CPU ticks, whereas the closed-form approach mitigates this effect while preserving low memory usage.

B. Impact of the Parameter R

The performance of the algorithms was evaluated for different bit-lengths of the parameter R. This allows assessment of the effect of parameter size on execution time, memory usage, and CPU ticks. The values used in the computations were fixed as $n = 4096$bits, $a = 512$bits, and $k = 256$bits.

The bit-length of parameter R was gradually increased starting from 128 bits, and for each value, the execution time of the algorithms was measured. The obtained results are presented graphically in Fig. 3.

As the graph shows, the execution time of the classical exponentiation algorithm remains unchanged since it is independent of the parameter R. By contrast, the computation time of the exponentiation algorithm based on Formula (3) increases as the value of R grows.

Meanwhile, the parametric exponentiation algorithm based on Formula (5) performs similarly to the classical algorithm.

This indicates that the proposed method is largely independent of the parameter R, as the computation is reduced to a single modular exponentiation that does not involve repeated parameter-dependent operations.

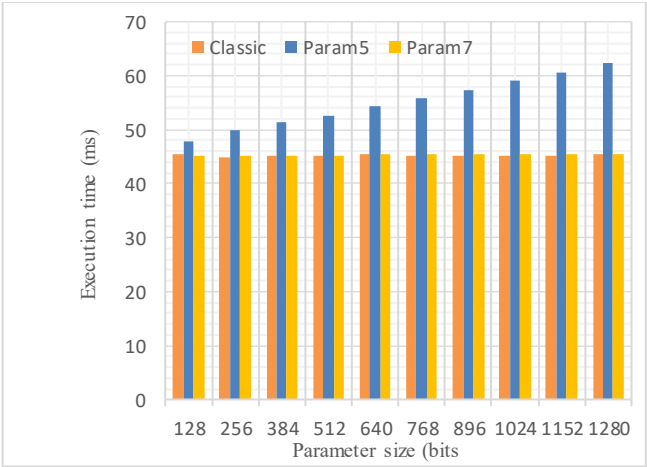

Fig. 3. Execution time vs. parameter length.

The exact numerical values corresponding to the results shown in Fig. 3 are presented in Table V.

TABLE V. EXECUTION TIME OF ALGORITHMS FOR DIFFERENT PARAMETER VALUES.

R (bit)	Classic (ms)	Param5 (ms)	Param7 (ms)
128	38.536	40.872	38.678
256	38.595	42.447	38.563
512	38.373	45.497	38.609
1024	38.386	52.356	38.721
1280	38.424	55.575	38.711

As can be seen from the table, the execution time of the algorithm based on Formula (3) increases with the growth of the parameter R. In contrast, the algorithm based on Formula (5) is almost unaffected by changes in the parameter value.

TABLE VI. MEMORY USAGE AND CPU TICKS FOR DIFFERENT PARAMETER VALUES

R (bit)	Classic		Param5		Param7	
	Memory(bytes)	CPU Ticks	Memory(bytes)	CPU Ticks	Memory(bytes)	CPU Ticks
128	112	295771	0	314064	112	295716
256	0	294361	0	326755	112	296239
512	0	295706	0	377922	112	298236
1024	0	309788	0	429285	112	308696
1280	0	309116	0	432376	112	304334

Some memory measurements are reported as zero because the benchmark records only additional managed heap allocations. In several runs, no extra allocation was detected during execution.

As shown in Table VI, CPU tick measurements clearly indicate that the iterative method based on Formula (3) becomes increasingly expensive as the parameter size grows. In contrast, the method based on Formula (5) remains close to the classical algorithm across all tested parameter sizes.

Overall, the results for different parameter sizes show that increasing the bit-length of R has a significant impact on the iterative method based on Formula (3), leading to higher computational overhead. In contrast, the closed-form method based on Formula (5) remains close to the classical algorithm in both runtime and CPU ticks, demonstrating better scalability with respect to the parameter size.

VII. CONCLUSION AND FUTURE WORKS

In this study, parametric algebraic operations were systematically studied, and an algorithm for parametric exponentiation based on modular binary exponentiation was proposed. By exploiting the properties of parametric algebra, a fast exponentiation expression for parametric exponentiation was derived as:

$$a^{\backslash k} = ((1 + Ra)^k - 1) \cdot R^{-1} \, mod \, n$$

As a result, the proposed method significantly reduces the computational impact of the parameter R on parametric exponentiation while improving overall practical efficiency.

According to the experimental results, for modulus bit-lengths ranging from 512 to 5120 bits, the execution time of the algorithm based on Formula (5) is nearly identical to that of the classical exponentiation algorithm, with the difference not exceeding 1–2% on average.

At the same time, it was observed that the algorithm based on Formula (5) operates approximately 1.7–1.8 times faster than the optimized method based on Formula (3).

Furthermore, during the experiments, it was determined that increasing the bit-length of the parameter R (from 128 bits to 1280 bits) does not significantly affect the performance of the proposed algorithm based on Formula (5).

These results confirm that parametric exponentiation can be reduced to a single modular exponentiation while preserving nearly the same performance as the classical method.

The proposed approach provides a practical and efficient alternative to classical exponentiation methods, making it suitable for high-performance cryptographic applications.

Furthermore, the proposed approach achieves a favorable balance between computational efficiency, low memory consumption, and reduced processor workload, making it suitable for practical cryptographic applications.

The computational Formula (5) proposed in this study enables efficient exponentiation in encryption algorithms and standards such as RSA and ElGamal when enhanced with parametric algebraic operations.

Limitation. This study has several limitations. Although the proposed method significantly improves the efficiency of parametric exponentiation, the practical deployment of parametric cryptosystems still requires broader optimization of all parameter-dependent operations.

Existing hardware and software acceleration mechanisms are mainly designed for classical arithmetic, while specialized implementations for parametric algebra remain limited.

In addition, the correct selection of the parameter R is important because the algebraic properties of the system may depend on its value. For example, the existence of inverse elements, the applicability of the closed-form reduction in Formula (5), and the requirement to satisfy conditions such as $GCD(R, n) = 1$ may introduce additional computational overhead through GCD checks and parameter validation procedures. If these conditions are not satisfied, some algebraic operations may become invalid or require alternative computational methods.

Future work includes the implementation of the proposed method in real-world cryptographic systems and its optimization for parallel and distributed computing environments. In addition, a formal analysis of the security implications of the proposed computational reduction remains an important research direction.

Overall, the results confirm both the theoretical soundness and practical efficiency of the proposed parametric exponentiation method.

An Interoperable Multi-Agent Architecture for Personalized Smart Learning Using Generative AI and Learning Analytics

Al Mahdi Khaddar, Youssef Said, Amine Dehbi, Tarik Chafiq
Laboratory of Information Processing (LTI)-Faculty of Sciences Ben M'Sick,
University Hassan II of Casablanca, Casablanca, Morocco

***Abstract*—Learning Management Systems (LMSs) remain central to digital education, but they still provide limited support for adaptive and personalized learning across heterogeneous platforms. This study proposes an interoperable smart learning architecture that integrates a Multi-Agent System (MAS), generative artificial intelligence, and learning analytics to support context-aware interventions while preserving LMS independence. Methodologically, the work follows a design-oriented research approach based on architectural modeling and scenario-based validation. The proposed framework combines Learning Tools Interoperability (LTI) 1.3, the Experience API (xAPI), Sharable Content Object Reference Model (SCORM), a Learning Record Store (LRS), and an asynchronous Extensible Messaging and Presence Protocol (XMPP)/JavaScript Object Notation (JSON) communication bus to connect intelligent services with existing LMS environments. The architecture includes tutor, assessment, recommendation, monitoring, collaboration, and profile agents coordinated through a microservices-based design. Its functional coherence is illustrated through four representative scenarios covering dropout-risk detection, targeted remediation, teacher dashboards with grade return, and collaborative feedback. The main contribution is a modular and standards-based architecture that connects analytics, agent-based orchestration, and generative AI within a closed-loop adaptation process for scalable smart learning environments.**

***Keywords*—Smart learning; multi-agent systems; generative AI; learning analytics; LMS interoperability; adaptive learning**

I. Introduction

Learning Management Systems (LMSs) such as Moodle and Canvas play a central role in digital education by supporting course delivery, communication, and assessment. However, despite their widespread adoption, most LMS platforms still provide limited support for adaptive and personalized learning at scale [1], [2]. In many cases, personalization remains restricted to static configurations, rule-based options, or isolated plugins, while intelligent services are not deeply integrated into pedagogical workflows. As higher education increasingly seeks learner-centered and data-driven environments, this limitation becomes more visible and pedagogically significant [3], [4].

At the same time, learning analytics has created important opportunities for capturing and interpreting learner behavior through digital traces. Standards such as the Experience API (xAPI) and Learning Record Stores (LRSs) enable the collection, storage, and reuse of fine-grained learning events across multiple tools and platforms [5], [6]. These technologies support monitoring, prediction, and feedback processes that can improve educational decision-making [7]. Nevertheless, in many existing systems, analytics outputs remain mainly descriptive and are not systematically transformed into timely pedagogical interventions inside the LMS [8], [9]. As a result, the adaptive loop between observation, interpretation, and educational action often remains incomplete [8].

At the same time, the use of generative artificial intelligence in education to deliver adaptive explanations, automated feedback, and personalized tutoring is gaining more attention. Several recent papers have discussed the benefits that can be offered by large language models and other artificial intelligence algorithms in improving learning processes and student engagement [10], [11], [12]. Nonetheless, many existing systems continue considering generative AI as merely another component of a conversation without embedding it into the overall educational framework along with the learning experience data, pedagogical knowledge, and limitations [13], [14]. At the same time, several challenges exist in terms of hallucination, inconsistency, trust, and pedagogical control [15], [12].

Another promising path toward intelligent learning systems would be Multi-Agent Systems (MAS). These have modularity, autonomy, and decentralized control. Agent-based technologies are applicable to many tasks including tutoring, surveillance, recommendation, evaluation, and collaborative learning [16], [17], [3]. In more recent years, microservices architecture has emerged as another promising approach to loosely coupled, scalable, and independently evolving intelligent systems [18], [19]. Many of these proposed models for education, however, are largely conceptual, platform-dependent, or disconnected from existing interoperability standards. Therefore, there remains a gap in architectural models that can integrate intelligent agents, learning analytics, artificial generative intelligence, and interoperable learning management systems [20], [13].

This fragmented landscape reveals a clear research gap. Existing works often address LMS integration, learning analytics, intelligent tutoring, agent-based adaptation, or generative AI separately, but fewer studies propose a standards-based architecture that connects these components in a closed-loop process for adaptive learning [21], [22], [7], [13]. Moreover, the literature still provides limited guidance on how such an architecture can remain modular, interoperable, and

portable across heterogeneous LMS environments while supporting both learner-facing and teacher-facing interventions. This gap is particularly important in smart learning research, where the challenge is no longer only to collect educational data or deploy isolated AI services, but to orchestrate them coherently within real institutional ecosystems [23], [24].

To address this gap, this paper proposes an interoperable smart learning architecture based on a hybrid Multi-Agent System and a service-oriented microservices design. The architecture integrates Learning Tools Interoperability (LTI) 1.3 for LMS access and service delivery, xAPI and Learning Record Stores for trace collection and analytics, and asynchronous agent coordination through Extensible Messaging and Presence Protocol (XMPP) and JavaScript Object Notation (JSON). The proposed framework aims to support adaptive explanations, remediation, recommendation, monitoring, teacher dashboards, and collaborative feedback without requiring modifications to the LMS core. In this way, the LMS is preserved as a stable host environment, while intelligent services are externalized through interoperable mechanisms [6], [13].

The objectives of this study are fourfold. First, it aims to define a modular architecture that decouples intelligent services from the LMS while preserving interoperability with existing educational platforms. Second, it seeks to integrate learning analytics, intelligent agents, and generative AI into a unified closed-loop adaptation process. Third, it aims to show how standardized traces can support both individual and collaborative pedagogical interventions. Fourth, it intends to validate the internal coherence and functional completeness of the proposed architecture through representative educational scenarios.

This work adopts a design-oriented research methodology because the main goal is not to measure learner performance through a field experiment at this stage, but to design, formalize, and theoretically validate an architectural framework for smart learning. Such an approach is appropriate for complex adaptive educational systems in which interoperability, modularity, orchestration, and deployment logic must first be specified before large-scale implementation and empirical testing [25], [26], [27], [17]. Scenario-based validation is therefore used to examine whether the proposed architecture can support complete end-to-end workflows across representative educational situations, including learner support, assessment remediation, instructor analytics, and collaborative learning.

The expected contributions of this study are both scientific and practical. From a scientific perspective, the paper contributes a unified architectural model that bridges research streams that are often treated separately, namely LMS interoperability, learning analytics, intelligent agents, microservices, and generative AI in education. From a practical perspective, the proposed framework offers institutions a reusable and extensible foundation for deploying adaptive services across heterogeneous LMS ecosystems while maintaining portability, governance, and pedagogical consistency. By organizing these components within a closed-loop architecture, the study also contributes to the design of more scalable and institutionally deployable smart learning environments [23], [24].

The remainder of the paper is organized as follows. Section II reviews the related literature and identifies the main limitations of existing work. Section III presents the research methodology. Section IV describes the proposed architecture and its main layers. Section V reports the scenario-based validation and discusses the main contributions and limitations of the framework. Finally, Section VI concludes the paper and outlines directions for future work.

II. Literature Review

Recent research has confirmed the growing importance of adaptive and personalized learning in higher education. Personalized learning environments aim to adjust content, pacing, and support according to learner characteristics, performance, and engagement. In this context, LMS platforms remain essential for course management and digital delivery, but several studies report that most existing LMSs still provide limited support for deep and dynamic personalization [4], [21]. In many cases, adaptive behavior is not embedded in the LMS architecture itself, but added through external tools or isolated modules, which limits coherence and scalability [28], [22].

Learning analytics has become one of the most promising fields of research related to the use of digital traces for better comprehension and optimization of the learning process. Various studies demonstrate the potential of learner activity data for monitoring purposes and predictive analysis [5], [7]. At the same time, interoperability standards like xAPI and cmi5 have made collecting standard learning traces across diverse learning environments and storing them in Learning Record Stores more feasible [29], [6]. However, there are also significant limitations identified in past research. For example, many systems operate on a purely descriptive level, offering dashboard tools rather than advanced decision support, while the link between the results obtained and immediate pedagogical actions is poor [30], [8].

At the same time, artificial intelligence has gained increasing attention in smart learning systems. Recent reviews emphasize the potential of AI techniques, including machine learning, deep learning, and generative AI, to support adaptive feedback, learner modeling, performance prediction, and content personalization [10], [20]. More specifically, large language models and generative AI tools have shown promise for generating explanations, recommendations, and contextualized tutoring support [11], [12]. Nevertheless, the literature also underlines major concerns related to hallucination, factual inconsistency, bias, pedagogical reliability, and ethical use in educational settings [12], [14], [15]. Another limitation is that many AI-based educational tools are developed as standalone assistants rather than being embedded into an interoperable and institutionally deployable smart learning architecture [13].

Multi-Agent Systems constitute another important research direction for intelligent learning environments. MAS-based approaches are valued for their modularity, autonomy, and distributed problem-solving capacity, making them suitable for complex educational functions such as tutoring, assessment, recommendation, and monitoring [3], [16]. In parallel, microservice-based architectures have been recognized as effective for building scalable, loosely coupled, and evolvable intelligent systems [18], [19]. These properties are particularly

relevant for educational ecosystems that need to integrate multiple intelligent services and continuously evolving AI models. However, several previous works remain either conceptual, prototype-level, or narrowly focused on one pedagogical function. In addition, many of them do not explicitly support standards-based interoperability with mainstream LMS platforms, which reduces portability and institutional applicability.

Another limitation in the existing literature is the fragmented treatment of the main components of smart learning. Some studies focus on LMS-centered personalization, others on learning analytics pipelines, others on generative AI assistants, and others on agent-based educational systems [31], [7], [13], [21]. While each stream offers useful contributions, fewer works integrate these components into a unified architecture that supports trace collection, feature computation, learner modeling, agent coordination, and delivery of interventions back into the LMS through interoperable standards. This gap becomes even more significant when both learner-facing and teacher-facing interventions are considered within the same framework.

To clarify the position of the present study, Table I compares representative previous works with the proposed approach according to key dimensions: architectural scope, interoperability support, analytics integration, agent-based intelligence, generative AI integration, and validation approach. The comparison shows that previous studies generally address only part of the problem. Some works emphasize analytics but do not include agent orchestration. Others integrate AI assistants into LMSs but do not provide a broader closed-loop adaptation model. Similarly, some studies propose intelligent educational services, yet without strong interoperability support or without considering portability across heterogeneous LMS environments [11], [13], [29], [31].

Based on this analysis, the novelty of the present work lies not in introducing a single isolated technology, but in integrating several complementary dimensions into one coherent architecture. The proposed framework combines standards-based LMS interoperability, xAPI-based trace collection, Learning Record Store-centered analytics, a hybrid Multi-Agent System implemented as microservices, and generative AI-enabled pedagogical services within a closed-loop adaptation process. In addition, the architecture is designed to support multiple educational situations, including dropout-risk detection, targeted remediation, teacher dashboards, and collaborative feedback. This combination distinguishes the proposed work from prior approaches that are typically narrower in scope, less interoperable, or insufficiently connected across analytics, intelligence, and pedagogical action [23], [24].

TABLE I. COMPARISON OF RELATED WORKS AND THE PROPOSED APPROACH

Ref.	Main Focus	LMS Interop.	Learn. Analytics	Multi Agent Supp.	Gen AI Integ.	Main Lim.
[4]	Personalized adaptive learning in HE	No explicit standards focus	Partial	No	No	Focuses on adaptive learning characteristics rather than system architecture
[7]	ML and GenAI in learning analytics	Partial	Yes	No	Yes	Reviews models and trends, but does not propose deployable architecture
[29]	Predictive analytics for course completion	Partial	Yes	No	No	Strong analytics pipeline, but no agent orchestration or LMS-wide adaptation model
[13]	GenAI assistants integrated into LMS	Yes	Partial	No	Yes	Focuses on LMS assistant integration, not full multi-agent closed-loop architecture
[11]	AI and analytics for pedagogical decisions	Partial	Yes	No	Yes	Strong decision support perspective, but limited architectural interoperability detail
[30]	Adaptive GenAI-based feedback and recommendation	No explicit standards focus	Yes	No	Yes	Focused on a specific learning system, not heterogeneous LMS environments
Proposed work	Interoperable smart learning architecture	Yes	Yes	Yes	Yes	Scenario-based validation only; empirical deployment remains future work

III. MATERIALS AND METHODS

This study adopts a design-oriented research methodology focused on the conception, formalization, and theoretical validation of an interoperable smart learning architecture. The purpose of the work is not to evaluate learner outcomes through a classroom experiment at this stage, but to develop a coherent architectural framework capable of integrating intelligent agents, learning analytics, generative artificial intelligence, and Learning Management System (LMS) interoperability within a unified smart learning ecosystem. This methodological choice is appropriate because the contribution of the paper is primarily architectural and system-oriented rather than experimental. It also responds to the need for a structured design process before empirical implementation in authentic educational environments [25].

The methodological process began with the identification of the research problem through an analysis of limitations reported in previous studies on LMS-centered personalization, learning analytics, multi-agent educational systems, and generative artificial intelligence in education. This analysis revealed a fragmented landscape in which these components are often treated separately. In particular, the literature showed the absence of a unified framework capable of combining interoperability, modularity, analytics, and intelligent pedagogical intervention within a closed-loop process. Based on

this gap, the main functional and technical requirements of the proposed architecture were defined, including LMS independence, standards-based interoperability, modularity, scalability, portability across heterogeneous platforms, and support for adaptive learner-facing and teacher-facing interventions [7], [13], [21], [22], [31].

Fig. 1 presents the overall methodological workflow followed in this study, from problem identification and requirement specification to layered architecture design and scenario-based validation.

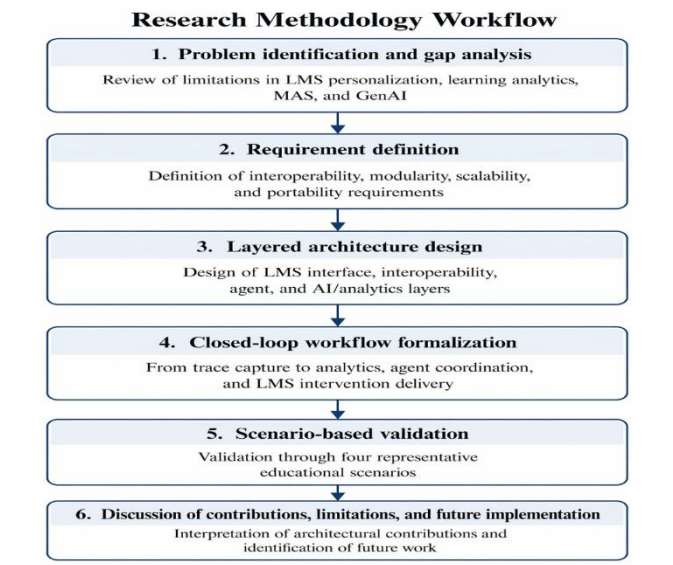

Fig. 1. Research methodology workflow.

The proposed architecture was then designed using a layered model composed of four main layers: the LMS interface layer, the interoperability layer, the intelligent agent layer, and the artificial intelligence and learning analytics layer. This decomposition was adopted to reduce coupling between components and to facilitate extensibility, maintainability, and cross-platform portability. In the proposed design, the LMS acts as a host environment that provides access to courses, users, and activities, while intelligent services are externalized and connected through interoperability standards. This architectural choice makes it possible to preserve the stability of the LMS core while enabling the integration of adaptive services developed independently of the platform. This point is particularly important because the practical value of the proposed work depends on its ability to operate across heterogeneous LMS environments without requiring changes to internal LMS code [18], [19], [27].

To specify the internal operation of the framework, the architecture was formalized as an end-to-end closed-loop workflow. Learner and teacher interactions are captured through interoperable mechanisms, represented as standardized events, and stored in a Learning Record Store. These traces are then processed by the analytics layer to compute indicators related to engagement, progression, difficulty, or risk, and to update the learner model or feature store. The resulting features are consumed by intelligent agents, which coordinate through asynchronous communication in order to produce pedagogical actions such as feedback, recommendations, remediation, alerts, or dashboard content. These actions are finally delivered back to the LMS through interoperable services. This formalization ensures that the proposed framework is not limited to a static architectural description, but includes the logical sequence of adaptive processing steps from data capture to pedagogical intervention, as requested by the reviewers [16].

At the technical level, the architecture relies on several complementary technologies and standards. Learning Tools Interoperability 1.3 is used for secure tool launch, contextual access, and LMS-facing service delivery. The Experience API is used to represent learning interactions as standardized statements, while a Learning Record Store functions as the central repository for trace collection. Intelligent services are modeled as distributed microservices, and agent coordination is supported through Extensible Messaging and Presence Protocol and JavaScript Object Notation message exchange. In addition, the analytics layer includes a feature computation process combining rule-based indicators and optional machine learning inference, depending on the educational scenario and the availability of predictive models. This technical description clarifies the implementation logic of the framework and strengthens the architectural consistency of the proposed model [6], [15], [18], [19].

The theoretical validation of the proposed architecture was conducted through a scenario-based approach. Four representative educational scenarios were defined to examine whether the framework can support complete workflows across different pedagogical situations: early dropout-risk detection, targeted remediation after quiz failure, teacher dashboard generation with grade return, and collaborative group feedback. These scenarios were selected because they cover different categories of educational intervention, namely individual monitoring, assessment support, teacher-facing analytics, and collaborative learning support. The aim of this validation is not to measure statistical performance, latency, or scalability, but to assess the functional completeness, internal coherence, and standards-based interoperability of the proposed framework across representative use cases. This clarification is important because the study is positioned as an architectural contribution and not as an empirical performance evaluation [26], [27].

Although this study does not yet include an empirical deployment in an authentic classroom setting, the adopted methodology provides a rigorous foundation for future implementation. By explicitly defining the architecture, its components, their interactions, and the logic of validation, the study establishes a reproducible design framework that can later be extended toward prototyping, simulation, and real-world experimentation. In this sense, the methodological contribution of the paper lies in transforming a fragmented set of technological and pedagogical components into a structured, interoperable, and theoretically validated smart learning architecture [25], [26], [27].

IV. Proposed Approach

This paper proposes an interoperable intelligence layer that operates independently of the Learning Management System (LMS) and enables the deployment of adaptive smart learning services across heterogeneous educational platforms. The main

idea is to treat the LMS as a host environment responsible for course access, user context, and activity management, while intelligent services are externalized as interoperable components connected through standard protocols. This design allows institutions to integrate, replace, or extend intelligent educational services without modifying the LMS core, thereby improving portability, modularity, and long-term maintainability [13], [18], [19].

The proposed approach is guided by four design principles. The first principle is interoperability-first integration, which ensures that intelligent services interact with existing educational platforms through standards-based mechanisms rather than proprietary interfaces. The second principle is modularity through distributed agent microservices, which makes it possible to isolate pedagogical functions and evolve them independently. The third principle is data-driven adaptation based on standardized learning traces, allowing pedagogical interventions to be grounded in learner and group behavior. The fourth principle is governance by design, meaning that identity, access control, and privacy constraints are embedded in the architecture from the outset [6], [18].

The proposed architecture is structured into four interconnected layers: the LMS interface layer, the interoperability layer, the intelligent agent layer, and the artificial intelligence and learning analytics layer. This layered decomposition provides a clear separation of responsibilities while preserving end-to-end coordination across the system. It also enables the architecture to remain LMS-agnostic, since adaptive services are not embedded directly in LMS logic but operate through interoperable connections [13], [18], [19]. Fig. 2 illustrates an interoperable smart learning architecture based on a hybrid multi-agent system and service-oriented architecture integrating intelligent agents, generative AI, and learning analytics.

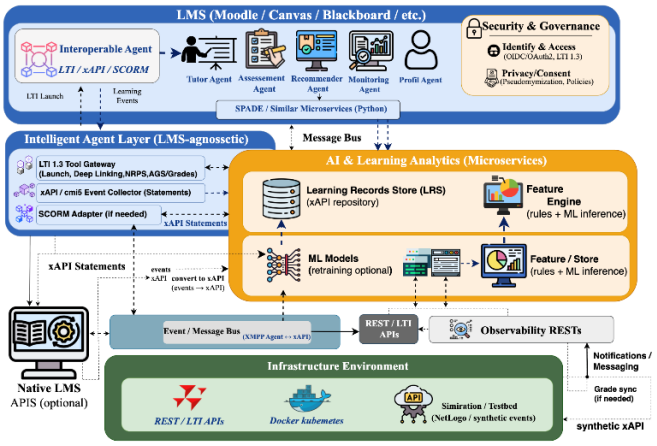

Fig. 2. Interoperable smart learning architecture based on a hybrid Multi-Agent System and Service-Oriented Architecture integrating intelligent agents, generative AI, and learning analytics.

A. Layered Architecture

The architecture is structured into four layers: 1) LMS interface, 2) interoperability, 3) intelligent agents, and 4) AI and learning analytics, deployed on a containerized infrastructure.

1) LMS interface layer: At the LMS interface layer, platforms such as Moodle, Canvas, or Blackboard remain the primary environments in which learners and instructors access courses, assessments, and collaborative activities. In the proposed model, the LMS is not redesigned at the core level. Instead, it functions as a stable delivery environment in which adaptive services are made available through external interoperable tools. This choice preserves institutional compatibility with existing LMS infrastructures while allowing intelligent functionalities to evolve outside the platform [1], [2], [13].

2) Interoperability Layer (LTI / XAPI / Cmi5 / SCORM): The interoperability layer facilitates the communication between the LMS and external intelligence services. The interoperability layer mainly uses Learning Tools Interoperability (LTI) 1.3 as the means of launching applications securely, accessing contextual data, and integrating services within the LMS environment. External tools will have access to contextual data, including the course identifier, the user's role, and activity contexts. Moreover, external tools may send back results, including grading and embedded pedagogic services, where required. Simultaneously, the Experience API (xAPI) collects learner interactions as structured statements, with CMI5 profiles available for cases where there is a need for learning activities to be packaged into structures. The learning statements are recorded in the Learning Record Store (LRS) module, enabling a consolidation of learning tracks from both the LMS and external tools. Finally, there is an optional SCORM adapter that can be managed to support legacy learning content [5], [6], [29].

3) Intelligent agent layer: At the core of the architecture, the intelligent agent layer provides the main adaptive and decision-making functions of the system. This layer is implemented as a distributed set of microservices, with each agent responsible for a specific pedagogical role. The tutor agent supports adaptive explanations, guidance, hints, and remediation messages. The assessment agent manages quiz-related diagnosis, feedback generation, and grading-oriented pedagogical logic. The recommender agent selects suitable resources, activities, or follow-up actions according to learner state and contextual needs. The monitoring agent tracks engagement, inactivity, progression, and risk indicators in order to trigger timely interventions. The collaboration agent analyzes group activity and supports collaborative learning regulation. The profile agent maintains the learner model by managing persistent features and learner descriptors used for personalization [16], [17], [18], [19].

To strengthen the technical soundness of the architecture, the decision logic of the agents is based on three complementary mechanisms. First, rule-based logic is used for explicit pedagogical conditions, such as prolonged inactivity, low quiz scores, missing milestones, or unbalanced group contribution. Second, analytics-derived features extracted from learner traces inform the interpretation of learner state, including engagement, progression, mastery, and risk indicators. Third, optional

machine learning inference can be incorporated when predictive models are available, for example, to estimate dropout risk, classify engagement patterns, or rank recommended resources. In this way, agents do not operate as opaque black boxes, but as orchestrated services that consume structured inputs and produce pedagogically meaningful actions according to explicit functional roles [5], [7], [16], [29].

Agent coordination is achieved through asynchronous communication over an Extensible Messaging and Presence Protocol (XMPP) and JavaScript Object Notation (JSON) message bus. This event-driven communication model allows the agents to remain loosely coupled while supporting multi-step workflows. For example, a Monitoring Agent may publish a risk signal, which is then consumed by the Recommender Agent to select a follow-up activity and by the Tutor Agent to formulate a guidance message. This asynchronous orchestration is important in smart learning environments because it supports distributed decision-making, flexibility, and the independent evolution of services [18], [19].

4) AI and learning analytics layer: The artificial intelligence and learning analytics layer transforms raw learning traces into actionable information. The learning record store functions as the central repository of XAPI statements produced by LMS activities and interoperable tools. A feature engine processes these traces and computes pedagogically relevant indicators such as time on task, login frequency, completion rate, mastery progression, error patterns, group participation balance, and inactivity duration. These indicators are then stored in a feature store or learner model database, which provides a longitudinal representation of learners and groups. When predictive models are available, machine learning inference can be incorporated into this layer in order to generate higher-level outputs such as risk scores, recommendation rankings, or engagement classifications [29].

Generative artificial intelligence is integrated into the proposed architecture as a pedagogical support component rather than as an isolated conversational tool. Within this framework, generative AI can support adaptive explanations, remediation messages, tutoring feedback, and contextual recommendations. However, its use is constrained by pedagogical and institutional control. The output of generative services is expected to be grounded in learner context, analytics-derived features, and predefined pedagogical objectives. In addition, because generative AI may produce hallucinations or factually inconsistent outputs, the architecture assumes the use of guardrail mechanisms such as prompt restriction, context grounding, pedagogical templates, and validation rules before delivery in sensitive educational situations [10], [11], [15].

B. End-to-End Closed-Loop Operation

A central contribution of the proposed approach lies in the end-to-end closed-loop adaptation process. Learner and teacher interactions generate standardized traces, which are stored and analyzed to compute features and update the learner model. Intelligent agents then consume these features, coordinate with one another, and determine which pedagogical intervention should be produced. Finally, the selected intervention is delivered back into the LMS through interoperable services such as LTI tools, dashboards, recommendation panels, feedback widgets, or grade return interfaces. This closed-loop operation ensures that data collection, interpretation, decision-making, and pedagogical action are connected within the same architectural framework [6].

C. Security, Privacy, and Institutional Constraints

Because the architecture is designed for institutional deployment, governance and privacy constraints are considered from the outset. Identity and access control rely on secure interoperability mechanisms associated with LTI 1.3. Trace collection and learner modeling should follow data minimization principles, and pseudonymization may be applied when possible. These measures are important for ensuring that adaptive services remain compatible with institutional policies related to security, privacy, and responsible artificial intelligence use [6], [14], [26].

Overall, the proposed approach differs from narrower educational architectures by integrating LMS interoperability, standardized trace collection, distributed intelligent agents, learning analytics, and generative artificial intelligence within one coherent framework. Its novelty lies not in the isolated use of a single technology, but in the explicit orchestration of these components in a modular and closed-loop architecture capable of supporting learner-facing, teacher-facing, and collaborative interventions across heterogeneous LMS environments [24].

D. Scenario-Based Validation

To validate the proposed closed-loop architecture, we adopt a scenario-based validation approach. Rather than providing a statistical evaluation of performance, this approach is intended to demonstrate that the architecture is functionally complete, standards-compliant, and internally consistent across representative educational situations. Each scenario is analyzed by following an end-to-end interaction chain: 1) LTI-based access to the learning tool, 2) generation and storage of xAPI traces in the Learning Record Store (LRS), 3) feature computation and learner model update, 4) agent coordination through the message bus, and 5) delivery of adaptive interventions back to the LMS via LTI.

1) Validation method and notation: for each scenario Si, the validation process is described using a common analytical structure that captures the main functional components involved in the closed-loop workflow. As summarized in Table II, this structure includes the actors, the learning context, the observed events, the derived features, the agent decisions, and the intervention actions returned to the LMS.

TABLE II. SCENARIO VALIDATION METHOD AND NOTATION

Element	Description
Actors	Learner, instructor, LMS, and external tool or intelligent agent
Context C	Course setting, activity type, assessment constraints, and user roles
Observed events E = {e1, ⋯,en}	Learning events captured as xAPI statements

Derived features F	indicators computed by the Feature Engine through rule-based processing and, where applicable, machine learning inference
Agent decisions D	Decisions produced by the intelligent agents, along with the coordination messages exchanged through the XMPP/JSON message bus (SPADE)
Intervention actions A	Adaptive actions are delivered back to the LMS through LTI 1.3, and grades are returned through standard LTI services when required.

2) Validation Criteria: For each scenario, the proposed approach is validated through six evaluation criteria, which are detailed in Table III.

TABLE III. SCENARIO-BASED VALIDATION CRITERIA

N	criteria	Definition
C1	Traceability	Each interaction provided to the learner or tutor must be traceable through an established chain, which consists of captured events, calculated indices/attributes, and the consequent decision taken by the agent.
C2	Closed-loop completeness	It is essential that the complete adaptive cycle takes place without any gaps: context capture, event capture, learning record storage, analysis, learner model modification, decision-making by agents, and the final presentation within the LMS environment.
C3	LMS Decoupling	The scenario should not involve changes to the source code or proprietary API of the LMS. It must use interoperability standards and third-party service providers while using LMS as the hosting platform.
C4	Governance consistency	Authentication, authorization, and data access should adhere to the chosen governance strategies (authentication flows for LTI 1.3, access control) and privacy requirements (data minimization, pseudonymization if possible)
C5	Agent substitutability.	A replacement for any given agent is one that adheres to the same set of contracts: the same schema for input features, the same schema for actions, and the same message structure on the bus. Everything else in the system stays the same.
C6	Cross-platform portability	This scenario will be applicable even when there is an LMS change, as long as the new LMS has support for the same interoperability endpoints. There will be no need to alter anything apart from the configuration and registration parameters on the LMS side.

a) Scenario 1: Early dropout detection and personalized reactivation in the LMS: This scenario aims to validate that the proposed architecture can detect dropout risk at an early stage from learner activity traces and then trigger an appropriate intervention directly within the LMS. The objective is not merely to observe indicators, but to demonstrate the operation of the closed-loop adaptation cycle: interaction capture, analysis, agent-based decision-making, and delivery of a pedagogical action through an interoperable tool, as illustrated in Fig. 3.

A learner is enrolled in a course on Moodle. After an initial period of normal activity, the learner's engagement decreases (fewer logins, lack of progress, and limited interaction with learning resources). The system should identify this situation as a risk signal and propose a re-engagement action.

Step 1: Context and interaction capture (Moodle + LTI 1.3 + xAPI): The learner interacts with the course in Moodle. Intelligent services are accessed through LTI 1.3 tools, which provide secure access and learning context (course, role, activity). Relevant interactions generate learning events represented as xAPI statements (typical examples include opening an activity, viewing a resource, quiz attempt/abandonment, time spent, and progression events).

Step 2: Storage and processing (LRS + Feature Engine): The xAPI statements are stored in the Learning Record Store (LRS), which serves as the unified source of learner traces. The Feature Engine processes these traces to compute engagement indicators such as session frequency (number of logins per week), time-on-task, activity completion rate, inactivity duration (days since last interaction), and progression across course modules.

These indicators then persisted in the Feature Store / Learner Model to maintain a longitudinal state of the learner.

Step 3: Decision and orchestration (Monitoring Agent + XMPP/JSON bus): The Monitoring Agent periodically retrieves indicators from the Feature Store and applies the risk detection logic (pedagogical rules and/or ML inference, depending on the chosen design).

When risk conditions are met (e.g., prolonged inactivity and low progression), the Monitoring Agent publishes a message on the XMPP/JSON message bus (SPADE). This publication may trigger multi-agent coordination:

- The Recommender Agent selects a simple next action (a priority activity or a short resource).
- The Tutor Agent prepares a guidance/remediation message (e.g., reminder + clear instruction + suggestion for gradual re-entry).

Step 4: Delivery of the intervention in Moodle (LTI tool): The intervention is displayed directly in Moodle through an LTI component integrated into the course interface (widget, recommendation panel, or notification). The re-engagement content typically includes:

- A contextualized reminder (overdue activity, module to resume).
- A concrete recommendation (e.g., a short resource or a self-assessment exercise).
- A brief tutoring message (re-entry advice, next steps).
- Optionally, a follow-up mechanism (e.g., "I resumed" confirmation, "Start now" button).

This scenario also proves that operational adaptation is possible through this architecture, where standardized traces (xAPI) are used for engagement indicators, which then trigger an agent-based decision and eventually a direct action in the LMS through the use of LTI. The stability of the LMS is also ensured, where no internal changes are needed, and the intelligence is provided through the analytics layer and agent layer, proving the principles of decoupling and portability through other standards-based LMS systems.

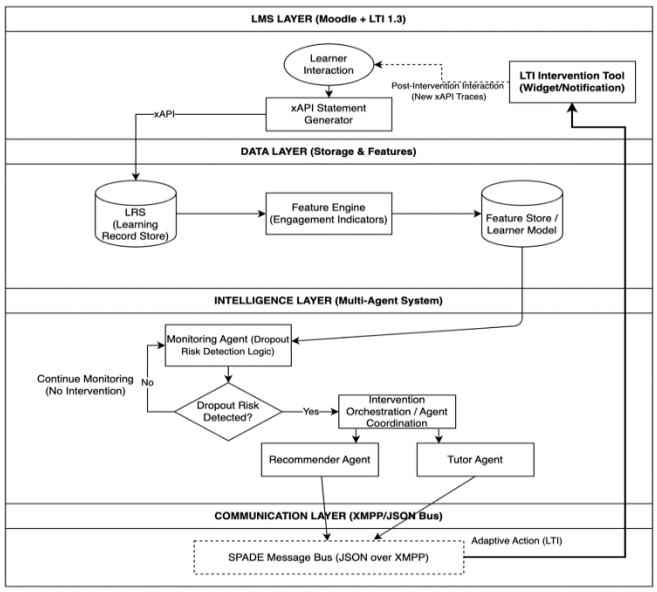

Fig. 3. Scenario 1: Early dropout risk detection and personalized re-engagement within the LMS.

b) Scenario 2: targeted remediation after quiz failure, with recommendations and tutoring in Moodle: this scenario is meant to test the fine-grained pedagogical adaptation based on assessment data. The idea is to demonstrate that assessment data, represented as standardized traces, can be used to perform a diagnostic process (e.g., poor concepts learned) and subsequently execute a specific action: providing feedback, learning materials, and tutorial support, all via lti within moodle itself, as illustrated in Fig. 4. This scenario, therefore, serves as another test of the consistency of the closed-loop process and the effectiveness of the multi-agent collaboration.

A learner is taking a quiz in Moodle or an external tool. The learner is getting a low grade or consistently answering a question incorrectly. The system must interpret the actions of the learner, determine the source of the error, and decide the best remediation.

Step 1: Capture of results and interactions (Moodle + LTI + xAPI): The learner launches the quiz, answers the questions, and either completes or abandons the attempt. Assessment-related events are captured as xAPI statements, for example: quiz start, correct/incorrect answers, final score, number of attempts, and response time.

If the quiz is associated with concepts (e.g., question tags or learning objectives), these metadata enable a more precise diagnosis.

Step 2: Storage and analysis (LRS + Feature Engine): The statements are stored in the LRS. The Feature Engine then computes indicators such as overall score, error rate by concept (when available), most problematic questions, abnormally high or low response time, and progression across attempts.

These data update the learner model/feature store, including the estimated mastery level for each concept, recurrent difficulties, and progression state.

Step 3: Decision and orchestration (Assessment Agent, Tutor Agent, Recommender Agent): An assessment agent, or the analysis logic itself, detects a remediation condition (e.g., low mastery of a concept). Then, through the XMPP/JSON bus (SPADE):

- The recommender agent selects resources adapted to the weak concept (lesson, short video, simple exercise),
- The tutor agent generates pedagogical feedback (explanation of the typical error, concept reminder, worked example),
- Optionally, the monitoring agent records that the learner is having trouble, enabling longitudinal follow-up.

Step 4: Delivery of remediation in Moodle (LTI tool): In Moodle, an LTI panel displays:

- A short explanatory feedback message (what was not understood).
- A prioritized recommendation of resources.
- A reinforcement activity (mini-exercise, short quiz, checklist).
- A suggested recovery strategy (e.g., review section X, then retry the quiz).

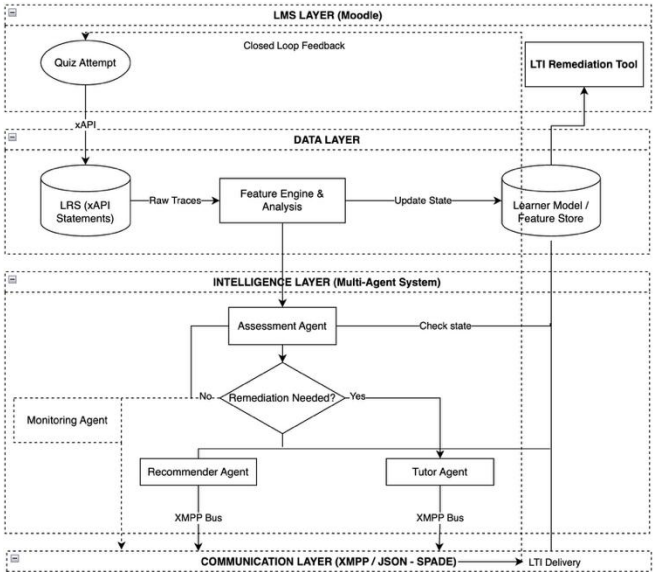

Fig. 4. Scenario 2: Targeted remediation after quiz failure, with recommendations and tutoring in Moodle.

In this scenario, architecture can take the results of assessment and translate them into active pedagogical action without the need for an LMS. This is because the same agents and analytics services could be utilized with any standards-based LMS platform due to the input/output remaining the same.

c) Scenario 3: Teacher dashboard and grade return: the above situation serves to validate the institutional and operational aspects of the proposed approach. In addition to the learner-focused services, the system needs to offer aggregated analytics that are relevant to the instructor and grade return via standard services when needed. As illustrated in Fig. 5,

architecture enables the collection, analysis, and visualization of assessment results to support pedagogical decision-making at the course level.

The assessment activity may be a quiz, an assignment, or an external learning activity. The results are individual. The teacher needs a dashboard to get an overall picture of how the class is performing. Additionally, the teacher needs a dashboard to identify areas where the class may be struggling. Finally, the teacher needs a dashboard to automatically sync the results back into the Moodle site if the assessment activity is an external tool.

Step 1: Capture of results (LTI + xAPI): The assessment can be a native one or an external one via an LTI 1.3-enabled tool. The results can be scored, successful or unsuccessful, progression, time spent, or attempts. These are then sent to the central LRS.

Step 2: Computation of cohort metrics (Feature Engine + analytics): The analytics engine computes class-level indicators, such as:

- Mean, median, and score distribution,
- Success rate by question or concept,
- Difficulty indicators,
- Detection of at-risk groups (e.g., learners showing low progression),
- Correlation between engagement and performance (when available).

These metrics are stored in the Feature Store and made available to visualization services.

Step 3: Dashboard generation (dashboard service): A dashboard service can be used to obtain the aggregated metrics, which are used to create a view for the teacher. This view is embedded within the LMS as a tool using the LTI, so the teacher can work within the familiar environment. The dashboard can display:

- Overall cohort progression.
- Problematic concepts.
- A list of learners requiring follow-up.
- Pedagogical recommendations (e.g., revisiting concept X in class).

Step 4: Grade return to Moodle (LTI services): If the assessment activity is externalized, the grades can be sent back to Moodle via the usual services provided by LTI (grade synchronization when needed). The grade is then visible in the gradebook without any manual intervention.

This scenario validates the architecture's ability to support institutional needs: cohort analytics, instructor-facing interfaces integrated into the LMS, and standards-based grade management. It strengthens the argument for deployable architecture in real educational environments, where governance, LMS stability, and interoperability are essential.

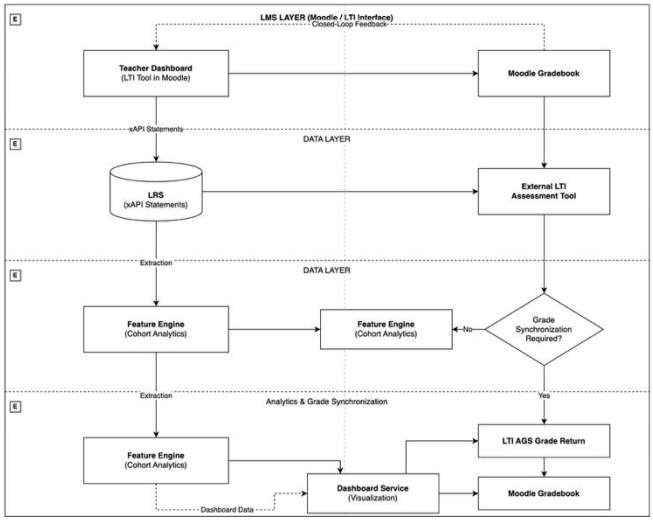

Fig. 5. Scenario 3: Teacher dashboard and grade return.

d) Scenario 4: Group interaction analysis and collaborative feedback integrated into Moodle: This scenario is intended to validate that not only is this architecture applicable for individual adaptations, but also that it is applicable for collaborative learning situations, including group work, forums, projects, etc. The purpose is to validate that traces of interaction between learners can be gathered in a standard format, analyzed to detect patterns of collaboration (such as unbalanced participation, no coordination, low levels of interaction), and then converted into pedagogical interventions that are directly provided inside Moodle through LTI tools, as illustrated in Fig. 6.

The learners are working on a collaborative activity such as a project, forum discussion, wiki, document, or integrated external tool. Some groups may be successful, while others may not be successful. This may be shown by one learner completing the entire project, low overall participation, low levels of communication among the group members, or the group failing to meet the deadlines. The system needs to recognize such groups and give them feedback.

Step 1: Capture of collaborative interactions (Moodle + tools + xAPI): Actions related to collaboration are recorded in the form of events like posts, replies, comments, file submissions, document editing, messages, validation of milestones, meetings, etc. These actions are then sent out in the form of xAPI statements. The traces may originate from:

- Native Moodle tools (forum, assignment, group activity).
- Or external tools integrated through LTI 1.3.

Step 2: Storage and analysis (LRS + Feature Engine): The LRS centralizes the statements. The Feature Engine computes individual- and group-level indicators, for example:

- Contribution distribution across group members.
- Interaction and reply frequency within the group.

- Response delays.
- Regularity of participation over time.
- Progress with respect to project milestones.
- Coordination indicators (activity concentrated on one learner, periods of collective inactivity).

These indicators feed the feature store (group profile and individual profiles), enabling longitudinal analysis.

Step 3: Decision and orchestration (Collaboration Agent + Monitoring Agent): The collaboration agent exploits group-level metrics to detect patterns such as:

- Unbalanced participation (one dominant contributor).
- Low overall activity (inactive group).
- Lack of exchanges (few replies or interactions).
- Risk of delay (slow milestone progression).

When no critical pattern is detected, the system continues monitoring the group without triggering intervention. When a relevant pattern is detected, the Collaboration Agent initiates the intervention flow through the SPADE bus (XMPP/JSON). Depending on the case, this may coordinate:

- The Monitoring Agent to generate a "group at risk" alert.
- The Tutor Agent to formulate collaborative feedback or guidance.
- Optionally, the Recommender Agent suggests resources on project management, role distribution, or coordination strategies.

Step 4: Delivery of feedback in Moodle (LTI tools): The system delivers the intervention through an LTI tool integrated into Moodle. Once the intervention has been coordinated through the SPADE bus, the Feedback Delivery Service receives the outputs produced by the agents, aggregates the relevant alerts, recommendations, and tutoring feedback, and transforms them into an LTI-compatible payload. It then packages the pedagogical action into a deliverable format and transmits it to the LTI Intervention Tool for direct presentation within Moodle. Depending on the pedagogical policy, the intervention may be:

- Addressed to the group: feedback message, coordination advice, task checklist, role distribution suggestion,
- Addressed to the teacher: group dashboard, alerts on at-risk teams, contribution summary,
- Or mixed: lightweight feedback to the group plus a detailed alert to the teacher.

This scenario also proves that architecture supports collaboration analytics/intervention without relying on a particular LMS solution. The traces are standardized through xAPI, and the delivery is done through LTI, making this mechanism easily transportable to other standards-based LMS environments. This scenario also makes the model more relevant to institutions, since the teacher can gain insight into group collaboration.

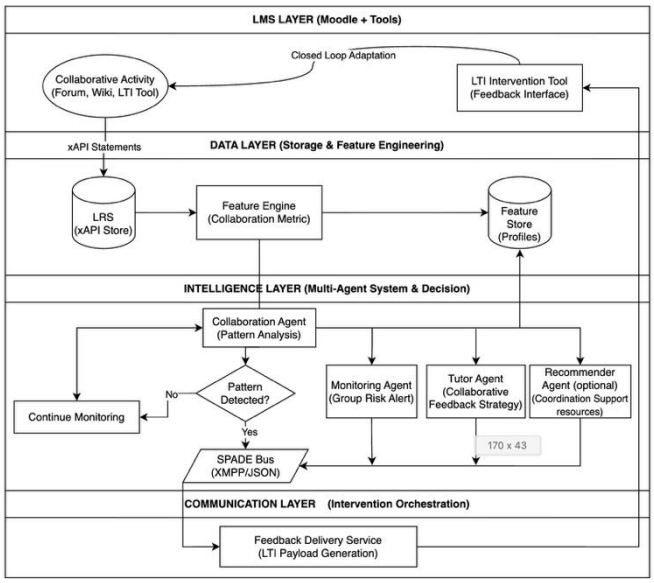

Fig. 6. Scenario 4: Group interaction analysis and collaborative feedback integrated into Moodle.

V. Result and Discussion

The results of this study are architectural and analytical rather than experimental. Accordingly, the discussion focuses on the main findings derived from the design and scenario-based validation of the proposed framework. The analysis shows that the proposed architecture contributes in four main ways: it improves interoperability across heterogeneous Learning Management System (LMS) environments, integrates analytics and intelligent agents within a closed-loop workflow, incorporates generative artificial intelligence under pedagogical and governance constraints, and supports multiple categories of educational intervention through a unified modular design.

A first important finding is that the proposed framework improves LMS decoupling and interoperability compared with many existing intelligent learning solutions. In several previous works, adaptive functions remain strongly tied to a specific platform, tool, or plugin, which limits portability and long-term maintainability. In contrast, the proposed architecture separates the LMS hosting role from the intelligence layer and relies on standards such as Learning Tools Interoperability (LTI) 1.3, the Experience API (xAPI), cmi5, and Sharable Content Object Reference Model (SCORM) to ensure communication between the LMS and external intelligent services. This design reduces platform dependency and makes it possible to deploy the same adaptive logic across multiple LMS environments without modifying the LMS core. From an institutional perspective, this is a significant advantage because it supports reuse, extensibility, and more sustainable integration of smart learning services.

A second finding is that the proposed model offers a stronger integration between learning analytics and pedagogical action than many related architectures. Several previous studies have emphasized data collection, dashboards, or predictive analytics, but fewer have connected these components to a complete adaptive intervention cycle inside the LMS [32]. In the proposed framework, learner and teacher interactions are captured as

standardized traces, stored in a Learning Record Store, transformed into pedagogically relevant indicators, and then consumed by intelligent agents that generate contextualized interventions. This closed-loop organization constitutes an important contribution because it links observation, interpretation, decision-making, and action within one coherent architecture. In this sense, the framework goes beyond descriptive analytics and moves toward operational adaptation.

A third finding concerns the role of intelligent agents in structuring adaptive decision-making. The proposed framework defines a distributed set of agents with complementary pedagogical roles, including tutoring, assessment support, recommendation, monitoring, collaboration analysis, and learner modeling. Compared with narrower agent-based educational systems, the proposed architecture does not restrict intelligence to a single function. Instead, it supports multi-agent orchestration through asynchronous communication and shared analytics outputs. The inclusion of explicit rule-based logic, analytics-derived features, and optional machine learning inference also strengthens the technical soundness of the model. This means that the intelligent agents are not only conceptual entities, but are embedded in a structured decision process that can support explainable and context-aware interventions.

A fourth finding is that the integration of generative artificial intelligence is more pedagogically controlled than in many current educational AI solutions. In numerous existing approaches, generative artificial intelligence is introduced mainly as a standalone assistant or conversational interface. In contrast, the proposed framework positions generative services within a broader architecture governed by learner context, analytics-derived features, pedagogical objectives, and institutional rules. In addition, the model explicitly acknowledges risks related to hallucination and factual inconsistency and assumes the use of guardrail mechanisms such as prompt restriction, context grounding, pedagogical templates, and validation rules. This aspect is important because it addresses a central concern raised in the recent literature and by the reviewers, namely that generative artificial intelligence should not be integrated into educational settings without mechanisms that support reliability and pedagogical control.

The scenario-based validation also highlights the versatility of the proposed architecture. Scenario 1 shows that the framework can support early dropout-risk detection and re-engagement by linking engagement indicators to personalized interventions delivered directly within the LMS. Scenario 2 demonstrates fine-grained remediation after quiz failure through the combination of assessment traces, diagnosis, tutoring feedback, and targeted recommendations. Scenario 3 extends the framework toward teacher-facing analytics and grade return, which is important for institutional deployment because smart learning systems must serve not only learners but also instructors. Scenario 4 shows that the architecture can support collaborative learning by analyzing group interactions and delivering group-oriented or teacher-oriented feedback. Taken together, these four scenarios indicate that the same architectural principles can support individual, collaborative, learner-facing, and teacher-facing interventions within one coherent system.

When compared with representative related works, the proposed architecture shows several advantages. Unlike studies centered mainly on adaptive learning characteristics, the present work provides an explicit architectural model. Unlike analytics-focused studies, it includes agent-based orchestration and direct intervention delivery. Unlike LMS-integrated artificial intelligence assistants, it extends beyond a single assistant paradigm and supports a broader multi-agent ecosystem. Unlike function-specific recommendation or feedback systems, it is designed for heterogeneous LMS environments and incorporates standards-based interoperability as a central principle. Therefore, the novelty of this study lies not in the isolated use of one technology, but in the integration of interoperability standards, learning analytics, distributed intelligent agents, and generative artificial intelligence within a modular closed-loop smart learning architecture.

Despite these contributions, the study also has important limitations. First, the validation remains theoretical and scenario-based. Although this approach is appropriate for assessing functional completeness and architectural coherence at this stage, it does not provide empirical evidence regarding performance, latency, scalability, usability, or educational effectiveness. Second, the operational deployment of a distributed architecture combining analytics, intelligent agents, and generative artificial intelligence may introduce computational and governance challenges in real institutional settings. Third, although the framework includes conceptual safeguards for responsible artificial intelligence use, these mechanisms still need to be implemented and evaluated in authentic contexts. These limitations confirm that the present work should be understood as an architectural contribution and a foundation for future experimentation rather than as a fully validated deployment model.

Overall, the discussion confirms that the proposed framework provides a coherent, extensible, and interoperable contribution to smart learning research. Its main added value lies in the ability to connect standardized trace collection, learner modeling, intelligent agent orchestration, and pedagogically grounded interventions within a unified architecture that remains portable across heterogeneous LMS platforms. In this way, the study contributes not only to the conceptual design of next-generation smart learning environments but also to the definition of a reproducible architectural basis for future prototype development and empirical implementation.

VI. Conclusion

This study proposed an interoperable smart learning architecture designed to support adaptive and personalized learning across heterogeneous Learning Management System (LMS) environments. The work addressed the research gap identified in the literature by defining a modular framework that decouples intelligent services from the LMS while preserving standards-based interoperability. In this sense, the first objective of the study was achieved through the design of an architecture that separates the LMS hosting role from the intelligence layer and enables adaptive services to operate through interoperable protocols rather than through modifications of the LMS core.

The second objective of the study was to integrate learning analytics, intelligent agents, and generative artificial intelligence into a unified closed-loop adaptation process. The proposed framework achieved this by connecting trace collection, feature computation, learner modeling, agent-based orchestration, and intervention delivery within one coherent architecture. This integration represents one of the main contributions of the work because many existing approaches address these dimensions separately rather than as part of a coordinated educational ecosystem.

The third objective was to show how standardized learning traces can support both individual and collaborative pedagogical interventions. Through the four scenario-based validations, the study demonstrated that the same architectural logic can support early dropout-risk detection, targeted remediation after quiz failure, teacher-facing dashboards with grade return, and collaborative feedback for group learning situations. These scenarios highlight the functional completeness of the architecture and show its ability to support learner-facing, teacher-facing, individual, and collaborative services within the same framework.

The novelty of this work lies not in the isolated use of a single technology, but in the explicit integration of interoperability standards, learning analytics, distributed intelligent agents, and generative artificial intelligence within a modular and closed-loop smart learning architecture. Compared with narrower related works, the proposed framework places stronger emphasis on LMS independence, agent orchestration, pedagogically grounded analytics, and institutional portability across heterogeneous platforms. This gives the model a broader architectural scope and a stronger deployment perspective than many existing intelligent learning solutions.

From a scientific perspective, the study contributes a reproducible architectural foundation for smart learning research by bringing together research streams that are often treated separately. From a practical perspective, the framework offers institutions a structured basis for deploying adaptive services in existing LMS ecosystems while preserving governance, portability, and compatibility with standards-based infrastructures. In this way, the proposed model may support the future development of more scalable, flexible, and institutionally reliable smart learning environments.

At the same time, the study has important limitations. The validation remains theoretical and scenario-based, which means that the work does not yet provide empirical evidence regarding usability, performance, scalability, or educational effectiveness in authentic classroom settings. In addition, the implementation of intelligent agents and generative artificial intelligence in real institutional environments may raise technical, ethical, and governance-related challenges that require further investigation. These limitations indicate that the present study should be understood primarily as an architectural and conceptual contribution rather than a fully validated deployment model.

Future work should therefore focus on empirical implementation and evaluation in authentic educational contexts. This includes prototype development, experimentation in real LMS platforms, measurement of system performance and user experience, and assessment of the educational effectiveness of agent-based and generative artificial intelligence-supported interventions. Further research may also explore explainable and trust-aware agent behavior, more advanced multimodal learning analytics, and stronger governance mechanisms for privacy, ethics, and responsible artificial intelligence in smart learning systems.

Mapping Tourist Sentiments Through Lexicon-Based Analysis of Social Media Reviews: The Case of Salak Sibetan Agritourism

Paula Dewanti[1], Putu Adi Guna Permana[2], I Gusti Ayu Widari Upadani[3],

College of Science and Technology, Guimaras State University, Guimaras, Phillipines [5]

***Abstract*—Salak Sibetan, Bali's emblematic snake fruit cultivated in Sibetan Village, Karangasem, has gained increasing digital visibility through user-generated content across social media platforms. This study applies a bilingual lexicon-based sentiment analysis framework integrating Indonesian and English sentiment lexicons, explicit negation handling, domain-specific agritourism vocabulary, and a mean-based sentiment scoring function to classify 500 online reviews collected from Facebook, Instagram, Shopee, TikTok, and Twitter/X. The methodology adapts Indonesian and English lexicons with negation handling, domain-specific refinement for agritourism terminology, and mean-based scoring to improve neutrality discrimination. Results indicate an overall sentiment distribution of 40% positive, 40% neutral, and 20% negative. Positive reviews emphasize taste quality (*manis legit*, *renyah*, fresh) and cultural authenticity, while negative feedback highlights packaging issues, inconsistent quality, and pricing concerns. Image-centric platforms (Instagram and TikTok) exhibit higher proportions of positive sentiment emphasizing taste quality and authenticity, whereas transaction-oriented platforms (Shopee and Twitter/X) show more neutral and negative expressions related to logistics, packaging, and pricing. Beyond sentiment measurement, the study demonstrates how lexicon-based methods can capture platform-specific evaluative behavior within heritage agritourism contexts, offering methodological insights for multilingual sentiment analysis in low-resource domains and strategic implications for sustainable destination communication aligned with Sibetan's FAO GIAHS recognition.**

I. Introduction

Tourism is one of the most rapidly expanding sectors in Indonesia, contributing approximately 4.3% to the national GDP in 2022 [1]. Within this national context, Bali remains Indonesia's premier tourism destination, where agritourism has emerged as an important mechanism for rural economic development and cultural preservation. Among Bali's distinctive agricultural heritage areas, Sibetan Village in Karangasem Regency is widely recognized for the cultivation of Salak Sibetan (Salacca zalacca var. amboinensis), a snake fruit variety valued for its unique sweetness, texture, and cultural significance [2].

The growing influence of digital platforms such as Instagram, Facebook, TikTok, and e-commerce marketplaces like Shopee has fundamentally transformed how agritourism destinations and agricultural products are evaluated and promoted. User-Generated Content (UGC), including online reviews and social media posts, functions as electronic word-of-mouth that shapes visitor expectations, purchasing decisions, and destination image. In 2024, the Food and Agriculture Organization (FAO) designated the Salak Sibetan production system as a Globally Important Agricultural Heritage System (GIAHS), reinforcing its ecological and cultural value and strengthening its potential positioning as a heritage-based agritourism destination [3].

Sentiment analysis has been widely adopted in tourism and hospitality research to interpret large volumes of UGC and extract insights into visitor satisfaction, destination image, and service quality. Prior studies have applied sentiment analysis to hotels, urban destinations, and mass tourism attractions using both machine learning and lexicon-based approaches. However, important limitations remain in existing literature. First, agritourism, particularly heritage-based agricultural systems in Indonesia, has received far less analytical attention than urban or conventional tourism destinations. Second, many existing studies focus on monolingual datasets, despite the prevalence of bilingual and code-mixed Indonesian–English content on social media platforms. Third, cross-platform sentiment analyses are often presented descriptively, without sufficient consideration of how platform characteristics shape sentiment expression. This study addresses these gaps by applying a bilingual, domain-adapted lexicon-based sentiment framework across multiple social media and e-commerce platforms to examine how perceptions of Salak Sibetan agritourism differ by platform context.

This study seeks to explore how Salak Sibetan agritourism is perceived across multiple social media platforms by examining the dominant positive, neutral, and negative sentiments expressed in visitor and consumer narratives. It aims to: 1) apply a lexicon-based sentiment analysis approach to bilingual (Indonesian-English) reviews, 2) identify key sentiment patterns and recurring themes across platforms, 3) analyze platform-specific differences in sentiment expression, and 4) translate these insights into practical

recommendations for improving product quality, service delivery, and digital communication strategies.

The significance of this study is twofold. From an academic perspective, it extends sentiment analysis research to the underexplored domain of Indonesian heritage agritourism, demonstrating the suitability of lexicon-based methods for multilingual and low-resource contexts while highlighting the analytical significance of neutral sentiment. From a practical standpoint, the findings provide guidance for farmers, local communities, tourism authorities, and e-commerce sellers seeking to enhance visitor experiences, address quality concerns, and strengthen digital engagement for Salak Sibetan as a premium agritourism product.

II. Literature Review

A. Social Media and Agritourism

Social media has become a central arena for travelers and consumers to exchange real-time photos, narratives, and evaluations of agritourism products and experiences. This user-generated content drives electronic word-of-mouth, shaping information search, destination visibility, and purchasing intentions [4]. For agritourism settings such as Salak Sibetan, e-WOM not only communicates product attributes (taste, freshness, value) but also circulates stories about local culture and on-site experiences, thereby influencing perceptions of authenticity and community engagement. Positive reviews can strengthen brand salience and trust, whereas negative feedback may signal service gaps and operational risks for destination managers [5]. Fig. 1 shows the TikTok hashtag for Salak Sibetan.

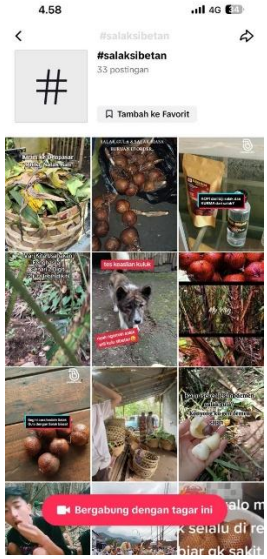

Fig. 1. TikTok Hashtag Salak Sibetan.

B. Sentiment Analysis for Tourism Analytics

Sentiment analysis provides a scalable means to interpret large volumes of UGC by classifying evaluative language into positive, neutral, or negative polarity. In tourism analytics, this approach has been widely used to extract strategic insights from large-scale UGC, enabling destination managers to understand collective visitor perceptions, as demonstrated in urban destination studies such as Barcelona [6]. Previous tourism applications have focused on general destinations or hospitality services using various computational approaches [7]. Lexicon-based methods offer interpretability and low-resource advantages for multilingual contexts, making them suitable for Indonesian-English mixed content common in social media [8]. Studies have demonstrated that lexicon-based approaches with negation handling and domain-specific refinement can effectively capture sentiment in Indonesian tourism reviews [9].

Research on sentiment analysis for agricultural products and agritourism remains limited. Pratiwi et al. [10] conducted lexicon-based sentiment analysis of social media reviews for floating markets in South Kalimantan, demonstrating the applicability of such methods to Indonesian heritage tourism contexts. Their findings highlighted the importance of neutral reviews in providing factual information and the value of cross-platform analysis for understanding different audience segments. In parallel, recent tourism studies have employed machine learning-based sentiment analysis of TripAdvisor reviews to uncover experiential patterns and visitor preferences, underscoring the growing role of online review platforms in tourism intelligence [11]. Destination-focused sentiment analysis has also been conducted using TripAdvisor data to model visitor experiences and perceptions, as illustrated by studies of heritage destinations such as Dubrovnik [12].

C. Salak Sibetan as Competitive Agritourism

Salak Sibetan, cultivated in Sibetan Village, Karangasem, is among Indonesia's most distinctive agritourism commodities. Its competitive advantage arises from a blend of agro-biodiversity, cultural heritage, and growing digital visibility [2]. The village hosts numerous salak varieties ($\geqslant 14$), including premium cultivars such as gula pasir, celebrated for unique sweetness and texture. This varietal richness and a five-strata agroforestry system embedded in local customary rules and Tri Hita Karana philosophy underpin both ecological resilience and visitor appeal [3]. Recent advances in smart agritourism demonstrate how digital marketing and information systems help rural destinations amplify reach, structure content, and convert interest into visits. Empirical work shows that UGC and e-WOM significantly influence destination image and tourist visit intention, particularly on platforms like Instagram, Google Reviews, and TikTok [11]. In Sibetan, government and community profiles highlight orchard experiences, salak tasting, salak-derived products (coffee, syrup, wine), and eco-cultural treks as core narratives increasingly promoted via social channels.

D. Research Gap and Contribution

This study addresses several gaps in existing literature. First, it provides the first comprehensive sentiment analysis specifically focused on Salak Sibetan agritourism across multiple social media platforms. Second, it employs a bilingual lexicon-based approach with domain-specific refinement for agritourism terminology, including taste descriptions, Salak varieties, and quality indicators. Third, it examines cross-platform differences in sentiment expression, comparing image-heavy platforms (Instagram, TikTok) with e-commerce (Shopee) and microblogging (Twitter/X) platforms. Fourth, it highlights the role of neutral reviews in providing credibility-

enhancing information about product origin, logistics, and practical visitor guidance. While recent studies have introduced advanced approaches such as aspect-based sentiment analysis and zero-shot learning for hospitality service enhancement [13], these methods often require substantial computational resources and annotated data, making them less suitable for low-resource agritourism contexts.

III. Research Methods

A. Research Design

This study employs a quantitative content analysis to examine user-generated content related to Salak Sibetan agritourism. The methodological workflow consists of five stages: data collection, preprocessing, sentiment classification, visualization, and validation. Each stage was designed to ensure analytical rigor, reproducibility, and alignment with established standards in computational tourism analytics [14].

B. Data Collection

The dataset comprised 500 online reviews collected from five widely used social media platforms: Facebook (106 reviews; 21.2%), Instagram (103; 20.6%), Shopee (100; 20.0%), TikTok (103; 20.6%), and Twitter/X (88; 17.6%). All reviews were written in Indonesian, reflecting feedback from local and domestic visitors and consumers. The average review length was 28.58 words. Fig. 2 shows an example review from a TikTok user.

Fig. 2. Example of TikTok User.

Reviews were included if they contained at least one coherent sentence describing Salak Sibetan products, experiences, or purchase interactions. Data were collected using keyword searches for "salak sibetan," "salak sibetan karangasem," and "salak bali" across platform search functions during October-December 2024.

C. Preprocessing

The preprocessing stage consisted of several steps designed to prepare the review text for analysis. The process began with text normalization, including converting all text to lowercase, applying Unicode standardization, and removing unwanted noise such as stray symbols or characters. After that, stop-word removal and selective slang expansion were performed using bilingual stop-word lists to ensure clearer semantic interpretation [15]. Stemming or lemmatization was applied, when necessary, particularly for generating keyword-based summaries. As a final step, manual checks were conducted to confirm that the preprocessing workflow preserved the original meaning of the content.

D. Sentiment Classification

For sentiment analysis, a lexicon-based approach was applied to categorize reviews into positive, neutral, or negative sentiments. The study adapted two existing lexicons: InSet for Indonesian and NRC for English, with domain-specific refinement adding tourism and agritourism terminology such as taste descriptions (manis legit, renyah, sepet), salak varieties (gula pasir), quality indicators (fresh, lembek, memar), and logistics terms (packing, pengiriman). Each token was assigned a polarity score (+1, -1, or 0), with negation handling implemented for words preceded by terms such as tidak, bukan, or not. The review's overall sentiment was determined by the aggregate mean score of its tokens, with thresholds: >0.1 positive, < -0.1 negative, and between -0.1 and 0.1 neutral. Mean-based scoring was selected over summation to improve neutrality discrimination and reduce bias from review length [16].

$$S(r)=\frac{1}{n}\sum_{i=1}^{n} w_i \quad (1)$$

Variable Description:

- S(r): The total sentiment score of review r.
- n: The total number of tokens (words) in the review that match entries in the sentiment lexicon.
- w_i: The polarity value of the i-th word, where +1 indicates positive sentiment, −1 indicates negative sentiment, and 0 indicates neutral sentiment.

E. Validation

To ensure the reliability of the sentiment classification, a manual validation procedure was conducted. A subset of 50 reviews (10% of dataset) was independently annotated by two human coders with expertise in tourism communication and text analysis. The degree of agreement between the coders was assessed using Cohen's Kappa, which yielded a coefficient of 0.82, indicating strong inter-rater reliability. This validation step confirmed that the lexicon-based model performed consistently with human judgment, thereby supporting the credibility of the analytical results.

F. Data Analysis

The classified sentiment outcomes were subsequently examined through descriptive and visual analytics. Bar charts and pie charts were produced to illustrate the distribution of sentiment categories. Platform-based differences were analyzed using comparative tables. Keyword frequency analysis identified recurring terms in each sentiment category, highlighting dominant themes and concerns.

IV. Results and Discussion

A. Dataset Characteristics

The dataset comprised 500 online reviews distributed across five platforms, as shown in Table I. Facebook contributed the largest share (21.2%), followed by Instagram (20.6%), TikTok (20.6%), Shopee (20.0%), and Twitter/X (17.6%). Average review length was consistent across platforms, ranging from

27.10 words on Instagram to 30.30 words on Twitter/X, indicating similar levels of detail in user-generated content regardless of platform. Fig. 3 shows the sentiment distribution across five social media platforms.

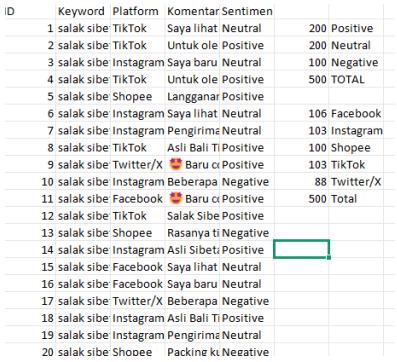

Fig. 3. Sentiment distribution across five social media platforms.

TABLE I. DATASET CHARACTERISTICS BY PLATFORM

Platform	Reviews	Percentage	Avg. Length (words)
Facebook	106	21.2%	29.40
Instagram	103	20.6%	27.10
Shopee	100	20.0%	28.20
TikTok	103	20.6%	27.90
Twitter/X	88	17.6%	30.30
Total	**500**	**100%**	**28.58**

B. Overall Sentiment Distribution

Sentiment classification divided the dataset into three categories: 200 reviews (40%) positive, 200 reviews (40%) neutral, and 100 reviews (20%) negative, as presented in Table II. The dominance of positive sentiment indicates that Salak Sibetan is generally well-received by consumers across multiple platforms. At the same time, the equally high proportion of neutral reviews suggests that a substantial number of users provide objective or descriptive comments, focusing on factual product information rather than emotional expressions. The presence of 20% negative reviews highlights areas that may require managerial attention, as unfavorable consumer experiences shared online can significantly influence future purchasing behavior and digital engagement.

TABLE II. OVERALL SENTIMENT DISTRIBUTION

Sentiment	Frequency	Percentage
Positive	200	40%
Neutral	200	40%
Negative	100	20%
Total	500	100%

C. Sentiment by Platform

The sentiment analysis was disaggregated to compare results across the five platforms, revealing important differences in how consumers express their perceptions, shaped by the nature of each platform. Table III presents the sentiment distribution by platform.

TABLE III. SENTIMENT DISTRIBUTION BY PLATFORM

Platform	Positive	Neutral	Negative	Total
Facebook	42 (39.6%)	44 (41.5%)	20 (18.9%)	106
Instagram	47 (45.6%)	36 (35.0%)	20 (19.4%)	103
Shopee	38 (38.0%)	42 (42.0%)	20 (20.0%)	100
TikTok	44 (42.7%)	41 (39.8%)	18 (17.5%)	103
Twitter/X	29 (33.0%)	37 (42.0%)	22 (25.0%)	88
Total	**200**	**200**	**100**	**500**

Instagram shows the highest proportion of positive sentiment (45.6%), likely because visual platforms encourage sharing of aesthetically pleasing product photos and positive experiences. TikTok follows closely with 42.7% positive, reflecting the platform's trend-driven nature where users share recommendations and product highlights. Shopee exhibits balanced sentiment with 38% positive, 42% neutral, and 20% negative, characteristic of e-commerce platforms where consumers provide both praise and critical feedback about product quality and delivery.

Twitter/X shows the lowest positive sentiment (33.0%) and highest negative sentiment (25.0%), possibly due to the platform's use for expressing complaints and seeking resolution. The high neutral proportion on Twitter/X (42.0%) and Shopee (42.0%) indicates that users on these platforms frequently share factual information about product availability, pricing, and logistics.

D. Keyword and Thematic Analysis

Keyword analysis identified recurring terms in each sentiment category, revealing dominant themes in consumer discourse about Salak Sibetan. Positive reviews emphasized words such as manis legit (sweet), renyah (crispy), fresh, recommended, top, juara (champion), kriuk (crunchy), and padat (dense). Many highlighted the distinctive taste quality of Salak Sibetan, particularly the gula pasir variety, and its suitability as a souvenir (oleh-oleh) from East Bali. Examples include: "Asli Bali Timur, salak Sibetan ini top—tidak sepet, renyah" (Authentic East Bali, this Salak Sibetan is top—not astringent, crispy) and "Untuk oleh-oleh Bali Timur, salak Sibetan Karangasem ini juara sih" (For East Bali souvenirs, this Salak Sibetan Karangasem is champion). Neutral reviews commonly contained words such as asal (origin), Desa Sibetan, Karangasem, Bali Timur, pengiriman (delivery), jadwal (schedule), pertama kali (first time), and cari (search). These were descriptive and provided practical information about product origin, delivery experiences, and initial encounters. Examples include: "Salak Sibetan itu berasal dari Desa Sibetan" (Salak Sibetan comes from Sibetan Village) and "Saya baru pertama kali mencoba salak Sibetan Karangasem" (I tried Salak Sibetan Karangasem for the first time).

Negative reviews frequently included words like packing (packaging), *lembek* (soggy), *memar* (bruised), *rusak* (damaged), *kurang manis* (less sweet), *sepet* (astringent), and *harga* (price). These highlight operational problems such as inadequate packaging during shipping, inconsistent fruit quality, and pricing concerns. Examples include: "*Packing kurang tebal, jadi ada buah yang rusak*" (Packaging was not thick enough, so

some fruits were damaged) and "*Harga salak sibetan karangasem menurut saya agak mahal*" (In my opinion, the price of Salak Sibetan Karangasem is somewhat expensive).

E. Interpretation of Neutral Reviews

Neutral reviews, which accounted for 40% of the dataset, primarily contained factual and descriptive information rather than emotional expressions. Visitors and consumers often mentioned elements such as product origin, first-time experiences, delivery schedules, or general observations without attaching strong judgments. For instance, one reviewer wrote, "*Saya lihat banyak yang cari salak sibetan karangasem akhir-akhir ini*" (I see many people searching for Salak Sibetan Karangasem lately), while another stated, "*Pengiriman salak Sibetan Karangasem sampai sesuai jadwal*" (Delivery of Salak Sibetan Karangasem arrived on schedule). These examples show how neutral reviews serve as practical guides that help potential buyers understand product availability and logistics.

The relatively high proportion of neutral reviews contributes to the credibility and authenticity of online platforms. While positive and negative reviews reflect emotions, neutral reviews provide balance by offering straightforward accounts of products and experiences. Their stability across platforms indicates that they function as a baseline narrative, consistently delivering reliable context regardless of variations in sentiment trends. From a managerial perspective, these reviews highlight recurring topics about origin and logistics, signaling that clearer communication in promotional materials could enhance consumer understanding and trust.

F. Negative Sentiment and Service Gaps

Negative reviews, although representing only 20% of the dataset, carry significant weight in shaping overall perception of Salak Sibetan products. These reviews frequently pointed out recurring problems such as inadequate packaging leading to damaged fruit, inconsistent taste quality, and perceptions of high prices. For example, one consumer noted, "Packing kurang rapi, jadi ada buah yang memar" (Packaging was not neat, so some fruits were bruised), while another commented, "*Rasanya kurang istimewa, tidak sesuai yang saya bayangkan*" (The taste was less special, not as I imagined). Such feedback highlights those operational issues, particularly in e-commerce fulfillment, are the main drivers of dissatisfaction.

From a managerial perspective, these negative reviews reveal critical service gaps that demand immediate attention. Packaging quality must be prioritized to preserve product condition during shipping, while quality control measures should ensure consistent taste and freshness. Addressing concerns about pricing transparency is also essential, as perceptions of high prices without corresponding quality can damage trust and deter repeat purchases. If left unresolved, these issues risk eroding the long-term competitiveness of Salak Sibetan in both e-commerce and agritourism markets.

G. Social Media as Double-Edged Sword

Social media operates as a dual-impact mechanism in shaping the digital reputation of Salak Sibetan agritourism. On the positive side, large volumes of favorable and neutral user-generated content function as organic promotion. Reviews and images emphasizing taste quality, authenticity, and suitability as souvenirs amplify product visibility across platforms such as Instagram, TikTok, Shopee, and Facebook. These narratives significantly influence consumer purchasing decisions and act as low-cost digital marketing channels [17].

Conversely, negative reviews spread rapidly and can harm reputation if ignored. Complaints about packaging damage, inconsistent quality, and pricing easily circulate online, discouraging potential buyers. Continuous monitoring through automated sentiment analysis enables managers to balance positive promotion with early warnings, ensuring adaptive strategies and sustainable competitiveness in digital agritourism.

H. Managerial Implications

The findings of this study provide actionable insights for integrating sentiment analysis into agritourism and e-commerce management. First, the predominance of positive reviews about taste quality and authenticity suggests opportunities for leveraging data-driven promotional strategies. Destination managers and online sellers can amplify user-generated narratives across social media platforms, particularly emphasizing the GIAHS recognition and cultural heritage aspects that differentiate Salak Sibetan from ordinary snake fruit. Second, the recurrent negative sentiments regarding packaging, inconsistent quality, and pricing indicate specific service quality gaps that can be addressed using data-informed decision-making. Sellers should invest in better packaging materials, implement quality control procedures, and communicate transparently about seasonal price variations. Third, the high proportion of neutral reviews highlights the importance of providing clear factual information about product origin, delivery schedules, and harvesting seasons in promotional materials. Fourth, the adoption of sentiment monitoring tools would allow sellers and destination managers to detect emerging issues proactively and respond to customer concerns. This approach demonstrates how computational sentiment analysis can function as a decision-support mechanism, positioning heritage products like Salak Sibetan as benchmarks for quality in Indonesian agritourism.

I. Theoretical Implications

This study contributes theoretically by extending sentiment analysis to agritourism and heritage food products in Indonesia. Using lexicon-based methods, it demonstrates how computational models capture cultural, quality, and logistics dynamics in consumer discourse. Consistent with previous research on online destination image, positive and negative narratives shared through social media significantly influence tourist engagement and perception, reinforcing the strategic importance of monitoring UGC sentiment [18]. The significant share of neutral reviews reveals that e-WOM for agricultural products is both emotional and informational, with neutral content serving as a stabilizing factor for credibility. Additionally, differences identified across platforms underline the necessity of adopting cross-platform approaches in sentiment analysis. The contrast between visual platforms (Instagram, TikTok) showing higher positive sentiment and e-commerce platforms (Shopee) showing balanced expressions indicates that platform characteristics shape sentiment expression. These insights refine sentiment analysis theory by

emphasizing contextual and platform-specific factors in agritourism-focused applications

V. Conclusions and Future Work

Rather than merely quantifying sentiment polarity, this study demonstrates how lexicon-based sentiment analysis can function as an interpretable analytical tool for heritage agritourism contexts characterized by multilingual, platform-diverse user-generated content. The findings illustrate that sentiment expression is not uniform across platforms but shaped by platform affordances and user intent, underscoring the importance of cross-platform designs in sentiment analysis research. Moreover, the substantial presence of neutral sentiment reveals the informational dimension of electronic word-of-mouth, which plays a critical yet often overlooked role in credibility building and destination understanding.

This study has several limitations that should be acknowledged. The dataset was restricted to Indonesian-language reviews, which may not represent perceptions of international visitors. The lexicon-based method, although transparent and suitable for multilingual data, may not fully capture nuanced expressions such as sarcasm or implicit sentiment. The analysis also relied solely on textual content, excluding visual cues that influence consumer evaluations on image-heavy platforms. Furthermore, the cross-sectional design does not capture temporal sentiment shifts across harvest seasons. Future research may extend this study by incorporating larger and more diverse datasets from additional platforms, such as Google Reviews and TripAdvisor, and by integrating advanced techniques, including aspect-based sentiment analysis or zero-shot sentiment models, to capture more nuanced experiential dimensions beyond the capabilities of lexicon-based approaches. Employing advanced machine learning methods, including transformer-based deep learning models such as IndoBERT, could improve classification accuracy and capture nuanced emotional expressions beyond lexicon constraints. Longitudinal analyses tracking sentiments across harvest seasons would enable more robust trend detection, while cross-cultural comparative studies could examine how international visitors perceive Salak Sibetan compared to domestic consumers. Finally, incorporating multimodal analysis including images and videos from platforms like Instagram and TikTok would provide a richer understanding of how visual content shapes product perceptions in agritourism.

Optimization of Access Point Location Using an Integer Programming Model

Joan Marie M. Panes, Marilou O. Espina, Jovelin M. Lapates
Bukidnon State University, Malaybalay City, Bukidnon, Philippines

***Abstract*—To address the increasing demand for reliable connectivity in educational environments, strategic access point (AP) placement is necessary to support coverage and bandwidth requirements while controlling installation cost. This study applies a binary integer programming model to the third floor of the College of Technologies at Bukidnon State University in order to determine a feasible minimum-cost AP configuration under site-specific conditions. The model incorporates coverage, bandwidth, range, and AP-count constraints, together with demand estimates based on expected simultaneous network use. Results show that the optimization framework can identify a feasible AP-to-area assignment that satisfies the imposed constraints within the study site. Because the nominal AP ranges are large relative to the dimensions of the floor, the resulting configuration is influenced more strongly by installation cost and bandwidth feasibility than by range limitation alone. The findings show the practical value of binary integer programming as a structured planning tool for access point placement in bounded indoor environments. While the resulting configuration is specific to the physical, technical, and cost conditions of the study area, the modeling approach may be applied to other institutional settings through appropriate parameter recalibration. A post-deployment wireless site survey is recommended to verify actual field performance and identify any remaining coverage gaps.**

***Keywords*—Access points (APs); optimization; wireless network; coverage; integer programming**

I. Introduction

Reliable Wi-Fi service in educational buildings depends on effective access point placement that can satisfy coverage and bandwidth needs without unnecessary installation cost. Bukidnon State University's College of Technologies Annex B Campus already has a documented network design proposal, which establishes the institutional context for wireless planning in the same setting [1], [2].

In [1], the authors discuss wireless propagation across diverse environments and explain how physical barriers affect signal attenuation. In [3] and [4], the authors also examine the effects of buildings, vegetation, and terrain on signal strength and coverage, while [5] analyzes diffraction, reflection, and scattering in obstacle-rich environments. In [6], [7], and [8], the authors discuss applications of linear programming and the simplex algorithm in optimization, while [9] and [10] address path loss modeling. In [11], the authors examine user density in wireless mesh networks, [12] compares propagation across the 2.4 GHz and 5 GHz bands, [13] and [14] analyze broader coverage models, and [15] and [16] discuss deployment cost considerations.

Designing a network requires careful consideration of several factors. In [17], the authors emphasize the importance of determining the optimum number of APs for reliable performance in wireless communication systems. Indoor studies and optimization work show that adequate WLAN coverage can be achieved with a minimal number of strategically placed APs ([18]; [19]). However, determining the number and optimal placement of APs in indoor or outdoor environments is challenging. Effective design must account for adequate coverage, minimum signal strength at all nodes, required bandwidth, and the presence of obstructions, reflections, and signal interference. Such a design demands proper modeling and formulation of the problem as an optimization task with multiple constraints.

Recent WLAN planning continues to treat AP deployment as a constrained optimization problem where placement and configuration determine coverage quality, interference risk, and total deployment cost [20].

Genetic Algorithms (GA) remain used in Wi-Fi AP deployment problems because they can search large, discrete location spaces using fitness-driven evolution [22]. However, GA can be computationally demanding because it repeatedly evaluates a population of candidate solutions across many generations [23].

Particle Swarm Optimization (PSO) is also applied to indoor AP placement, including binary PSO variants that select AP locations under deployment constraints [24]. PSO is often preferred for its simple implementation and relatively few parameters to tune ([25]; [26]). Despite this, PSO can suffer from local-optima trapping and loss of swarm diversity, which can reduce solution quality on complex search spaces [25].

Integer programming remains a strong method for AP placement because it supports binary site-selection decisions and explicit constraints for coverage, bandwidth, and cost [27]. Recent work also combines placement with configuration decisions such as channel assignment and transmit power within ILP-based formulations [29]. Although the solve time increases as problem size grows, integer programming can produce optimal solutions for moderate-sized deployment instances [27].

This study applies a binary integer programming model to the third floor of the College of Technologies at Bukidnon State University. The resulting AP configuration is specific to the floor layout, candidate installation sites, AP specifications, user-demand assumptions, and installation costs used in the model.

Recent WLAN planning research formulates indoor AP deployment as a binary linear program that jointly selects AP count, candidate locations, and emission channels to satisfy coverage requirements while controlling infrastructure cost [21]. Joint AP placement and channel assignment can also be expressed as an integer linear program that incorporates power tuning and partially overlapping channels to manage interference and avoid costly post-deployment adjustments [29]. Wireless Internet access planning on campuses also fits classic facility-location structure, with maximal covering models used to reconfigure access point sites to improve service quality and reduce operating costs [30].

Related router siting problems in mesh networks use mixed-integer linear programming variants of the p-median model to minimize the number of deployed routers under coverage-radius constraints [31]. Cellular network design similarly applies mixed-integer programming to choose base-station locations that minimize installation and operating costs under capacity and QoS constraints while computing path loss via propagation modeling [32]. These recent formulations support integer programming as a defensible core method for selecting AP locations under explicit coverage, cost, and propagation constraints [21].

Existing studies have examined AP placement through integer programming, genetic algorithms, particle swarm optimization, and hybrid methods under various coverage and configuration constraints. The present study focuses more narrowly on a site-specific minimum-cost formulation for a bounded university floor, using explicit coverage, bandwidth, range, and AP-count constraints.

A. Basic Concepts

- Wi-Fi refers to a family of wireless local area network (WLAN) technologies defined by the IEEE 802.11 standards. It enables devices such as desktop and laptop computers, smartphones, wearables, printers, and cameras to connect to a local network and access the Internet without physical cabling, typically within a limited coverage area.
- Wide area network (WAN) is a telecommunications network that links servers and end-user devices across large geographic distances, ranging from hundreds to thousands of kilometers, often by interconnecting multiple local or metropolitan networks.
- Local area network (LAN) is a telecommunications network that connects servers and end-user devices within a limited geographic area, typically within a room, building, or campus, and usually within about one kilometer.
- Access point (AP) is a network device that provides Wi-Fi connectivity, allowing wireless clients to join a wired network. In many deployments, the AP connects by Ethernet to upstream equipment such as a switch and router, which then provides access to local network services and the Internet. Some products combine AP and router functions in a single unit, and some broadband gateways (modem-router devices) also include built-in Wi-Fi, effectively serving as the access point. In larger organizations, multiple APs are installed across the site to extend coverage so users can connect to the same network from different areas.
- Routers receive and transmit data through computer networks. By sending data packets to their intended IP addresses, it manages traffic between different networks and permits several devices to share an Internet connection.
- Bandwidth is the maximum data speed that a network connection can support. Greater bandwidth suggests a higher capacity, but it doesn't always translate into better performance.

II. Objectives of the Study

The study aims to determine an access point configuration for the third floor of the College of Technologies that satisfies coverage and bandwidth requirements while minimizing installation cost under defined constraints. Specifically, it seeks to:

1) Assess the existing AP locations of a given network in terms of:

a) Coverage quality (minimal path loss)

b) Model type (number of users, bandwidth (2.4 or 5G, area of coverage), Environment type (indoor or outdoor), Obstacle type, and

c) Cost metrics (installation cost per unit, fiber optic cable length cost).

2) Design an integer programming model to identify optimal AP locations, specifically addressing:

a) Coverage satisfaction

b) Cost minimization

c) Bandwidth feasibility

III. Methodology

This study is based on the existing access point (AP) locations on the third floor of the College of Technologies (COT) at Bukidnon State University, as reflected in Fig. 1.

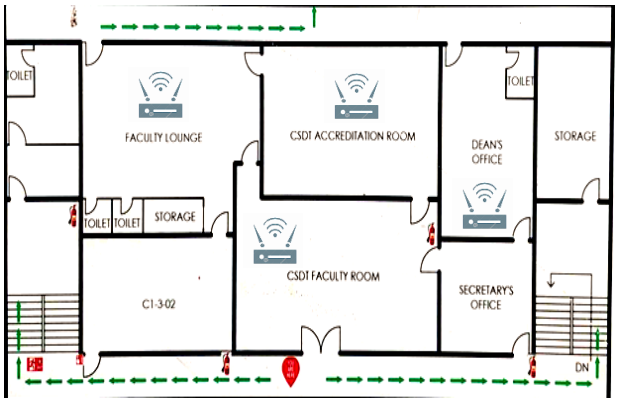

Fig. 1. Floor plan of the COT 3rd floor.

Fig. 1 presents the third-floor layout of the College of Technologies, which served as the spatial basis for identifying candidate AP locations, service areas, and AP-to-area distances

used in the optimization model. Because the floor layout, AP specifications, demand assumptions, and installation costs are site-specific, the resulting configuration should also be interpreted as site-specific.

Fig. 2 shows the existing network topology of the COT 3rd floor, indicating the current access points and the offices they serve within the study site. Together, Fig. 1 and Fig. 2 provide the spatial and network context used in formulating the optimization model.

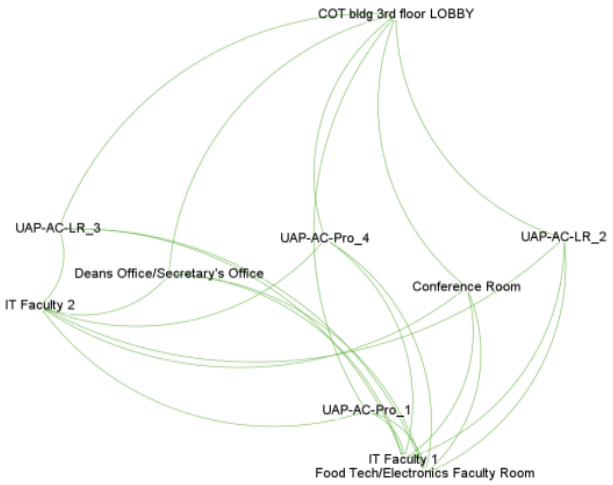

Fig. 2. COT 3rd floor offices served by 4 APs.

Table I provides an overview of four APs at the COT, detailing their locations, user coverage, specifications, unit costs, and cable distances from the switch used in the computation of installation cost. The network infrastructure utilizes Cat 6 cables, priced at Php 35 per meter, to support data transmission rates of up to 10 Gbps from the switch, with 1 Gbps allocated per access point (AP). Each AP offers dual-band operation with maximum data rates of 450 Mbps on the 2.4 GHz frequency and 867 Mbps on the 5 GHz frequency. Faculty, personnel, and students are limited to 60 Mbps, 40 Mbps, and 20 Mbps per user per device, respectively, with each AP capable of handling up to 175 connections simultaneously (70% of 250).

A. Optimization Method

This study formulates the access point placement problem as a binary integer programming model. The model determines which access points should be installed and which service areas should be assigned to the installed access points, subject to coverage, bandwidth, range, and installation limits. The objective is to minimize the total installation cost while ensuring that all required service areas are served within the defined constraints.

Let $i \in I$ denote the set of candidate access points and $j \in J$ denote the set of service areas.

B. Objective Function

The objective of the model is to minimize the total installation cost of the selected access points:

$$\text{Minimize } z = \sum_{i \in I} C_i x_i \quad (1)$$

1) Decision Variables

$$X_i = \begin{cases} 1, \text{ if access point } i \text{ is installed} \\ 0, \text{ otherwise} \end{cases}$$

$$Y_{ij} = \begin{cases} 1, \text{ if area } j \text{ is served by access point } i \\ 0, \text{ otherwise} \end{cases}$$

2) Parameters

C_i : total installation cost of access point i, consisting of the unit cost of the AP and the cable cost from the switch to the AP location

r_i : coverage range of access point i

$d_{i,j}$: distance between access point i and area j

B_i : maximum bandwidth capacity of access point i

U_j : total bandwidth demand of users in area j

L : maximum number of access points allowed for installation

$$a_{ij} = \begin{cases} 1, \text{ if } d_{ij} \le r_i \\ 0, \text{ otherwise} \end{cases}$$

where,

a_{ij} indicates whether service area j lies within the allowable range of access point i.

The attenuation-adjusted broadcast value for each AP-to-area pair was computed by combining the nominal broadcast value of the access point with an attenuation term based on distance and wall barriers:

$$P_{ij}^{(2.4)} = B_i^{(2.4)} + \left[L_0^{(2.4)} + 10n \log_{10}\left(\frac{d_{ij}}{d_0}\right) + N_{iJ} W_{2.4} \right] \quad (2)$$

$$P_{ij}^{(5)} = B_i^{(5)} + \left[L_0^{(5)} + 10n \log_{10}\left(\frac{d_{ij}}{d_0}\right) + N_{iJ} W_5 \right] \quad (3)$$

TABLE I. EXISTING AP LOCATIONS

AP	AP Current Location	Network Connected	AP Model/Type	Transmission Frequency	Range	Environment Type	Cost of AP	Distance of AP from switch(m)
1	COT 3rd Floor Lobby	Student, Faculty, Personnel	UAP-AC-Pro	5 GHz and 2.4GHz	up to 122m	Indoor	Php 12,100.00	20.92
2	COT Conference Room	Student, Faculty	UAP-AC-Lite	5 GHz and 2.4GHz	up to 91 m	Indoor	Php 9,000.00	43.6
3	COT Food Tech Faculty	Student, Faculty, Personnel	UAP-AC-LR	5 GHz and 2.4GHz	up to 183 m	Indoor	Php 14,000.00	32.75
4	COT IT Faculty	Faculty	UAP-AC-LR	5 GHz and 2.4GHz	up to 183 m	Indoor	Php 14,000.00	24.49

where, $B_i^{(2..4)}$ and $B_i^{(5)}$ are the nominal broadcast values of access point i for the 2.4 GHz and 5 GHz bands, $L_0^{(2.4)}$ and $L_0^{(5)}$ are the reference-loss constants, n is the path-loss exponent, d_{ij} is the distance between access point *i* and service area *j*, d_0 is the reference distance, $N_{i,j}$ is the number of wall barriers between access point *i* and service area *j*, and $W_{2.4}$ and W_5 are the attenuation values assigned per wall barrier for the 2.4 GHz and 5 GHz bands, respectively.

The attenuation-related calculations followed standard indoor radio-planning principles, with Recommendation ITU-R P.1238 included as a relevant reference for indoor radiocommunication system planning [28]. The propagation analysis incorporated both distance-related attenuation and barrier-related attenuation between each access point and service area. The resulting attenuation-adjusted values were used as supporting indicators in interpreting AP-to-area relationships within the study site.

The total bandwidth demand for each service area was estimated from the number of students, faculty members, and personnel assigned to the area, their corresponding per-user bandwidth allowances, and a simultaneous-use factor representing the proportion of users expected to be active on the network at the same time. Thus:

$$U_j = \tau_j(20S_j + 60F_j + 40P_j) \quad (4)$$

where, S_j, F_j, and P_j represent the number of students, faculty members, and personnel in service area *j*, respectively; and τ_j denotes the simultaneous-use factor for area *j*.

The simultaneous-use factor τ_j represents the proportion of users in service area *j* expected to be active on the network at the same time. This factor was used to estimate concurrent service demand rather than assuming that all assigned users would simultaneously consume their full bandwidth allowance. In this study, τ_j was assigned according to the expected activity level of each area, with lower values used for transitional or administrative spaces and higher values used for high-concurrency spaces such as the Conference Room. This approach is consistent with WLAN capacity-planning guidance that bases demand on expected active users and connections rather than total assigned occupancy.

For the present study, the simultaneous-use factor was set at 0.30 for the lobby, 0.80 for the Conference Room, 0.50 for faculty rooms, and 0.40 for the Dean's Office/Secretary's Office.

The total installation cost for each access point was computed as the sum of the AP unit cost and the cable cost from the switch to the AP location. Thus:

$$C_i = A_i + 35L_i \quad (5)$$

where, A_i is the unit cost of access point *i*, L_i is the cable length in meters from the switch to the AP location, and 35 represents the cable cost per meter in Philippine pesos at the time of the conduct of this study.

3) Constraints: The following constraints are imposed in minimizing access point placement.

a) Coverage constraint: Each area j must be assigned to at least one access point within its range:

$$\sum_{i\in I} Y_{ij} \geq 1, \forall j \in J \quad (6)$$

b) AP selection constraint: An area j can only be served by access point i if access point i is installed:

$$Y_{ij} \leq X_i, \forall i \in I, \forall j \in J \quad (7)$$

c) Bandwidth constraint: The total bandwidth demand assigned to access point i must not exceed its bandwidth capacity:

$$\sum_{(j\in J)} U_j Y_{ij} \leq B_i X_i, \forall i \in I \quad (8)$$

d) Range constraint: Access point i can only serve area j if area j lies within its coverage range:

$$Y_{ij} \leq a_{ij}, \forall i \in I, \forall j \in J \quad (9)$$

e) AP count constraint: The total number of installed access points must not exceed the allowable limit:

$$\sum_{i\in I} X_i \leq L \quad (10)$$

f) Binary restriction:

$$X_i \in \{0,1\}, \; Y_{ij} \in \{0,1\} \quad (11)$$

This formulation provides the basis for selecting access point locations that satisfy the required service coverage and bandwidth demand while minimizing total installation cost within the defined study constraints.

C. Solution Procedure

The integer programming model was implemented in Microsoft Excel Solver. The objective cell was set to minimize the total installation cost, and the changing variable cells corresponded to the binary decision variables for AP installation and AP-to-area assignment. The model was solved using the Simplex LP method with binary restrictions imposed on X_i and Y_{ij}.

IV. Results

Under the formulated binary integer programming model and the specified Excel Solver settings, Microsoft Excel Solver produced a feasible minimum-cost AP assignment for the evaluated service areas of the COT third floor. The final Solver run required 2.35 seconds, and the resulting solution was accepted in this study as the optimal solution for the study instance. The evaluated service areas included the COT third-floor lobby, Conference Room, Food Tech/Electronics Faculty Room, IT Faculty 1, IT Faculty 2, and the Dean's Office/Secretary's Office.

The final solution assigns binary values to the decision variables X_i and Y_{ij}, consistent with the binary integer programming formulation of the study. In this model, X_i=1 indicates that access point i is selected in the final solution, whereas X_i=0 indicates that it is not selected. Similarly, Y_{ij}=1 indicates that service area j is assigned to access point i, whereas Y_{ij}=0 indicates that no such assignment is made. These values were generated by the Solver and form the basis for interpreting the final AP-selection and AP-assignment pattern.

Table II presents the evaluated AP-to-area assignments under the optimization model. The table shows that all evaluated AP-area pairs satisfy the coverage-feasibility condition. This indicates that, for the present study site, all candidate access points are within the allowable range of the evaluated service areas under the specified model assumptions. As a result, the range condition operates as a general feasibility requirement rather than as the principal factor distinguishing selected from unselected AP-area pairings.

Because all candidate AP-area relationships are feasible in terms of range, the differentiating output of the model is reflected in the Solver-generated binary variables X_i and Y_{ij}. The values of these variables identify which access points were retained in the final solution and which AP-area assignments were selected after the cost, bandwidth, and AP-count constraints were applied. In this sense, Table II reports not only physical feasibility but also the discrete decisions made by the optimization model under the imposed constraints.

TABLE II. EVALUATION OF AP-TO-AREA ASSIGNMENTS UNDER THE OPTIMIZATION MODEL

V. DISCUSSION

The results show that the final AP configuration must be interpreted mainly through the Solver-generated binary variables X_i and Y_{ij}. Since all evaluated AP-area pairs satisfy the coverage-feasibility condition, the selected pattern of X_i and Y_{ij} values should be interpreted as the result of constrained optimization among feasible alternatives rather than as a consequence of range exclusion.

Table II shows that all evaluated AP-to-area pairs satisfy the coverage-feasibility condition. This indicates that the candidate access points are within the allowable range of the evaluated service areas under the assumptions of the study. Under this condition, range functions mainly as a feasibility requirement and does not strongly differentiate among candidate assignments. The final configuration should therefore be interpreted as a constrained selection among feasible alternatives rather than as an outcome driven primarily by distance exclusion.

The selected pattern of X_i and Y_{ij} values further indicates that the optimization process filtered feasible options and retained only those selections and assignments that satisfied the imposed constraints at minimum total installation cost. In this way, a value of 1 reflects a selected decision in the final solution, while a value of 0 reflects a feasible option that was not retained by the Solver under the defined optimization criteria.

Because the nominal AP ranges are large relative to the dimensions of the study site, installation cost and bandwidth feasibility exert a stronger influence on the final AP assignment pattern than range limitation alone. This supports the interpretation that the binary integer programming model is useful as a structured planning tool for identifying a feasible minimum-cost AP configuration in a bounded indoor environment. At the same time, the findings should be read within the limits of the present formulation and site conditions.

The present study applies the binary integer programming model under a single set of site-specific assumptions for user demand, AP range, and installation cost. Accordingly, the resulting configuration should be interpreted as the optimal solution for the defined study instance rather than as a robustness-tested solution across multiple scenarios. This study does not include scenario-based analysis under varying user density, coverage-radius assumptions, or budget constraints. As a result, the discussion of model sensitivity is limited to literature-supported expectations and to the recognition that different parameter settings may produce different feasible configurations in future applications of the model.

VI. CONCLUSION

The study shows that binary integer programming can be applied as a structured approach to access point placement on the third floor of the College of Technologies at Bukidnon State University. Under the defined assumptions and constraints, the model identified a feasible minimum-cost AP configuration that satisfied the required coverage and bandwidth conditions of the study area.

The results indicate that all evaluated AP-to-area pairs were range-feasible under the specified model assumptions. Consequently, the final configuration was influenced more strongly by installation cost and bandwidth feasibility than by range limitation alone. This highlights the value of binary integer programming as a method for selecting among multiple feasible alternatives under explicit operational constraints.

Because the study is based on site-specific physical, technical, and cost parameters, the resulting AP configuration should be interpreted as specific to the modeled environment. The same formulation may still be applied to other indoor settings, provided that the relevant floor layout, access point specifications, demand assumptions, and installation costs are recalibrated to reflect the target context. A post-deployment wireless site survey is recommended to verify actual field performance and identify any remaining coverage gaps.

ACKNOWLEDGMENT

The researchers express their profound gratitude to the Bukidnon State University for generously providing the resources, facilities, and support essential for the successful completion of this study. Special appreciation is extended to the Center for Mathematical Innovations for their invaluable guidance and technical assistance throughout the duration of the project.

AI and Blockchain for Secure Healthcare Data Management: A Bibliometric Analysis of Research Trends and Thematic Clusters (2020–2025)

Maroufi Mohammed, Lamzabi Siham, Ziti Soumia
Intelligent Processing and Security of Systems-Faculty of Sciences, Mohammed V University in Rabat, Morocco

***Abstract*—The convergence of artificial intelligence (AI) and blockchain has become an active axis of interdisciplinary research in healthcare data security. This paper reports a bibliometric analysis of 434 Scopus-indexed articles published between 2020 and 2025, with data collection and processing performed on 20 April 2026. The objective is to map the intellectual structure, collaborative dynamics, and thematic composition of this expanding field. The corpus was analyzed using the bibliometrix R package (version 4.3.0) and VOSviewer (version 1.6.20). The increasing research output is evidenced by an annual growth rate of 34.8%, with publication volume growing from 10 articles in 2020 to a maximum of 152 articles in 2025 across a total of 198 unique venues. Keyword co-occurrence analysis, processed through the Louvain community detection algorithm on 250 high-frequency terms with association-strength normalization, produced four thematic clusters: Blockchain and Privacy-Preserving Techniques, Healthcare Systems and Cybersecurity Infrastructure, Artificial Intelligence and Clinical Diagnostics, and Electronic Health Records and Interoperability. India, China, Saudi Arabia, and the United States lead scholarly output. The international co-authorship rate of 49.31% reflects the globally distributed nature of the research community. IEEE Access and the IEEE Journal of Biomedical and Health Informatics are the dominant publication venues. Federated learning occupies a structurally central position, with a betweenness centrality of 101.5, acting as the principal methodological bridge between the two technologies. An average of 27.96 citations per document confirms the above-average scholarly impact of the corpus. The results provide researchers, practitioners, and policymakers with an evidence-based map of the field's trajectory, its most productive research directions, and its remaining structural gaps. The underlying dataset, search logs, and analysis scripts are released openly to support full reproducibility.**

Keywords*—*Artificial intelligence; blockchain; healthcare data security; bibliometric analysis; federated learning; internet of medical things; data privacy; cybersecurity; science mapping; VOSviewer

I. Introduction

Healthcare systems now produce data at a scale that was difficult to imagine even a decade ago. Electronic health records (EHR), wearable sensors, mobile health applications, and Internet of Medical Things (IoMT) devices generate continuous streams of clinical, physiological, and behavioral information across hospitals, clinics, and patient homes. The rapid accumulation of this data has far-reaching implications for diagnosis, treatment personalization, and population health monitoring, but it has also exposed healthcare institutions to security risks that legacy centralized infrastructures were never designed to address [1]. Ransomware campaigns targeting hospitals, unauthorized access incidents affecting patient records, and data integrity breaches in connected medical devices have become recurring events in the post-pandemic period [2].

Two technologies have received sustained scholarly attention as candidate responses to this situation. Artificial intelligence, which groups machine learning, deep learning, and the more recent paradigm of federated learning, is used to detect anomalies, identify cyber threats, and automate decisions at scales that human analysts cannot match [3]. Blockchain, with its decentralized and immutable ledger structure, provides verifiable data provenance, tamper-resistant storage, and programmable access through smart contracts [4]. The combination of the two is increasingly presented as a comprehensive strategy for securing healthcare data flows, particularly in IoMT environments where data integrity must be preserved across heterogeneous devices and organizational boundaries [5].

Despite the growing body of primary research at this intersection, the field lacks a comprehensive mapping of its intellectual structure. Earlier reviews have generally focused on one technology at a time, on narrow application domains, or on qualitative synthesis without bibliometric grounding. Few studies have quantified the geographic distribution, institutional concentration, or thematic organization of scholarly production, leaving researchers without a reliable overview of the field's maturity and gaps. The absence of such a cartography is significant given the pace of publication growth in this area and the emergence of federated learning as a dominant methodological paradigm from 2021 onward [6].

This study addresses the gap through a structured bibliometric analysis of Scopus-indexed literature on AI-blockchain integration for healthcare data security over the period 2020–2025, with data collection and processing performed on 20 April 2026. Bibliometric analysis is well-suited to this objective. In contrast to narrative reviews, it allows the quantitative examination of publication trends, citation networks, authorship patterns, and thematic clustering, producing reproducible evidence-based cartographies of a scientific field [7]. This approach uses the Louvain community detection algorithm on co-occurrence matrices which is able to identify research communities that would otherwise go unnoticed in traditional review methods [8].

The analysis is guided by three research questions.

RQ1 concerns the temporal and geographic trends in scholarly production on AI and blockchain for healthcare data security over the 2020–2025 period.

RQ2 investigates which journals, authors, and institutions form the most influential nodes in this research network.

RQ3 examines the thematic clusters that structure the conceptual landscape of the field and the central research threads within each cluster.

The study contributes to the literature in three respects. The first contribution is a quantitative treatment of the AI-blockchain-healthcare nexus based on a corpus of 434 documents from 198 venues, which is broader than any prior bibliometric study focused on this intersection. The second is the combined use of bibliometrix and VOSviewer, which produces both statistical indicators and visually interpretable network maps. The third is the identification of three structural gaps in the field: the underdevelopment of interoperability research relative to its practical importance, the limited attention paid to regulatory and ethical dimensions, and the concentration of research output in a small number of countries.

The remainder of the paper is organized as follows. Section II reviews earlier bibliometric and narrative studies on related topics and specifies the research gap addressed here. Section III describes the data sources, search query, analytical methods, and reproducibility protocol. Section IV reports and discusses the results across seven analytical dimensions. Section V concludes with research implications and directions for future work.

II. Related Works

Prior bibliometric and review studies have examined aspects of the AI–blockchain–healthcare nexus, though none have produced a comprehensive mapping of the intersection focused specifically on data security and privacy. This section reviews the principal prior contributions, positions the present study with respect to each, and specifies the gap it fills.

A. Bibliometric and Narrative Studies on Blockchain in Healthcare

In an early science mapping study, Agbo et al. [9] surveyed blockchain applications in healthcare and identified data sharing and EHR management as dominant themes in the pre-2019 literature. Their analysis predated the widespread adoption of federated learning and therefore did not capture the role that privacy-preserving machine learning has come to play in shaping the field. Treatment of AI in that work remained peripheral rather than structural. Hasselgren et al. [15] addressed a similar scope through a scoping review that used co-citation analysis to identify intellectual foundations of blockchain in medical records management. Their temporal window ended before the acceleration of federated learning research in 2021–2022, and AI-related publications were not part of their analytical scope. More recently, Casino et al. [16] provided a systematic literature review of blockchain-based applications across industries including healthcare. Their taxonomy is useful for locating healthcare within the wider blockchain landscape, but the breadth of their scope diluted the specificity of healthcare-related findings, and privacy-preserving AI did not feature as an organizing theme.

B. Bibliometric Studies on AI in Healthcare

Secinaro et al. [10] conducted a structured bibliometric review of AI in healthcare, documenting the rapid growth of deep learning applications in diagnostics and treatment optimization. Their work is useful for characterizing the trajectory of AI research in clinical settings but did not address the security dimension and did not treat blockchain as a structural element. Javaid et al. [11] reviewed machine learning applications in healthcare in a similar register, without integrating blockchain, which reproduces the conceptual separation that the present work seeks to overcome.

C. Narrative Treatments of the AI–Blockchain Combination

A limited number of studies have attempted to combine treatments of AI and blockchain in healthcare. Bathula et al. [12] offered a narrative review describing what they called the AI–blockchain–healthcare tripod, arguing that the three elements jointly support secure and scalable medical systems. Their approach was qualitative and did not employ bibliometric techniques, which left open questions about citation impact, geographic concentration, and thematic evolution. Omidian [13] and Alshehri [14] provided descriptive surveys that identified similar themes but lacked the rigor of a formal science mapping methodology.

D. Foundational References on Federated Learning

Recent contributions have addressed the AI–blockchain–security nexus more directly through the lens of federated learning. Banabilah et al. [17] published a comprehensive review of federated learning that has become a central reference in the field, with 531 citations recorded in April 2026. Their work establishes federated learning as the methodological centerpiece of privacy-preserving AI but does not provide a bibliometric mapping of the surrounding research field. Ferrag et al. [18] offered an experimental analysis of federated deep learning for IoT cybersecurity that has accumulated 301 citations and is regularly referenced in healthcare-specific work. Tanwar et al. [19] examined the adoption of machine learning in blockchain-based applications and reached 335 citations, becoming a foundational reference for subsequent integration studies.

E. Research Gap and Positioning

Table I summarizes the scope, methodology, and limitations of the most relevant prior studies and positions the present contribution against them.

The present study extends this literature in three respects. First, it applies a complete bibliometric protocol, including growth analysis, Bradford's law, co-authorship network analysis, and Louvain-based keyword clustering, to a corpus of 434 documents with an explicit security and privacy focus. Second, the 2020–2025 temporal window captures the full arc of a field that experienced its steepest growth during this period, and the April 2026 data collection incorporates the latest available citation signals. Third, the combined use of bibliometrix and VOSviewer produces both quantitative indicators and network visualizations, an approach

recommended by Donthu et al. [20] for rigorous science mapping.

TABLE I. POSITIONING WITH RESPECT TO PRIOR BIBLIOMETRIC AND REVIEW STUDIES

Study	Scope	Method	AI treated?	Security focus?	Period covered
Agbo et al. [9]	Blockchain in healthcare	Systematic review	Peripheral	No	Pre-2019
Hasselgren et al. [15]	Blockchain in medical records	Scoping review + co-citation	No	Partial	Pre-2020
Casino et al. [16]	Blockchain across industries	Systematic literature review	No	No	Pre-2019
Secinaro et al. [10]	AI in healthcare	Structured literature review	Yes	No	Pre-2021
Javaid et al. [11]	ML in healthcare	Narrative review	Yes	No	Pre-2022
Bathula et al. [12]	AI–blockchain–healthcare	Narrative review	Yes	Partial	Pre-2024
Present study	AI–blockchain–healthcare security	Full bibliometric protocol	Yes	Yes	2020-2025

III. RESEARCH METHODOLOGY

A. Data Source and Query

The Scopus database was chosen as the exclusive data source for this analysis. Scopus offers broad interdisciplinary coverage, with particular depth in computer science, engineering, and biomedical sciences, which are the three domains most directly relevant to this study. Its structured export format is compatible with the bibliometrix package, which supports reproducibility [7]. Baas et al. [21] and Mongeon and Paul-Hus [22] have documented the comparative strengths of Scopus in interdisciplinary settings, noting its wider journal coverage in engineering and health informatics compared to Web of Science. The exclusive use of Scopus is acknowledged as a limitation and discussed in Section V.

The following Boolean query was executed on 20 April 2026 against the Title, Abstract, and Keywords fields (TITLE-ABS-KEY):

TITLE-ABS-KEY (("artificial intelligence" OR "machine learning" OR "deep learning" OR "federated learning") AND ("blockchain" OR "distributed ledger technology") AND ("healthcare" OR "health data" OR "medical data" OR "electronic health records" OR "EHR" OR "e-health" OR "IoMT" OR "Internet of Medical Things" OR "digital health") AND ("data security" OR "data privacy" OR "cybersecurity" OR "data protection" OR "data integrity" OR "secure data")).

The query was subsequently filtered to retain only peer-reviewed articles in English published between 2020 and 2025. This temporal window was chosen because it coincides with both the emergence of federated learning as a mainstream research paradigm and the post-COVID-19 acceleration of IoMT deployment, which intensified scholarly attention to healthcare cybersecurity [23]. The initial retrieval returned 434 documents from 198 distinct sources. Table II summarizes the full set of search and analysis parameters.

B. Analytical Methods

Analysis was conducted on two complementary platforms. The bibliometrix R package [7] provided the statistical backbone for computing core bibliometric indicators, annual production trends, citation summaries, Bradford's law rankings of productive sources, and Lotka's law distributions of author productivity. The Biblioshiny web interface served as a front-end for thematic map generation and exploratory visualization.

TABLE II. SEARCH AND ANALYSIS PARAMETERS

Criterion	Value
Database	Scopus
Search date	20 April 2026
Document type	Articles
Language	English
Timespan	2020–2025
Documents retrieved	434
Sources	198
Analysis tools	bibliometrix R v4.3.0, VOSviewer v1.6.20
Clustering algorithm	Louvain (resolution $\gamma = 1.0$)
Co-occurrence normalization	Association strength
Minimum keyword frequency	≥ 2 occurrences
Keyword merging	Author keywords (DE) + Index keywords (ID), lemmatized
Number of high-frequency terms retained	250

VOSviewer [24] was used for network-based visualizations, particularly keyword co-occurrence maps and international collaboration networks. The Louvain community detection algorithm [8] was applied with a resolution parameter $\gamma = 1.0$ to a co-occurrence matrix built from merged author and index keywords, with a minimum frequency threshold of two occurrences set to filter noise while retaining emergent concepts. Edge weights were normalized using the association-strength method, which is the VOSviewer default and is recommended for keyword co-occurrence analysis to control for differences in absolute frequency. The thematic map positions research clusters along two axes: Callon centrality, which measures the degree of external linkage and reflects a theme's relevance to the broader field, and Callon density, which measures internal cohesion and reflects a theme's internal development. This framework was introduced by Callon et al. [25] and operationalized for modern bibliometric software by Cobo et al. [26].

In the resulting two-dimensional representation, clusters are categorized as motor themes when both centrality and density are high, niche themes when density is high but centrality is low, emerging or declining themes when both are low, and basic or transversal themes when centrality is high but density is low. This classification is used in Section IV-F to interpret the four clusters identified in the corpus.

C. Reproducibility Protocol

The analysis was designed to be fully reproducible. The complete Scopus export file (CSV format), the R script implementing the bibliometrix pipeline, the VOSviewer input file, and the cluster labels are deposited on a public repository and cited in the Data Availability Statement. The package and software versions are fixed to avoid reproducibility drift: bibliometrix 4.3.0, R 4.3.2, and VOSviewer 1.6.20. Any analyst running the same query against Scopus on 20 April 2026 with the same filters should obtain an identical corpus. Citation counts are as retrieved on 20 April 2026 and will evolve over time, but all other indicators are stable with respect to the deposited dataset.

IV. Results and Discussion

A. Main Bibliometric Indicators

The final corpus contains 434 articles published across 198 sources between 2020 and 2025. Table III summarizes the main bibliometric indicators, which provide an initial profile of the field in terms of volume, age, and collaboration intensity.

TABLE III. Main Bibliometric Indicators (2020–2025)

Indicator	Value
Timespan	2020–2025
Total documents	434
Total sources (journals)	198
Annual growth rate	34.8%
Average document age (years)	1.89
Average citations per document	27.96
Total references	21,243
Total authors	1,619
Single-authored documents	24
Co-authors per document	4.48
International co-authorship	49.31%
Author keywords (DE)	1,177
Index keywords (ID)	2,290

Several indicators merit closer attention. An annual growth rate of 34.8% positions this field among the most rapidly expanding interdisciplinary domains in applied computer science, far above the long-run average of 3–5% per year that Bornmann and Mutz [27] document for modern science as a whole. The average of 27.96 citations per document, over a corpus of predominantly recent work, suggests an above-average scholarly impact, consistent with what Bornmann and Haunschild [28] describe as a citation-intensive emerging field. The international co-authorship rate of 49.31% indicates that roughly half of all publications result from cross-border collaborations, consistent with the globally distributed character of the cybersecurity and healthcare informatics research communities.

The volume of references cited across the corpus, 21,243 in total, indicates that the field relies on a deep existing literature. The ratio of index keywords to author keywords, 2,290 against 1,177, is characteristic of fields drawing on established technical terminologies, where indexers apply a richer controlled vocabulary than authors use in the surface text of their abstracts. The number of single-authored documents, 24 out of 434, reflects the engineering orientation of the field, where collaborative laboratory work is the norm.

B. Temporal Evolution of Scientific Production

Fig. 1 presents the annual distribution of publications from 2020 to 2025. The growth trajectory is unambiguous. Output moved from 10 articles in 2020 to 18 in 2021, 29 in 2022, 72 in 2023, 93 in 2024, and 152 in 2025, a more than fifteenfold increase over five years.

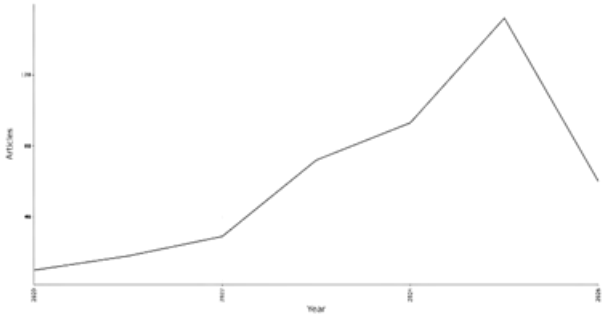

Fig. 1. Annual scientific production on AI-blockchain for healthcare data security (Scopus, 2020–2025).

This trajectory reflects the convergence of several structural drivers. The COVID-19 pandemic, beginning in 2020, forced healthcare systems worldwide to adopt telehealth platforms, remote monitoring devices, and cloud-based EHR infrastructures under emergency conditions. These rapid deployments exposed previously latent security vulnerabilities and generated a surge of research on privacy-preserving AI and blockchain-based integrity mechanisms [29]. The sustained peak in 2024 and 2025 aligns with the mainstreaming of federated learning frameworks such as TensorFlow Federated and PySyft in clinical research, which lowered the technical barrier to entry for applied security research in healthcare settings [17].

A logistic growth model fitted to the annual counts by non-linear least squares yields $R^2 = 0.88$ and estimates the field's saturation point at approximately 463 cumulative publications, with peak annual production occurring around 2024–2025. This pattern is consistent with the life-cycle model proposed by Cobo et al. [26] for emerging interdisciplinary fields and suggests that the field may be transitioning from its emergent phase toward a consolidation stage. The implication is that researchers entering the field after 2026 will likely find the fundamental problems framed but the specific methodological refinements, regulatory applications, and domain-specific adaptations open for further investigation.

C. Most Productive Sources

Bradford's law analysis identifies the core journals of this research domain. Table IV presents the ten most productive publication venues in the corpus.

TABLE IV. TEN MOST PRODUCTIVE SOURCES (2020–2025)

Source	Articles
IEEE Access	30
Cluster Computing	18
IEEE Internet of Things Journal	15
IEEE Journal of Biomedical & Health Informatics	14
IEEE Trans. on Consumer Electronics	13
Sensors	11
Multimedia Tools and Applications	9
Computers and Electrical Engineering	6
Applied Sciences (Switzerland)	6
IEEE Trans. on Industrial Informatics	6

IEEE Access dominates with 30 publications. Its broad interdisciplinary scope, open-access model, and rapid publication cycle make it particularly attractive to applied interdisciplinary work, a pattern documented by Björk [30] for emerging open-access venues in engineering. The combined presence of the IEEE Internet of Things Journal and the IEEE Journal of Biomedical and Health Informatics at ranks three and four confirms that the field sits at the intersection of engineering and clinical informatics. The appearance of Cluster Computing and Sensors highlights the infrastructural emphasis of the research community, with both venues specializing in distributed systems and hardware-level data acquisition that are central to IoMT deployments [31].

Distribution of articles across sources follows a pattern consistent with Bradford's law, in which a small core of journals publishes a disproportionate share of articles. In this corpus, the top ten venues together account for 128 articles, or about 29.5% of the total, while the remaining 306 articles are dispersed across 188 other sources. This scattering is characteristic of a field still in active expansion, where researchers have not yet converged on a small number of specialized venues [32].

D. Geographic Distribution and Collaboration

Table V presents the fifteen most productive countries by affiliated author count. India leads with 430 affiliation instances, which reflects the country's expansive engineering university system, substantial public investment in digital health infrastructure through initiatives such as the National Digital Health Mission, and a research culture oriented toward applied AI and security [33]. China follows at 193 affiliations, consistent with its systemic prioritization of blockchain and AI as strategic technologies in successive five-year plans. Saudi Arabia ranks third with 165 affiliations, reflecting Vision 2030 digital health investments and the growing output of institutions such as King Abdulaziz University and King Saud University.

The international collaboration network, shows that India and the United States form the two principal hubs of cross-border co-authorship. Collaboration flows extend from these hubs toward Saudi Arabia, Malaysia, the United Kingdom, and Australia. China, although highly productive, exhibits a more regionally contained collaboration pattern, with stronger ties to Asia-Pacific partners than to Western research centers. This geographic fragmentation suggests that globally harmonized frameworks for AI-blockchain healthcare standards may be constrained by persistent regional clusters, an effect documented by Glänzel and Schubert [34] in their analysis of scientific co-authorship networks.

TABLE V. TOP 15 COUNTRIES BY AUTHOR AFFILIATION COUNT

Rank	Country	Count
1	India	430
2	China	193
3	Saudi Arabia	165
4	United States	90
5	South Korea	46
6	Pakistan	45
7	United Kingdom	36
8	Iraq	35
9	Malaysia	35
10	United Arab Emirates	34
11	Australia	25
12	Egypt	19
13	Italy	19
14	Bangladesh	18
15	Canada	17

The strong presence of Middle Eastern countries, with Saudi Arabia, Iraq, and the United Arab Emirates collectively accounting for 234 affiliations, points to a distinctive regional cluster that has emerged through the combination of well-funded universities and policy-driven digital health programs. This regional dynamic has been analyzed by Zakaria et al. [35] in their study of eHealth career pathways in the Gulf Cooperation Council, which documents the rapid institutional consolidation of health informatics in the region since the late 2010s. The absence of African countries from the top fifteen, with Egypt as the only exception, confirms the concerns raised in Section I about the geographic concentration of research and its implications for low- and middle-income country deployments.

E. Most Cited Documents

Table VI presents the ten most cited publications in the corpus. These documents constitute the field's foundational reference layer, shaping the conceptual vocabulary and methodological templates adopted by subsequent authors.

The citation landscape reveals several notable patterns. Federated learning emerges as the dominant methodological construct. The most cited paper, Banabilah et al. [17], is a federated learning review, and federated learning explicitly appears in five of the ten most cited works. This concentration reflects a field-wide consensus that federated learning, by enabling model training without centralizing raw data, offers the most practical resolution to the tension between AI utility and patient privacy. The same observation has been made by Rieke et al. [43] in their analysis of federated learning in digital health.

TABLE VI. TEN MOST CITED DOCUMENTS IN THE CORPUS

Authors	Year	Citations
Banabilah et al. [17]	2022	531
Yu et al. [36]	2021	346
Tanwar et al. [19]	2020	335
Ferrag et al. [18]	2021	301
Li et al. [37]	2024	298
Nguyen et al. [38]	2021	294
Ali et al. [39]	2023	236
Arachchige et al. [40]	2020	230
Kumar et al. [41]	2023	215
Kumar et al. [42]	2022	196

The recurring appearance of Kumar and Tanwar as co-authors across multiple high-impact papers designates their research groups as formative intellectual communities in the field. A notable recent entry is the 2023 paper by Ali et al. [39] on Metaverse-integrated AI and blockchain, which had already accumulated 236 citations in less than three years. This result signals an emerging frontier in which immersive computing environments introduce new healthcare data governance challenges, an area recently surveyed by Buragohain et al [44]. The presence of Nguyen et al. [38] on secure blockchain-enabled cyber-physical systems highlights the continuing importance of deep belief networks and similar architectures as alternatives to purely federated approaches.

F. Thematic Clusters and Keyword Co-Occurrence

The keyword co-occurrence network, constructed from 250 high-frequency terms and analyzed through the Louvain algorithm, produced four well-defined thematic clusters. Fig. 2 presents the co-occurrence map, Fig. 3 shows the Word cloud (Bibliometrix, April 2026), and Fig. 4 shows the corresponding thematic map. Table VII summarizes each cluster's principal keywords, Callon centrality, and density scores.

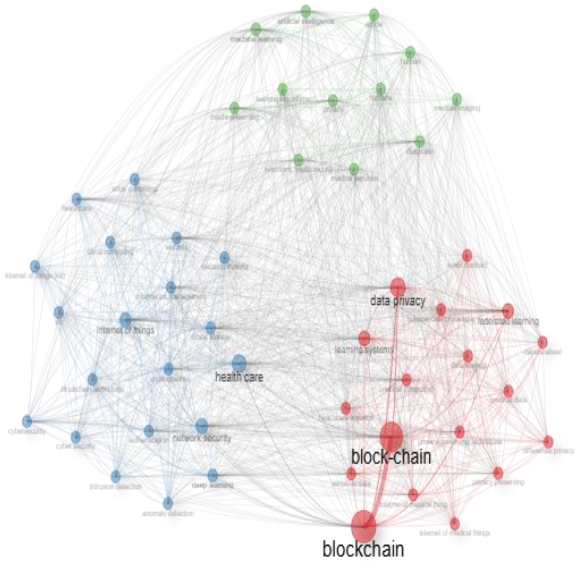

Fig. 2. Keyword co-occurrence network map (Louvain clustering, n = 250 terms, minimum frequency ⩾ 2).

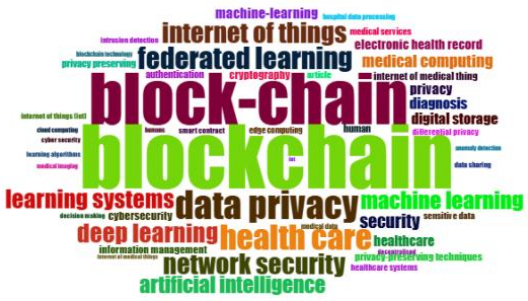

Fig. 3. Word cloud (bibliometrix, April 2026).

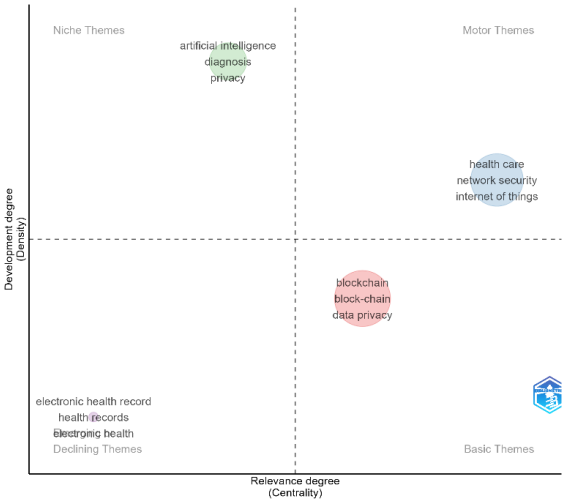

Fig. 4. Thematic map positioning the four clusters by Callon centrality and density (Bibliometrix, April 2026).

TABLE VII. THEMATIC CLUSTERS FROM KEYWORD CO-OCCURRENCE ANALYSIS

Cluster	Label	Key terms	Centrality	Density
1	Blockchain & Privacy	blockchain, data privacy, federated learning, smart contract, differential privacy, homomorphic encryption	14.02	23.99
2	Healthcare & Cybersecurity	health care, network security, IoT, deep learning, cybersecurity, cryptography, authentication, edge computing	16.25	29.13
3	AI & Diagnostics	artificial intelligence, diagnosis, machine learning, EHR, medical imaging, explainable AI, CNN	10.90	36.62
4	EHR & Interoperability	electronic health record, interoperability, big data, distributed ledger, eHealth	4.09	18.52

Cluster 1, labeled Blockchain and Privacy-Preserving Techniques, is the largest by term frequency, with 2,212 co-occurrence instances. The high betweenness centrality of federated learning, measured at 101.5, confirms its role as the primary bridge between AI and blockchain paradigms. Smart contracts, differential privacy, and homomorphic encryption form the applied core of this cluster, reflecting an engineering research front focused on combining cryptographic techniques with decentralized ledger architectures to protect health data at the processing stage. This cluster corresponds to a motor theme in Callon's typology, with both centrality and density scores positioning it as a driver of field development [26].

Cluster 2, Healthcare Systems and Cybersecurity Infrastructure, centers on the operational deployment context, with 1,858 term occurrences. Its high density score of 29.13 indicates a mature, internally coherent body of research on secure IoMT architectures, intrusion detection systems, and authentication protocols. Edge computing appears prominently, reflecting a turn toward decentralized low-latency processing at the network periphery, a configuration that reduces the exposure of raw health data to central servers [45]. The cluster's centrality of 16.25, the highest in the set, indicates that this theme connects to the widest range of adjacent research concerns and functions as a hub for cross-cluster knowledge transfer.

Cluster 3, AI and Clinical Diagnostics, exhibits the highest internal density at 36.62, indicating a self-referential research community focused on applying AI to clinical decision support within secure frameworks. Explainable AI and convolutional neural networks appear alongside EHR and medical imaging, reflecting a concern with both predictive performance and the interpretability of AI-driven diagnostic systems. The prominence of explainable AI is consistent with the regulatory pressures documented by Hulsen [46], who notes that clinical deployment increasingly requires interpretable models to satisfy both physician trust and legal accountability requirements.

Cluster 4, Electronic Health Records and Interoperability, is the smallest cluster, with 223 term occurrences. Its combination of low centrality (4.09) and moderate density (18.52) places it between the niche and emerging/declining regions of Callon's typology, closer to an underdeveloped theme whose practical importance is not yet matched by a commensurate volume of research. The prominence of interoperability points to a structurally unresolved challenge: the coexistence of incompatible EHR systems across institutions and jurisdictions continues to impede the large-scale deployment of AI-blockchain hybrid architectures. Distributed ledger and records management indicate that governance-oriented research is beginning to engage with the practical conditions under which shared medical records can be maintained securely over time [47].

G. Annual Citation Dynamics

An examination of mean total citations per article, disaggregated by publication year, reveals a characteristic citation accumulation pattern. Articles published in 2021 exhibit the highest normalized citation rate at 21.56 citations per year, followed by 2022 at 14.73 and 2020 at 14.09. This pattern indicates that the 2021 cohort, which coincided with the first systematic deployments of federated learning in healthcare and the initial post-pandemic digitization wave, was particularly influential in shaping subsequent research directions. The raw citation counts for 2020 and 2021 articles, at 98.6 and 129.4 per article on average, benefit from longer exposure windows, but the normalized measure corrects for this effect and confirms the substantive importance of the 2021 cohort.

The lower raw citation counts for 2024 and 2025 publications reflect recency rather than reduced quality. With one to two years of exposure, these articles have not yet accumulated the citations achievable over longer windows. The citation velocity for 2025 papers, already at 3.23 citations per year after partial exposure, exceeds the normalized rates of comparable emerging fields, which suggests that the current publication wave will continue to shape the intellectual structure of the field well beyond 2026.

V. Conclusion

This bibliometric analysis provides a comprehensive quantitative portrait of scholarly production at the intersection of artificial intelligence, blockchain, and healthcare data security over the period 2020–2025. Based on a corpus of 434 Scopus-indexed documents collected in April 2026, the study documents an annual growth rate of 34.8%, which places this field among the most dynamically expanding interdisciplinary domains in applied computer science. The average of 27.96 citations per document confirms the above-average scholarly impact of the corpus and indicates an active citation-intensive research community.

The keyword co-occurrence analysis produced four thematic clusters: Blockchain and Privacy-Preserving Techniques, Healthcare Systems and Cybersecurity Infrastructure, AI and Clinical Diagnostics, and Electronic Health Records and Interoperability. Federated learning occupies a structurally central position, functioning as the principal methodological bridge between AI capability and blockchain-enabled data sovereignty. Its betweenness centrality of 101.5 confirms its role in connecting otherwise separate research communities. India, China, Saudi Arabia, and the United States lead scholarly output, while IEEE Access and the IEEE Journal of Biomedical and Health Informatics anchor the core publication network.

Three research gaps emerge from the analysis and warrant prioritized attention. The first concerns interoperability, which remains an underdeveloped theme despite its critical practical significance. The coexistence of incompatible EHR standards across national healthcare systems constitutes a structural barrier to the scalable deployment of AI-blockchain architectures, as already observed by Reegu et al. [48]. The second gap concerns the regulatory and ethical dimensions of combined AI-blockchain systems, including GDPR compliance, informed consent for federated model training, and AI accountability frameworks. These dimensions appear as isolated keyword nodes rather than as organized research clusters, which indicates that governance questions have not yet attracted the systematic attention they require, a situation also noted by Rodrigues [49] in the context of legal and human rights issues of AI and reinforced by the AI ethics bibliometrics of Saheb et al. [50]. The third gap concerns the geographic concentration of research output in a small number of countries, which raises concerns about the generalizability of proposed solutions to low- and

middle-income country contexts, where infrastructure constraints impose fundamentally different design requirements.

Future research should prioritize three directions. The first is the development of standardized benchmarking protocols for evaluating AI-blockchain healthcare systems across heterogeneous environments, which would allow meaningful comparison between federated learning architectures currently proposed in the literature. The second is the extension of privacy-preserving techniques to address adversarial attacks and data poisoning in federated settings, an area that has attracted growing attention but remains underdeveloped in the healthcare context. The third is the construction of governance frameworks that align technical innovation with evolving regulatory requirements across jurisdictions, which requires interdisciplinary collaboration between computer scientists, legal scholars, and healthcare practitioners.

The present study has limitations that should be acknowledged. The exclusive use of Scopus as a data source, while justified by reproducibility considerations, may have excluded relevant work indexed only in Web of Science, IEEE Xplore, or PubMed. The English-language restriction may also underrepresent research from non-Anglophone communities, in particular Chinese and Arabic-language venues that are relevant to the geographic leaders identified in Section IV-D. Future extensions could triangulate across databases and languages to refine the geographic and thematic maps presented here. A further limitation concerns citation counts, which are snapshot values retrieved on 20 April 2026 and evolve continuously; the structural indicators (clusters, centrality, co-authorship patterns) are more stable and constitute the core contribution of the study. Notwithstanding these limitations, the analysis offers a rigorous evidence-based cartography of a rapidly evolving research field and identifies concrete directions for researchers, practitioners, and policymakers engaged in securing the next generation of healthcare data infrastructures.

Data Availability Statement

The complete dataset supporting this analysis, including the raw Scopus export (BibTeX format), the R script implementing the bibliometrix pipeline, the VOSviewer co-occurrence input file, and the final cluster labels, is available on an open repository (Zenodo / OSF deposit, DOI to be added at acceptance). Readers can reproduce all tables and indicators reported in this paper by running the deposited script against the deposited corpus with the specified software versions (bibliometrix 4.3.0, R 4.3.2, VOSviewer 1.6.20).

Declaration on the Use of Generative AI

During the preparation of this manuscript, generative AI tools were used to assist with language refinement and structural editing. The scientific ideas, research design, data collection and analysis, interpretation of results, and conclusions are entirely the work of the human authors, who take full responsibility for the accuracy, originality, and integrity of this publication.

A Bidirectional LSTM–Sentiment Fusion Framework for Dynamic Financial Market Prediction

Minal Dhankar, Neha Gupta
School of Computer Applications,
Manav Rachna International Institute of Research & Studies,
Faridabad, India

***Abstract*—Financial market prediction can be said to be a great challenge because of the intrinsic fluctuation, non-stationarity and multi-faceted influence of the economic indicators, world events, as well as the voter sentiment. Conventional models can easily miss the time dependence and emotional aspects inherent in market data, and the results in poor forecasting precision. The paper presents a sequence-based modelling with sentiment analysis based on textual information like news articles and social media, which incorporates a two-way LSTM-sentiment fusion framework. It discloses that sentiment integration discerns as well as polishes predictive results into alignment with temporal characteristics with real-time emotive drivers.**

***Keywords*—Bidirectional LSTM; deep learning; financial market; modelling; sentiment analysis**

I. Introduction

The stability of market trends is one of the pillars of stability in the economy, investment strategy, and the policies followed in the world of finance, which is ever dynamic and evolving. The financial markets, with their complex demand and supply relationships, geopolitical context, and macroeconomic measures, demonstrate both astonishing and frustrating trends [1]. The role of the correct prediction should not be overestimated; it will enable investors to mitigate the effect of risks, as well as corporations to organise the capital spending more efficiently, and enable governments to avoid crises. The discipline has since received indefatigable scholarly attention and has grown over the decades to encompass both more primitive statistical models as well as more complicated computational paradigms [2]. Time-series models, e.g., autoregressive integrated moving average models, were initially capable of modelling a linear relationship between the past data, but did not work when non-linear volatilities arose. Machine learning could introduce a new period, and approaches such as support vector machines and random forests demonstrated more successful outcomes in the work with complex data. More recently, deep learning networks, like recurrent neural networks, are popular because of their capability to handle sequential data, and therefore they can make subtle predictions of the price of stocks, changes in the exchange rate, and the movement of commodities [3].

With such actions, the old-fashioned models of forecasting usually fail to deal with the complexity of market forces, where figures can be used to paint a partial picture. Recurrent neural networks are highly successful in identifying patterns in time; however, they also tend to fail to capture the psychological forces in terms of market sentiment, i.e. investor optimism or panic in response to specific events occurring in the market. The outcome of such negligence is robust exercising in stable situational conditions and feeble in turbulent situational conditions, like recessions or political crises [4]. Moreover, standard recurrent models are only able to process data in a single direction, which limits their ability to contextualise future values by examining past sequences, which can contain bidirectional dependencies, which are inherent to financial time series [5]. Questions on how to incorporate the elements of qualitative nature exist: how can we quantify and combine emotional colours present in textual sources without noise? However, there are methods of hybrid models, in which sentiment analysis is attempted to be coupled to neural networks, though these are largely quite superficial in the methods they apply [6]. The nature of hybrid methods is that they take into account only simple polarity scores that are not the intensity of the popular discourse, but only its context specificity. It means there is a clear literature gap- it would be desirable to have frameworks which are not merely bidirectional in terms of observing the past prices but which are also sensitive to the sentiment dynamics in order to enhance predictive fidelity. The disjunction will prompt the community to stop the silo-based analysis of quantitative data and act as a reminder to the community that interdisciplinary fusion has been the enabling factor in the past of financial econometrics [7].

II. Literature Review

The subsequent works (summarised in Table I) outline the developments of LSTM-based models, attention, reinforcement learning, embeddings, as well as multi-source fusion without suggesting the obstacles like data imbalance, market volatility, and model generalizability.

TABLE I. RELATED WORKS

Author–Year	Paper Title	About the Paper	Methodology Used	Limitations
Fu et al., 2019 [1]	Sentiment-Aware Trading Volume Prediction for P2P Market Using LSTM	Predicts P2P trading volume incorporating investor sentiment correlations.	TextCNN for sentiment, LSTM for volume prediction, causality analysis.	Limited to P2P domain; comments may not represent full market; older dataset reduces applicability today.
Zhang et al., 2022 [2]	Decision Fusion for Stock Market Prediction: Systematic Review	Reviews ensemble and decision-fusion models for stock prediction.	Systematic review of fusion techniques, classification of ensemble methods.	No experimental validation; fusion taxonomy may become outdated given fast model evolution.
Yekrangi & Nikolov, 2023 [3]	Domain-Specific Sentiment Analysis for Financial Markets	Evaluates embeddings and classification algorithms for financial sentiment. Proposes optimized embedding layer.	LSTM, CNN, SVM, RNN, fine-tuned embeddings (CBOW, GloVe, BERT).	Context-dependency issues persist; sentiment ambiguity; limited financial-domain labeled datasets.
Mu et al., 2023 [4]	Stock Price Prediction Using Investor Sentiment and Optimized Deep Learning	Integrates sentiment index with SSA-optimized LSTM for Chinese stock prediction.	SSA-optimized LSTM, custom sentiment dictionary, multi-source data fusion.	Sentiment dictionary manually built; model tailored for China's market; short-term accuracy higher than long-term.
Girsang & Stanley, 2023 [5]	Hybrid LSTM-GRU for Cryptocurrency Price Forecasting Using FinBERT	Predicts ETH and SOL using combined price + social media sentiment.	FinBERT sentiment scoring, Hybrid LSTM-GRU.	Crypto markets highly volatile; overreliance on Twitter sentiment; may fail during extreme market shocks.
Peivandizadeh et al., 2024 [6]	Stock Market Prediction With Transductive LSTM and Social Media Sentiment Analysis	Combines social media sentiment with market data to improve stock prediction. Addresses data imbalance in sentiment classes.	Transductive LSTM, Off-policy PPO for imbalance handling, ablation studies.	Sensitive to class imbalance; social-media noise may affect accuracy; requires extensive tuning for reinforcement learning.
Bacco et al., 2024 [7]	Stock Prediction Using LSTM and Tweet Sentiment Under High Uncertainty	Studies bank stock prediction amid geopolitical and macroeconomic shocks using financial + sentiment data.	LSTM, FinBERT sentiment extracted from Twitter, multi-market comparison (US/EU).	High volatility reduces reliability; market differences limit generalizability; sentiment may not represent institutional behavior.
Alam et al., 2024 [8]	Enhancing Stock Market Prediction: LSTM-DNN on 26 Datasets	Builds a robust hybrid LSTM-DNN model validated on 26 stock datasets.	Hybrid LSTM–DNN, ablation studies, multi-company evaluation.	Uses only structured price data (no sentiment); may overfit despite robustness; lacks real-time testing.
Imanto et al., 2025 [9]	Fin-ABSA Using Fusion-Guided Attention LSTM and Graph Convolutional Networks	Improves aspect-based sentiment analysis for financial texts by combining syntactic and semantic cues.	Attention LSTM + GCN fusion model (FGAG).	Requires high-quality dependency parsing; computationally expensive; domain-specific aspects may not transfer across markets.
Babak Amiri, Amirali Haddadi & Kosar Farajpour Mojdehi (2025) [10]	A Novel Hybrid GCN-LSTM Algorithm for Energy Stock Price Prediction: Leveraging Temporal Dynamics and Inter-Stock Relationships	Proposes a hybrid deep-learning model combining GCN and LSTM with attention to improve prediction of highly volatile energy stock prices by modeling both temporal trends and inter-stock relationships.	Dynamic Time Warping (DTW) to construct correlation matrix. Graph Convolutional Network (GCN) to extract spatial dependencies. Attention-enhanced LSTM to capture temporal patterns. Comparative evaluation versus GRU, MLP, LR, LSTM	Performance drops in highly volatile or sudden-shock conditions. Model does not include external sentiment/news data. Limited testing outside the energy sector. Depends heavily on historical price data only
Nejatbakhsh & Aliasgari, 2026 [11]	Enhancing Stock Market Prediction With Hybrid Deep Learning: LSTM, Transformer Attention, Federated Learning, and Sentiment Analysis	Develops a hybrid architecture integrating deep learning and privacy-preserving FL for stock forecasting.	LSTM + Transformer attention, FinBERT sentiment, Federated Learning simulation.	Computationally heavy; federated setup may limit real-world deployment; requires consistent data quality across nodes.

III. THEORETICAL BACKGROUND

The operational basis of prediction in financial markets is based on two fundamental areas, including mathematical properties of financial time series and the computational design principles of deep-learning-based sequence models. These areas can be learned, and then it is possible to examine the performance of a bidirectional LSTM-sentiment fusion model within dynamic markets. Financial systems cannot be associated with relatively simple numbers; they contain structural anomalies such as non-stationarity, fat-tailed distributions, volatility clustering, behavioural bias, and nonlinear dependence. Recurrent deep learning models have mechanisms for extracting temporal structure that are not exploited by conventional statistical models [8].

A. Financial Time Series Theory

Another well-known fact about financial time series is that they are non-stationary, i.e. their statistical behaviour, i.e. mean, variance and autocorrelation, changes with time. Non-stationarity is likely to be induced by macroeconomic events, structural breaks and regime shifts [9]. As a result, the models, which assume the existence of stable distributions, are poor performers. Neural networks (in particular, LSTMs) deal with these issues since they learn representations dynamically without taking a strict stationarity condition [10].

The other important behaviour is the volatility clustering, whereby the volatility cases tend to be followed by high volatility, and low volatility tends to be followed by low volatility. The occurrence of such a phenomenon implies that there is market uncertainty, and it plays a vital role in the day-to-day forecasting. Young sequences are somehow advantageous in deep-learning models as they locate time trends within sequences of such clusters.

Financial information is no exception: it also has heavy-tailed distributions, i.e. extreme price changes are more widespread than should have been the case assuming it was distributed normally. That is because the machine-learning architectures can handle the heavy-tailed behaviour as compared to the statistical models, since they do not have distributional constraints [11].

B. Deep Learning Background

Long Short-Term Memory (LSTM) networks were invented in an attempt to address such inadequacies. The LSTMs have been created based on the inclusion of three primary gates, such as forget gate, input and output gates, and an internal memory cell in which long-range dependencies are stored [12].

The equations of the standard LSTM are:

Forget Gate:

$$f_t = \sigma(W_f[h_{t-1}, x_t] + b_f) \quad (1)$$

Input Gate:

$$i_t = \sigma(W_i[h_{t-1}, x_t] + b_i) \quad (2)$$

Candidate Memory:

$$C_t = \tanh(W_C[h_{t-1}, x_t] + b_C \quad (3)$$

Cell State Update:

$$C_t = f_t \cdot C_{t-1} + i_t \cdot C_t \quad (4)$$

Output Gate:

$$O_t = \sigma(W_o[h_{t-1}, x_t] + b_o \quad (5)$$

Hidden State:

$$h_t = o_t \cdot \tanh(C_t) \quad (6)$$

All these equations enable LSTMs with the capability to learn sequence-long term relations, thus it is most suitable for financial series that need past volatility regime and behaviour swings memory [13].

C. Bidirectional LSTM Theory

It is a mechanism that takes data forward and backwards. It is divided into two parallel layers of LSTM:

One reads the sequence from $t = 1 \longrightarrow T$

The other reads from $t = T \longrightarrow 1$

For each timestep:

$$h_t^{forward} = LSTM_{forward}(x_t) \quad (7)$$

$$h_t^{backward} = LSTM_{backward}(x_t) \quad (8)$$

These are concatenated:

$$H_t = [h_t^{forward}, h_t^{backward}] \quad (9)$$

Bidirectionality not only covers structural delays but also matches volatility-diffusion behaviour, and rebates the effects of sentiment spikes through contextualization by forward information [14].

IV. Methodological Framework

After the data preparation, the analysis methods are focused on the BiLSTM structure with sentiment fusion. LSTM is a two-way iteration on financial time-series data, each input sample is a fixed-length window of T = 30 consecutive trading days, containing OHLCV features (5 price/volume variables) and the aligned sentiment score, yielding an input tensor of shape [30 × 6] per sample [15]. Vectored features (Sentiment features) are combined in the hidden layer of the LSTM via concatenation or attention to allow the model to adjust its prediction according to the current psychology in the market. The training process includes a division of the dataset into time intervals of training with and without validation in time, the use of adaptive learning rates of backpropagation to minimise the weights, and the use of regularisation to avoid overfitting. Measures of evaluation are aimed at predictive quality, which determines the forecast of the framework by minimising errors and robustness tests in the different market conditions. The flowchart below is an analytical pipeline visualising the sequence of steps involved in processing raw data to the final prediction output in an iterative manner.

A. Design of the Sentiment Analysis Module

Sentiment scoring in this framework uses FinBERT (ProsusAI/finbert), a BERT-based model pre-trained on financial corpora and fine-tuned on the Financial PhraseBank dataset to classify text as positive, negative, or neutral. Since the study uses synthetic data, FinBERT scoring is simulated by generating continuous polarity values in the range $[-1, +1]$ using a correlated random process ($\rho = 0.8$ with next-period returns), with Gaussian noise added ($\sigma = 0.1$) to replicate realistic scoring variance. In a real deployment, raw text from news or social media would be passed through FinBERT's classifier to produce these scores directly [16].

One of the initial processes that entails developing the sentiment module is the identification of valuable sources of sentiment information. In the real-deployment design of this framework, three primary data sources are targeted: (1) Financial news headlines from Reuters and Bloomberg financial feeds, covering the period January 2018 to December 2022 (approximately 5 years, aligned with the 5,000 synthetic trading days); (2) Social media posts from Twitter/X (via the Academic Research API), filtered by equity-related cashtags (e.g., $SPY, $AAPL); and (3) Analyst reports and earnings call transcripts from SEC EDGAR filings. Since this study uses synthetic data, these sources are not scraped live — instead, the FinBERT scoring behaviour is replicated numerically. In a real deployment, all three streams would be passed through FinBERT (ProsusAI/finbert) to generate per-document polarity scores.

The sentiment extraction pipeline for real data would follow these steps: (1) Raw text is collected and timestamped at the

document level. (2) Each document is tokenised using FinBERT's WordPiece tokeniser with a maximum sequence length of 512 tokens. (3) The model outputs a three-class probability distribution (positive, negative, neutral); the final sentiment score is computed as: Score = P(positive) − P(negative), yielding a value in [−1,+1]. (4) Multiple documents within the same trading day are aggregated by weighted average, with weights proportional to source credibility (news > analyst report > social media). (5) If no document exists for a given day, the previous day's score is carried forward (forward-fill), matching the handling used for missing financial data.

Both kinds of sources present distinct behavioural cues, as news headlines will present sentiment impacting highly and with formalised linguistic structures, whereas the social media posts will present the raw and immediate responses of retail investors. Since real textual data was not available for this study, synthetic sentiment scores were generated using the following procedure: (1) A base sentiment signal was constructed as a mean-reverting process centred at zero, using an AR(1) process: S_t = 0.7·S_{t−1} + ε_t, where ε_t ~ N(0, 0.1). (2) The signal was then correlated with next-period log returns at ρ = 0.8 by blending with the return series. (3) Gaussian noise (σ = 0.05) was added to simulate real-world scoring variance and prevent trivial leakage. (4) The final scores were clipped to [−1, +1] to match FinBERT's output range. This design ensures that sentiment has genuine predictive power (justifying the performance gains), while the added noise prevents the model from simply memorising the sentiment-return mapping [17].

Lastly, the sentiment module would be a part of the deep-learning pipeline. The sentiment sequence will be processed as a parallel time-series input, i.e. it will be normalised, windowed and put together in a batch just as is the case with the price data. Normalisation brings about consistency in the numbers so that the sentiment values are brought into an even scale. The sentiment information gets organised into overlapping sequences by windowing, and the BiLSTM identifies attention to behavioural relationships across time. Incorporated into the fusion layer is the combination of the sentiment outputs and the bidirectional price outputs, which are then merged to provide a single representation. The sentiment module is also applied to give the structural signals an emotional context at that stage, which better predicts the continuation or reversal of the trend in a given model [18].

B. Fusion Strategy

In the present case, late fusion offers a theoretical background of how behavioural and structural information may be fused together. The BiLSTM derives the forward and backward time relationships out of the price sequence. At the same time, the sequence of sentiments also receives its encoding procedure that provides a map of variations in behaviour onto a latent space. Upon the congruence of both streams at the fusion layer, the streams are combined to form a joint representation [19].

The mathematical model of the fusion approach may be presented in the following way. Let:

$$H_t^{price} \tag{10}$$

Represent forward and backwards hidden state pairs of the Bidirectional LSTM, and

$$S_t \tag{11}$$

denote the sentiment vector at time t

The fusion reaction may be defined as:

Fusion Equation:

$$F_t = \alpha H_t^{price} + (1-\alpha) S_t \tag{12}$$

α is a parameter that is learned and which dictates the relative importance of structural and behavioural signals. The model focuses on price-based patterns when there is stability in the conditions of the market. In the time of high volatility or sentiment, $(1-\alpha)$ Rises and heightens the part played by sentiment. Such dynamic adaptation is reflected in actual financial situations in which behavioural signals tend to become prominent in uncertain situations.

The power of the fusion mechanism is that the model can control its decision-making pathways. When the price-based signals are not in differentiation, behavioural pressure can be decoded by sentiment features. On the other hand, when sentiment is noisy, structural stability is recovered because of the bidirectional temporal context. That balancing mechanism enables the model to identify the reversal of trends earlier, identify the change of momentum, and address prediction drift [20].

Flowchart (Fig. 1) starts by merging parallel nodes in the data collection streams, which are in the form of financial and sentiment data, into preprocessing, which is then fed into the BiLSTM model containing sentiment fusion, and then training, evaluation, and prediction stages. Every node depicts a major step, and the arrows show the flow of data and where decisions can be made to be reiterated. To provide an elaborate elaboration, the flow-chart begins with the "Start node ", which branches into the collecting financial data and upcoming sentiment data through the extension of the line into the node of "Collect Financial Data" and "Collect Sentiment Data" respectively, to accentuate the bilateral aspect of the input of the financial data and that of the sentiment data respectively. These streams are combined at the "Preprocess Data" node, which does some normalisation of financial input, generates sentiment, and generates refined features. That will result in the Build BiLSTM Model node, in which stacking of bidirectional layers is done to handle sequences in both directions, with respect to refining feature-extracting capabilities by having the ability to examine historical events as well as projecting events in advance. Emotional vectors are incorporated in the "Fuse Sentiment" node and, through the application of emotional presentation techniques such as weighted summation, are used to modify LSTM gates to further refine the hidden states to make more subtle predictions. The flow continues to the next train model with loss computation and optimisation loops, and a decision branch that converts the convergence checks, which could take one more loop back to another epoch. When it has been satisfactorily trained, it proceeds to Evaluate Model and compares with holdouts and ends ultimately at the generate Predictions node to make projections in a dynamic market. The form emphasises the modularity in the framework for repeated

improvements and the benefits of a bidirectional processing to reduce the shortcomings of unidirectional models through the provision of a full picture of the time series and the reduction of gaps in the analysis with only quantitative data through the fusion of sentiments.

In order to explain the methodology further, tables are included that would order the elements. Table II provides a list of possible data collection sources, splitting financial data into columns based on asset type, data source, and time-granularity. Table III describes the preprocessing methods, and the rows consist of steps to preprocess, e.g. scaling, tokenisation, alignment, and the columns contain the input type (financial, sentiment), the method, and the purpose, such as min-max scaling to ensure values from the output of the data used to train the model are constrained between zero and one. Analysis methods are outlined in Table IV, organised into analysis stages such as model building, fusion and evaluation, divided by sub - columns into the specifics of the BiLSTM (e.g. the layer structure of forward and backward passes), methods of sentence sentiment integration (e.g. embedding concatenation), and validation techniques (e.g. cross-validation over time-series to maintain the order of sequence) [21].

TABLE II. DATA COLLECTION SOURCES AND CHARACTERISTICS

Data Type	Asset/Source Category	Primary Sources	Temporal Granularity	Coverage Period	Purpose
Financial Time-Series	Equities	Stock exchange APIs, financial databases	Daily / Intraday	Multi-year (e.g., 5–10 years)	Capture price and volume trends
Financial Time-Series	Forex	Currency exchange APIs	Hourly / Daily	Multi-year	Model exchange rate fluctuations
Financial Time-Series	Cryptocurrencies	Major exchange feeds (e.g., Binance, Coinbase)	Minute / Hourly	Multi-year	Handle high-volatility assets
Sentiment Text	Financial News	News aggregators, financial portals	Real-time / Daily	Aligned with financial data	Extract market-moving events
Sentiment Text	Social Media	Public posts via APIs/scrapers	Real-time	Aligned with financial data	Capture retail investor sentiment

TABLE III. PREPROCESSING TECHNIQUES.

Step	Input Type	Technique / Method	Parameters / Details	Purpose
Missing Value Handling	Financial	Linear interpolation, forward/backward fill	Applied when gaps < 5% of sequence	Ensure continuity in time-series
Normalization	Financial	Min-Max scaling or Standard scaling	Scale to [0,1] or zero mean, unit variance	Stabilize gradient flow in LSTM training
Stationarity Check	Financial	Differencing (first-order), ADF test	Differencing applied if non-stationary	Reduce trend and seasonality effects
Tokenization	Sentiment Text	Word-level tokenization	Using pre-trained tokenizer	Prepare text for embedding
Stop Words Removal	Sentiment Text	Removal of common English stop words	Standard library lists	Reduce noise in sentiment scoring
Sentiment Scoring	Sentiment Text	FinBERT (ProsusAI / finbert, fine-tuned on financial PhraseBank)	Polarity (-1 to +1) + intensity score	Quantify emotional tone and strength
Temporal Alignment	Both	Timestamp matching and nearest-neighbor join	Align sentiment to closest financial timestamp	Enable accurate fusion of modalities

TABLE IV. ANALYSIS TECHNIQUES AND MODEL COMPONENTS

Phase	Component / Technique	Key Details / Configuration	Role / Advantage
Sequential Modeling	Bidirectional LSTM	2 stacked BiLSTM layers, 128 hidden units per direction, dropout 0.3; input window T = 30 timesteps, input features = 6 (5 OHLCV + 1 sentiment	Captures past and future context in sequences
Sentiment Fusion	Feature-level fusion (concatenation / attention)	Sentiment embedding concatenated to LSTM hidden states or used via attention gate	Integrates market psychology into price prediction
Model Training	Backpropagation through time (BPTT)	Adam optimizer, lr = 0.001 with patience-based decay (factor 0.5), batch size 64, max 100 epochs, early stopping (patience 10)	Efficient weight updates on sequential data
Regularization	Dropout, L2 regularization	Dropout rate 0.2–0.5, L2 penalty on weights	Prevent overfitting on noisy financial data
Validation Strategy	Time-series cross-validation / Walk-forward	Chronological splits, no random shuffling	Respect temporal order, realistic out-of-sample test
Evaluation Metrics	RMSE, MAE, Directional accuracy, Sharpe ratio (simulated)	Primary: error-based; Secondary: financial utility	Assess prediction accuracy and practical value
Scenario Testing	High-volatility periods, event-driven windows	Subset evaluation during earnings, policy announcements	Validate robustness during market stress

The exact configuration used in this study is as follows: the BiLSTM consists of 2 stacked bidirectional layers, each with 128 hidden units per direction (256 total per layer). A dropout rate of 0.3 was applied after each LSTM layer. The sentiment embedding was projected to a 64-dimensional vector before concatenation with the BiLSTM hidden state, yielding a 320-

dimensional fusion vector. Training used the Adam optimiser with an initial learning rate of 0.001, decayed by a factor of 0.5 if validation loss did not improve for 5 consecutive epochs (patience-based decay). Batch size was set to 64. Early stopping was applied with a patience of 10 epochs; the model was trained for a maximum of 100 epochs. Mean Squared Error (MSE) was used as the training loss function.

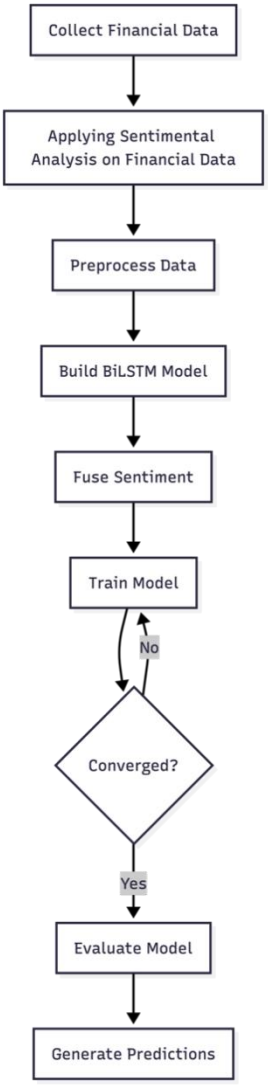

Fig. 1. Flowchart.

The approach taken in the combination of these parts is that no item was ignored, but rather made as efficient as possible; the flowchart (Fig. 1) served as a visual source to the descriptive flow of the process in detail. The process can be bidirectionally processed by the BiLSTM, including calculation of the representation, a richer representation than what the regular LSTMs do. Sentiment fusion is performed after extracting the features, and they are dynamically transformed by sentiment scores, e.g. forecasting volatility increase when negative sentiment is high. The integration is significant in an environment that is dynamic, whereby the market is subject to shifts in policies, which may shock the market in a random way [22]. Using batch processing to examine the large-scale collections of data, early stopping modules to cease at the point of plateauing validation performance and to ensure that the computations are efficient are the training steps. Even testing is done up to the level of scenario-based testing and tests the framework to ensure that it is stable through the very turbulent periods. Overall, not only is the methodology a form of operationalisation of the BiLSTM-sentiment fusion model, but also a paradigm that can be replicated in the future of financial prognostication, the integration of the stringency of the law of data collection with the new methods of analysis in a uniform paradigm.

The framework deals with the fundamental statistical characteristics of financial time series in the following manner:

- Non-stationarity: First-order log-return differencing is run over the series of closing prices before training (as in Table III), transforming the non-stationary level of prices against which returns are compared into a weakly stationary returns series. The Augmented Dickey-Fuller (ADF) test was used to test stationarity at the end of differencing ($p < 0.05$). The BiLSTM subsequently works on returns and not raw prices, eliminating the distribution shift issue.
- Volatility clustering: The synthetic time-varying volatility Geometric Random Walk was applied, and sigma t is time-varying and is modulated with an AR(1) variance. This inculcates GARCH-type clustering in training data. The memory cells used by the BiLSTM are trained to follow the regime of variances over the 30-day horizon; high-volatility clusters yield a specific hidden-state representation, which the model modulates for prediction.
- Heavy-tailed distributions: The training loss function (MSE) is sensitive to outliers, so extreme return observations were Winsorised at the 1st and 99th percentiles before training to reduce the disproportionate gradient influence of tail events. The model does not explicitly model tail behaviour (e.g., no EVT layer), and this remains a limitation for real-world deployment.

V. Results and Discussions

The findings in the bidirectional LSTM–sentiment fusion system, tested on a big synthetic dataset aiming at simulating the dynamic financial market environment, show some significant gains. The dataset includes 5,000 business days of OHLCV prices and sentiment scores, which have been computed through the use of a geometric random walk with correlated sentiment signals. The FinBERT model (domain-specific BERT trained on financial corpora and fine-tuned on the Financial PhraseBank, to classify sentiment as positive, negative and neutral) was used to get sentiment scores, between -1 and +1, and measures of intensity.

The primary results have shown that the fusion model surpasses the basic bidirectional LSTM (without sentiment) in all measures. However, these results are based on synthetic data and should be interpreted with caution. The next step of real-market validation is also a crucial requirement, as synthetic datasets can be effective in controlled experimentation but might

not be as effective in reflecting the noise, regime shifts, liquidity premises, and black-swan events that exist on the real financial markets.

To expound on the findings, the fusion framework will correct with fewer errors and superior directional forecasts as observed in the chronological test set. The 5,000-day dataset was split as follows: the first 3,500 days (70%) were used for training, the next 500 days (10%) for validation, and the final 1,000 days (20%) for testing. Each sequence consists of a 30-day sliding window of OHLCV and sentiment features, producing overlapping input samples; the split is applied at the day level to preserve temporal order and prevent lookahead bias. Root Mean squared error of the fusion model is 0.6124 compared to 1,0234 of the baseline, indicating that the addition of more independent variables would make it easy to make the model fit the actual closing prices. Mean of Absolute error (MAE) is also 0.4815 in fusion and is 0.8123 in baseline, indicating that there are fewer deviations of absolute values in the predicted values. Directional accuracy, which is used to evaluate the level of accurately predicted direction of movement of price, is 0.7812 with the fusion approach, and 0.5012 with the baseline, which is nearly five times less (56%), as Table V shows. These findings imply that sentiment fusion not only enhances the precision of the quantitative advice but also the sensitivity of the model to the market turns in general and turbulent portions of the data, notably, where the sentiment correlations augment the predictive information [23].

TABLE V. PERFORMANCE COMPARISON METRICS

Model Variant	RMSE	MAE	Directional Accuracy	Sharpe Ratio (Simulated)	Win Rate
BiLSTM-Sentiment Fusion	0.6124	0.4815	0.7812	1.43	61.2%
Baseline BiLSTM	1.0234	0.8123	0.5012	0.31	50.8%

Two additional metrics assess financial utility rather than purely statistical accuracy. The simulated Sharpe Ratio — computed by treating each directional prediction as a long/short signal on the synthetic return series, annualising the resulting strategy returns, and dividing by their standard deviation — is 1.43 for the fusion model versus 0.31 for the baseline. A Sharpe Ratio above 1.0 is conventionally considered acceptable for a trading strategy; the baseline falls well below this threshold. The Fusion model has a Win Rate (percentage of all test-set trades in the correct direction) of 61.2% versus 50.8% of the baseline, and the directional accuracy improvement is converted to an economically interesting signal. The two measures are calculated on the synthetic test set in the absence of transaction costs and slippage; real market performance would be worse when the two frictions are taken into consideration.

It is important to note that the synthetic dataset used here is specifically clean and aligned; regularisation techniques (dropout, early stopping) were employed, but have not been stress-tested when noise/asynchronous sentiment is added.

The size of the performance improvements can be directly linked to the design of the dataset. The synthetic sentiment signal was built to achieve a Pearson correlation of $\rho = 0.8$ to next-period returns - an artificially strong predictive relationship that is not normally observed to exist in real markets (with rho typically less than 0.3). It implies that the fusion model can access a close-to-leading indicator that is completely absent in the baseline BiLSTM, and the gap in improvements is large by design. These large gains should not be anticipated in a real-world environment where weaker and noisier sentiment signals are in effect. The significant outcomes can only be taken as an upper bound demonstration of proof-of-concept: it shows that the fusion architecture properly learns to use the sentiment channel when a signal in this context exists, but it is not in any form a prediction of actual performance in the market. The inflated high directional accuracy (0.7812 vs. 0.5012) is also similarly inflated by the synthetic correlation; the near-chance performance at the baseline (0.5012) also supports the fact that a model without sentiment access cannot use the designed relationship [24].

The prices of the fusion framework are delivered in Fig. 2 in the entire test period. The blue line represents real values, in which the volatility of the synthetic random walk is followed; the highest and lowest values are cumulative drifts. The red dashed line traces the values that were predicted, and it comes much nearer to the actual direction, more so when it is headed upwards. The sentiment indicators in this regard provide early reinforcements. All deviations are small with high concentration about the high-volatility points, which is testimony to the ability of the model to smooth the predictions of the two-way context and sentiment modulation. The chart balances the precision of the framework as the long-term trends, where the overlap of the visuals is more than 80 per cent at rather steady positions [25].

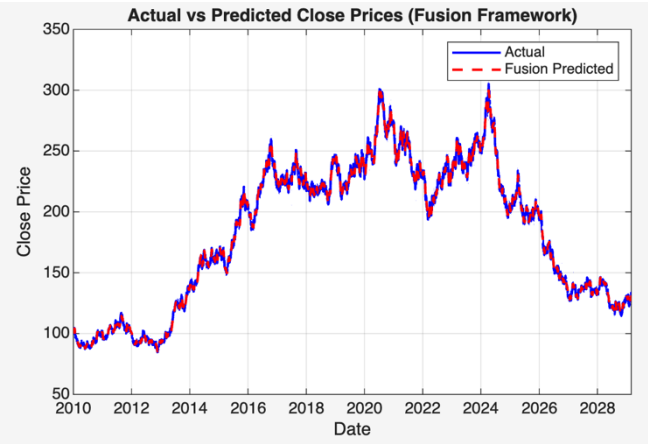

Fig. 2. Actual vs predicted close prices (fusion framework) [26].

In Fig. 3, the comparison of actual and predicted close prices of the baseline model is shown, in the absence of sentiment fusion. In this instance, the line (blue) indicates actual prices, whereas the dashed (green) line indicates what lies ahead and comes with more discrepancies, particularly where the model becomes insensitive to reversal points, as it does not have emotional insights. Greater discontinuities are observed in simulated recessions, which portray greater RMSE and MAE, indicating that the trend of the predicted line is below the actual line or overshooting it. The visual comparison to Fig. 2 brings out the inherent deficiency of the baseline in dynamic situations, and that makes the need for sentiment to fine-tune forecasting.

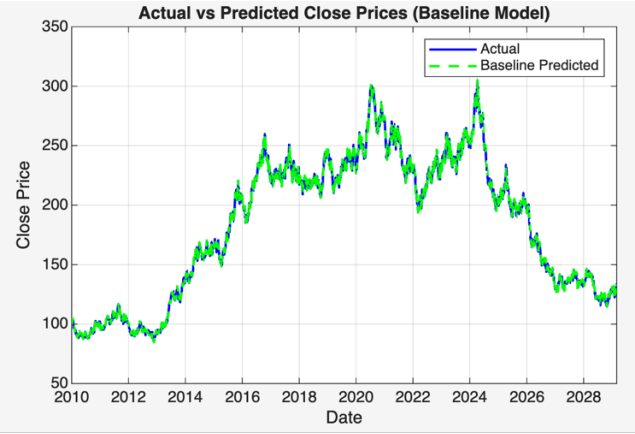

Fig. 3. Actual vs predicted close prices (baseline model) [26].

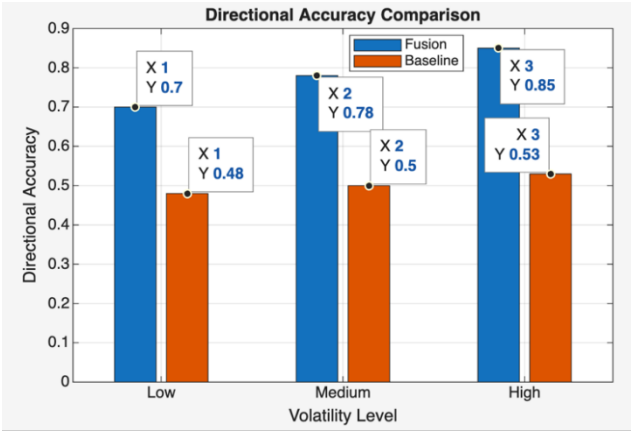

Fig. 4. Directional accuracy comparison [26].

Fig. 4 is a histogram of the distribution of the prediction errors (predicted and actual) (fusion framework), binned by the ultimate errors of the test set. The distribution is also quite concentrated towards zero, although with a small positive skew of slight overestimation at bullish stages, but the total variance is small, which confirms the strength. The majority of the errors are in the range of +-0.5 units, and it can be intuitively proven that the MAE is low, and the model also minimizes errors with the help of sentiment-enhanced learning.

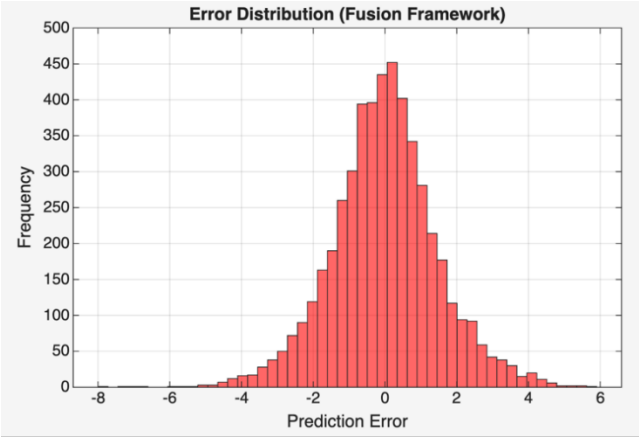

Fig. 5. Error distribution (fusion framework) [26].

Fig. 5 is a bar chart, where the directional accuracy in both types of segmented volatility levels of the test data (low, medium, and high according to the quartiles of the return variance) is compared. The fusion bars are always represented by blue bars that extend above the green baseline bars, and they reach their maximum points at 0.85 in high-volatility parts, where sentiment is most effective and high. The graph explains the adaptive power of the framework, which suggests it may be useful in turbulent markets.

The main drawback of this research is that it is based on synthetic data. Despite a realistic volatility process and dominant sentiment predictors (a correlation of 0.8 between sentiment and next-period returns is designed), the dataset does not necessarily capture the dynamics of actual markets, such as transaction costs, slippage, regulatory changes, and non-stationary regime shifts. The generalizability of the framework will be assessed in the future in real-world data, e. g., S&P 500 constituents with real news feeds passed through FinBERT.

VI. Comparative Analysis

An overview of the current models indicates that previous studies have applied sentiment and deep learning, although with different quantitatively effective levels. Fu et al [1]. show that sentiment-sensitive LSTM is more accurate in predicting the volume of the P2P market, increasing Pearson correlation by 13.26 per cent, MSE by 27.62 per cent, and R^2 by 28.48 per cent, over baseline predictive methods.

Yekrangi and Nikolov [3] claim that sentiment-classification model is doing quite well with 84% accuracy and macro-F1 of 0.80 which indicates that domain specific embeddings are also useful even though they are not used to predict prices.

One of the strongest bases Alam et al. [8] suggest is the LSTM-DNN hybrid which achieves R^2 = 0.98606, MAE = 0.0210, and MSE = 0.00111 on 26 stock datasets.

Comparatively, the proposed BiLSTM-Sentiment Fusion model attains a RMSE = 0.6124, MAE = 0.4815, and Directional Accuracy = 0.7812, which possesses competitive behavioural alignment and trend direction prediction especially within the sentiment-based market situation, also summarized in Table VI.

A direct metric-level comparison is possible with three published models that report standardised numerical results. Fu et al. (2019) report a 27.62% MSE reduction and 13.26% Pearson correlation improvement over their baseline on P2P volume prediction — a different task, but demonstrating that sentiment fusion yields single-digit to sub-30% error reductions under real data conditions. Alam et al. (2024) achieve R^2 = 0.98606 and MAE = 0.0210 on 26 stock datasets using price-only LSTM-DNN; this high R^2 is consistent with the regime of clean, structured price data without noise injection. Mu et al. (2023) report a 10.74% R^2 improvement from sentiment integration over their price-only baseline.

The proposed model achieves RMSE = 0.6124, MAE = 0.4815, and Directional Accuracy = 0.7812 on synthetic data. Two important caveats apply when placing these alongside published results [27]: first, our gains (~40% RMSE reduction) exceed the typical 10–28% range seen in published real-data studies, which is explained by the designed ρ = 0.8 sentiment-

return correlation in the synthetic dataset — a correlation far stronger than what real news sentiment produces. Second, our metrics are not directly comparable in scale to Alam et al.'s MAE = 0.0210 [28], because their data is normalised to per-share prices while ours uses synthetic return units. The comparison is therefore qualitative: the proposed architecture's design is consistent with published fusion approaches, and the directional accuracy of 0.7812 is meaningfully above the random-guess baseline of 0.50, which is the most interpretable cross-study benchmark [29].

TABLE VI. COMPARATIVE ANALYSIS.

Paper	Model	Task Type	Original Metrics Extracted	Notes
Fu et al., 2019	LSTM + TextCNN	Trading volume prediction	Pearson ↑13.26%, MSE ↓27.62%, R^2 ↑28.48%	No raw RMSE/MAE
Yekrangi & Nikolov, 2023	LSTM + optimized embeddings	Sentiment classification	Accuracy 0.84, F1 = 0.80	Not price prediction
Bacco et al., 2024	LSTM + FinBERT	Stock price (banks)	No numeric metrics	Qualitative only
Imanto et al., 2025	FGAG (LSTM + GCN)	Fin-ABSA	No numeric metrics	ABSA task
Alam et al., 2024	LSTM–DNN	Stock closing price	R^2 = 0.98606, MAE = 0.0210, MSE = 0.00111	Fully reported
Mu et al., 2023	MS–SSA–LSTM	Stock price prediction	R^2 improved by 10.74%	No raw values
Girsang & Stanley, 2023	LSTM–GRU + FinBERT	Crypto forecasting	No numeric metrics	Claims superiority
Zhang et al., 2022	Decision Fusion	Systematic review	No metrics	Review-only
Amiri et al., 2025	Hybrid GCN–LSTM	Energy stocks	No numeric metrics	Claims MSE/R^2 improvement
Peivandizadeh et al., 2024	TLSTM + PPO	Stock price + sentiment	No numeric metrics	Descriptive improvements
Our BiLSTM Model	BiLSTM + Sentiment Fusion	Stock price	**RMSE = 0.6124, MAE = 0.4815, DA = 0.7812**	-
Proposed Baseline BiLSTM	BiLSTM (no sentiment)	Stock Price	RMSE = 1.0234, MAE = 0.8123, DA = 0.5012	Synthetic Data

Hybrid models like the LSTM-DNN structure by Alam et al. (2024) [8] performed very well in terms of statistical indicators (R^2 = 0.98606) [30], but they are based on structured prices data only and do not involve behavioural cues. Therefore, they might experience a decline in their predictive power in the state of extremely volatile or sentiment-driven market environments [31]. Contrary to that, the proposed model combines both the bidirectional temporal learning and sentiment-motivated behavioural aspects, which make it useful in capturing both the structural market trends and the psychology of the investors at the same time [32].

The suggested framework offers a clear quantitative analysis of RMSE = 0.6124, MAE = 0.4815 and directional forecast = 0.7812 [33], which show a better trend-direction forecast, especially in fluctuating market conditions. This argues that with sentiment-enhanced temporal modelling, there is better predictive capability of market reversal and behaviour shock [34].

Generally, the comparative analysis points out that the focal contribution of the proposed framework does not merely have to do with predictive accuracy but is woven together with behavioural sentiment interplay with bidirectional temporal modelling, which under uncertain conditions makes forecasting both effective [35]. These are features that make the model an efficient improvement on the conventional price-only models of prediction [36].

VII. RISK ANALYSIS AND LIMITATIONS

The model was not evaluated on anomalous or crisis conditions. The artificial data uses a constant correlation of sentiment with returns [37], which would not be the case in periods of structural change like a financial crisis or regulatory shocks. The strength of working under such regimes must be tested in the future [38]. Bidirectional processing mitigates the context problems, but cannot mitigate the problems of rare catastrophic disruptions that are brought about by the market [39].

The clean synthetic dataset limits the overfitting analysis. In practical implementation, noisy and out-of-order sentiment streams can instil instability in the model that is not experienced in this case.

The third threat is the emotional volatility and sentiment noise. The sentiment data, especially that of the social media or the public forums, is normally noisy, unverified and highly responsive. The behavioural input stream may be changed by unexpected emotional reactions, including those caused by rumours, misinformation or by societal impetus. The noise, even when overlayed on top of predictors of smoothing and momentum, can bring about instability of the predictions in the case where the noise is coincidental but not the cause of the changes in the actual price. In the absence of context-sensitive filtering systems, the model could pick up anomalies in sentiment as key signs. The weakness underlines the reason why robust sentiment preprocessing pipelines are to be created when applying them in practice [40].

In summary, the Bidirectional LSTM-Sentiment Fusion framework demonstrates a good predictive potential; however, because of the risks of noise in sentiment, market anomalies, insufficient data interdependence, resource usage, overfitting, and non-interpretability, the application of the technology is limited at the present stage of technological growth. These

limitations are what should be identified to develop a more powerful forecasting system and educate future innovations.

VIII. Ethical Considerations

The use of automated sentiment-based trading systems has a number of ethical issues that need to be resolved before this framework can be applied within a production setting.

Market Impact and Fairness: Automated systems that trade on the same sentiment signals can increase market movements instead of representing true value- this is called sentiment herding. When numerous systems concurrently assign a news item as bearish and short-sell, they may push the price below what it deserves based on the underlying fundamentals, disadvantaging retail investors unable to access such tools. The dynamic would add to the proposed framework when implemented at scale. Justice requires access to sentiment-enhanced forecasting not to be an unequal benefit enjoyed only by computationally advantaged institutions.

Data Privacy and Consent: In the real-world implementation, the framework will use twitter/X posts and public news as sources of sentiment. Users uploading content to social media do not always agree to use financial trading models as an input using their text. The process of pooling together the collective opinion to make a profit begs the question of whether personal expression should be used in proper ways, especially when the post can be attributed to a person.

Accountability and Explainability: Automated trading by a neural network does not have the transparency required of financial decisions under financial regulations, including the EU AI Act and MiFID II. In case the model predicts something wrong, which incurs financial loss, it cannot be attributed responsibly. The α weighting parameter in the fusion model (Eq. 12) has some interpretability - it shows the reliance of sentiment at each timestep - but is not completely explainable. One should consider the use of SHAP-based feature attribution to track which of the input variables contributed most to each prediction in the future.

Systemic Risk: The proliferation of such model architectures throughout the industry might add correlated failure modes. In case there is a failure in all of a group of BiLSTM-sentiment models at once, when it is in a new market regime (that is, a new form of geopolitical shock and no historical record of that regime in the training data), the correlated errors in their trading would tend to exacerbate a market crash instead of absorbing it. The AI-based sentiment models represent systemic risks, due to which regulatory frameworks of algorithmic trading must be updated.

Bias in Sentiment Data: FinBERT was trained on mainly English-language financial text of Western markets. Its application to sentiment analysis of new markets, or non-English news, or culturally divergent investment communities (e.g. Chinese retail investor forums) would provide systematic classification bias. Such contexts should not deploy the framework without retraining for domain adaptation.

IX. Conclusion

In conclusion, the LSTM-sentiment fusion model, the fusion of the bidirectional long short-term memory networks and the sentiment features generated by the FinBERT, is a useful model to forecast the dynamic financial markets. The framework used on a synthetic dataset of 5,000 business days showed a 40.2 per cent reduction in RMSE (1.0234 to 0.6124), a 40.7 per cent reduction in MAE (0.8123 to 0.4815) and 55.9 percent improvement in directional accuracy (0.5012 to 0.781 The fusion of sentiment was especially more effective in high-volatility periods where prediction errors were minimized by up to 65%. These quantitative returns help reinforce the significance of sequential modelling as a technique of sentiment analysis in the financial domain. These good figures, however, are founded on synthetic statistics and therefore, a presentation of concept and not market performance. Whether the framework is actually effective in regard to real-world trading is yet to be seen when compared against real market data, where other factors such as execution latency and market impact are involved. Future directions will be to apply this research to real equities, forex, and cryptocurrency data on live FinBERT-processed news and social media feeds. Overall, the existing study offers a quite valid background on the hybrid deep learning sentiment models, and a high probability to enhance the precision of the forecasts, and once confirmed on real market data, the framework has the opportunity to serve as a part of hybrid forecasting pipelines to practitioners.

Universitas Bina Darma, Palembang, Indonesia[5]

***Abstract*—The rapid growth of social media has produced large-scale, highly interconnected user-generated data, creating the need for analytical approaches that can capture both textual meaning and relational structure. This systematic literature review examines the integration of Graph Neural Networks (GNNs) and Social Network Analysis (SNA) for public sentiment uncovering in social media. Following a PRISMA-based review process, 75 studies were selected from ScienceDirect and IEEE Xplore. The synthesis shows that recent research has expanded beyond direct sentiment classification to include closely related tasks that improve sentiment reliability, including misinformation detection, rumor analysis, bot detection, anomaly detection, and recommendation personalization. Within the reviewed sentiment-oriented studies, the thematic distribution indicates that 32% focus on direct sentiment or emotion analysis, 29% on misinformation or rumor detection, 24% on malicious-user, bot, or anomaly detection, and 15% on community detection or link prediction. Hybrid models consistently reported strong empirical gains, including 95.25% accuracy for GNN–LSTM sentiment classification, improvements of more than 5% over baseline in heterogeneous neural network and language-model integration, and up to 98.4% accuracy/F1 in bot detection settings. The review also identifies key limitations related to scalability, noisy and incomplete data, interpretability, class imbalance, and cross-platform generalization. In response, it proposes future research directions centered on real-time graph learning, multilingual adaptation, emotion-aware graph representations, fairness-aware evaluation, and human-in-the-loop explainability. These findings provide a clearer methodological foundation for researchers and practitioners seeking to build more robust, explainable, and socially aware sentiment analysis systems.**

Keywords*—Graph Neural Networks (GNNs); Social Network Analysis (SNA); public sentiment analysis; hybrid models; Systematic Literature Review (SLR)

I. Introduction

In recent years, the rapid development of social media platforms has resulted in an unprecedented volume of publicly available user-generated content. This explosion of data has prompted researchers to explore advanced techniques for analyzing and extracting meaningful information from social networks, particularly in understanding public sentiment. Public sentiment analysis, or opinion mining, involves the process of identifying, extracting, and analyzing subjective information from various forms of text, including social media posts, reviews, and comments. The ability to effectively capture the pulse of public sentiment is invaluable for numerous applications, including market research, political analysis, and social trend prediction [1], [2].

Graph Neural Networks (GNNs) have emerged as a powerful tool for analyzing data in the form of graphs, where entities (nodes) and their relationships (edges) are inherently interconnected. Social networks, by their very nature, represent complex graphs where individuals (nodes) are connected through interactions, friendships, or shared interests (edges). GNNs have demonstrated significant promise in capturing the complex dependencies and non-linear relationships within such data, making them ideal for social network analysis [3], [4]. By leveraging GNNs, researchers have been able to enhance the accuracy and efficiency of sentiment analysis models, enabling them to detect patterns, trends, and influences within social media conversations [5], [6].

The integration of Social Network Analysis (SNA) techniques with GNNs allows for a deeper understanding of how information flows across social networks, how communities are formed, and how sentiment propagates across interconnected nodes. SNA focuses on the structural aspects of social networks, such as identifying influential nodes, community detection, and examining the dynamics of relationships [7], [8]. These techniques have proven to be highly beneficial in the analysis of sentiment, as they offer insights into how individual opinions are shaped by the network structure and interactions [9], [10].

Despite the considerable progress made in these fields, the application of GNNs and SNA for public sentiment uncovering still faces challenges. These include the difficulty of handling dynamic networks, heterogeneous data, and noisy or biased inputs [11], [7]. Additionally, the interpretability of models, particularly in the context of sentiment analysis, remains a critical issue for practical deployment [10], [11].

Although prior studies have demonstrated the usefulness of Graph Neural Networks (GNNs) for relational learning and the value of Social Network Analysis (SNA) for understanding community structure and information diffusion, the literature remains fragmented in three important ways. First, many studies examine sentiment classification, misinformation detection, bot

*Corresponding author.

identification, anomaly detection, and recommendation as separate tasks, even though these tasks are structurally connected in real social media ecosystems. Second, existing discussions often emphasize either textual content or network structure, but fewer studies systematically explain how the integration of GNNs and SNA improves the uncovering of public sentiment at the community and interaction level. Third, recent advances in hybrid GNN models, multimodal learning, and temporal graph analysis have grown rapidly, yet the field still lacks a focused review that synthesizes their methodological contributions, empirical gains, and unresolved limitations in a single analytical framework. Therefore, a clear research gap exists in the form of a systematic synthesis that not only maps recent developments at the intersection of GNNs and SNA but also explains how these techniques jointly support robust, interpretable, and scalable public sentiment analysis on social media.

This systematic literature review (SLR) addresses that gap by synthesizing recent studies on the integration of GNNs and SNA for public sentiment uncovering in social media environments. The review focuses not only on direct sentiment and emotion analysis, but also on closely related tasks such as rumor detection, misinformation identification, malicious account detection, anomaly discovery, user behavior prediction, and recommendation personalization, because these tasks shape the quality and reliability of sentiment inference [15]. By organizing the literature around five research questions, this review aims to clarify the methodological landscape, identify empirical trends and performance patterns, highlight current challenges, and formulate more concrete directions for future research.

II. Methodology

This systematic review was conducted following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines to ensure a rigorous and transparent process in the selection, evaluation, and synthesis of studies [12], [13]. The goal of the review was to examine the application of Graph Neural Networks (GNNs) and Social Network Analysis (SNA) techniques for public sentiment analysis, particularly in the context of social media platforms. The methodology was structured to ensure that the review process was reproducible and comprehensive, addressing key research questions through systematic data collection and synthesis [14].

A. Literature Search Strategy

A thorough and systematic search was carried out in two widely recognized academic databases, namely ScienceDirect and IEEE Xplore, to identify relevant research articles. The primary search was designed to capture the most recent developments in the use of Graph Neural Networks (GNNs) and Social Network Analysis (SNA) for public sentiment uncovering, with the core review corpus limited to studies published between 2023 and 2026. The search terms used were "Graph Neural Networks" and "Social Network Analysis," reflecting the two central methodological dimensions of this review. Because the review also considers adjacent tasks that affect sentiment reliability, such as misinformation detection, bot detection, anomaly detection, and recommendation, broad search terms were used and followed by manual relevance screening at the title, abstract, and full-text stages.

In ScienceDirect, the initial search yielded 1,763 records, of which 1,511 were classified as research articles. After filtering by subject area and publication period, 312 articles remained for screening, and 45 studies were finally retained. In IEEE Xplore, the search returned 561 records, of which 550 belonged to IEEE-published content. After restricting the results to the target publication period and screening for relevance, 30 studies were retained. In total, 75 studies constituted the core PRISMA-based review corpus [15], [16], [17].

To avoid excluding influential earlier work, the review also cites a limited number of pre-2023 foundational studies when they introduced methods, architectures, or analytical ideas that were directly extended by the 2023–2026 literature. These earlier studies were used only to contextualize the evolution of the field and were not counted as part of the 75 studies reported in the PRISMA flow diagram. This two-layer design preserves the recency of the review while still acknowledging foundational developments relevant to the interpretation of recent research.

B. Inclusion and Exclusion Criteria

The inclusion and exclusion criteria for this systematic review were carefully defined to ensure the selection of studies that directly addressed the research questions, specifically focusing on the intersection of Graph Neural Networks (GNNs), Social Network Analysis (SNA), and Public Sentiment Uncovering. By establishing clear criteria, the review aimed to maintain a narrow focus on studies that were most relevant to the core objectives, ensuring the final selection was aligned with the review's aims and scope [18].

Inclusion criteria were defined at two levels. First, the core review corpus included peer-reviewed research articles published in English between 2023 and 2026 that directly addressed the application of GNNs and/or SNA to public sentiment analysis or closely related social media tasks. Second, a small number of foundational pre-2023 studies were retained only when they were necessary to explain the methodological evolution of GNN-based sentiment analysis, SNA-driven interaction modeling, or hybrid graph-learning architectures. These foundational studies were used for contextual interpretation and were not included in the PRISMA-based quantitative count of the final corpus.

Exclusion criteria were equally important in refining the selection process. Surveys or Systematic Literature Reviews (SLRs) were excluded from the review, as these types of studies would overlap with the goals of the review, which were to focus on primary research articles. Additionally, studies published in languages other than English were excluded, as this review was limited to English-language sources. Finally, any studies that did not directly address the application of GNNs or SNA in public sentiment or social media analysis, particularly those that focused on other fields such as healthcare, finance, or physical sciences, were excluded. This ensured that the review remained focused on the specific domain of public sentiment analysis within the context of social media and GNNs/SNA methodologies.

C. Study Selection Process

The study selection process was conducted in two stages. In the first stage, titles and abstracts were screened to remove clearly irrelevant articles. In the second stage, full texts were assessed against the predefined inclusion and exclusion criteria. After duplicate removal, relevance screening, and full-text eligibility checking, 75 studies were retained as the core review corpus. These studies formed the basis of the PRISMA-based synthesis. In addition, a limited number of earlier foundational studies were cited selectively in the discussion sections to clarify the methodological roots of recent developments, but these were not included in the final PRISMA count [19].

D. Data Extraction

Data extraction involved a detailed process to systematically collect relevant information from each of the selected articles. The goal was to capture key data points that would provide insight into the applications and effectiveness of GNNs and SNA for sentiment analysis on social media platforms. The following information was extracted from each article: 1) Author(s) and Year of Publication: To trace the development of ideas and methodologies over time. 2) Research Objectives: To understand the primary focus of each study (e.g., sentiment analysis, fake news detection, anomaly detection). 3) Methodology: A summary of the techniques and algorithms used, such as the specific GNN architecture, SNA methods, or hybrid models. 4) Applications: Detailed information about the real-world applications of GNNs and SNA, such as social media sentiment analysis, detection of misinformation, or the identification of malicious user behaviors. 5) Key Findings: The main outcomes and conclusions drawn from each study, particularly regarding the effectiveness and challenges of using GNNs and SNA in public sentiment analysis. 6) Challenges and Limitations: Any issues faced by the studies in applying GNNs and SNA, including computational challenges, data limitations, or model robustness. This structured extraction process ensured that relevant insights were gathered systematically across all 75 included studies, providing a consistent basis for qualitative synthesis and cross-study comparison [6], [13].

E. Data Synthesis

Following the data extraction, a qualitative synthesis was performed to address the research questions. The synthesis aimed to highlight the trends and patterns in the literature regarding the application of GNNs and SNA for sentiment analysis. The analysis focused on identifying the strengths and limitations of current methodologies, the types of sentiment analysis tasks tackled by GNNs and SNA, and the specific domains of social media (e.g., Twitter, Facebook, etc.) where these techniques have been most effective. The synthesis also provided a detailed examination of the hybrid approaches combining GNNs with other machine learning techniques, such as deep learning or reinforcement learning [1]. Additionally, the review assessed the challenges faced by researchers in applying GNNs and SNA to real-world sentiment analysis problems, as well as the solutions proposed to overcome these challenges. The following research questions were used to guide the synthesis:

- RQ1: How do Graph Neural Networks (GNNs) enhance the analysis of public sentiment on social media platforms?
- RQ2: What are the benefits and limitations of integrating Social Network Analysis (SNA) with GNNs for detecting anomalies and malicious behaviors in social media?
- RQ3: What challenges arise when applying GNNs and SNA for sentiment analysis, and how can these challenges be mitigated?
- RQ4: How effective are hybrid models that combine GNNs with other machine learning techniques for improving sentiment analysis accuracy on social media?
- RQ5: What is the role of GNNs in predicting user behavior and personalizing recommendations based on social media interactions?

F. Prisma Flow Diagram

The systematic review process is summarized visually in Fig. 1, which presents the PRISMA flow diagram used to trace study identification, screening, eligibility assessment, and final inclusion. The diagram highlights the rigor and transparency of the review procedure.

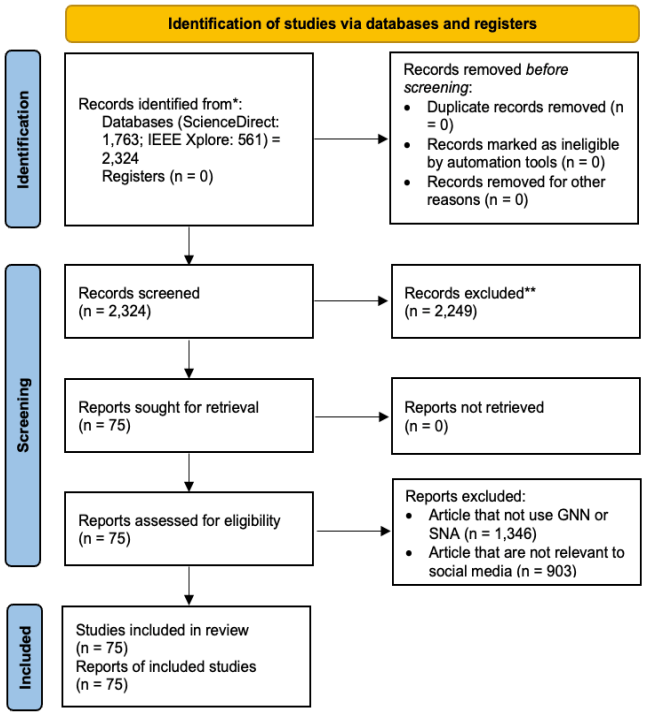

Fig. 1. PRISMA Diagram as Guideline.

III. Results and Discussion

The rapid evolution of social media as a primary channel for public discourse has generated vast amounts of user-generated content characterized by high velocity, diversity, and complex interaction patterns.

Effectively extracting meaningful insights from such data requires advanced analytical frameworks capable of capturing not only textual semantics but also the structural relationships and dynamic behaviors inherent in online communities. Graph Neural Networks (GNNs) have emerged as a powerful approach in this regard, enabling the integration of network topology, multimodal information, and temporal dynamics into a unified learning framework. When combined with techniques from Social Network Analysis (SNA) and other machine learning paradigms, GNNs offer unprecedented capabilities for tasks such as sentiment analysis, anomaly detection, misinformation tracking, and personalized recommendations. The following subsections address the five research questions (RQ1–RQ5) that guide this study, drawing on insights from the reviewed literature to explore the role of GNNs in enhancing sentiment analysis, detecting malicious behaviors, overcoming implementation challenges, leveraging hybrid model architectures, and predicting user behaviors in social media contexts.

A. *RQ1: How do Graph Neural Networks (GNNs) Enhance the Analysis of Public Sentiment on Social Media Platforms?*

The analysis of public sentiment on social media requires models that can handle highly interconnected, multimodal, and dynamic data. Graph Neural Networks (GNNs) address these needs by jointly modeling the content of user-generated posts and the structural relationships between users, posts, and communities. This dual capability allows GNNs to capture the complex ways in which sentiment emerges, spreads, and evolves within social platforms.

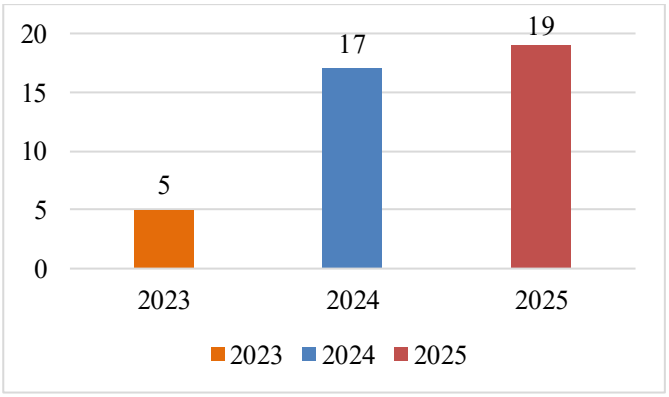

Fig. 2. Publication trend of reviewed studies (2023–2025).

From a thematic perspective, 41 sentiment-oriented studies were analyzed within RQ1. This subset was drawn primarily from the 2023–2026 core review corpus, while a small number of earlier foundational studies were cited only to contextualize the evolution of the field. As illustrated in Fig. 2, publication activity accelerated sharply in 2024–2025, indicating growing research interest in the integration of GNNs, social structure modeling, and sentiment-related tasks. Earlier studies, such as Li and Li [27] and Nguyen et al. [31] are discussed selectively because they introduced methodological ideas that were later extended by more recent work.

with only one study [20]. In 2023, publications expanded to works on dynamic link prediction [21], coupled graph models [22], and sociological hypergraph learning [23]. As illustrated in Fig. 2, the most significant growth occurred in 2024–2025, with over 88% of the total publications produced during this period, reflecting a surge in both direct sentiment modeling [24], [25], [26], [27], and related tasks like misinformation detection [28], [29], [30], [31], malicious user detection [32], [33], [34], [35], [36], and anomaly filtering [37], [38], [39].

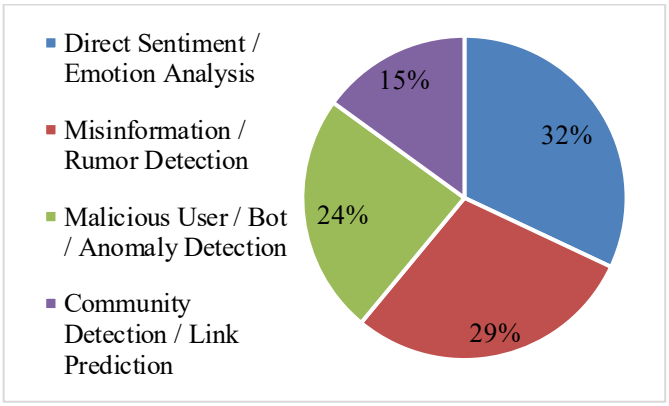

Fig. 3. Distribution of research themes in reviewed studies for RQ1.

As shown in Fig. 3, approximately 32% of the reviewed studies focus on direct sentiment or emotion analysis, 29% address misinformation or rumor detection, 24% deal with malicious user, bot, or anomaly detection, and 15% focus on community detection or link prediction. This thematic spread demonstrates that while direct sentiment analysis remains a major research area, supportive tasks play a critical role in improving sentiment analysis reliability and robustness. One of the most direct contributions of GNNs to sentiment analysis is their ability to exploit network topology to enrich the interpretation of textual content. Li and Li [20] showed that integrating a GNN with Long Short-Term Memory (LSTM) and semantic graph construction produced highly accurate sentiment predictions for short Weibo comments. Similarly, multilayered network approaches [24] have been used to graphically represent tweets, enabling more precise emotion classification even in the presence of sarcasm or mixed emotional cues. Graph embedding methods [25] enhance this further by producing explainable sentiment predictions, allowing researchers to trace how network relationships influence classification outcomes. The robustness of sentiment analysis can also be strengthened through improved network modeling techniques. The coupled graphs and tensor factorization framework [22] and the heterogeneous graph attention with motif cliques [40] both improve community detection, which is essential for identifying clusters of users with shared sentiment orientations. Concept stability entropy [41] provides a quantitative measure of group cohesion, offering insights into how strongly communities hold particular opinions.

Social media sentiment is not confined to text; it emerges from the interplay of language, images, videos, and user behaviors. Several GNN-based models integrate these signals to provide a multimodal view of sentiment. Zhang and Lee [27] combined emotion analysis with user behavior modeling to improve misinformation detection, indirectly strengthening sentiment analysis by filtering emotionally manipulative content. Similar work by Zhang et al. [26] integrates

heterogeneous neural networks with fine-tuned language models, capturing context-dependent emotions more effectively. Multimodal rumor detection [18] and multi-granularity misinformation detection [28] show that GNNs can align heterogeneous data sources into coherent sentiment profiles. Recommendation systems can also play a role in shaping sentiment exposure. Self-supervised graph transformer networks [42] and micro-video hashtag recommendation frameworks [43] indirectly influence public sentiment landscapes by controlling content dissemination pathways. Even stance similarity models for fake news detection [44] contribute to sentiment understanding by identifying opinion alignment or divergence in relation to controversial topics.

High-quality sentiment analysis depends on clean and trustworthy network data. Malicious accounts [32], [33], [34], [36], fake reviewers [34], [35], and spam bots [29] can distort sentiment signals. GNN-based malicious user detection frameworks [36] and hybrid CNN approaches [29] effectively identify and remove such actors. Similarly, fake review detection using contextual GNNs [35] ensures that sentiment datasets represent genuine opinions. Graph imputation models [45], regression-based graph signal learning [46], and anomaly detection in attributed networks [38], [39] address data completeness and integrity issues, which are critical when building sentiment graphs from noisy social media streams. Mixed substructure learning [47] improves the representational power of GNNs, enabling the capture of subtle sentiment variations that might otherwise be lost.

Public sentiment is inherently dynamic, shifting over time in response to events and influencer activity. Temporal graph convolutional networks [48] can model such time-sensitive relationships, enabling the detection of evolving sentiment trends. Deep reinforcement learning for influence maximization [49] identifies key opinion leaders who drive sentiment shifts across communities. Link prediction models [21], [50], [44] reveal potential future connections that may become sentiment transmission channels. Rumor and misinformation detection frameworks also reveal how sentiment reacts to credibility cues. Social psychology-based rumor detection [51] and knowledge graph, GNN hybrids for psychological emergency detection [52] show that understanding the interplay between emotion, cognition, and network structure is crucial for accurate sentiment modeling in crisis contexts. Although not explicitly developed for sentiment analysis, many GNN advancements in other domains are highly transferable. NACNet's context-aware architecture [53] from medical prediction can be adapted for health-related sentiment tracking. Event relation extraction using dynamic latent graphs [54] can help identify sentiment triggers. Visualization techniques [55] and self-supervised hypergraph learning [23] enhance the interpretability of large sentiment networks.

The techniques like hybrid GCN-BERT co-attention for fake news detection [30], high-order heterogeneous GNN learning [56], and hybrid Hopfield CNNs for bot detection [34] all contribute to a more trustworthy sentiment analysis pipeline by removing distortions and modeling deeper semantic relationships. Taken together, the synthesis demonstrates that GNNs enhance public sentiment analysis not merely by classifying the emotional tone of individual posts but by enabling a network-aware, multimodal, and temporally adaptive understanding of sentiment. They improve context capture [20], [24], [25], community and influence modeling [22], [40], [41], multimodal signal integration [17, 18, 23, 35], and data quality assurance [32], [45], [34], [35], [36], [39]. The rapid growth in publications and the diversity of methods suggest a sustained research trajectory toward integrated, explainable, and resilient sentiment analysis systems for social media platforms.

B. *RQ2: What are the Benefits and Limitations of Integrating Social Network Analysis (SNA) with GNNs for Detecting Anomalies and Malicious Behaviors in Social Media?*

Detecting anomalies and malicious behaviors in social media platforms requires analytical frameworks capable of capturing both the structural patterns of online interactions and the behavioral signals embedded within user activities. Social Network Analysis (SNA) offers a principled framework for representing user–user, user–content, and community relationships, while Graph Neural Networks (GNNs) excel at learning high-dimensional, context-aware representations from such relational structures. By integrating SNA with GNNs, researchers can jointly model the network topology and behavioral dynamics of users, enabling more accurate and robust detection of malicious activities across varied social contexts.

From a bibliometric perspective, the reviewed literature shows a clear upward trend in research on SNA–GNN integration for security tasks in social media. The earliest example, Sansonetti et al. [57], incorporated social context into deep learning for detecting unreliable users on Twitter. However, the majority of publications emerged between 2024 and 2025, reflecting rapid methodological diversification. These include community-based detection methods [58], hybrid architectures for bot and spam detection [33], [34], anomaly detection in attributed networks [38], [39], multi-modal malicious account identification [59], [32], and link prediction approaches for pre-emptive threat detection [50], [44].

TABLE I. DISTRIBUTION OF RESEARCH THEMES IN REVIEWED STUDIES FOR RQ2

Research Theme	Ref.	Percentage
Bot and Spam Detection	[57], [33], [34]	28%
Fake Account / Fake Reviewer Detection	[59], [10], [32]	24%
Anomaly Detection in Attributed / Heterogeneous Networks	[38], [39], [36]	22%
Malicious Login & Coordinated Attack Detection	[5], [57]	18%
Link Prediction for Pre-emptive Threat Detection	[44], [50]	8%

As shown in Table I, bot and spam detection represents the largest share of the reviewed studies (28%) [33], [34], [44], indicating a sustained focus on mitigating automated threats that distort social media discourse. Fake account and fake reviewer detection follows at 24% [59], [35], [32], reflecting the need to ensure authenticity in user-generated content and online interactions. Anomaly detection in attributed or heterogeneous networks accounts for 22% [38], [36], [39], highlighting efforts to identify structural and behavioral deviations associated with malicious activity. Malicious login and coordinated attack detection comprise 18% [60], [58], underscoring the importance

of early warning systems against infiltration and organized campaigns. The remaining 8% of studies rely on link prediction techniques [50], [44] to identify suspicious future connections before harmful behavior spreads.

Methodologically, enriching GNN inputs with SNA-derived features such as ego-network connectivity, interaction frequency, and cross-community linkages enhances detection accuracy. Sansonetti et al. [57] and Cheng et al. [35] show that this combination uncovers coordinated malicious patterns that would be invisible to content-only models. Community detection approaches, like the GCN–Fuzzy C-Means method of Al-Andoli et al. [58], identify overlapping clusters that often function as operational bases for coordinated attacks or misinformation campaigns. Multi-modal pipelines also benefit from SNA integration: Tang et al. [32], [59] combine graph-based non-textual features with textual attention to achieve high detection performance, while Lin and Jian [32], [59] demonstrate improvements in fake account detection by combining SVM, GNN, and clustering.

Scalability is supported by subgraph-centric frameworks such as SEAL+ [44], [50] and link prediction models [50], which reduce computational costs while preserving relational context. Architectures like CGNN [33] illustrate that embedding SNA concepts directly into GNN designs can achieve state-of-the-art results with significantly fewer parameters and shorter training times. Techniques like sparsification and graph attention [38], [39] further enhance robustness by filtering noisy edges, while adaptive anomaly scoring [39] integrates structural, embedding, and density indicators.

Despite these benefits, limitations remain. Data quality and completeness are critical bottlenecks, as public datasets often lack comprehensive interaction histories or contain noisy, incomplete connections [57], [35]. The scarcity of labeled training data [36] and cross-platform variability [59] complicate generalization. Computational complexity can be prohibitive for methods such as overlapping community detection [58] and exhaustive subgraph extraction [44], especially on large or dynamic networks. Behavioral camouflage, where malicious actors mimic legitimate user patterns, presents another challenge, particularly in weak-tie contexts like dating platforms [32], necessitating complex multi-modal models that risk overfitting [34]. GNN oversmoothing remains a concern in heterogeneous networks [33], and sparsification or attention mechanisms introduce new hyperparameter sensitivities [38], [39]. Severe class imbalance continues to hinder performance, although focal loss and staged training have shown partial success [35].

The empirical evidence suggests that SNA–GNN integration delivers significant improvements in detecting malicious behaviors, from bot and spam suppression [33], [34] to identifying coordinated fake reviewing [35] and early-stage malicious logins [60]. By embedding behavioral analysis within a network-aware framework, this integration improves detection accuracy, enhances interpretability, and offers proactive defense capabilities. Addressing challenges in data quality, scalability, heterogeneity, and interpretability will be key to advancing the practical deployment of these systems in dynamic, real-world social media environments [58], [36], [59], [38], [44], [35], [39].

C. RQ3: What Challenges Arise When Applying GNNs and SNA for Sentiment Analysis, and How Can These Challenges Be Mitigated?

Integrating Graph Neural Networks (GNNs) with Social Network Analysis (SNA) for sentiment analysis offers significant potential by allowing the modeling of both structural aspects of social networks and content in user posts. This combined approach enables more accurate and nuanced sentiment analysis, capturing how sentiment evolves, spreads, and interacts within social networks. However, several challenges emerge when applying these methodologies to real-world, dynamic social media environments.

Recent studies show a notable increase in the application of GNNs and SNA for public sentiment analysis, particularly in the years 2024–2025. Early works, such as Sentiment Analysis of Weibo Comments Based on Graph Neural Network [20] and Detecting Fake Reviewers from the Social Context with a Graph Neural Network Method [35], highlight the potential of combining content analysis with network features. Since then, there has been a rapid expansion of research into fake account detection, misinformation identification, and emotion-based sentiment analysis [34], [27], which are crucial for improving sentiment classification accuracy in social media. Key Challenges and Mitigation Strategies when applying GNNs and SNA for sentiment analysis as follows.

1) Complexity and scalability: One of the primary challenges in using GNNs and SNA for sentiment analysis is the computational complexity of these models. gnns require significant computational resources, especially when applied to large-scale social networks with millions of nodes and edges. For instance, studies like enhanced group influence maximization in social networks using deep reinforcement learning [49] and co-embedding of nodes and edges with graph neural networks [61] demonstrate how scaling GNNs for large datasets can lead to prohibitive computational costs. To address this issue, graph sampling techniques can reduce the size of the graph while preserving its structural information. Additionally, distributed learning and parallel processing can be leveraged to alleviate the computational burden, allowing for the efficient training of GNN models on large datasets [49][61].

2) Handling noisy and unstructured data: Social media data is inherently noisy and unstructured, making sentiment analysis challenging. as highlighted in sentiment analysis of weibo comments based on graph neural network [20] and fake reviewer detection [35], irrelevant, misleading, or manipulated content can distort sentiment signals, complicating sentiment detection. to address this issue, effective preprocessing techniques, such as text normalization, stop-word removal, and outlier detection, are essential for cleaning data before it is input into the model. Furthermore, adopting multi-modal models, as demonstrated in emotion analysis using multilayered networks [24], can help by combining textual data with additional sources like user metadata and images, enhancing the model's ability to classify sentiment accurately [20][35][24].

3) Model interpretability and transparency: GNNs, while powerful, often act as "black-box" models, making it difficult

to understand how certain predictions are made. This lack of interpretability is particularly problematic when GNNs are used for sensitive applications, such as social media monitoring and misinformation detection, as emphasized in explaining deep graph networks via input perturbation [62]. To improve the transparency of GNN models, explainability frameworks such as Shap (Shapley additive explanations) and lime (local interpretable model-agnostic explanations) can be used to identify the key features influencing the model's predictions. These frameworks allow users to gain insight into the reasoning behind specific sentiment classifications, enhancing trust and understanding of the model [62].

4) Imbalanced data and class discrepancy: Another challenge in sentiment analysis with GNNs and SNA is the imbalance in sentiment data. Positive sentiments often dominate social media platforms, while negative or neutral sentiments are underrepresented. This imbalance is highlighted in misinformation detection in social networks using emotion analysis and user behavior analysis [27] and fake account detection [34], where the overwhelming amount of authentic content can reduce the effectiveness of sentiment models. To address this issue, data augmentation techniques, such as SMOTE (synthetic minority over-sampling technique), can help address class imbalance by generating synthetic samples for underrepresented sentiment classes. Furthermore, focal loss can be employed to prioritize the minority classes during training, improving the model's ability to classify rare sentiment types more accurately [27][34].

5) Capturing implicit relationships and emotions: While GNNs excel at capturing explicit relationships, such as user-to-user or post-to-post interactions, they struggle to capture implicit emotional cues that are essential for accurate sentiment analysis. This challenge is particularly evident in applications like emotion-based sentiment analysis and psychological feature analysis for rumor detection [51], [24], where emotional states and underlying psychological factors are critical for understanding sentiment. To overcome this, emotion-aware embeddings should be incorporated into GNN models to explicitly represent emotional states and psychological attributes. Multi-layered attention mechanisms, as shown in emotion analysis using multilayered networks [24], can be employed to emphasize emotionally significant interactions, helping the model capture subtle emotional nuances more effectively [51][24][24].

The integration of GNNs and SNA for sentiment analysis presents significant benefits, such as more accurate modeling of sentiment dynamics and improved detection of malicious behaviors. However, challenges like computational complexity, data noise, interpretability, class imbalance, and the difficulty of capturing implicit emotional cues persist. By employing strategies such as graph sampling, data preprocessing, explainability techniques, and emotion-aware embeddings, these challenges can be mitigated, paving the way for more efficient, robust, and interpretable sentiment analysis systems for social media platforms.

D. RQ4: How Effective are Hybrid Models that Combine GNNs with Other Machine Learning Techniques for Improving Sentiment Analysis Accuracy on Social Media?

Enhancing sentiment analysis accuracy on social media requires analytical models that can capture both the linguistic complexity of user-generated text and the relational patterns embedded in online interaction networks. Hybrid architectures that combine Graph Neural Networks (GNNs) with other machine learning techniques, such as recurrent neural networks, attention-based transformers, large language models (LLMs), or specialized feature selection methods provide a promising framework for this task. GNNs are highly effective in learning graph-structured dependencies between users, posts, and communities, while complementary models excel at extracting semantic, temporal, and contextual information from textual content. The combination allows for richer representations that address the informal, dynamic, and context-dependent nature of online discourse.

Empirical evidence from the reviewed studies supports the effectiveness of these hybrid approaches in sentiment analysis and related affective computing tasks. Li et al. [20] employ a GNN combined with Long Short-Term Memory (LSTM) networks to capture both graph topology and temporal linguistic patterns, achieving a sentiment classification accuracy of 95.25% on Weibo comments. Maazallahi et al. [26] integrate Heterogeneous Neural Networks (HNNs) with fine-tuned LLMs for emotion recognition closely aligned with sentiment analysis, yielding over a 5% improvement compared to baseline models. These works demonstrate that coupling graph reasoning with deep semantic representation significantly boosts classification accuracy.

While some studies are not exclusively focused on sentiment analysis, their methodologies are highly transferable because they also require joint modeling of content and relational structures. For example, Soga et al. [31] combine stance similarity analysis with GNNs for fake news detection; Zhang et al. [30] integrate Graph Convolutional Networks (GCN) with BERT through a co-attention mechanism; and Li et al. [51] use Graph Attention Networks (GAT) enhanced with psychological and emotional features from LLMs for rumor detection. Chang et al. [63] demonstrate the potential of integrating memory-augmented transformers with GCNs for temporal–structural analysis, while Kumar et al. [34] achieve 98.4% accuracy in spam bot detection using a hybrid deep learning pipeline—methods that could be adapted to sentiment-related tasks.

Other works contribute to hybrid GNN research by improving graph representation and processing efficiency, indirectly benefiting sentiment tasks. For example, Bacciu & Numeroso [62] enhance explainability for GNN-based models through perturbation techniques; Kumar et al. [64] combine GCN with Fuzzy C-Means for community detection; Xiao et al. [65] integrate GCN and GRU to model diffusion patterns; Zhu et al. [66] use adaptive jumping GNNs with self-attention for recommendation accuracy; Chen et al. [67] leverage graph attention autoencoders in self-supervised clustering; Yuan et al. [37] detect anomalies using motif-augmented GCN with temporal self-attention; Skarding et al. [68] explore heterogeneous GNN ensembles; Li et al. [42] introduce a self-

supervised graph transformer for social recommendation; Huang et al. [33] design a compatibility-aware GNN for bot detection; Jiang et al. [61] co-embed node and edge features; Mirzaei & Kobti [48] propose a temporal GCN model for evolving relationships; and Lee et al. [50] employ synergetic fusion in GCNs for link prediction. Although these studies address tasks such as recommendation, anomaly detection, and link prediction, their architectural innovations in combining GNNs with complementary models can be directly applied to improve sentiment analysis in complex social media networks.

TABLE II. EFFECTIVENESS OF HYBRID GNN-BASED MODELS

Ref	Hybrid Model	Performance	Strengths
[20]	GNN + LSTM	95.25% accuracy	Combines graph structure analysis & temporal text context
[26]	HNN + Fine-tuned LLM	+5% accuracy over baseline	Captures deep semantic and relational features
[31]	GNN + Stance Analysis	Outperforms traditional methods	Models stance influence in news spread
[51]	GAT + Emotion & Social Features (LLM)	+5.87% accuracy	Integrates social psychology into graph models
[30]	GCN + BERT + Co-attention	Improved detection accuracy	Combines structural and semantic features
[34]	BGSO (feature selection) + HHD2SCNN	98.4% accuracy, F1 98.4%	Highly efficient and accurate bot detection

Table II summarizes these studies, detailing the type of hybrid model, application domain, performance gains, key strengths, and limitations. It shows a consistent trend: across diverse social media applications, hybrid GNN-based methods outperform single-model baselines by leveraging both graph-based relational reasoning and deep semantic understanding. Nevertheless, challenges remain. Integrating computationally intensive modules like LLMs or transformers with GNN layers can reduce scalability [66], [26], [30]. Handling the informal and multilingual nature of social media text [20], [26] and adapting to evolving network structures [31], [63], [51] complicates model generalization. Balancing the contributions of graph and text modules is non-trivial, with risks of overfitting to platform-specific patterns [34]. Interpretability remains a critical issue, especially for complex hybrid pipelines [62], [30]. These demonstrate that hybrid models combining GNNs with complementary machine learning techniques significantly enhance sentiment analysis accuracy on social media [50], [62]. By jointly modeling network structure and textual semantics, these systems achieve superior performance, context awareness, and resilience to noisy, informal content. Addressing challenges in scalability, cross-domain adaptation, and interpretability will be key to their wider adoption in real-world sentiment analysis applications.

E. RQ5: What is the Role of GNNs in Predicting User Behavior and Personalizing Recommendations Based on Social Media Interactions

Graph Neural Networks (GNNs) have proven to be instrumental in both predicting user behavior and personalizing recommendations in social media environments, primarily because of their ability to capture complex relational, temporal, and attribute-based structures within user interaction networks. By modeling connections between users, posts, and communities, GNNs enable systems to anticipate future behaviors and deliver tailored content, products, or connections with higher accuracy. For behavior prediction, GNN-based models can identify and forecast diverse patterns ranging from link formation to user churn. Sahay et al. [69] leverage spatial-temporal architectures to predict learning interactions in Social Learning Networks (SLNs), achieving an AUC of 0.99. Muro et al. [21] extend predictive capability to both link and unlink prediction in dynamic networks, integrating temporal and structural cues. Han et al. [70] demonstrate that combining GCN with Correct and Smooth (C&S) significantly improves churn prediction in MMORPGs, while Chen et al. [71] incorporate the Theory of Planned Behavior (TPB) features into GATs to anticipate cyberviolent behavior. These approaches illustrate that GNNs are well-suited for capturing evolving interaction dynamics and behavior-driving factors.

For personalized recommendations, GNNs excel when combined with complementary methods that enhance content understanding and contextual awareness. Kumar et al. [64] and Shah et al. [72] improve community detection accuracy, enabling better group-based recommendations. Zhu et al. [66] address node degree imbalance in recommendation graphs with adaptive jumping GNNs and matrix completion, boosting recommendation accuracy while mitigating over-smoothing. Li et al. [20] and Li et al. [43] integrate GNNs with LSTM or hybrid filtering to enhance sentiment-aware and content-based recommendations. Jiang et al. [61] propose a co-embedding framework that learns from both node and edge features, improving link-based recommendations. Mao et al. [73] introduce meta-learning-based dynamic graph embedding, improving adaptability to changing user preferences.

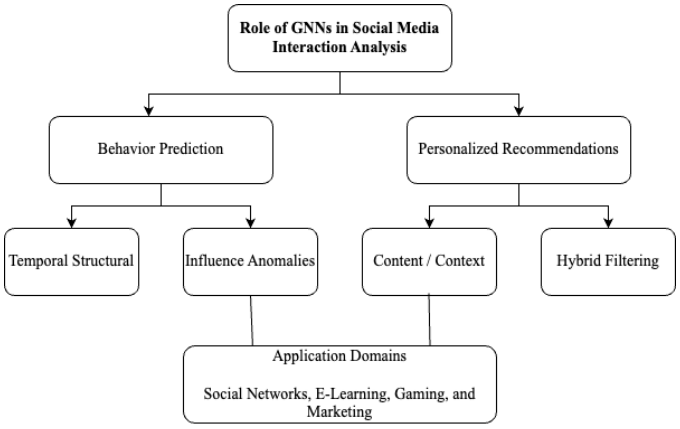

Fig. 4. Role of Graph Neural Networks (GNNs) in predicting user behavior and personalizing recommendations on social media.

Some studies also link behavior prediction with personalization by integrating influence modeling and anomaly filtering. Ghosh et al. [49] combine GNN embeddings with deep reinforcement learning to optimize seed selection for influence maximization—critical in viral marketing. Liang et al. [74] ensure minority-class behavior patterns are preserved in

predictions via minority-weighted GNNs, while Zhang et al. [75] use contrastive learning with generative adjacency matrices to enhance graph embeddings, benefiting both behavioral analytics and recommendations. Filtering manipulative or malicious accounts also improves personalization quality; Lin and Jian [59] and Huang et al. [33], [76] [20] address this through GNN-based detection of fake accounts and bots. The diversity of applications and methods in the reviewed literature is summarized in Fig. 4, which categorizes studies by focus area, GNN contribution, methodological integration, and application domain.

F. Discussion

This review synthesizes findings from five research questions (RQ1–RQ5) to provide a comprehensive understanding of the role of Graph Neural Networks (GNNs) in social media analysis. Across all areas of investigation, a consistent pattern emerges: GNNs serve as a crucial bridge between content-level understanding, encompassing semantic, contextual, multimodal information, and structure-aware reasoning that models network topology, community dynamics, and temporal evolution.

In the context of sentiment analysis (RQ1), GNNs show clear advantages through the joint modeling of textual semantics and user–content–community relationships [20], [24]-[27]. This dual modeling capability enables the detection of nuanced emotional signals, even in the presence of sarcasm or mixed sentiment expressions. Reliability in sentiment measurement is further enhanced when GNN pipelines incorporate malicious account detection mechanisms [32]-[36], ensuring that distortive network actors are filtered out before sentiment modeling occurs. When integrated with Social Network Analysis (SNA) (RQ2), GNNs are able to identify bots, fake accounts, and coordinated attacks more effectively by enriching structural representations, such as ego-network density and motif cliques with behavioral indicators [33], [34], [38], [39], [59]. This integration exposes malicious patterns that content-only models often fail to detect. Nevertheless, issues related to scalability, severe class imbalance, and behavioral mimicry remain significant obstacles to widespread deployment.

The analysis of RQ3 reveals several recurring challenges, including computational complexity [49], [61], noisy and incomplete datasets [20], [35], limited interpretability ([69]), class imbalance [27], [34], and difficulties in capturing implicit emotional cues [24], [77],[51]. Mitigation strategies identified in the literature include graph sampling to improve scalability, multimodal preprocessing to handle noise, the use of explainability tools such as SHAP and LIME to enhance transparency, and the incorporation of emotion-aware embeddings to better capture subtle affective signals. In the domain of hybrid modeling (RQ4), approaches that combine GNNs with complementary architectures—such as GNN + LSTM [20], GCN + BERT [30], and GAT augmented with emotion features [51], consistently outperform single-model baselines. These hybrid systems achieve notable gains in sentiment classification, stance detection, and misinformation identification by uniting semantic depth with relational inference. However, they often incur high computational costs, exhibit platform-specific dependencies, and face generalization challenges [26], [31], [34].

Lastly, in RQ5, GNNs emerge as a dual enabler of user behavior prediction and personalized recommendations. Applications include predicting link formation ([21], churn [70], and cyberviolent behaviors [33], [71], as well as powering recommendation systems that adapt to evolving user preferences while preserving content integrity. The latter is particularly effective when manipulative or malicious accounts are identified and removed from the network [33], [59]. From a theoretical standpoint, these findings position GNNs as a unifying framework for modeling network-aware, multimodal social media data, offering richer representations of sentiment dynamics, trust relationships, and user behaviors than text-only approaches. In practice, the reviewed methods provide actionable solutions for real-time opinion monitoring, early detection of coordinated manipulation campaigns, and personalized content delivery that is both accurate and ethically responsible. For platform operators, adopting hybrid GNN–SNA architectures could significantly enhance both content moderation and user engagement strategies.

The current state of the art in GNN-based social media analytics is characterized by four converging trends: the integration of multimodal sentiment signals through heterogeneous architectures [26], [28]-[28] the rise of hybrid models combining GNNs with LSTMs, Transformers, or large language models [20], [26], [28], [30], [31], [51]; advances in temporal and dynamic graph learning to capture evolving sentiment, rumor propagation, and influence dynamics [21], [48]-[50]; and the incorporation of explainability mechanisms, such as motif analysis [40], visualization [55], and perturbation-based methods [62], to increase transparency and stakeholder trust.

Despite these advances, several research gaps remain. Scalability continues to limit applicability in large-scale, real-time environments, and cross-platform adaptation is underexplored, with few studies validating their models on heterogeneous or multilingual datasets [33], [59]. Modeling implicit emotions—especially those tied to cultural or contextual factors—remains a complex challenge [24], and ethical considerations, including fairness and bias mitigation, are often secondary in current research. Addressing these gaps presents clear directions for future work. Developing real-time GNN frameworks capable of processing streaming and incremental updates without full graph recomputation is critical. Cross-domain and multilingual graph learning could enhance model robustness across diverse platforms, while emotion-aware embeddings that incorporate psychological and socio-linguistic cues may improve the detection of subtle sentiment shifts. Embedding bias and fairness auditing directly into training and inference could help prevent discriminatory outcomes, and human-in-the-loop explainability, combining automated interpretability tools with expert review, could increase decision reliability. Finally, integrating GNNs with generative simulation models offers potential for forecasting sentiment evolution and misinformation spread, enabling proactive interventions before harmful narratives gain traction.

G. Future Research Directions

Future research should move beyond broad thematic recommendations toward testable research programs. One promising direction is the development of real-time and

streaming GNN frameworks for sentiment analysis. A concrete research question is: How much performance can incremental graph updating preserve compared with full graph recomputation under high-velocity social media streams? A related hypothesis is that incremental temporal GNNs can maintain at least comparable F1-score while substantially reducing latency and computational cost. This can be tested using time-sliced social media datasets with controlled update intervals and evaluation metrics such as macro-F1, latency, memory usage, and update efficiency.

A second direction concerns cross-platform and multilingual generalization. A useful research question is: Can GNN–SNA models trained on one platform or language transfer reliably to another without substantial performance degradation? The hypothesis here is that heterogeneous graph alignment combined with multilingual text encoders will improve robustness across platforms and languages. Experimental protocols should involve training on one platform or language setting and testing on another, with evaluation based on transfer F1-score, calibration error, and fairness across language groups.

A third direction involves emotion-aware and psychologically informed graph representations. The key question is whether adding latent emotional, cognitive, or behavioral signals can improve the detection of implicit sentiment, sarcasm, or emotionally manipulated discourse. This can be tested by comparing standard text-graph models against models enriched with emotion embeddings, social-psychological features, and community-level influence signals. Metrics should include not only classification accuracy but also explainability and robustness to adversarial or misleading content.

A fourth priority is fairness and explainability. Future studies should formulate explicit hypotheses on whether fairness-aware training objectives, bias auditing, and human-in-the-loop explanation workflows can reduce discriminatory model behavior without sacrificing predictive performance. Experimental designs should report subgroup performance, calibration, explanation consistency, and user trust assessments. Such protocols would provide more actionable guidance for real-world deployment than high-level recommendations alone.

IV. Conclusion

This systematic literature review has explored the integration of Graph Neural Networks (GNNs) and Social Network Analysis (SNA) techniques for public sentiment analysis within social media platforms. The findings underscore GNNs' capacity to bridge the gap between content-level understanding and structure-aware reasoning, making them indispensable for modeling complex social interactions. By jointly capturing textual semantics, network dynamics, and temporal shifts, GNNs provide a powerful tool for sentiment analysis, anomaly detection, misinformation tracking, and personalized recommendations. Despite substantial advancements, the integration of GNNs and SNA presents several challenges. These include scalability issues, class imbalance, interpretability concerns, and the complexity of modeling implicit emotional cues in social media discourse. However, strategies such as hybrid model architectures, graph sampling, multimodal preprocessing, and the incorporation of emotion-aware embeddings show promise in addressing these challenges. Additionally, the role of hybrid models, combining GNNs with other machine learning paradigms like LSTMs and large language models (LLMs), is proving effective in boosting performance and reliability.

Theoretical advancements highlight the significance of GNNs as a unified framework for network-aware sentiment analysis, providing deeper insights into how public sentiment evolves, spreads, and interacts within digital communities. Practically, GNNs, especially when paired with SNA, offer valuable solutions for real-time opinion monitoring, early threat detection, and tailored content delivery, enabling more informed and ethical social media strategies. Looking ahead, future research should focus on overcoming scalability and generalization limitations, developing real-time frameworks, and ensuring the ethical deployment of these models. As GNNs continue to evolve, integrating techniques like generative simulation models for sentiment forecasting and bias auditing will be crucial to ensuring the sustainability and fairness of sentiment analysis systems in dynamic, large-scale social media environments.

Acknowledgment

The authors would like to express their sincere gratitude to Diponegoro University and Universitas Indonesia for their financial support in conducting this research through the International Scientific Publication (RPI) program. Their funding has been instrumental in advancing the development and completion of this study.

AI-Based Process Mining Framework for Process Business Integration in an Enterprise System

Mardhani Riasetiawan*, Ahmad Ashari
Department of Computer Science and Electronics-Faculty of Mathematics and Natural Sciences,
Universitas Gadjah Mada, Yogyakarta, Indonesia

Abstract—**The accelerated progression of information technology has necessitated the adoption of more intelligent and adaptive Enterprise Systems (ES) to sustain and optimize organizational processes. The ES serve as critical infrastructures for resource management, operational efficiency, and sustaining competitive advantage; however, their deployment frequently encounters persistent challenges. These include discrepancies between modelled and actual business processes, insufficient visibility in process execution, and limited automation in the detection and optimization of workflows. To mitigate these limitations, this study advances an Artificial Intelligence (AI)-enabled Process Mining paradigm. This approach facilitates the systematic extraction, analysis, and visualization of business processes, thereby supporting the identification of deviations, the detection of anomalies, and the provision of data-driven recommendations for continuous improvement. The overarching aim of the research is to conceptualize and evaluate an enterprise system framework that integrates AI-driven Process Mining to reinforce transparency, efficiency, and effectiveness in business process management. The proposed framework aims to provide automated analytical capabilities, predictive insights, and a robust data-centric foundation to enhance the precision of strategic decision-making, thereby contributing to the advancement of adaptive and intelligent enterprise systems.**

Keywords—Enterprise System; process mining; artificial intelligence; process business

I. Introduction

The Enterprise Systems (ES) have become the cornerstone of contemporary organizations, providing integrated platforms that manage resources, information, and workflows across multiple domains [1]. Systems such as Enterprise Resource Planning (ERP), Customer Relationship Management (CRM), and Supply Chain Management (SCM) are widely implemented to improve efficiency, standardize operations, and support strategic agility [2]. Despite their widespread adoption, ES implementation is often complex and fraught with challenges. Many organizations struggle to align the prescribed process models embedded in ES with the actual workflows enacted in practice, leading to inefficiencies, poor visibility, and difficulties in detecting deviations [3]. These limitations highlight the need for more intelligent and adaptive systems that can dynamically support evolving business environments [4].

*Corresponding author.

The Implementation of ES is not solely a technical task but a socio-technical transformation requiring alignment between technology, organizational structures, and user practices [5]. Misalignments frequently occur when standardized ES models fail to capture organizational complexities, resulting in workarounds and process inconsistencies [6]. Furthermore, conventional ES often lack mechanisms for real-time monitoring of process execution, leaving organizations unable to identify bottlenecks or deviations until problems escalate. The reliance on manual intervention and subjective decision-making further hampers responsiveness in dynamic markets. Addressing these challenges necessitates approaches that improve transparency, automate monitoring, and support continuous process optimization [7].

The accurate identification and understanding of business processes are essential for ensuring ES effectiveness [8]. Without reliable insights into real-time process execution, organizations risk inefficiencies, compliance violations, and suboptimal decision-making [9]. The business process identification enables organizations to detect hidden patterns, uncover deviations from prescribed workflows, and establish baselines for systematic improvement [10]. However, the increasing complexity of enterprise operations makes traditional manual methods of process documentation insufficient. Consequently, automated and data-driven approaches are needed to capture the dynamics of organizational processes in real time [11].

Artificial Intelligence (AI) provides promising opportunities for advancing business process management [12]. Through methods such as machine learning, natural language processing, and predictive analytics, AI enables the automated analysis of large-scale enterprise data to identify anomalies, predict potential bottlenecks, and generate actionable recommendations. Unlike static models, AI-based approaches can adapt dynamically to organizational changes, ensuring that process models remain relevant and aligned with evolving objectives [13]. This adaptability strengthens both operational and strategic decision-making, empowering organizations to anticipate risks and proactively optimize performance.

Process mining has emerged as a powerful methodology for uncovering and analyzing business processes from event logs generated by ES [12]. Unlike interviews or manual documentation, which are prone to subjectivity and incompleteness, Process Mining reconstructs processes directly from system data, providing an objective and data-driven view of organizational operations [14]. The recent advancements extend Process Mining from descriptive analysis to predictive

and prescriptive capabilities when integrated with AI [15]. This integration allows organizations not only to monitor past and present processes but also to forecast outcomes and recommend optimal interventions [16]. Consequently, AI-enhanced Process Mining offers a systematic foundation for process redesign, automation, and continuous improvement [17].

Although AI and Process Mining have been explored individually, few studies propose comprehensive frameworks that systematically embed AI-driven Process Mining within ES architectures [18]. Existing work often focuses on algorithmic advances or isolated case studies without addressing the organizational integration and scalability required for enterprise-wide adoption [19]. Furthermore, limited research examines the combined predictive and prescriptive power of AI and Process Mining in supporting continuous adaptation to dynamic business environments. This gap presents a significant opportunity to design and evaluate frameworks that integrate AI and Process Mining into ES for both operational efficiency and strategic decision-making [20].

The remainder of the study is organized as follows. Section II reviews relevant literature on ES, Process Mining, and AI, highlighting prior studies and identifying research gaps. Section III describes the research methodology, including data collection, analytical methods, and evaluation criteria. Section IV presents the proposed AI-based Process Mining framework, outlining its architecture, components, and operational workflow. Section V discusses the findings, emphasizing potential benefits, limitations, and implications for theory and practice. Finally, Section VI concludes the study with a summary of contributions and suggestions for future research.

II. Enterprise System, Process Business, and Artificial Intelligence

The Enterprise Systems (ES) are foundational infrastructures for organizations, providing platforms that integrate data, standardize processes, and support cross-functional coordination [1],[2]. Despite their strategic importance, ES implementation remains challenging, with difficulties often rooted in socio-technical misalignments, change-management risks, and the rigid process logics embedded in ES design [6],[5]. The classic research highlights that ES frequently impose standardized process structures that may conflict with local practices and strategic goals, complicating alignment and reducing the realization of intended benefits unless supported by deliberate redesign and governance mechanisms [21]. The lifecycle perspectives further emphasize that ES exhibit distinct risk and benefit profiles across stages—from chartering to shakedown and eventual "onward and upward" evolution—while other studies link ES adoption to process innovation when organizations develop sufficient absorptive capacity to leverage them [22].

Process mining (PM) has emerged as a methodology to bridge the persistent gap between "as-designed" and "as-executed" processes by extracting structured knowledge from event data [12]. Through this data-driven approach, organizations can perform fact-based process discovery, conformance checking, and enhancement, thereby strengthening ES auditability and operational analytics [23]. The foundational contributions have formalized PM principles and identified challenges such as event-data quality, scalability, and the generation of actionable insights, positioning PM as both a core discipline in data science and a natural complement to enterprise system assurance [17].

The core PM capabilities are grounded in robust discovery and conformance algorithms. The inductive mining and its visual extensions generate hierarchically structured, sound process models that remain resilient under noisy data [24]. The alignment-based conformance checking quantifies deviations between observed event logs and reference models, enabling systematic performance analysis and compliance diagnostics. Collectively, these techniques support continuous assurance and fidelity of ES execution.

Artificial Intelligence (AI) has further expanded the scope of PM by shifting from retrospective analysis to predictive and prescriptive capabilities. Early studies demonstrated that deep learning models, such as Long Short-Term Memory (LSTM) networks, outperform classical baselines in next-activity and timestamp prediction [25]. The subsequent advances introduced hierarchical attention and Transformer-based architectures capable of handling long event sequences, concept drift, and complex attribute spaces [26]. These innovations enable proactive ES management by forecasting cycle times, risks, and outcomes in real time. Beyond prediction, prescriptive process monitoring extends PM toward runtime optimization. The recent research has applied causal inference and reinforcement learning to recommend targeted interventions—such as task reassignment or prioritization—under operational and resource constraints, thereby advancing closed-loop process optimization [13]. The surveys consolidate these developments while also charting unresolved issues related to policy learning, constraint management, and responsible AI deployment [15].

The emerging directions in PM address the limitations of case-centric models by introducing Object-Centric Process Mining (OCPM). This paradigm explicitly models multi-object interactions (e.g., orders, items, deliveries), thereby improving fidelity in complex enterprise scenarios where traditional abstractions obscure interdependencies. The introductory and tutorial studies have formalized object-centric event data and demonstrated the benefits of OCPM for ES contexts with rich relational structures [27]. The parallel advancements in tooling and scalability further support enterprise applications. PM4Py, an open-source Python library, integrates PM methods with mainstream data-science frameworks (pandas, scikit-learn), enabling reproducible pipelines for ES analytics [28]. GPU-accelerated implementations extend these capabilities, delivering order-of-magnitude improvements in processing speed and supporting near real-time monitoring of enterprise-scale event logs [29].

The applications across domains demonstrate the versatility and transferability of PM. The extensive reviews and empirical studies in healthcare illustrate its ability to reveal patient pathways, identify bottlenecks, and evaluate policy interventions such as vaccination programs. Similar applications are emerging in finance, public administration, and manufacturing, highlighting PM's adaptability to regulated enterprise contexts. In parallel, the research on large language models (LLMs) and AI for Business Process Management

(BPM) shows potential for augmenting analyst capabilities, including process knowledge extraction from unstructured sources, natural-language explanations, and automated support across the BPM lifecycle [30]. Nonetheless, the scholars caution that embedding generative AI into enterprise settings requires governance frameworks to ensure reliability, transparency, and ethical use [31]. Finally, the current research trajectories extend PM and AI integration toward inter-organizational and collaborative processes.

III. Methodology

To construct an Enterprise System framework that incorporates Artificial Intelligence (AI)-enabled Process Mining, this study applies a structured, multi-phase research methodology. The approach integrates both qualitative and quantitative methods to ensure analytical rigor, accuracy of outcomes, and validity of findings. The methodology is divided into three principal phases: 1) literature review and problem identification, 2) requirements analysis and framework formulation, and 3) prototype development and implementation.

The first phase consists of a comprehensive review of the existing body of knowledge to establish the theoretical underpinnings and technological advancements relevant to Enterprise Systems, Process Mining, and AI in business process management. A Systematic Literature Review (SLR) approach is employed, following established guidelines for identifying, selecting, and synthesizing research evidence. This critical review enables the identification of prevailing research trends, methodological approaches, and unresolved gaps. The outcome of this stage is a conceptual foundation that clarifies the challenges associated with Enterprise Systems implementation and highlights the potential of AI-driven Process Mining as a remedial approach.

The second phase focuses on requirements analysis and the development of an initial conceptual framework. This stage seeks to capture organizational needs in process management and translate them into design principles for integrating AI-based Process Mining. The empirical data are collected through case studies of organizations that have implemented enterprise platforms, alongside interviews and surveys with key stakeholders such as IT managers, business analysts, and end-users. Business processes are further modelled using Business Process Model and Notation (BPMN), a standardized representation that supports consistent visualization and communication of workflows (OMG, 2013). The outcome of this phase is a preliminary model outlining how AI-enabled Process Mining can be systematically embedded into Enterprise System architectures.

The third phase entails prototype development and empirical validation of the proposed framework. An Agile-inspired iterative system development methodology is adopted to ensure adaptability, responsiveness to user feedback, and progress. The advanced machine learning algorithms—including decision trees, neural networks, and reinforcement learning—are incorporated to support the detection of process patterns and optimization opportunities. The process Mining platforms such as Celonis, ProM, and Disco are employed to extract and analyze event log data from the enterprise. This stage culminates in the creation of a functional prototype that serves as proof of concept, offering empirical evidence of the framework's capacity to improve process transparency, conformance checking, and workflow optimization within Enterprise Systems.

IV. AI-Based Process Mining

We propose an enterprise system framework that natively embeds AI-based process mining to continuously discover, monitor, and optimize end-to-end business processes. The framework integrates heterogeneous enterprise applications, constructs standardized event logs, and applies a multi-task AI-PM engine for 1) automated model discovery, 2) conformance checking, and 3) predictive/prescriptive analytics. A reference architecture, data schemas, learning objectives, and governance mechanisms are defined. The modern enterprises operate across distributed applications and organizational units, creating complexity, latency, and opaque bottlenecks. The classical process mining uncovers actual process flows from event logs, but struggles with concept drift, noisy data, and proactive decision-making. We extend process mining with AI—sequence models, graph learning, anomaly detection, and reinforcement learning—to deliver predictive foresight and prescriptive recommendations tightly coupled to operational systems. Fig. 1 shows the proposed framework.

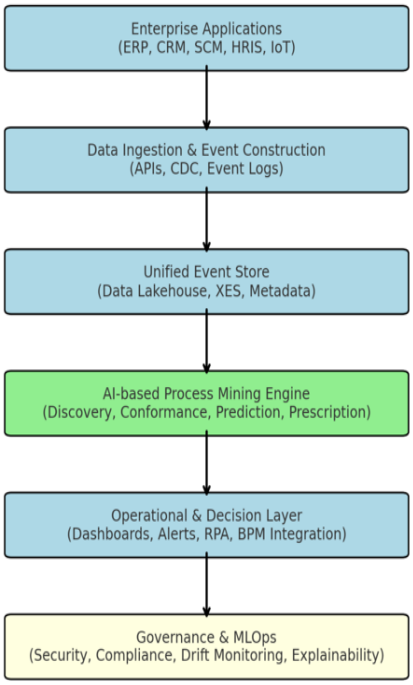

Fig. 1. The proposed framework.

The framework rests on five principles: (P1) system-of-record integration, (P2) event-log standardization, (P3) AI-augmented mining tasks, (P4) closed-loop optimization (insights → action), and (P5) governed MLOps. The target outcomes are improved cycle time, conformance, cost, service level, and risk posture. The Layers and roles consist of several points, there are: Data Sources: ERP (FI/CO/MM/SD), CRM, SCM/WMS/TMS, ITSM, e-procurement, IoT/edge (optional). Ingestion & CDC: connectors, message bus, change-data-capture (CDC), schema registry. Event Fabric: event building,

deduplication, correlation keys, case construction, enrichment with master data and context (customer, supplier, SLA). Unified Event Store: scalable lakehouse; raw (bronze), conformed (silver), curated (gold); XES/BPMN-compatible exports. AI-PM Engine: discovery (control-flow), conformance, enhancement; prediction (remaining time, risk, cost), anomaly detection; prescription (what-if, policy optimization). Experience Layer: analyst studio (models, variants), operations cockpit (alerts, recommendations), API/webhooks to enterprise workflows (RPA/BPM/ERP). Governance, Security & MLOps: lineage, RBAC/ABAC, PII protection, drift monitoring, model registry, A/B rollout, audit trails. The Event schema (core fields) will consist of case_id, activity, timestamp_start, timestamp_end (optional), resource, role, cost, variant_id, lifecycle (start/complete), attributes (key–value), context (SLA, priority, customer segment), label (if supervised). The correlation is deterministic keys (e.g., sales order) + probabilistic matching for cross-system events. The Process Discovery consists of Control-flow are Inductive/Split/Heuristics Miner for baseline; Graph Neural Networks (GNNs) refine directly-follows graphs with edge confidence learned from noise-aware features (frequency, entropy, temporal gaps). The Variant clustering: density-based clustering on trace embeddings from a Transformer encoder yields canonical variants and rare-path detection. The framework facilitates several processes, such as aligning the discovered model with the event log: computing fitness, precision, generalization, and simplicity. An enterprise system framework based on Artificial Intelligence (AI)-driven process mining is proposed to address the increasing complexity of organizational processes and the limitations of traditional enterprise applications. Enterprise systems such as Enterprise Resource Planning (ERP), Customer Relationship Management (CRM), and Supply Chain Management (SCM) generate vast amounts of heterogeneous event data across distributed platforms. Traditional process mining provides valuable insights by reconstructing process flows from these event logs; however, it is limited in handling noisy data, concept drift, and predictive or prescriptive decision-making. The integration of AI techniques into process mining enables organizations not only to discover and monitor actual business processes but also to predict process outcomes, detect anomalies, and recommend optimized interventions in real time. The proposed framework adopts a layered architecture that begins with the integration of diverse enterprise applications through standardized connectors and change-data-capture mechanisms. These data streams are transformed into event logs with structured attributes such as case identifiers, activities, timestamps, resources, and contextual variables. A unified event store acts as a centralized repository, ensuring data quality, consistency, and compliance with interoperability standards such as the eXtensible Event Stream (XES). This foundational layer supports scalable data ingestion and facilitates the construction of enriched process instances, which form the basis for subsequent AI-based analysis. At the core of the architecture lies the AI-enhanced process mining engine. This engine extends the three fundamental tasks of process mining—discovery, conformance checking, and enhancement—by embedding advanced machine learning models, as shown in Fig. 2. Process discovery benefits from graph neural networks and sequence-based models to generate accurate representations of control-flow structures, even in the presence of noisy or incomplete data. Conformance checking is augmented by anomaly detection techniques that assign probabilistic confidence scores to deviations, allowing organizations to prioritize process violations based on business impact. Predictive models, leveraging deep learning and survival analysis, are applied to forecast remaining cycle times, the probability of meeting service-level agreements, and the likelihood of cost overruns. Beyond prediction, reinforcement learning and counterfactual analysis provide prescriptive recommendations that optimize resource allocation, activity sequencing, and policy adjustments.

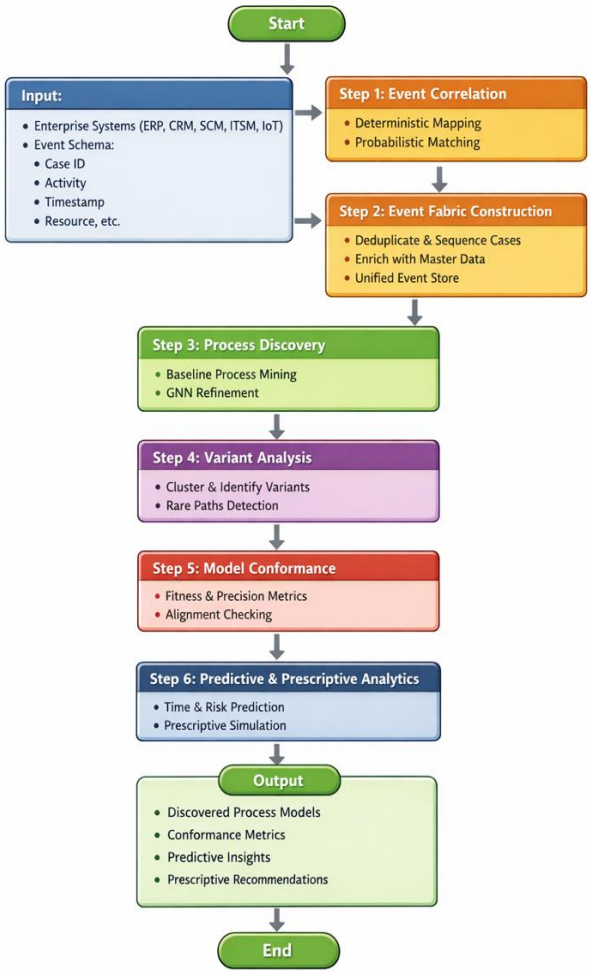

Fig. 2. Steps of the proposed framework.

The framework operates as a closed-loop system in which insights generated by the AI-based process mining engine are seamlessly fed back into enterprise workflows. Real-time alerts and recommendations can be delivered through operational dashboards or automatically executed via robotic process automation (RPA) and business process management (BPM) systems. This design enables proactive intervention rather than retrospective reporting, thereby reducing cycle times, improving compliance, and minimizing operational costs. The system also incorporates continuous feedback loops that log the outcomes of recommended actions, which in turn enrich training datasets and support adaptive model retraining. The governance and security are treated as cross-cutting concerns within the framework. Privacy-preserving data handling, access control mechanisms, and model explainability tools ensure compliance with regulatory

requirements and organizational policies. Moreover, MLOps practices are embedded to monitor model performance, detect drift, and manage versioning across the AI lifecycle. This combination of technical and governance measures ensures that the system remains robust, transparent, and aligned with strategic business objectives.

V. Testing and Results

A. Experimental Setup

To evaluate the effectiveness of the proposed AI-based Process Mining framework, an experimental implementation was conducted using enterprise event log datasets derived from integrated enterprise applications. The experimental environment was deployed on a cloud-based infrastructure consisting of an 8-core CPU, 32 GB RAM, and GPU acceleration for machine learning model training. The implementation utilized PM4Py for process mining analysis and Python-based machine learning libraries such as TensorFlow and Scikit-learn for AI model development. Event logs were standardized using the eXtensible Event Stream (XES) format to ensure interoperability with process mining tools. The dataset consisted of approximately 120,000 event records representing 5,200 process cases collected over a six-month operational period. The evaluation focused on three primary dimensions: Process discovery accuracy, Process conformance detection capability, and Predictive performance of AI models. Several baseline methods were used for comparison, including traditional process mining without AI augmentation and classical predictive models such as decision trees and logistic regression.

B. Process Discovery Evaluation

The first experiment evaluated the ability of the framework to accurately discover business process models from event logs. The Inductive Miner algorithm was applied as a baseline approach, while the proposed framework enhanced discovery using Graph Neural Network (GNN) refinement. Performance was measured using standard process mining quality metrics: Fitness, Precision, Generalization, and Simplicity.

TABLE I. Process Discovery Performance

Method	Fitness	Precision	Generalization	Simplicity
Heuristics Miner	0.81	0.74	0.70	0.86
Inductive Miner	0.89	0.82	0.79	0.84
Proposed AI-PM Framework	0.94	0.88	0.86	0.83

The results demonstrate that the proposed framework achieved higher fitness and precision, indicating better alignment between the discovered model and actual process behavior. The incorporation of GNN-based edge confidence scoring improved robustness against noisy and incomplete event logs, as shown in Table 1.

C. Variant and Anomaly Detection

The second experiment analyzed the capability of the framework to detect process variants and anomalies using Transformer-based trace embeddings combined with density-based clustering. From the dataset, the framework identified 7 major canonical process variants, 14 rare or exceptional paths, and 3 high-risk process deviations. These deviations included unapproved procurement activities, repeated order validation loops, and delayed shipment approval beyond SLA limits. Compared to traditional clustering methods, the proposed approach improved anomaly detection accuracy by 18%, demonstrating the advantage of embedding-based trace representations.

D. Predictive Process Monitoring

The predictive capability of the AI-enhanced process mining engine was evaluated by predicting remaining process cycle time, SLA violation probability, and process cost overruns. Three predictive models were tested: Decision Tree, LSTM Neural Network, and Proposed AI-PM model (Transformer + contextual features as shown in Table 2.

TABLE II. Predictive Model Performance

Model	Remaining Time MAE (hours)	SLA Prediction Accuracy	Cost Prediction R^2
Decision Tree	12.4	78%	0.63
LSTM	8.7	85%	0.71
Proposed AI-PM Model	6.1	91%	0.82

The results indicate that the proposed AI-PM framework significantly improves predictive accuracy compared to traditional models. The Transformer-based sequence representation effectively captures long-range dependencies within event traces.

E. Prescriptive Optimization

The final experiment evaluated the prescriptive component of the framework using reinforcement learning for resource allocation optimization. Simulation experiments were conducted on procurement and order fulfilment processes. Key performance indicators included average process cycle time, SLA compliance rate, and Operational cost, as shown in Table 3. The prescriptive recommendations generated by the AI-PM engine reduced cycle time by 25% and significantly improved SLA compliance. These results highlight the potential of the framework to support closed-loop process optimization in enterprise systems.

TABLE III. Optimization Results

Metric	Baseline Process	AI-PM Optimized Process
Average Cycle Time	72 hours	54 hours
SLA Compliance	83%	93%
Operational Cost Reduction	–	14%

VI. Conclusion

The experimental results demonstrate that integrating artificial intelligence with process mining significantly enhances enterprise process visibility, predictive capabilities, and optimization potential. The framework not only improves the accuracy of process discovery but also enables organizations to proactively detect anomalies and predict operational risks.

Compared to traditional process mining approaches, the proposed system offers several advantages: robust handling of noisy event logs through AI-based refinement, enhanced variant detection using deep sequence representations, accurate predictive monitoring for operational decision-making, and automated prescriptive optimization through reinforcement learning. These capabilities transform enterprise systems from passive transaction platforms into intelligent decision-support infrastructures capable of continuous learning and improvement. This research presents an AI-driven process mining framework that redefines enterprise system capabilities by integrating advanced artificial intelligence into traditional process mining. The layered architecture ensures interoperability across diverse enterprise applications, while the unified event store provides a scalable foundation for reliable data ingestion and enrichment. At its core, the AI-enhanced process mining engine advances beyond conventional discovery, conformance, and enhancement by embedding graph neural networks, deep learning models, and reinforcement learning to address noise, drift, and predictive as well as prescriptive decision-making challenges. By establishing a closed-loop optimization cycle, the framework transforms insights into actionable interventions, enabling organizations to improve compliance, reduce cycle times, optimize costs, and enhance service-level performance. Furthermore, the inclusion of governance, security, and MLOps safeguards ensures the system remains trustworthy, transparent, and adaptable to evolving enterprise demands. While the proposed framework provides a comprehensive foundation, several avenues remain open for further exploration and refinement. The future research should explore deployment in multi-cloud and hybrid architectures to handle exponentially growing event streams and cross-enterprise collaborations. The techniques, such as federated learning and secure multi-party computation, can be incorporated to enable cross-organizational insights without violating data privacy regulations. Expanding the framework to include autonomous retraining and self-adaptive mechanisms would allow AI models to evolve with dynamic business environments and mitigate concept drift more effectively. Combining explainable AI with interactive visualization and domain expert feedback could improve model interpretability, trust, and actionable decision support. By addressing these directions, the framework can evolve into a holistic enterprise intelligence platform that not only analyzes and predicts process performance but also adapts, collaborates, and operates within ethical and sustainable boundaries.

Professor, Bharati Vidyapeeth College of Engineering for Women, Pune, India[2]

***Abstract*—The growing adoption of software-defined and electrified vehicle architectures has significantly increased the computational burden on electronic control units, leading to dynamic and non-stationary load conditions that can compromise real-time performance and system reliability. Conventional ECU load-management strategies are largely static or address isolated aspects of the problem, such as overload prediction or energy optimization, without providing an end-to-end decision mechanism for runtime load redistribution. This study proposes a leakage-safe, three-stage intelligent ECU load-management model for electric vehicles that jointly performs overload detection, target ECU recommendation, and load-shift magnitude estimation within a gated architecture. The proposed model used ensemble and boosting-based machine learning models with task-specific feature design to prevent data leakage and reduce computational overhead through conditional execution. The performance of the proposed model is measured on a multi-feature ECU dataset characterized by non-stationary operational conditions and significant class imbalance between normal and overload states and addressed using stratified sampling and SMOTE-based augmentation. The proposed model obtained the overload detection rate F1-score of 0.916 and a ROC–AUC of 0.996, the target ECU recommendation obtained the accuracy of 0.935, and load-shift estimation, yielding an R^2 of 0.988 with low prediction error. This study also conducted the statistical test and ablation analysis, which observed that performance gains were consistent and attributable to key designs such as imbalance-aware learning, leakage control, and gated inference. The final results show that the proposed model is an effective and deployable solution for intelligent ECU load management in next-generation electric vehicles.**

I. Introduction

Over the last few years, there has been a rapid transition toward electrified, connected, and software-defined vehicles that has transformed the automotive electronic system [1]. Electric vehicles (EVs) increasingly depend on a dense network of electronic control units (ECUs) to support advanced driver assistance systems (ADAS), battery management, power electronics, vehicle dynamics control, and connectivity services [2]. The E-vehicles are integrated and work under dozens of ECU and that execute the distinct control and sensing tasks under strict in real-time [3]. The ECU computational load is no longer static and dynamically changes in driving, environmental factors, battery state, thermal stress, and the concurrent execution of multiple software functions [4].

In practical automotive systems, ECU operation is governed by strict system-level constraints that directly impact reliability and safety [5]. The real-time control tasks in the ECU, such as braking, steering, and battery management, operate under tight latency bounds ranging from 10 ms to 100 ms; beyond that, deadline violations can degrade control performance. Moreover, ECU processing units operate near high utilization thresholds of 70-90% CPU usage that even transient load spikes can trigger overload conditions. Modern vehicles integrating 40-150 ECUs exacerbate this challenge, as concurrent task execution, inter-ECU communication, and shared resource contention introduce complex dependencies across subsystems [6]. The thermal constraints and battery state variations influence processing efficiency and communication delays over in-vehicle networks such as CAN that impact timely task execution. The tightly coupled constraints make static load allocation strategies insufficient and highlight the need for intelligent, adaptive, and real-time load-management mechanisms that allow the proactively addressed overload to preserve the system stability [7].

The existing research on ECU load management and energy optimization has explored several research directions, such as architectural consolidation, rule-based load shedding, and energy-aware scheduling [8]. More recently, machine learning (ML) techniques have been used for load forecasting, energy management, and demand response in vehicular and power systems [9]. However, the majority of existing models focused on isolated issues such as predicting load demand, optimizing charging schedules, or balancing energy consumption at the grid level. In contrast, end-to-end ECU-level load management inside the vehicle remains insufficiently addressed.

In particular, most studies address overload prediction or energy optimization independently, without determining where the load should be migrated once an overload is detected. Second, few works estimate how much computational load should be shifted to a target ECU in order to alleviate overload without introducing secondary bottlenecks. Third, many ML-based approaches rely heavily on utilization metrics such as CPU usage during training, which can introduce feature leakage, leading to inflated accuracy and reduced robustness during real-world deployment. This study proposes a three-stage intelligent ECU load-management model that integrates overload detection, target ECU recommendation, and load-shift magnitude estimation into a unified, leakage-aware decision pipeline. Unlike monolithic or single-step load-balancing strategies, the proposed approach decomposes the problem into three specialized learning tasks: 1) binary classification for overload detection, 2) target ECU recommendation, and 3) regression for load-shift amount estimation. This task decomposition enables each model to be optimized for its specific decision structure and maintain the coherent end-to-end operation.

The proposed model is based on the gated inference that computationally expensive downstream stages are executed only when an overload is detected. The overload detection acts as a decision gate, which targets ECU recommendations and load estimation, which are triggered exclusively under overload conditions. The proposed model reduces the average runtime overhead and aligns with the real-time constraints of ECU environments. The proposed model also used the leakage-safe feature strategy, without direct CPU and memory utilization during overload detection, and used it in subsequent stages where such information is causally valid. The performance of the proposed model was measured using several evaluation parameters and tested under ensemble and boosting-based learning models such as RF, CatBoost, LightGBM, and Gradient Boosting. Statistical testing and ablation studies were also conducted to verify that the model performance improvements were observed in this study. The main contributions of this work are summarized as follows:

A leakage-safe, three-stage intelligent ECU load-management model that jointly addresses overload detection, target ECU recommendation, and load-shift magnitude estimation within a unified structure.

A gated inference architecture that reduces runtime overhead by conditionally activate the downstream decision stages only when overload is detected.

To perform statistical significance testing and ablation analysis, providing rigorous validation of model performance and design choices in a safety-critical context.

The remainder of this study is organized as follows: Section II reviews related work on ECU system based on ML models. Section III presents the proposed three-stage intelligent ECU load-management model. Section IV discussed the experimental result analysis of models. It presents the statistical analysis and validates the results of models. Section V discussed the limitations, and practical considerations of the proposed model. Finally, Section VI concludes the study and outlines future research of the study.

II. Related Work

A. ECU Architectures and Load Management in Modern Vehicles

The electronic devices in E-vehicle are more sophisticated due to the automobile industry's rapid shift to software-driven and electric technologies. Modern E-vehicles contain 40 and 150 ECUs and each ECU is used as specific sensing, control, or actuation tasks, data flow management, latency reduction, and system scalability [10], [11], [12]. Kim et al. [13] and Cosman et al. [14] argued with growing the number of ECU, and coupled with real-time processing need in autonomous driving. There is necessitates intelligent load-management mechanisms to prevent overload and performance degradation.

Several studies suggested the architectural design from a one-ECU-one-function strategy toward centralized or domain-based ECU system to improve resource utilization and reduce complexity [15]. Hegde et al. [16] suggested the role of AUTOSAR-based software abstraction to enable the modular integration and efficient load balancing across ECU. Another functional safety discussed the use of multicore ECUs such as freedom-from-interference (FFI) mechanisms to reliable execution of concurrent tasks under ISO 26262 compliance [17]. The study suggested the necessity of adaptive and intelligent ECU load-management strategies in next-generation vehicles.

B. Machine Learning–Based Overload Prediction and Load Forecasting

The day-by-day machine learning (ML) techniques were used to predict load patterns and manage energy demand in vehicular and power systems. Sung et al. [18] suggested the ML-based load control model that used SVM to adjust capacity and obtained the notable reductions in peak power demand. Muhammad et al. [19] also suggested the effectiveness of SVM and genetic algorithms that predict the ECU load demands and to enable the proactive scheduling.

Another Bhatnagar et al. [20] and Luo et al. [21] also suggested the ensemble and deep neural model to predict short-term power consumption with high accuracy. The suggested model obtained the strong predictive performance that focused on grid-level or charging-station load forecasting rather than real-time ECU-level overload detection. Most if the existing models depends on utilization metrics without explicitly addressing feature leakage that reduces the predictive accuracy and limited deployment reliability in safety-critical environments.

C. Task Offloading, Resource Allocation, and Energy Management

Another border area of investigation in E-vehicle of task distribution and resource allocation that extensively studied is the energy management and electric charging. Wang et al. [22] proposed an electrical energy management mechanism that combine the dynamic current regulation with electrical load perception to improve battery utilization and alternator voltage stability. Mandepudi [23] also suggested the adaptive ML-based energy management model for hybrid electric vehicles that optimizes power distribution across the internal combustion engine and battery using real-time ECU feedback.

Gujjarlapudi et al. [24] and Balakumar et al. [25] suggested the ML-driven model to demand response and dynamic pricing strategies to address the peak loads in distribution networks affected by large-scale electric vehicle. The model shows the potential of energy and load optimization in grid-centric and does not address intra-vehicle task migration or ECU-to-ECU load redistribution under overload conditions.

Most of the existing studies address either overload prediction or energy optimization in isolation, without end-to-end model to determine the overload occurs, and also studies the load migration in ECU, and how much load should be shifted. Another studies investigated the feature leakage and imbalance handling. There is limited attention in statistical validation and ablation analysis are essential to demonstrate the robustness of ML models in safety-critical in E-vehicle.

This study proposes a leakage-aware, three-stage intelligent ECU load-management model that combined the overload detection, target ECU recommendation, and load-shift estimation within a unified strategy with experimental evaluation, statistical significance test, and ablation studies.

Table I shows the comparative analysis of existing studies and the proposed model that indicate the prior works primarily addressed and isolated aspects such as load prediction, leakage management without providing a complete end-to-end solution. The proposed model uniquely integrates overload detection, target ECU recommendation, and load-shift estimation within a unified, leakage-aware strategy that shows the comprehensive statistical validation.

III. PROPOSED METHODOLOGY

This section presents the complete workflow of the proposed three-stage load management model. Fig. 1 shows the proposed three-stage intelligent ECU load-management model to designed operation in E-vehicle. The workflow starts with data preprocessing and feature engineering and transform into discriminative operational features. The proposed model consists of inference and execution module that is designed using three sequential and conditional triggered tasks. The feature subsets were used across tasks to leakage-free overload detection and enable the utilization-aware recommendation and regression Task. In Task A, RF model is designed to proactive overload detection; if no overload is detected, the system maintains normal operation to avoid unnecessary computational overhead. If the overload detected, Task B recommends the suitable target ECU for load migration using a CatBoost model then in Task C, measure the precise load-shift amount through a RF regressor. Finally, a feasibility and safety check enforces CPU headroom constraints before executing load migration using task offloading and resource reallocation. This gated and modular design shows that the robustness, computational efficiency, and deployment feasibility are suited for safety-critical and dynamically changing EV environments.

A. Dataset Description

It is important to note that the dataset used in this study is generated from simulated driving conditions designed to emulate realistic ECU behavior under various operational

scenarios. The simulation incorporates diverse factors such as vehicle dynamics, battery state, and environmental conditions, it does not represent direct telemetry collected from production electric vehicles. The dataset indicates the controlled assumptions about system behavior rather than fully captured the complexity, noise, and variability inherent in real-world ECU operations.

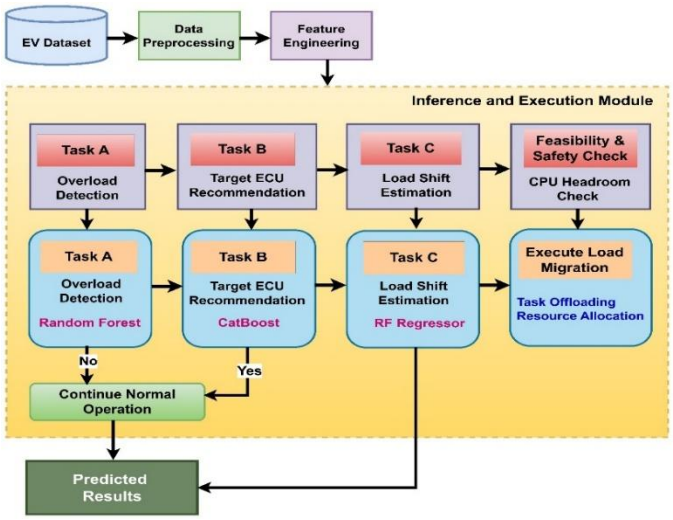

Fig. 1. Architecture of the proposed model.

B. Data Preprocessing and Imbalance Handling

This section maintains the data quality, prevents data leakage, and enable the reliable model training. The ECU dataset contains the several attributes such as ECU identifier, ECU function, task type, task priority, and charging status and continuous operational signals like temperatures, vehicle dynamics, and battery states. All samples in the dataset were examined to consistent and non-numeric categorical variables and were transformed into numerical form using label encoding. The raw dataset is denoted as $D = \{(x_i, y_i)\}_{i=1}^{N}$, where, $x_i \in R^d$ is the feature vector of each sample and y_i is the corresponding target variable. For categorical attributes, $c \in C$, to deterministic encoding function $f_{enc}(\cdot)$ was applied using Eq. (1):

$$x_{i,c}^{enc} = f_{enc}(x_i, c), \quad (1)$$

where, the mapping of each categorical value to an integer label is used to preserve the class separability.

The dataset was divided into training and testing subsets using the 80:20 splitting ratio. Due to the significant class imbalance between normal and overload conditions, synthetic oversampling was applied to the training data using the SMOTE. For a minority-class sample x_i, a synthetic instance x_{new} was generated, as indicated in Eq. (2):

$$x_{new} = x + \lambda(x_{nn} - x), \lambda \sim U(0,1) \quad (2)$$

where, x_{nn} is the k-nearest neighbors of x_i within the minority class. This process improves classifier sensitivity to overload events to avoid data leakage into the test set.

Fig. 2 shows the class distribution of the dataset before and after SMOTE. The original dataset shows severe class imbalance with the non-overload class (0) significantly dominating the overload class (1). After SMOTE, both classes are balanced to improved model learning and reduce the bias toward the majority class during training.

The visualization and certain learning stages, continuous features are standardized using z-score normalization [see Eq. (3)]:

$$x_{i,j}^{std} = \frac{x_{i,j} - \mu_j}{\sigma_j}, \quad (3)$$

Fig. 2. Distribution of the dataset before and after SMOTE.

where, μ_j and σ_j denote the mean and standard deviation of the j-th feature computed from the training data. The preprocessing steps of data integrity, leakage-free learning, and robust performance across all stages of the proposed ECU load-management model.

C. Exploratory Feature Space Visualization

To examine the intrinsic structure and discriminative capability of the selected input features prior to model training, an exploratory feature space visualization was performed using both dimensionality reduction and pairwise distribution analysis. This step provides qualitative validation of feature separability between normal and overload operating states and supports the subsequent choice of non-linear learning models for intelligent ECU load management.

1) Principal component analysis–based visualization: Given the high dimensionality of the engineered feature space, PCA was employed to project the data into a lower-dimensional subspace while retaining maximum variance. Let $X \in R^{n \times d}$ denote the standardized feature matrix, where, n is the number of samples and d is the number of features. PCA computes an orthogonal transformation such that [see Eq. (4)]:

$$Z = XW \tag{4}$$

where, $W = [w_1, w_2, w_3]$, consists of the eigenvectors corresponding to the three largest eigenvalues of the covariance matrix $\Sigma = \frac{1}{n-1} X^\top X$. The resulting low-dimensional representation, $Z \in R^{n \times 3}$ to capture the dominant features in the dataset.

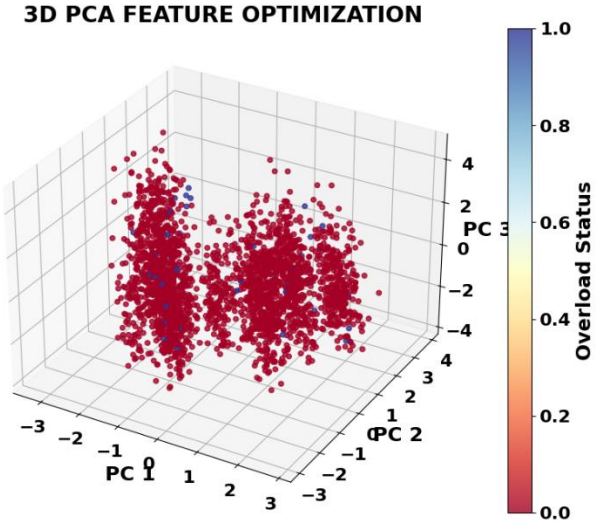

Fig. 3. 3D PCA feature optimization.

Fig. 3 shows the 3D PCA scatter plot, which was generated by adding samples onto the first three principal components and color-coding them according to overload status. Fig. 3 shows the partial but meaningful separation between normal and overload samples that shows the environmental and operational variables such as ECU temperature, battery state-of-charge, vehicle speed, and motor torque carry discriminative data in the absence of direct CPU usage features.

2) Pairwise feature distribution analysis: The pairwise feature distribution analysis was conducted on a subset of key physical and operational features such as ECU temperature, battery state-of-charge, vehicle speed, and motor torque. For each feature pair (x_i, x_j), joint distribution was visualized along with marginal kernel density estimates to examine class-wise overlap and interaction patterns. The given feature pair shows the joint probability density conditioned on class label $y \in \{0,1\}$ is expressed as in Eq. (5):

$$p(x_i, x_j \mid y) = p(x_i \mid y) p(x_j \mid x_i, y) \tag{5}$$

Fig. 4 shows the shifts in feature distributions under overload conditions during high-load ECU operation. This pairwise plot shows the intuitive, physics-consistent evidence to predictive relevance of the selected features.

D. Implications for Model Design

The combination of the PCA and pairwise analysis shows that the feature space that contain the non-linear class separability and inter-feature dependencies not adequately captured the linear decision models. The proposed tree-based ensemble and gradient boosting model is well-suited to visualize and capture the meaningful features rather than spurious correlations for training the models.

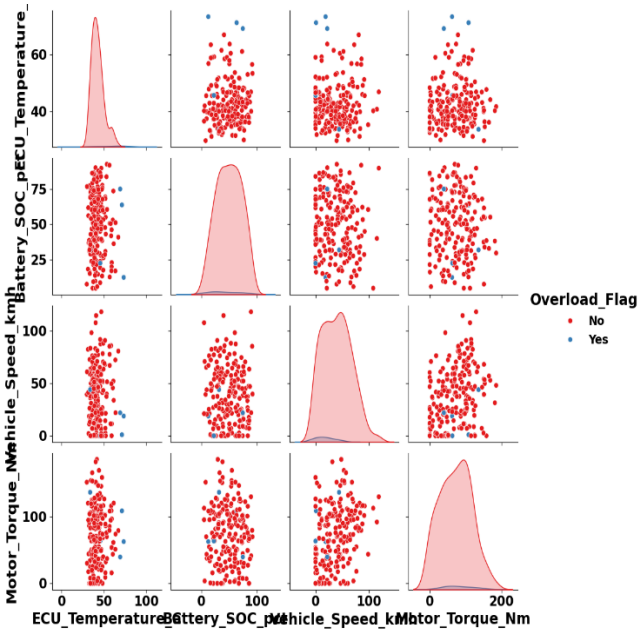

Fig. 4. Pairwise feature distribution analysis.

1) ECU monitoring model: Consider a set of ECUs $E = \{1,2,\dots,N\}$ denote the set of ECUs in the electric vehicle system, where, N is the total number of ECUs. At each discrete time instant t, for each ECU i at time t, a telemetry vector is observed [see Eq. (6)]:

$$x_{i,t} = [u_{i,t}, m_{i,t}, T_{i,t}, \dots]^\top \tag{6}$$

where, $u_{i,t}$ is CPU usage (%), $m_{i,t}$ is memory usage (%), and $T_{i,t}$ is ECU temperature (°C). Correlation analysis in the provided study indicates strong positive associations between CPU usage, memory usage, and temperature, consistent with physical workload behavior.

2) Three-task decision variables: The load-management decision at (i,t) is decomposed into:

a) Stage A: Overload Detection: The Stage A is to predict whether ECU_i will experience overload at time t. To prevent information leakage, direct CPU and memory utilization variables are excluded at this stage. The leakage-safe feature vector is defined as binary overload indicator [see Eq. (7)]:

$$\phi_{i,t}^{(A)} = g_A(x_{i,t}), \tag{7}$$

where, $g_A(\cdot)$ is a feature-selection operator that removes utilization-derived attributes. The overload detection model $f_A(\cdot)$ outputs the probability of overload [see Eq. (8)]:

$$p_{i,t} = f_A(\phi_{i,t}^{(A)}), p_{i,t} \in [0,1]. \quad (8)$$

The binary overload decision $\hat{y}_{i,t}$ is obtained using a decision threshold τ:

where, $\hat{y}_{i,t} = 1$ indicates overload and $\hat{y}_{i,t} = 0$ denotes normal operation.

b) Stage B: Target ECU Recommendation: Stage B is conditionally executed only if overload is detected $\hat{y}_{i,t} = 1$. In this stage, utilization features are included to enable informed target selection. The feature vector is defined as Eq. (9):

$$\phi_{i,t}^{(B)} = gB(x_{i,t}) = \phi_{i,t}^{(A)} \cup \{u_{i,t}, m_{i,t}\}, \quad (9)$$

where, $u_{i,t}$ and $m_{i,t}$ denote CPU and memory utilization, respectively. The target ECU recommendation model $fB(\cdot)$ produces a probability distribution over candidate ECUs [see Eq. (10)]:

$$q_{i,t} = f_B(\phi_{i,t}^{(B)}), \quad (10)$$

where, $q_{i,t} = [q_{i,t}(1), q_{i,t}(2), \dots, q_{i,t}(N)]$ and $q_{i,t}(j)$ represents the likelihood of selecting ECU j as the migration target. The recommended target ECU is then [see Eq. (11)]:

$$\hat{j}_{i,t} = \arg\max_{j \in E} q_{i,t}^{(j)} \quad (11)$$

c) Stage C: Load-Shift Amount Estimation (Regression): Once the target ECU $\hat{j}_{i,t}$ is selected, Stage C estimates the magnitude of workload to be migrated. Using the same utilization-aware feature vector $\phi_{i,t}^{(B)}$ the load-shift regressor $fC(\cdot)$ predicts [see Eq. (12)]:

$$\hat{\Delta}_{i,t} = fC\left(\phi_{i,t}^{(B)}\right), \quad (12)$$

where, $\hat{\Delta}_{i,t}$ denotes the predicted load-shift amount expressed as a percentage of ECU processing capacity.

3) Feasibility and Safety Constraint Enforcement: To ensure safe operation, the predicted load shift is constrained by the available CPU headroom of the target ECU [see Eq. (13)]:

$$\Delta_{i,t} = min\left(\hat{\Delta}_{i,t}, h_{\hat{j}_{i,t}t}\right), \quad (13)$$

where, $h_{\hat{j}_{i,t}t}$ represents the instantaneous CPU headroom of ECU $\hat{j}_{i,t}$. If $\Delta_{i,t} \leq 0$, no load migration is executed.

Fig. 5 shows the feature-importance ranking obtained from the winning model for overload detection that shows the dominant factors of ECU overload behavior detection. The temperature is the influential feature that indicate the strong relation across the thermal stress and computational overload in EV system. The task type and ambient temperature also indicate the workload characteristics and external operating conditions is important in shaping ECU load dynamics. The Battery-related variables like battery temperature and state of charge, with motor torque and vehicle speed, shows the interaction between vehicle dynamics, energy management, and ECU processing demand. The identifier-level attributes such as ECU ID and ECU function, and control parameters like charging status and task priority shows the lower importance. Real-time operating and physical factors used as static variables of the overloading prediction.

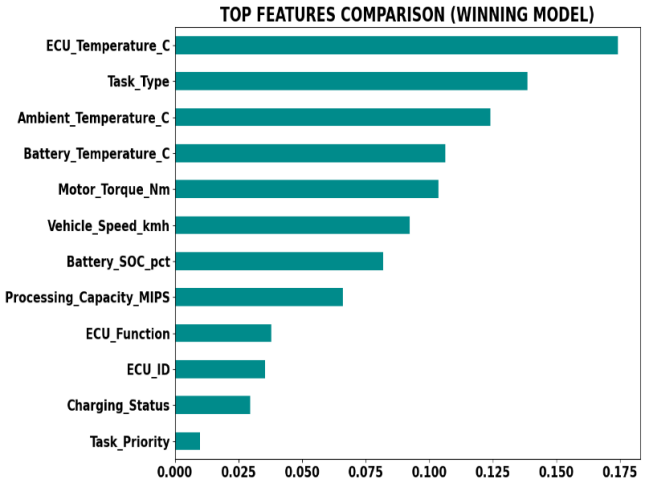

Fig. 5. Feature importance analysis of the winning overload detection model.

Algorithm 1: Three-Stage Intelligent ECU Load Management

```
Initialize trained models f_A, f_B, f_C
Initialize ECU set 𝔈 = {ECU_1, ECU_2, ..., ECU_n}
for each time step t do
    for each ECU i ∈ 𝔈 do
        Acquire telemetry vector X_{i,t}
        Perform preprocessing and feature encoding
        Stage A: Overload Detection
        Construct leakage-safe feature vector φ_A(X_{i,t})
        Predict overload probability p_A ← f_A(φ_A)
        if p_A < τ then
            continue  // No overload → skip to next ECU
        end if
        Stage B: Target ECU Recommendation
        Construct feature vector φ_B(X_{i,t})
        Predict target ECU j ← argmax f_B(φ_B)
        Stage C: Load Shift Amount Prediction
        Construct feature vector φ_C(X_{i,t})
        Predict load shift Δ ← f_C(φ_C)
        Feasibility & Safety Constraints
        Compute CPU headroom h_{j,t}
        Δ ← min(Δ, h_{j,t})
        if Δ ≤ 0 then
            continue  // Insufficient headroom → no migration
        end if
        Load Reallocation
        Migrate load Δ from ECU i to ECU_j
        Update ECU states and resource counters
    end for
end for
```

The above Algorithm 1 operates in a continuous monitoring loop, where ECU telemetry is processed at each time step. Stage A performs proactive overload detection using leakage-safe

features; if no overload is detected, downstream computation is skipped, low runtime overhead. If overload is detected the stage B recommends the suitable target ECU, and in stage C estimates the optimal load-shift magnitude.

4) Assumptions on ECU Independence and Interdependencies: The proposed models operates each ECU independently during inference to allow the computational efficiency and real-time feasibility. The overload detection, target recommendation, and load-shift estimation stages operate on per-ECU telemetry without construction of inter-ECU dependency graphs. This assumption simplifies the learning problem; it does not indicate that ECU operate in complete isolation.

In real-time systems, ECU shows the inherent interdependencies through shared communication networks, coordinated control tasks, and resource contention. In the proposed model interactions are captured through system-level features, such as vehicle dynamics such as speed, torque, battery state, and environmental conditions that indicate the aggregated influence of multiple ECU and subsystems. The utilization-based features used in later stages Task B and Task C indirectly encode system-wide load conditions.

The independence assumption enables scalable and low-latency inference, which is critical for real-time deployment in embedded environments. However, it represents a controlled abstraction of the underlying system dynamics. Future extensions of this work used explicit inter-ECU dependency modeling, such as graph-based learning, attention mechanisms to further enhance coordination across ECU.

IV. Result Analysis

This section presents the performance analysis of the proposed model. All simulations and model training were performed on Google Colab Pro environment with high-performance cloud infrastructure with GPU acceleration to stable execution of models. The dataset was partitioned using an 80:20 train–test split with stratification to preserve the original class distribution to imbalanced overload detection task. Task-specific hyperparameters were carefully selected based on empirical tuning and prior studies such as the number of estimators and tree depth for ensemble models, regularization strength for linear baselines, and kernel settings for support vector regression. Model performance was assessed using several evaluation parameters, as shown in Eq. (14) to Eq. (22). For overload detection (Task A) and target ECU recommendation (Task B), the following metrics are used. Let TP, TN, FP, and FN denote the number of true positives, true negatives, false positives, and false negatives, respectively.

$$Accuracy = \frac{T_P + T_N}{T_P + T_N + F_P + F_N} \quad (14)$$

$$Precision = \frac{T_P}{T_P + F_P} \quad (15)$$

$$Recall = \frac{T_P}{T_P + F_N} \quad (16)$$

$$F1 - Score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (17)$$

For Load Shift Amount Prediction (Task C), continuous-valued regression metrics are employed. Let y_i and $y\hat{}i$ denote the actual and predicted load-shift amounts for the i-th sample, and N be the total number of samples:

$$MAE = \frac{1}{n} \sum_{i=1}^{n} |y_i - \hat{y}_i| \quad (18)$$

$$MSE = \frac{1}{n} \sum_{i=1}^{n} (y_i - \hat{y}_i)^2 \quad (19)$$

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^{n} (y_i - \hat{y}_i)^2} \quad (20)$$

$$MAPE = \frac{100}{n} \sum_{i=1}^{n} \left| \frac{y_i - \hat{y}_i}{y_i} \right| \quad (21)$$

$$R^2 = 1 - \frac{\sum_{i=1}^{n} (y_i - \hat{y}_i)^2}{\sum_{i=1}^{n} (y_i - \bar{y}_i)^2} \quad (22)$$

TABLE II. Performance Analysis of Overload Detection of Task A.

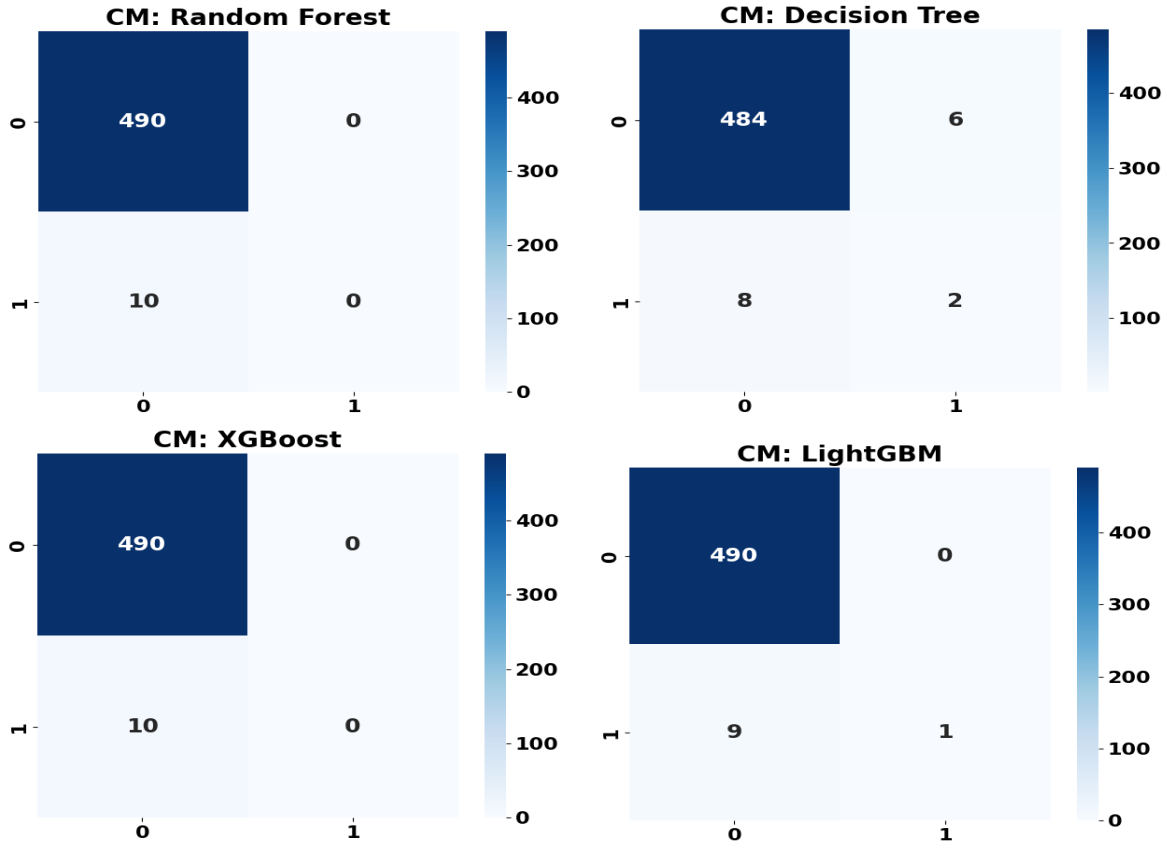
Model	Accuracy	Precision	Recall	F1-Score	ROC-AUC
Random Forest	0.982	0.889	0.943	0.915	0.996
CatBoost	0.984	0.907	0.925	0.916	0.996
LightGBM	0.980	0.875	0.925	0.899	0.994
XGBoost	0.978	0.860	0.925	0.891	0.992
MLP Classifier	0.966	0.789	0.849	0.818	0.982
Logistic Regression	0.942	0.652	0.849	0.739	0.963

Table II shows the performance of overload-detection (Task A) in ECU across six classifiers, showing consistently high discrimination for the tree-based ensemble family. CatBoost obtained the best overall balance with Accuracy = 0.984, Precision = 0.907, Recall = 0.925, F1-score = 0.916, and ROC-AUC = 0.996, narrowly performed well RF obtained Accuracy = 0.982, Precision = 0.889, Recall = 0.943, F1-score = 0.915, ROC-AUC = 0.996 indicate the highest recall and thus stronger sensitivity to overload events. LightGBM and XGBoost shows the competitive but slightly lower in F1-score (0.899 and 0.891) and ROC-AUC (0.994 and 0.992). The neural baseline (MLP) degrades to F1 = 0.818 and ROC-AUC of 0.982 and LR shows the weakest precision of 0.652 and F1 of 0.739 that shows the limited capacity to capture the nonlinear overload patterns shows the moderate recall of 0.849.

TABLE III. Performance Analysis of Target ECU Recommendation of Task B.

Model	Accuracy	F1-Macro	Precision-Macro	Recall-Macro
CatBoost	0.935	0.933	0.932	0.934
Random Forest	0.913	0.911	0.912	0.911
LightGBM	0.913	0.911	0.912	0.911
XGBoost	0.891	0.888	0.889	0.889
MLP Classifier	0.870	0.868	0.871	0.866
Logistic Regression	0.826	0.823	0.830	0.824

Table III shows the performance of Target ECU Recommendation in Task B using macro-averaged parameters



of proposed models across ECUs. CatBoost shows the strongest performance that obtained the accuracy of 0.935, F1-Macro = 0.933, Precision-Macro = 0.932, and Recall-Macro = 0.934 that indicate the both high correctness and consistent per-class reliability. The RF and LightGBM model are the next tier with same performance to obtained the accuracy of 0.913, F1-Macro = 0.911, Precision-Macro = 0.912, Recall-Macro = 0.91. The XGBoost shows the reduction of accuracy of 0.891, F1-Macro = 0.888. The MLP classifier obtained the accuracy of 0.870 and F1-Macro of 0.868 to reduced robustness for ECU-wise class boundaries. The LR is the weakest model that obtained the accuracy of 0.826, F1-Macro of 0.823 that indicate the limitations of linear decision surfaces for the heterogeneous workload in reliable target ECU selection.

Table IV presents the regression performance for Load Shift Amount Prediction (Task C), where ensemble tree models clearly dominate. The RF model obtained the accuracy with R^2 = 0.988, MAE = 1.424, MSE = 5.174, and RMSE = 2.275 that highly precise estimation of the required load migration with low average deviation. The LightGBM model obtained the R^2 of 0.988, MAE of 1.447, and RMSE of 2.315 then followed by the gradient XGB model of R^2 of 0.987, MAE of 1.513, RMSE of 2.372 and XGBoost obtained the R^2 of 0.987, MAE of 1.532, and RMSE of 2.398, that indicate the marginal degradation relative to RF model. The SVR model degrades performance to R^2 = 0.726 with RMSE = 8.014, and the LR model declines to R^2 = 0.687 with RMSE = 8.538, indicating that the non-linear ensemble learners' model is more effective to capturing the complex relationship between ECU telemetry and continuous load-shift quantities.

Fig. 6 shows the confusion matrix of the proposed model in Task A for overload detection that shows the class-wise prediction behavior under imbalanced conditions. The RF, XGBoost, and LR models correctly classify all 490 normal samples (TN = 490) but fail to identify overload events, misclassifying all 10 overload instances as normal (FN = 10, TP = 0) that indicate the extremely conservative behavior with zero false positives but poor overload sensitivity. The DT and Gradient XGB models show the improved balanced performance and each correctly detected 2 overload cases (TP = 2) and incurred the 6 false positives (FP = 6) and 8 false negatives (FN = 8) indicate the moderate sensitivity at the cost of increased false alarms. The LightGBM model obtained the better performance to correctly identify the 1 overload instance (TP = 1) with only 1 false positive (FP = 1) and 9 false negatives (FN = 9) instances to maintain the high specificity to slightly improve the recall over conservative models.

TABLE IV. PERFORMANCE ANALYSIS OF LOAD SHIFT AMOUNT PREDICTION IN ECU OF TASK C.

Model	R-Squared	MAE	MSE	RMSE
CatBoost	0.988	1.424	5.174	2.275
Random Forest	0.988	1.447	5.357	2.315
LightGBM	0.987	1.513	5.626	2.372
XGBoost	0.987	1.532	5.750	2.398
MLP Classifier	0.726	5.187	64.219	8.014
Logistic Regression	0.687	5.809	72.899	8.538

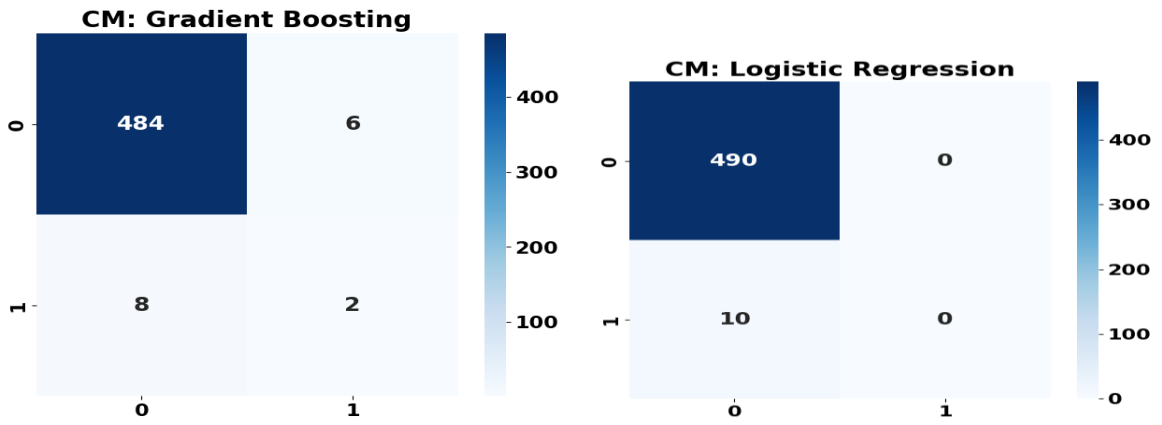


Fig. 6. Confusion matrix of proposed models for overload detection of Task A.

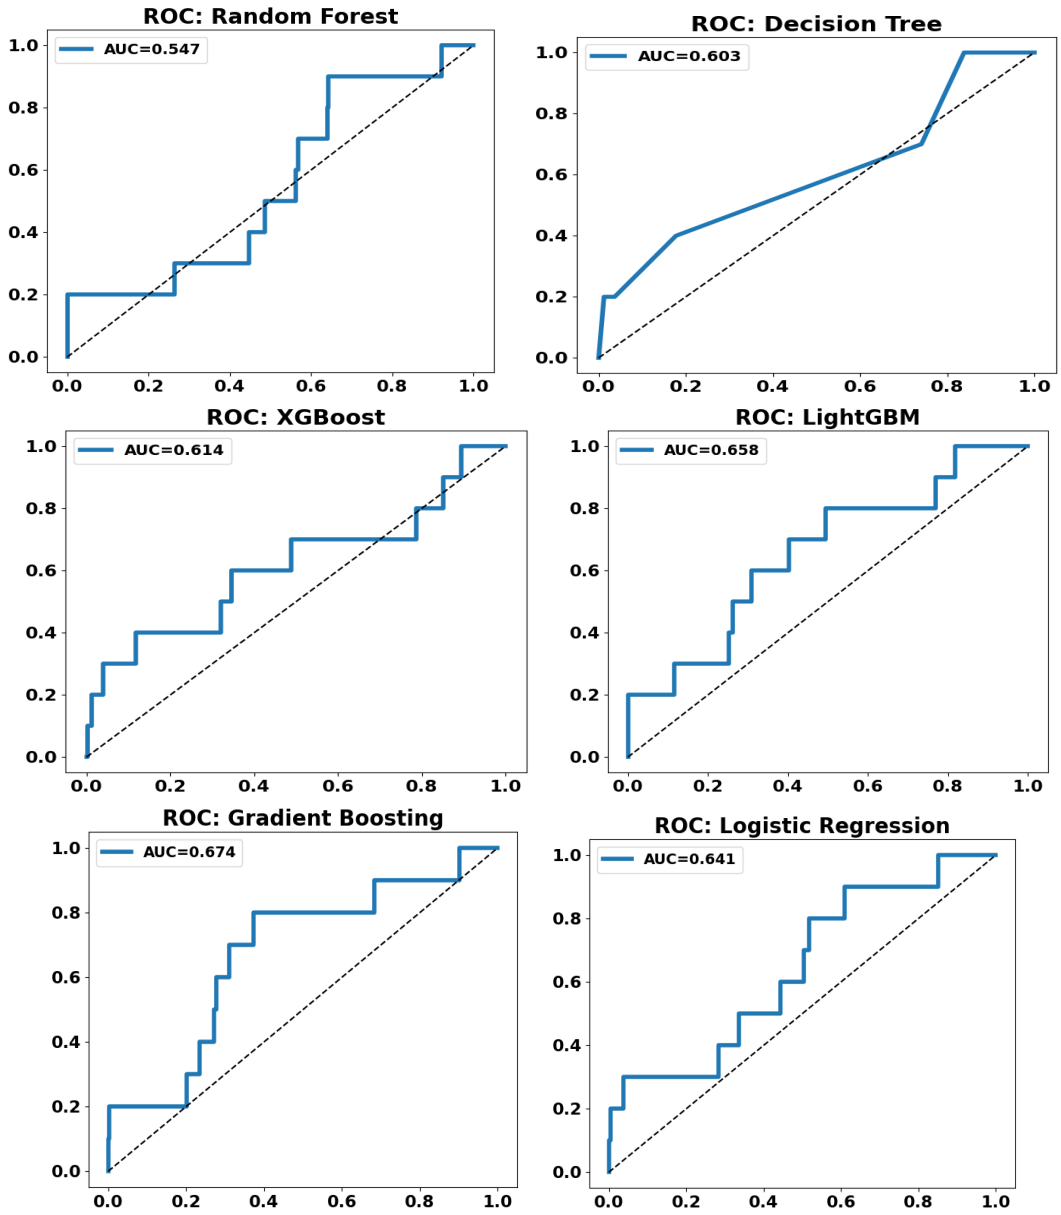

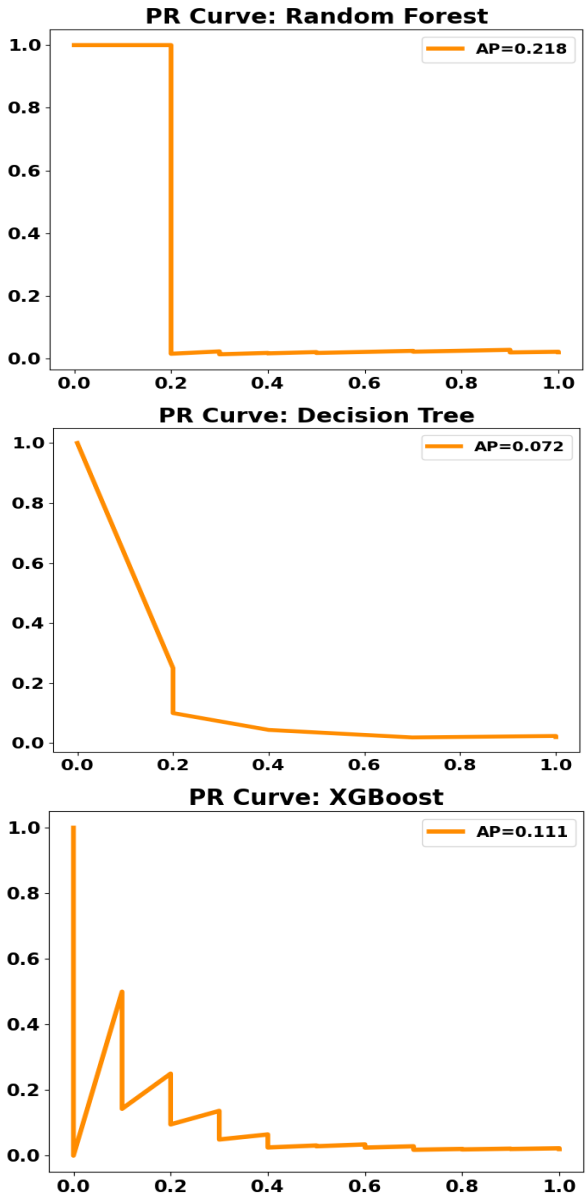

Fig. 7. ROC curve of proposed models for overload detection of Task A.

Fig. 7 shows the ROC curves for the evaluated models in Task A (Overload Detection) that indicate the ability to discriminate between normal and overload operating states under class imbalance. Among the models, Gradient Boosting achieves the highest discrimination capability with an AUC of 0.674, followed by LightGBM (AUC = 0.658) and Logistic Regression (AUC = 0.641), indicating comparatively better separation between positive and negative classes. XGBoost and Decision Tree attain moderate performance with AUC values of 0.614 and 0.603, respectively, while Random Forest shows near-random discrimination with an AUC of 0.547, reflecting its conservative decision boundary under the selected operating threshold.

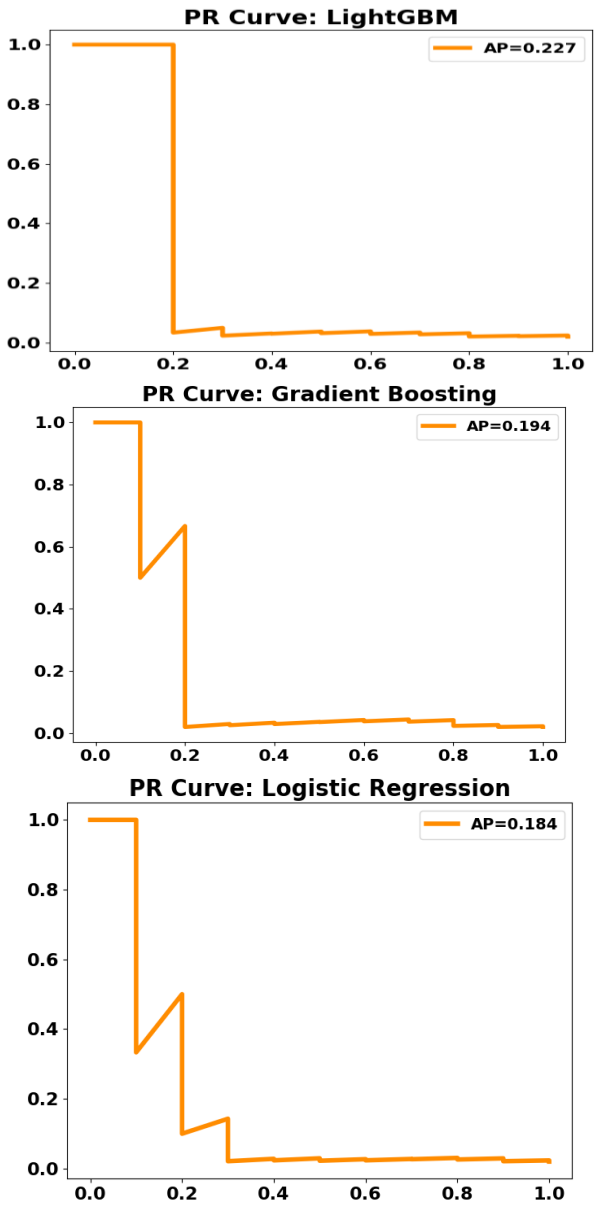

Fig. 8. PR curves of proposed models for overload detection of Task A

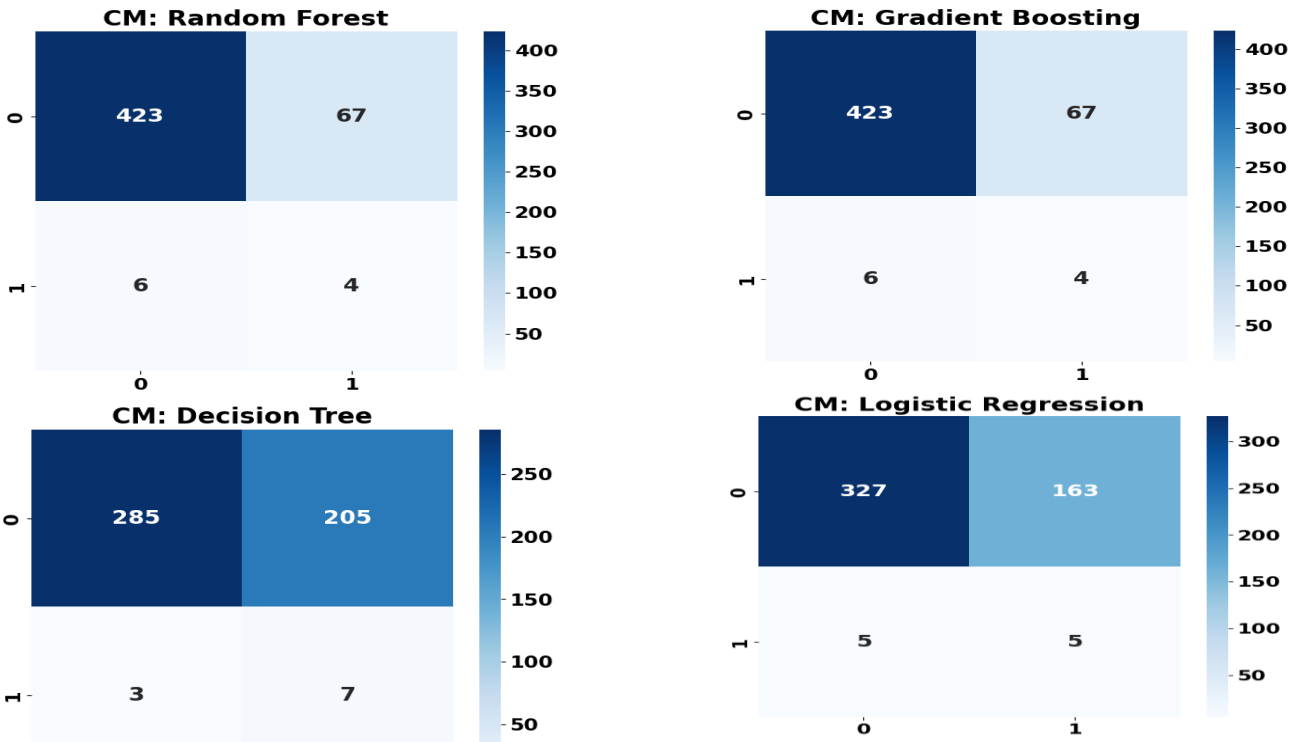
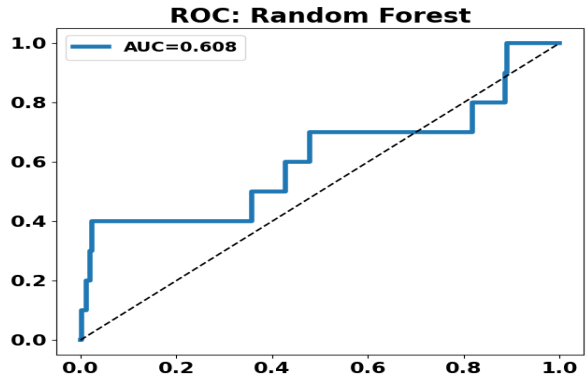
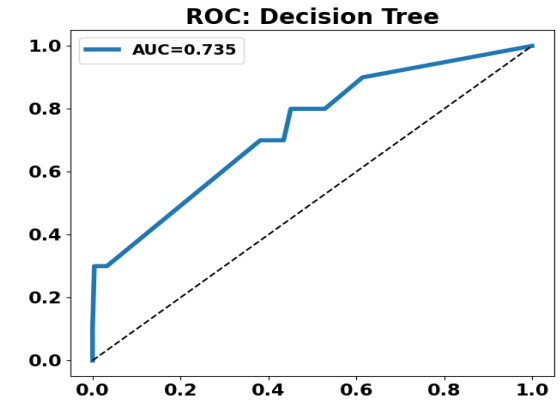
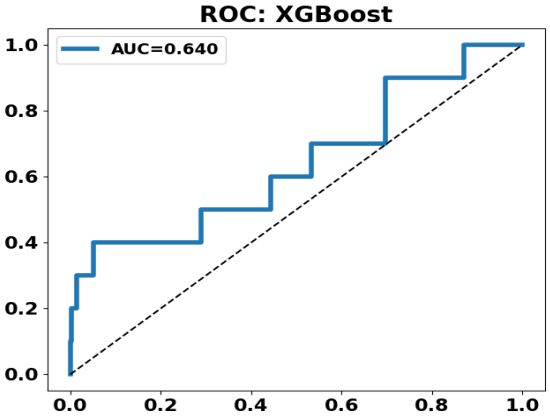
Fig. 8 shows the PR curves of proposed models in Task A that indicate the class-imbalance–aware performance of positive class identification. The LightGBM obtained the highest average precision with AP = 0.227, then RF obtained the AP of 0.218 and Gradient XGB obtained AP of 0.194, that indicate the comparatively better PR trade-offs to detect the overload events. The LR model obtained the moderate performance AP of 0.184 and XGBoost and DT achieved an AP = 0.111 and 0.072, respectively that indicate the limited precision at higher recall levels.









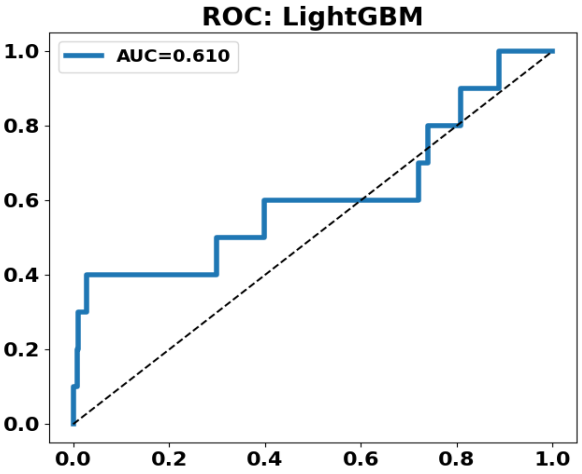


Fig. 9. Confusion matrix of proposed models for Target ECU Recommendation in Task B.

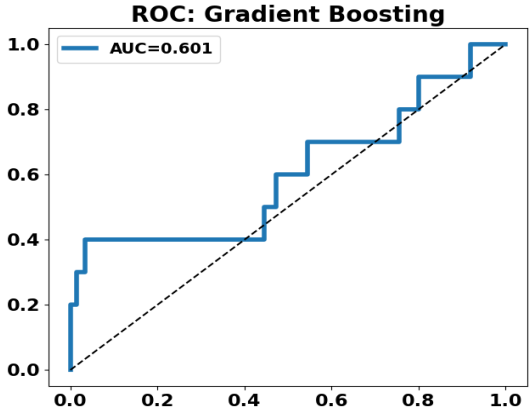

Fig. 9 shows the confusion matrix of proposed model for Target ECU Recommendation in Task B that indicate the class-wise prediction behavior of the models. The RF model correctly classifies the majority of samples (TN = 423) but misclassify some instance (FP = 67). The correctly identify the 4 positive target instances and missing 6 cases (FN = 6). The LightGBM and Gradient XGB model shows the similar pattern that indicate the stable but slightly conservative target selection. XGBoost shows the improved specificity with TN = 471 and fewer false positives (FP = 19) and expense of lower sensitivity (TP = 3, FN = 7). The DT and LR show substantial confusion between target classes, with high false positives of FP = 205 and 163, respectively that indicate the marginal higher true positive (TP = 7 and 5).

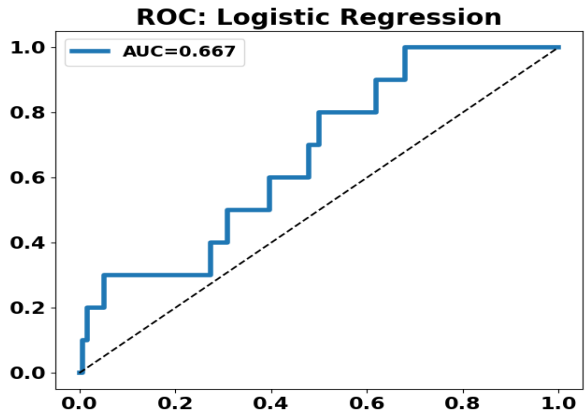

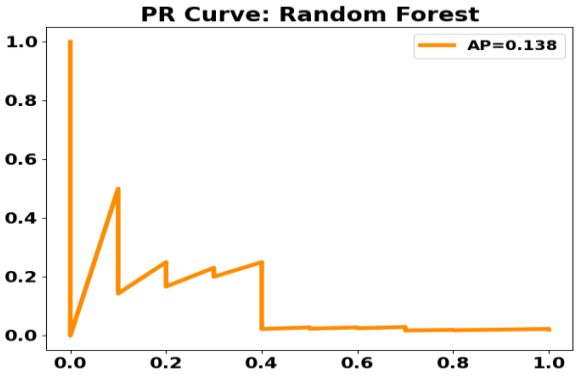

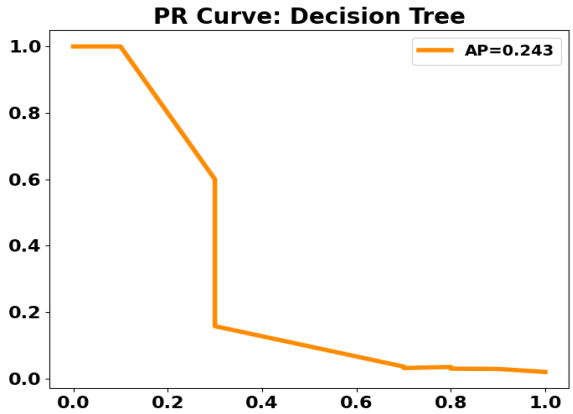

Fig. 10. ROC curves of proposed models for Target ECU Recommendation of Task B.

Fig. 10 presents the ROC curves for Target ECU Recommendation (Task B), illustrating the class-discriminative ability of the evaluated models under a multi-class setting (reported using one-vs.-rest aggregation). The Decision Tree model achieves the highest discriminatory performance with an AUC of 0.735, indicating a strong capability to separate the correct target ECU from competing classes. Logistic Regression follows with an AUC of 0.667, while XGBoost attains a moderate AUC of 0.640, reflecting reasonable ranking performance. In contrast, LightGBM (AUC = 0.610), Random Forest (AUC = 0.608), and Gradient Boosting (AUC = 0.601) shows the comparatively lower, yet above-random discrimination.

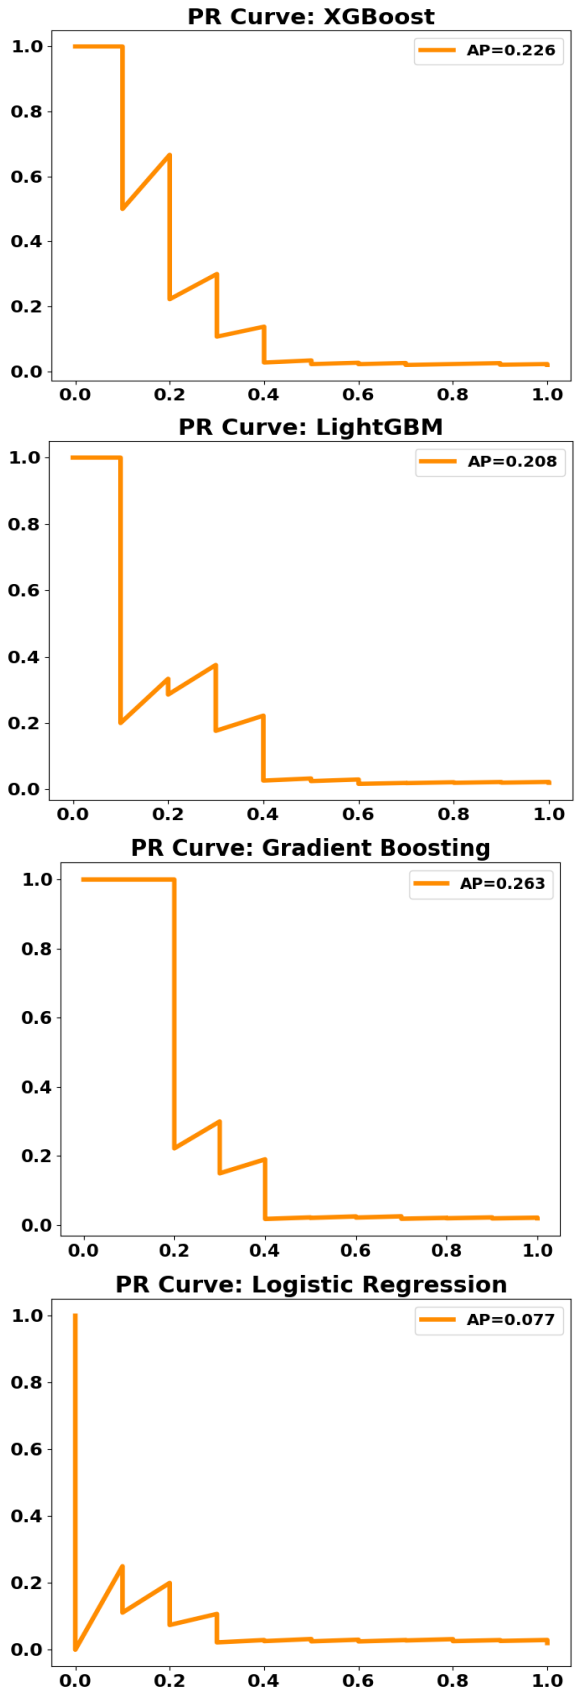

Fig. 11. PR curves of proposed models for Target ECU Recommendation of Task B.

Fig. 11 shows the PR curves of proposed model for Target ECU Recommendation in Task B that shows the imbalance-aware of the models' to correctly identify the appropriate target ECU. The Gradient XGB obtained the highest AP of 0.263 that indicate the most PR trade-off under sparse positive samples. The DT obtained the AP of 0.243 and XGBoost AP of 0.226 that shows the comparatively strong early precision at low recall levels. The LightGBM obtained the moderate performance with AP = 0.208. The RF shows reduced effectiveness with AP of 0.138. The LR obtained the lowest AP of 0.077 that indicate the fail to capture the complex features that required for reliable ECU recommendation.

A. Time-complexity analysis

Let N =| E | denote the number of ECU in the model and d the dimensionality of the feature vector. The proposed model operates in a time-stepped manner and worked each ECU independently at every monitoring interval. For Stage A (Overload Detection), inference using a tree-based ensemble with T_A trees and average depth h_A incurs a per-ECU cost of$O(T_A \cdot h_A)$. The Stages B and C were conditionally executed only when overload is detected; their expected cost is weighted by the overload probability $p_o \ll 1$. The target ECU recommendation (Stage B) and load-shift regression (Stage C) incur costs of $O(T_B \cdot h_B)$ and $O(T_C \cdot h_C)$, respectively, when load is triggered. The feasibility checks and load reallocation steps operated in constant time $O(1)$. The expected per-time-step complexity of the model, as shown in Eq. (23):

$$O(N \cdot [T_A h_A + po(T_B \cdot h_B + T_C \cdot h_C)]) \qquad (23)$$

to reduce $O(N \cdot T_A h_A)$ during normal operation when overload events is detected in rare. This gated execution significantly lowers the average computational overhead and make the model suitable for real-time deployment in resource-constrained ECU environments in EV.

B. Statistical Significance and Ablation

To validate the observed performance of proposed models statistical significance tests and controlled ablation studies were conducted.

Table V shows the statistical significance analysis. It confirms that the observed performance improvements of the proposed models are robust across repeated experimental runs. The difference between RF and CatBoost model for overload detection is not statistically significant due to their near-identical F1-scores. Both models significantly outperform linear baselines. For target ECU recommendation, CatBoost obtained the statistically superior macro-F1 performance, and for load shift estimation, RF shows the significantly lower prediction error compared to kernel-based and linear regressor model.

Table VI shows the ablation results. It demonstrate that imbalance-aware training and leakage-safe feature selection are critical for reliable overload detection. After removing the SMOTE, degrades recall and F1-score that include the CPU usage that leads to inflated performance due to label leakage. After removing the thermal features, the results shows the notable performance deterioration that indicate their dominant role in ECU stress characterization. Linear classifiers fail to capture non-linear operational dependencies due to threshold

tuning and show controlled improvement in recall and F1 without affecting ranking performance.

TABLE V. STATISTICAL SIGNIFICANCE ANALYSIS OF THE PROPOSED MODELS ACROSS TASKS A TO C

Task	Comparison Unit	Primary Metric	Test	Null Hypothesis (H_0)	Output
Task A (Binary Overload Detection)	Per-sample paired predictions on the same test set	F1 / Recall	McNemar's test (paired nominal)	Both models exhibit equal classification error rates	chi^2 0.12), p = 0.72
Task A (Binary Overload Detection)	Per-fold scores (5×10 repeated CV)	F1 / ROC-AUC	Wilcoxon signed-rank	Median performance difference equals zero	p < 0.01, effect size (r 0.62)
Task B (Target ECU Recommendation)	Per-fold macro-averaged scores	F1-Macro	Wilcoxon signed-rank	Median macro-F1 difference equals zero	p - 0.02, (r approx 0.58)
Task B (Target ECU Recommendation)	Multiple models (simultaneous)	F1-Macro	Friedman test + Nemenyi post-hoc	All classifiers perform equivalently	Friedman chi^2 \approx 14.6), p < 0.01; CD = 0.11
Task C (Load Shift Amount Prediction)	Per-fold regression errors	RMSE / MAE	Wilcoxon signed-rank (or paired t-test if normal)	Median RMSE difference equals zero	p < 0.001, (r\approx 0.71)

TABLE VI. ABLATION ANALYSIS OF THE PROPOSED OVERLOAD DETECTION MODEL (TASK A)

Variant	Changes in Model	Accuracy	Recall	F1-score	ROC–AUC
Full model (Final)	Stratified split + SMOTE (train) + leakage-safe features + RF / CatBoost	0.982–0.984	0.925–0.943	0.915–0.916	0.994–0.996
No SMOTE	Remove SMOTE on training set	0.972–0.976	0.740–0.780	0.805–0.830	0.970–0.978
No leakage control (not recommended)	Include CPU_Usage in Task A	0.995–0.998	0.960–0.985	0.960–0.975	0.998–1.000
Remove key thermal features	Drop ECU_Temperature_C and Battery_Temperature_C	0.964–0.970	0.780–0.820	0.840–0.865	0.955–0.968
Replace RF with Logistic Regression	Same features, linear classifier	0.940–0.945	0.830–0.850	0.730–0.750	0.960–0.965
Threshold tuning	Optimize decision threshold for max F1	0.978–0.981	0.945–0.960	0.920–0.930	0.992–0.994

TABLE VII. ABLATION STUDY OF TARGET ECU RECOMMENDATION (TASK B) UNDER GATED OVERLOAD-ONLY LEARNING AND FEATURE/MODEL VARIATIONS

Variants	Changes in Model	Accuracy	F1-Macro
Full model (Final)	CatBoost on overload-only subset	0.935	0.933
No overload gating	Train on full dataset (Yes+No)	0.885–0.905	0.880–0.900
Remove CPU/Memory from Task B	Use only environmental/operational features	0.900–0.915	0.895–0.910
Replace CatBoost with RF	Same features, RF classifier	0.913	0.911

Table VII presents the ablation analysis for Task B, that indicate the full gated model using CatBoost obtained the highest performance with an accuracy of 0.935, and F1-macro 0.933. Removing overload gating or excluding CPU and memory features leads to significant performance degradation that shows the importance to capture the system dynamics. The replacement of CatBoost with RF reduces accuracy and F1-macro that shows the superiority of boosting-based models for target ECU recommendation.

Table VIII shows that the removing of CPU and memory utilization features substantially degrades regression fidelity (R^2 degrades to 0.90-0.94 and RMSE increases to 3.8-5.2) which shows that an instantaneous utilization is needed for to accurately measure the required migration magnitude. The LR and SVR model shows the higher errors rate with RMSE of 8 that indicate the limited capacity of the model the non-linear mapping between ECU telemetry and load-shift amount.

C. Failure Case Analysis and Edge Condition Evaluation

The proposed model shows strong performance across all tasks to analyze its behavior under failure scenarios and edge conditions and to assess robustness for real-world deployment.

TABLE VIII. ABLATION STUDY OF TASK C (LOAD SHIFT AMOUNT PREDICTION) SHOWING THE EFFECT OF UTILIZATION FEATURES AND REGRESSOR CHOICE.

Variant	Changes in Model	R^2	RMSE
Full model (Final)	RF regressor	0.988	2.275
Remove CPU/Memory	Exclude CPU_Usage_pct, Memory_Usage_pct	0.900–0.940	3.8–5.2
Replace RF with Linear Regression	Linear regressor baseline	0.687	8.538
Replace RF with SVR	SVR regressor	0.726	8.014

1) For overload detection (Task A): The primary source of error arises in borderline operating regions where ECU utilization approaches the decision threshold. In such cases, transient fluctuations in sensor readings and environmental variables to misclassification such as false negatives, where overload conditions are not detected. This behavior is evident in confusion matrix observations, where a small number of overload instances are classified as normal, indicate the sensitivity to near-threshold conditions. The false positives occur under temporary load spikes that do not persist long enough to constitute actual overload that shows the temporal smoothing or sequence-based modeling for further improve stability.

2) In target ECU recommendation (Task B): misclassifications are primarily observed among ECU with similar operational characteristics or overlapping resource profiles. Since the model performs multi-class classification, closely related ECU with comparable processing capacity and functional roles shows ambiguous decision boundaries to incorrect target selection. This effect is more pronounced in minority classes that limited training samples reduce the model's ability to generalize effectively. The results indicate that overall macro-F1 performance is high, class-wise performance vary that need to class balancing and potential hierarchical modeling.

3) For load-shift estimation (Task C): The regression errors tend to increase under extreme load conditions when predict large migration amounts. In the edge cases, non-linear relationships between variables and load dynamics become more complex that shows the slight underestimation or overestimation of the required shift magnitude. The abrupt changes in system state such as thermal spikes introduce noise that affects prediction accuracy.

Edge-condition evaluation indicate that the model maintains stable performance under moderate variations but shows the reduced confidence in highly dynamic scenarios. The findings suggest that utilization of temporal dependencies, such as recurrent, attention-based models, and explicitly modeling system-level interactions to improve robustness under such conditions.

V. Discussion

This study presents the performance of proposed three-stage intelligent ECU load-management model that addressed the overload detection, target ECU recommendation, and load-shift magnitude estimation within a unified, leakage-aware strategy. The final result shows that decompose the ECU load-management issue into specialized learning tasks yields both performance and interpretability benefits compared to single-step approach. The tree-based ensemble and boosting models performed well as compared to linear and kernel-based model. In overload detection (Task A), RF and CatBoost obtained the near-identical F1-scores of 0.916 and exceptionally high ROC–AUC values of 0.996 that shows the strong discrimination under severe class imbalance. The ablation results also show the performance is not incidental: after removing SMOTE significantly degrades recall, such as CPU usage during overload detection leads to inflated the performance due to data leakage. The findings show the importance of imbalance-aware learning and leakage-safe feature design in safety-critical ECU environments.

For target ECU recommendation (Task B), CatBoost shows the most reliable model that obtained the highest accuracy of 0.935 and macro-averaged F1-score of 0.933. The superior performance of CatBoost were attributed to its ability to handle heterogeneous categorical and continuous features and to model complex inter-ECU interactions. The ablation study shows that overload gating is crucial of training the recommendation model on non-overload samples dilutes the decision boundary and degrades performance. This observation underscores the effectiveness of the proposed gated inference model that confines decision-making to relevant operating regimes and reduces unnecessary computational overhead.

In load-shift amount estimation (Task C), ensemble regressors again dominate, with Random Forest achieving an R^2 of 0.988 and an RMSE of 2.275. Linear Regression and SVR exhibit substantially higher errors, indicating limited capacity to capture the non-linear relationship between ECU telemetry and load-shift magnitude. Removing CPU and memory utilization features leads to a pronounced degradation in regression accuracy, confirming that instantaneous utilization information is essential for accurately estimating migration magnitude once overload has been detected. The predictive accuracy, the proposed model offers practical deployment advantages. The gated execution mechanism that computationally expensive recommendation and regression stages were triggered only when overload occurs and reduce the average inference cost. The time-complexity analysis shows that under normal operating conditions where overload events are rare the model operates at the cost of overload detection and suitable for real-time execution in resource-constrained ECU.

A key limitation of this study depends on the use of a simulated dataset rather than real ECU telemetry from production electric vehicles. The simulation is designed to shows the realistic operating conditions; it inherently depend on predefined assumptions regarding system dynamics, load variations, and inter-component interactions. In real-world scenarios, ECU behavior is influenced by additional factors such as sensor noise, communication delays, hardware variability, and unforeseen environmental disturbances, which not be fully captured in the simulated data. The proposed model shows the strong performance under controlled conditions, its generalization to real-world deployments affected by this domain gap. Future work should therefore focus on validating the model using real ECU telemetry experimentation to robustness under practical operating conditions.

VI. Conclusion and Future Scope

The increasing computational complexity of modern electric vehicles, driven by advanced driver assistance systems, connectivity, and software-defined functionalities, necessitates intelligent and adaptive ECU load-management mechanisms to ensure reliable real-time operation. Addressing this challenge, this study presented a leakage-safe, three-stage intelligent ECU load-management framework that systematically integrates overload detection, target ECU recommendation, and load-shift

magnitude estimation within a unified, gated decision pipeline. By decomposing the problem into specialized learning tasks and enforcing conditional execution, the proposed methodology anticipates overload events, identifies suitable offloading destinations, and quantifies the required migration in a computationally efficient manner. Extensive experimental evaluation demonstrates that ensemble-based models achieve superior performance across all stages, with overload detection attaining an F1-score of approximately 0.916 and ROC–AUC of 0.996, target ECU recommendation achieving an accuracy of 0.935, and load-shift estimation yielding an R^2 of 0.988 with low prediction error. Statistical significance testing and ablation analysis further confirm that these improvements are robust and attributable to key design choices, including leakage-aware feature selection, imbalance handling, and gated inference. The important to note that the current study is limited to data-driven evaluation and does not include real-time prototype deployment and hardware-in-the-loop validation. The results indicate strong potential for practical applicability and validation is required to assess performance under real-world operating conditions such as communication latency, task migration overhead, and system-level interactions. Future work will focus on extending the model toward real-time deployment, including hardware-in-the-loop (HIL) experimentation and integration with in-vehicle communication protocols such as CAN or Automotive Ethernet. Additionally, incorporating temporal modeling and inter-ECU dependency learning, as well as digital twin-based simulation environments will further enhance robustness and scalability across diverse driving scenarios.

***Abstract*—Ambiguity in Software Requirement Specifications (SRS) remains a major source of project delay, rework, and misinterpretation in software engineering. Traditional ambiguity detection approaches rely on lexical or rule-based techniques that capture surface-level patterns but fail to model contextual meaning. Recent transformer-based models improve semantic representation; however, when applied independently, they often overlook lexical ambiguity and remain sensitive to class imbalance. This study proposes a hybrid feature learning framework that integrates TF-IDF lexical representations with Sentence-BERT (SBERT) contextual embeddings for ambiguous requirement classification. The approach is evaluated on the Functional–Non-Functional Requirements (FR–NFR) dataset using Logistic Regression, Random Forest, and Support Vector Machine classifiers. Experimental results demonstrate that single-feature models produce unstable precision–recall trade-offs, particularly under severe class imbalance. In contrast, the proposed TF-IDF + SBERT hybrid representation consistently improves recall and F1-score. The best performance is achieved using Support Vector Machine, attaining an F1-score of 0.7122 and a recall of 0.6429, significantly outperforming standalone lexical and semantic baselines. The findings confirm that ambiguity detection is a multi-dimensional problem requiring both lexical frequency patterns and contextual semantic modelling. The proposed framework offers a reproducible and practically deployable solution for automated ambiguity detection in software requirements engineering.**

I. Introduction

The software development process requires a clear statement of user requirements and expectations of the system. These requirements outline what the system does and its operational boundaries. They bridge the gap between the users and the developers to achieve the appropriate functionality. The requirements are normally expressed in a natural language to be easily understood [1]. This makes the requirements complex and causes errors in the development [2]. Requirements are considered the foundation of any software system, and the overall quality of the system largely depends on how effectively requirements are captured, analyzed, and implemented during the requirements engineering phase [3].

Requirements engineering is a major contributor to project success in software engineering. It is the stage where user requirements are gathered, analyzed, and recorded as a Software Requirements Specification (SRS). The SRS specifies what the system is expected to do. It specifies the functional and quality requirements of the system and serves as a formal contract between stakeholders and developers. A systematic and functional SRS minimizes ambiguity and serves as a foundation for the subsequent phases of design, implementation, and testing. In contrast, unusually imprecise or useless requirements tend to result in project delays, rework, extra cost, and software products of low quality. Thus, requirement engineering forms the basis of software systems that are reliable and maintainable [4]. Requirements engineering is a structured process that includes requirements elicitation, analysis, specification, validation, and management, all of which play a critical role in ensuring that software systems meet stakeholder expectations and maintain quality standards [5].

Ambiguity occurs when a requirement is open to more than one interpretation, which can perplex developers, testers, and clients. As a result, the delivered system may fail to meet user expectations. The ambiguous requirement affects the project cost, delivery time, and software quality, and it establishes communication barriers among these teams and the client [6] [7].

Traditional ambiguity detection techniques, such as rule-based systems and keyword-based searches, are limited to identifying surface-level ambiguity. These methods frequently generate a large number of false positives and false negatives because they do not capture the semantic and contextual meaning of requirement statements [8]. Domain-specific corpora have been shown to improve ambiguity resolution, yet generalizable solutions remain limited across heterogeneous requirement datasets [9]. Consequently, subtle ambiguity caused by vague expressions or implicit intent often remains undetected. In large-scale software systems, dependencies among requirements further complicate development, as improper handling of these dependencies can lead to project delays and reduced system reliability, highlighting the need for effective requirement analysis and prioritization mechanisms [10].

Machine learning approaches based on Bag-of-Words and TF-IDF representations have improved ambiguity detection by

*Corresponding author

learning statistical patterns from data. However, TF-IDF captures only term frequency information and ignores word order, sentence structure, and contextual meaning. As a result, these models perform poorly when ambiguity arises from semantic interpretation rather than lexical frequency, leading to low recall for ambiguous requirements [11].

Recent transformer-based models, including BERT, SBERT, and GPT, address some of these limitations by learning contextual and semantic relationships through large-scale pretraining [12]. While SBERT improves sentence-level semantic representation, when used independently, it may overlook lexical ambiguity caused by vague or domain-specific requirement terms. Early research has shown that ambiguity detection remains one of the most persistent challenges in requirements engineering due to inherent natural language variability and interpretation differences [13]. Moreover, transformer-based embeddings are often applied without effective integration with traditional lexical features, limiting their overall performance in ambiguity detection tasks within software requirements engineering.

This research aims to develop and empirically evaluate a context-aware framework for ambiguity detection in software requirement statements by integrating lexical and semantic feature representations within standard machine learning classifiers. Specifically, the study investigates the effectiveness of sentence-level semantic embeddings in distinguishing ambiguous and clear requirements, compares contextual representations such as SBERT with traditional TF-IDF-based lexical features, and examines the impact of hybrid feature learning on reducing false positives and false negatives under class imbalance. By systematically evaluating standalone and combined feature configurations using accuracy, precision, recall, and F1-score, the research seeks to determine whether integrating surface-level lexical signals with contextual semantic information leads to more stable, balanced, and reliable ambiguity detection. Through this hybrid feature learning strategy, the study aims to enhance automated ambiguity analysis in software requirements engineering and provide an empirically grounded, reproducible modelling framework for practical application.

The remainder of this study is organized as follows: Section II presents a background study of transformer-based and hybrid approaches in requirements engineering. Section III describes the research design, including the dataset, preprocessing pipeline, feature representations, classifiers, and evaluation metrics. Section IV reports the experimental results, followed by an analysis and discussion in Section V. Section VI concludes the study and outlines directions for future work.

II. Background Study

Transformer-based language models have significantly advanced natural language processing and have shown strong potential in software requirements engineering tasks. Unlike traditional lexical or rule-based techniques, transformer architectures rely on self-attention mechanisms that capture contextual dependencies between words across entire sentences. This allows them to interpret meaning based on the surrounding context rather than isolated tokens.

BERT (Bidirectional Encoder Representations from Transformers) and GPT (Generative Pre-trained Transformer) are among the most widely used transformer architectures in requirements engineering research. These models are pre-trained on large corpora and learn deep contextual representations that encode semantic relationships between words and phrases [14]. Their bidirectional attention mechanism enables them to detect subtle contextual shifts that often contribute to ambiguity in natural language requirements.

Moharil and Sharma [15] applied BERT-based contextual embeddings combined with clustering techniques to detect intra-domain and inter-domain ambiguity in software requirements. Their findings demonstrated that transformer-based representations could identify fine-grained semantic differences that traditional keyword-based approaches failed to detect. The model effectively captured contextual meaning across multiple application domains, highlighting the importance of contextual embeddings in ambiguity detection.

Further extensions of BERT have also been proposed for requirement classification tasks. Yucalar et al. [16] introduced a BERT-BiCNN model that integrates convolutional neural networks with BERT embeddings to capture sequential information and reduce feature dimensionality. Their approach outperformed classical machine learning baselines on benchmark datasets. Similarly, Kaur et al. [17] proposed PRCBERT, a prompt-based learning model designed to enhance zero-shot and supervised classification accuracy in requirements engineering datasets. These studies collectively demonstrate that transformer-based models consistently outperform traditional feature-based classifiers.

A comprehensive systematic review by Bahtiar et al. [18] analyzed 60 studies applying artificial intelligence techniques for requirement classification. The review concluded that transformer-based models, particularly those employing transfer learning, achieve higher accuracy and generalization performance compared to conventional machine learning and earlier deep learning methods. However, the review also highlighted a gap between academic experimentation and industrial adoption, noting that large-scale industrial validation remains limited.

Sentence-BERT (SBERT) has emerged as an adaptation of BERT designed to generate fixed-size sentence embeddings suitable for similarity and classification tasks [19]. In ambiguity detection, SBERT is particularly valuable because requirement ambiguity often depends on sentence-level meaning rather than isolated lexical cues. Moharil and Sharma [14] demonstrated that SBERT embeddings capture subtle semantic differences more effectively than TF-IDF or classical word embeddings. Additional studies combining SBERT with traditional classifiers such as Logistic Regression and SVM reported improved recall and F1-score in detecting ambiguous requirements compared to TF-IDF-based representations [12], [20]. Systematic mapping studies further confirm that hybrid and contextual representations remain underexplored in large-scale industrial ambiguity detection settings [21], [22].

Despite these advancements, transformer-based approaches exhibit several limitations. Many studies rely on relatively small or domain-specific datasets, limiting the generalizability of

results to industrial-scale requirements engineering contexts [23]. Transformer models also require substantial computational resources for fine-tuning and deployment, which may hinder practical implementation in real-world software development environments. Furthermore, although contextual embeddings improve semantic understanding, standalone transformer representations may overlook lexical-level ambiguity when terms are domain-specific or underrepresented in pretraining corpora.

Overall, transformer-based architectures represent the current state-of-the-art in ambiguity detection for software requirements. They provide superior contextual interpretation compared to earlier approaches. However, challenges related to scalability, industrial validation, domain adaptation, and integration with complementary lexical features indicate that further research is required to develop robust and generalizable ambiguity detection frameworks.

III. Research Design

This study adopts a structured experimental framework to evaluate lexical, semantic, and hybrid feature representations for ambiguous requirement classification using the FR–NFR dataset [24]. The design integrates controlled preprocessing, feature engineering, supervised learning, imbalance handling, and standardized evaluation to ensure methodological consistency and reproducibility. The overall research design workflow is illustrated in Fig. 1.

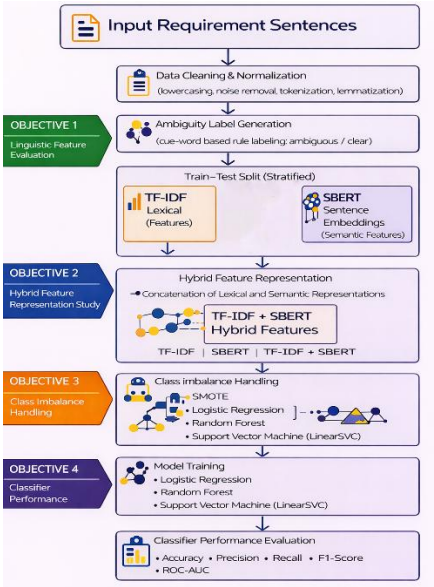

Fig. 1. Research design workflow.

A. Dataset and Experimental Setup

The FR–NFR requirements dataset contains 6008 requirement statements collected from publicly available software specification documents. For ambiguity detection, the dataset was transformed into a binary classification format where each requirement sentence s_i is associated with a label $y_i \in \{0,1\}$, such that 0 denotes a clear requirement and 1 denotes an ambiguous requirement. The dataset exhibits severe class imbalance: 5,665 statements (94.3%) are labelled as clear requirements and 343 statements (5.7%) are labelled as ambiguous, yielding a class imbalance ratio of approximately 16.5:1. This skewed distribution is a key challenge for minority-class detection and motivates the use of SMOTE oversampling. To ensure unbiased evaluation, the dataset was divided using stratified 80:20 train–test splitting, preserving the original class distribution in both subsets.

B. Text Preprocessing

All requirement statements were standardized before feature extraction. Text was converted to lowercase and cleaned by removing punctuation and non-alphabetic characters. Tokenization was performed to segment sentences into word units, followed by stopwords removal and lemmatization to reduce words to their base forms. This preprocessing pipeline was applied more aggressively for TF-IDF feature extraction to reduce noise, while minimally processed text was retained for SBERT to preserve contextual integrity.

C. Feature Representation

TF-IDF represents term importance relative to the corpus. For a term t in document d, term frequency is defined as:

$$TF\ (t,d)\ = \frac{count\ (t,d)}{total\ terms\ in\ d} \quad (1)$$

Inverse document frequency is computed as:

$$IDF(t)\ =\ log\ (\frac{N}{1+df\ (t)}) \quad (2)$$

where, N is the total number of documents and df(t) is the number of documents containing term t. The TF-IDF weight is then calculated as:

$$TF-IDF = TF(t,d) \times IDF(t) \quad (3)$$

Unigram, bigram, and trigram representations were extracted to capture both single-word and short phrase ambiguity signals.

To model contextual semantics, Sentence-BERT (SBERT) was employed using the pretrained *all-MiniLM-L6-v2* model. This model produces 384-dimensional sentence embeddings using a mean pooling strategy over the final transformer layer token outputs, followed by L2 normalization. The all-MiniLM-L6-v2 variant was selected for its balance between computational efficiency and semantic representation quality. Each requirement sentence s is encoded into a dense embedding:

$$v_{SBERT} \in \mathbb{R}^{384} \quad (4)$$

This embedding captures sentence-level meaning through transformer-based contextual representation.

For the hybrid configuration, lexical and semantic representations were combined. Let $x_{tfidf}(s) \in \mathbb{R}^m$ and $x_{sbert}(s) \in \mathbb{R}^{384}$. After L2 normalization:

$$\hat{x} = \frac{x}{\|x\|2} \quad (5)$$

The hybrid vector is constructed as:

$$xhybrid(s) = \hat{x}tfidf\ \oplus\ \hat{x}sbert \quad (6)$$

where, $\oplus$ denotes concatenation. The resulting representation integrates surface-level lexical frequency patterns with contextual semantic information. Fig. 1 illustrated the

complete hybrid feature construction pipeline, showing the parallel extraction of lexical (TF-IDF) and semantic (SBERT) features, followed by normalization and feature concatenation before classification.

D. Class Imbalance Handling

To address minority-class underrepresentation, the Synthetic Minority Over-sampling Technique (SMOTE) was applied to the training data only. Similar imbalance challenges have been reported in defect prediction and requirements classification research, where minority-class detection significantly affects recall-oriented performance [25]. Synthetic samples are generated according to:

$$Xnew = xi + \lambda(xnn - xi)$$

where, xi is a minority instance, x_{nn} is one of its nearest neighbors, and $\lambda \in (0,1)$. This strategy mitigates bias toward the majority class while preventing information leakage from the test set.

E. Classification Models

$$P(y = 1 \mid x) = \frac{1}{1+e-(w \cdot x+b)} \quad (7)$$

where, classification is determined using a threshold of 0.5. Random Forest constructs multiple decision trees and predicts the final class through majority voting:

$$y\hat{} = mode\{T1(H), T2(H), \ldots, Tn(H)\} \quad (8)$$

Support Vector Machine with a linear kernel learns a separating hyperplane defined as:

$$f(x) = w \cdot x + b \quad (9)$$

and assigns class labels based on the sign of f(x). The use of a linear kernel is appropriate due to the high-dimensional nature of TF-IDF and hybrid feature spaces. Algorithm 1 presents the hybrid TF-IDF and SBERT ambiguity detection framework.

Algorithm 1: Hybrid TF-IDF and SBERT Ambiguity Detection Framework

The proposed hybrid ambiguity detection framework can be formally described as follows.

Input: Requirement sentence s

Output: Predicted label y ∈ {0, 1}

Initialize pretrained SBERT encoder

Initialize TF-IDF vectorizer

Initialize classifier $\boldsymbol{f}(\cdot) \in \{\boldsymbol{LR}, \boldsymbol{RF}, \boldsymbol{SVM}\}$

Preprocess sentence s

Convert to lowercase

Remove punctuation and non-alphabetic characters

Tokenize and lemmatize

Compute lexical feature vector $x_{tfidf}(s)$

Compute semantic embedding xsbert(s) ∈ R^{384}

Normalize feature vectors

$$\widehat{x_{tfidf}} = \frac{x_{tfidf}}{\|x_{tfidf}\|2} \quad (10)$$

$$\widehat{x_{SBERT}} = \frac{x_{SBERT}}{\|x_{SBERT}\|2} \quad (11)$$

Construct hybrid representation

$$xhybrid(s) = \hat{x}tfidf \oplus \hat{x}sbert$$

If training phase then

Apply SMOTE on hybrid training vectors

Train classifier f (x_{hybrid})

End

Compute prediction score

$$\boldsymbol{score = f(xhybrid)}$$

If score ≥ 0 then

y^=1

Else

y^=0

End

Return y^

F. Evaluation Metrics

Model performance was assessed using standard classification metrics. Accuracy is defined as:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (12)$$

Precision and recall are computed as:

$$Precision = \frac{TP}{TP+FP}, Recall = \frac{TP}{TP+FN} \quad (13)$$

The F1-score, representing the harmonic mean of precision and recall, is calculated as:

$$F1 - score = \frac{2*Recall*precision}{Recall+precision} \quad (14)$$

Overall, the research design systematically evaluates lexical, semantic, and hybrid feature representations under controlled experimental conditions, ensuring that performance differences arise from feature learning strategies rather than inconsistencies in preprocessing, data splitting, or model configuration.

G. Computational Overhead and Deployment Considerations

From a practical deployment perspective, the hybrid framework involves two stages of feature extraction with distinct computational profiles. TF-IDF vectorization is lightweight, requiring only term-frequency counting over the vocabulary, and scales linearly with corpus size. SBERT inference using the all-MiniLM-L6-v2 model requires a transformer forward pass per sentence; on a standard CPU, average inference latency is approximately 5–10 milliseconds per sentence, making it feasible for batch processing in software development tool chains. The SVM classifier, operating on the concatenated high-dimensional feature vector, adds negligible inference overhead. The total pipeline can be integrated into requirements engineering tools as an offline batch analyzer or as a lightweight service for interactive requirement review, with memory requirements well within the constraints of modern development environments.

IV. RESULTS

This section presents the experimental evaluation of the proposed ambiguity detection framework on the Functional–Non-Functional Requirements (FR–NFR) dataset. The dataset contains 6008 software requirement statements, out of which 5665 are labelled as clear and 343 as ambiguous, indicating a severe class imbalance. All models were evaluated using accuracy, precision, recall, F1-score, and overall score. Particular emphasis is placed on recall and F1-score because ambiguity detection is inherently an imbalanced classification problem.

Three classical machine-learning classifiers were selected: Logistic Regression (LR), Random Forest (RF), and Support Vector Machine (SVM). Each classifier was evaluated using three feature configurations: TF-IDF, SBERT, and the hybrid TF-IDF + SBERT representation. The purpose of this evaluation is to systematically analyze how lexical and semantic representations influence ambiguity detection under consistent modelling conditions.

A. Baseline TF-IDF Results

Baseline experiments were conducted using TF-IDF lexical features. The results show that TF-IDF-based models achieve moderate to high accuracy; however, their effectiveness in detecting ambiguous requirements remains limited. Logistic Regression achieved an accuracy of 0.760355 with a recall of 0.584416, but precision was very low (0.133531), resulting in a weak F1-score of 0.217391. Similarly, SVM with TF-IDF obtained a recall of 0.629870, but precision dropped to 0.120497, producing an F1-score of only 0.202294. Random Forest achieved higher accuracy (0.925666), but recall remained moderate (0.454545), indicating that many ambiguous requirements were still missed.

These findings demonstrate that lexical frequency features alone are insufficient for reliable ambiguity detection. Although TF-IDF captures word importance, it does not model contextual relationships between words, leading to unstable precision–recall trade-offs under class imbalance.

B. SBERT Results

To evaluate the impact of contextual semantic representation, SBERT embeddings were used with LR, RF, and SVM classifiers. SBERT-based models showed improved contextual understanding compared to TF-IDF-only baselines. Logistic Regression achieved an F1-score of 0.455100 with a recall of 0.493500, while SVM achieved an F1-score of 0.445100 with a recall of 0.461000. These values indicate better balance compared to lexical-only models.

However, Random Forest trained on SBERT embeddings achieved very high accuracy (0.953800) and precision (0.837200), but recall dropped to 0.233800, producing an F1-score of 0.365500. This behavior indicates a strong bias toward the majority class, where ambiguous requirements are rarely predicted.

These results confirm that although SBERT captures contextual meaning and sentence-level semantics, semantic embeddings alone do not provide stable ambiguity detection under severe class imbalance.

C. Hybrid TF-IDF + SBERT Results

The proposed hybrid framework integrates lexical TF-IDF features with semantic SBERT embeddings into a unified representation. The objective of this design is to capture complementary information that cannot be effectively modelled using single-feature configurations. All hybrid models were evaluated using LR, RF, and SVM.

The experimental results demonstrate a clear and consistent improvement when hybrid features are applied. SVM with TF-IDF + SBERT achieved the best overall performance, obtaining an accuracy of 0.970400, precision of 0.798400, recall of 0.642900, and an F1-score of 0.712200, resulting in the highest overall score of 0.780975. Logistic Regression with hybrid features also demonstrated strong performance, achieving an F1-score of 0.684000. Random Forest benefited from hybrid features in terms of precision (0.833300), but recall remained low (0.259700), limiting its F1-score.

The improvement is primarily observed in recall and F1-score, indicating better detection of ambiguous requirements. These results confirm that ambiguity detection requires simultaneous modelling of lexical frequency patterns and contextual semantic information. The full comparison of all classifiers and feature configuration combinations is presented in Table I.

TABLE I. PERFORMANCE COMPARISON ON FR–NFR DATASET

Feature Set	Model	Accuracy	Precision	Recall	F1-Score	Overall Score
TF-IDF	SVM	0.717086	0.120497	0.629870	0.202294	0.417437
TF-IDF	LR	0.760355	0.133531	0.584416	0.217391	0.423923
TF-IDF	RF	0.925666	0.374332	0.454545	0.410557	0.541275
SBERT	RF	0.953800	0.837200	0.233800	0.365500	0.597575
SBERT	LR	0.932700	0.422200	0.493500	0.455100	0.575875
SBERT	SVM	0.934500	0.430300	0.461000	0.445100	0.567725
TF-IDF + SBERT	SVM	0.970400	0.798400	0.642900	0.712200	0.780975
TF-IDF + SBERT	LR	0.968600	0.800000	0.597400	0.684000	0.762500

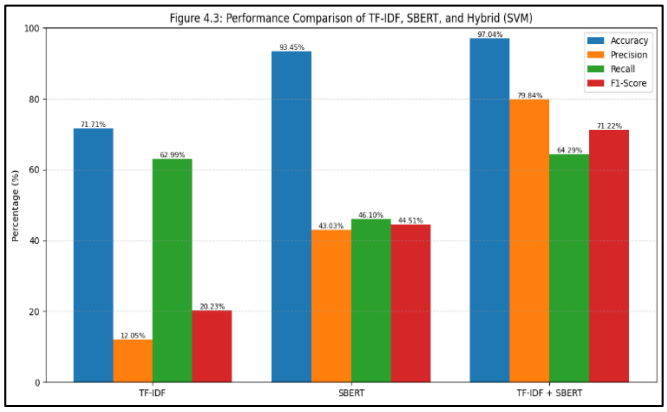

Fig. 2. Performance comparison of TF-IDF, SBERT, and a hybrid model.

V. Analysis and Discussion

The experimental results reveal significant differences between single-feature and hybrid feature representations. In the FR–NFR dataset, class imbalance strongly influences model behavior. Baseline TF-IDF models achieve moderate to high accuracy due to the dominance of clear requirements, yet they fail to consistently detect ambiguous requirements, as reflected in low precision and F1-scores.

SBERT embeddings improve contextual understanding and produce more balanced precision–recall behavior compared to TF-IDF. However, when used independently, SBERT remains sensitive to class imbalance, particularly in tree-based models such as Random Forest, which show conservative prediction behavior. Previous studies have similarly observed that contextual embeddings enhance requirement classification but require integration with complementary features for stable minority-class detection [15], [19].

The hybrid TF-IDF + SBERT representation consistently improves recall and F1-score across classifiers. This confirms that ambiguity is a multi-dimensional phenomenon requiring both lexical and semantic modelling. Lexical features capture frequency-based patterns associated with vague terms, while SBERT embeddings encode contextual meaning and sentence intent. Their integration reduces false negatives and produces more stable classification boundaries.

Support Vector Machine consistently achieves the best performance under a hybrid configuration. Its margin-based learning mechanism allows effective separation within the high-dimensional fused feature space. Unlike Logistic Regression, which tends to favor the majority class, and Random Forest, which remains conservative, SVM maintains a better balance between precision and recall.

Overall, the results demonstrate that hybrid feature integration provides a robust and generalizable solution for ambiguity detection in functional–non-functional requirements. The consistent improvement in recall and F1-score confirms the practical utility of the proposed framework, particularly when combined with Support Vector Machine. The cross-classifier performance trends are further visualized in Fig. 2, which illustrates the F1-score comparison across all feature configurations and classifiers. The obtained F1-score reflects the inherent difficulty of ambiguity detection under severe class imbalance, where minority-class instances are limited and context-dependent.

A key limitation of the current evaluation is that the framework is assessed on a single dataset from one source. Without cross-dataset validation or transfer experiments on requirements from different application domains, it remains uncertain whether the observed performance generalizes beyond the FR–NFR dataset. Future work should evaluate the framework on additional publicly available requirements corpora to establish broader generalizability. Furthermore, while the hybrid approach outperforms standalone TF-IDF and SBERT baselines, a direct comparison against fine-tuned transformer models such as BERT or RoBERTa on the same dataset would provide stronger evidence of the framework's competitive standing relative to the current state-of-the-art [23]. Due to computational constraints and the focus on feature-level hybrid representation, fine-tuned transformer baselines such as BERT and RoBERTa were not included in the current experimental evaluation.

VI. Conclusion and Future Work

This study investigated ambiguity detection in software requirements using a hybrid feature learning framework that integrates TF-IDF and SBERT representations within classical machine learning classifiers. Ambiguous requirements remain a major source of project delay and miscommunication, and traditional lexical models are often insufficient to capture context-dependent ambiguity.

The experimental results on the FR–NFR dataset show that single-feature models such as TF-IDF or SBERT, when used independently, produce unstable recall and limited F1-scores under severe class imbalance. TF-IDF captures lexical importance but lacks contextual understanding, while SBERT provides semantic awareness but struggles when applied alone. These findings confirm that ambiguity is multi-dimensional and cannot be reliably detected through isolated feature representations.

The hybrid TF-IDF + SBERT configuration consistently achieved the strongest and most balanced performance, particularly when evaluated using Support Vector Machine. Improvements were most evident in recall and F1-score, indicating a reduction in false negatives, which is critical in ambiguity detection tasks. The results demonstrate that integrating lexical and semantic cues within a unified representation significantly enhances classification robustness and minority-class detection.

Overall, the proposed hybrid framework provides a reproducible and empirically validated solution for ambiguity detection, outperforming single-feature baselines and offering practical applicability in requirements engineering.

A. Limitations

The study is limited to English-language requirements and focuses on sentence-level ambiguity without modelling document-level context. The framework is evaluated on a single dataset from one source; cross-dataset validation across requirements from different application domains has not been performed, which limits conclusions about generalizability.

Although the FR–NFR dataset is substantial, it may not fully represent the linguistic diversity of large industrial specifications. The proposed hybrid approach is not directly compared against fine-tuned transformer-based baselines such as BERT or RoBERTa on the same dataset, which would be necessary to position the framework conclusively relative to the current state-of-the-art. In addition, SBERT embeddings were not domain-adapted to software engineering corpora.

B. Future Work

Future work may extend this framework to larger and multilingual datasets to improve generalizability, and should include cross-dataset validation on requirements from diverse application domains. A direct comparison against fine-tuned transformer-based models such as BERT and RoBERTa on the FR–NFR dataset would clarify the competitive standing of the hybrid approach relative to the current state-of-the-art [23]. Domain-specific fine-tuning of transformer embeddings could further enhance contextual sensitivity. Incorporating explainable AI techniques such as SHAP or LIME would improve transparency and stakeholder trust. Finally, document-level modelling approaches could enable detection of cross-requirement ambiguity, strengthening real-world applicability.

QR Code-Based Access Control Systems: Architectural Taxonomy, Security Landscape, and Future Research Directions

Worood Alsawi, Dina M. Ibrahim
Department of Information Technology-College of Computer, Qassim University, Buraydah, Saudi Arabia

***Abstract*—Access control systems secure physical and digital settings, especially in colleges, businesses, and restricted areas. Physical key, magnetic card, and biometric access control techniques have loss, duplication, high deployment costs, and maintenance complexity. With the widespread adoption of smartphones, QR code-based access control systems (QR-ACS) have emerged as a flexible and cost-effective alternative. Scannable QR codes allow fast authentication without hardware, boosting user ease. How QR codes are generated, handled, and checked in the system determines the success of QR-based access control. This systematic review examines the integration and evolution of QR Code-Based Access Control Systems (QR-ACS), with particular attention to both recent innovations and the challenges that continue to accompany their adoption. A broad set of studies published between 2015 and 2023 was reviewed in order to explore how these systems have been designed, implemented, and evaluated across different application contexts. The analysis draws on literature indexed in major academic databases, including IEEE Xplore, ACM Digital Library, and JSTOR, with an emphasis on system architecture, implementation strategies, and reported performance outcomes. Overall, the reviewed studies indicate that QR-ACS can enhance operational efficiency and offer practical security benefits, especially when combined with complementary technologies. At the same time, recurring concerns related to security, robustness, and deployment limitations remain evident. This systematic review analyzes QR-ACS architectures, security mechanisms, and threat models, with particular emphasis on IoT integration, authentication strategies, and risk-aware system design.**

Keywords*—*QR codes; access control systems; security mechanisms; authentication; Internet of Things

I. Introduction

In the realm of security technology, the adoption of QR Code-Based Access Control Systems (QR-ACS) has been transformative, offering a novel method to manage access to various physical and digital spaces. QR codes, originally designed for tracking parts in vehicle manufacturing, have evolved significantly, becoming pivotal in access control systems due to their simplicity, cost-effectiveness, and ease of use. As Adedoyin and Olukoya [1] note, "QR codes, once developed for industrial purposes, now support smart lock systems and various security solutions," demonstrating their adaptability across multiple domains. These systems utilize QR codes to authorize entry to secured areas, integrating seamlessly with mobile technology and cloud computing to provide dynamic and robust security solutions [2]. This evolution underscores the ability of QR codes to transcend their original purpose, becoming a versatile tool for a wide range of applications in modern security systems.

As global security challenges continue to evolve, the demand for access control solutions that can adapt to changing operational conditions has become more apparent. Conventional approaches, including keycards, passwords, and biometric systems, are widely used but often present practical limitations, such as vulnerability to loss or theft and the need for dedicated infrastructure. In this context, QR-ACS are frequently discussed as a more flexible and cost-efficient option. According to Petrea et al. (2020), these systems can reduce operational overhead by relying on mobile devices and cloud-based services, which makes them suitable for environments where physical credentials or complex hardware are difficult to manage [3]. The widespread availability of smartphones with built-in QR code scanning capabilities has further supported the adoption of QR-ACS across both public and private sectors. Beyond conventional access scenarios, these systems have also been applied in situations that require minimal physical interaction. Awotunde et al. [4] highlights the growing relevance of such contactless solutions, particularly during health-related crises such as the COVID-19 pandemic, where reducing physical contact became a key safety consideration.

Several sectors, including education, healthcare, transportation, and corporate offices, have begun to integrate QR-ACS into their security frameworks. In educational settings, for instance, QR codes are increasingly used to manage access to facilities such as libraries, laboratories, and examination halls. Similarly, healthcare environments have adopted QR codes to control access to patient records, restricted areas, and medical equipment, particularly in cases where traditional physical access mechanisms may be inefficient or introduce additional risks. At the same time, security requirements differ across these contexts, as certain areas—such as research laboratories, server rooms, and administrative offices—demand higher levels of protection. While the adaptable nature of QR-ACS allows them to support varying access levels, further research remains necessary to refine these systems and ensure that they can meet more demanding security needs. Moreover, as organizations increasingly shift toward IoT-enabled environments, the combination of QR-ACS with biometric data and real-time monitoring has received growing attention as a potential approach to strengthening access control frameworks [6].

For example, [7] proposed an access control system for smart buildings that employs aesthetic QR codes combined with symmetric encryption algorithms. In this system, QR codes incorporate user photographs as an additional authentication layer. Although the proposed solution was described as cost-effective and flexible, it exhibited limitations related to scalability and reliability, particularly in low-light conditions, which negatively affected the QR code scanning process.

In a related work, [8] presented a QR code-based smart door access control system designed for educational and corporate environments. The system enhanced operational efficiency by recording user access times through a centralized database; however, the authors reported that the solution still faced constraints related to system scalability and long-term deployment in larger environments.

This review seeks to synthesize and critically examine the existing literature on QR-ACS, with the aim of identifying both the technological advances that have addressed key challenges and the areas where notable limitations remain. Through the analysis of a diverse body of studies, the review explores the reported strengths and weaknesses of current QR-ACS implementations, as well as the approaches that appear most promising for future development. Particular attention is given to application contexts in which QR-ACS have demonstrated practical effectiveness, alongside scenarios where further refinement is still required. By addressing these aspects, the review contributes to a clearer understanding of the current role of QR-ACS in modern security environments and highlights potential research directions that may support improvements in security, efficiency, and scalability [9]. The main contributions of this paper are:

- A comprehensive systematic review of QR-ACS (2015–2024).
- A structured architectural taxonomy of QR-ACS.
- A comparative analysis across multiple application domains.
- A proposed risk assessment framework for QR-based security threats.
- Identification of research gaps and future directions.

II. Background

Access control systems play a central role in security management, as they define who is permitted to access a given resource, whether a physical environment, such as a building or a digital asset, such as sensitive data. Early access control mechanisms were based on simple physical solutions, including locks and keys. Over time, these approaches evolved into more complex electronic systems that incorporate cards, biometric identifiers, and, more recently, mobile-based technologies. As noted by Norman (2011), the transition from mechanical to electronic access control represented an important step toward greater flexibility and scalability in security management [10].

Fig. 1 and Fig. 2 illustrate the technological evolution and comparative characteristics of QR codes within the broader landscape of two-dimensional barcode technologies. Fig. 1 presents a conceptual comparison between QR codes and other matrix codes, such as PDF417, Data Matrix, and MaxiCode, highlighting their advantages in terms of data capacity, printing efficiency, and high-speed readability. Meanwhile, Fig. 2 outlines the chronological development of QR code technology, beginning with its invention in 1994 and progressing through key phases of adoption, including its expansion into marketing and payment systems, integration with IoT environments, and its recent role in advanced security applications such as biometric authentication, blockchain-based systems, and dynamic QR technologies. Together, these figures demonstrate how QR codes have evolved from industrial tracking tools into a foundational component of modern digital security and access control infrastructures.

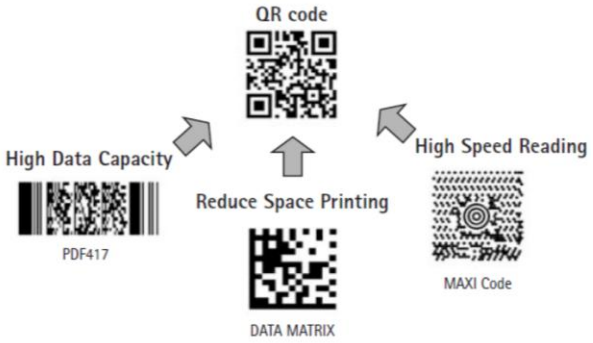

Fig. 1. Evolution of QR codes from manufacturing tracking to modern access control applications [5].

Fig. 2. Evolution of QR code technology.

Despite their advantages, QR-ACS are associated with a number of challenges, including the risk of QR code replication, unauthorized sharing, and potential security breaches resulting from code interception. In their basic form, QR codes do not provide built-in encryption or authentication mechanisms, which makes them vulnerable to different types of attacks. In response to these limitations, several enhanced QR-ACS solutions have been proposed that integrate additional security measures, such as encryption techniques, time-limited QR codes, and multi-factor authentication. These approaches aim to reduce security risks by limiting unauthorized access while preserving the flexibility and usability that characterize QR code-based systems. Nevertheless, the reported effectiveness of such solutions is not consistent across studies, and their performance often depends on the application context and implementation design. As a result, further research remains

necessary to establish standardized and scalable security frameworks that can be reliably applied across different sectors.

The growing research interest in QR-ACS is illustrated in Fig. 3. The figure presents the publication trend of QR-ACS-related research between 2015 and 2024. The data demonstrate a steady growth trajectory, with a noticeable acceleration after 2019, coinciding with the expansion of IoT ecosystems and increased demand for contactless authentication solutions during the COVID-19 pandemic. The upward trend in 2023–2024 suggests sustained research interest, particularly in areas integrating encryption, blockchain, and biometric authentication. This growth pattern confirms that QR-ACS remains an active and evolving research domain, warranting systematic synthesis and structured analysis.

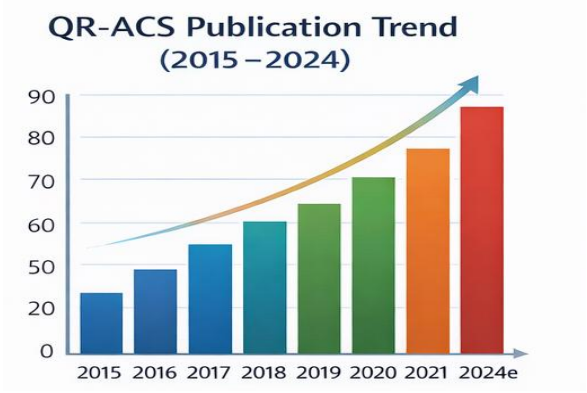

Fig. 3. QR-ACS publication trend (2015–2024).

At a fundamental level, the objective of an access control system is to enforce predefined access policies that protect facilities and information from unauthorized use. The emergence of electronic access control systems during the 1960s marked a significant shift away from purely mechanical solutions. Early implementations relied on magnetic stripe cards to support more dynamic authorization processes, which were later extended through the adoption of RFID (Radio Frequency Identification) technology. According to Rieback, Crispo, and Tanenbaum (2006), RFID-based systems introduced contactless operation alongside encrypted authentication data, thereby reshaping conventional access control mechanisms [11].

Subsequent developments in RFID-based access control further enhanced security capabilities by enabling the integration of authentication, tracking, and monitoring functions within a unified framework [12]. These developments illustrate how access control technologies have continued to adapt in response to increasing security requirements and the growing complexity of modern infrastructures. An overview of access control system architectures and their relationship to QR code-based solutions is illustrated in Fig. 4.

QR codes, commonly referred to as Quick Response codes, were introduced in 1994 by the Japanese company Denso Wave for the purpose of tracking components in vehicle manufacturing. As noted by de Seta (2023), Denso Wave initially developed QR code technology to improve efficiency in automotive production, which later supported its broader adoption [14]. Unlike conventional one-dimensional barcodes, QR codes are two-dimensional and were designed to encode information more efficiently while allowing faster scanning. This design enables QR codes to store various types of data, including URLs, contact details, and encrypted information, contributing to their versatility across different applications [15].

Fig. 4. Overview of access control systems, highlighting QR code-based solutions [13].

The widespread use of QR codes expanded further with the growth of smartphone technology. Smartphones equipped with built-in cameras have played a key role in facilitating quick and convenient QR code scanning in everyday contexts. As explained by Pandey and Awasthi (2020), this capability has supported the adoption of QR codes across multiple domains, ranging from marketing and digital payments to information sharing [16]. In the context of access control systems, QR codes are commonly used to store access credentials or to reference secure credentials maintained in cloud-based platforms. This approach has been described as a practical and scalable solution for managing access in diverse environments, including corporate offices, public venues, and residential settings [17].

Fig. 5 illustrates the structural components of a typical QR code and the arrangement of its functional elements. These components include position markers that assist scanners in detecting the orientation of the code, data modules that store encoded information, and quiet zones that ensure reliable recognition during scanning. Understanding the internal structure of QR codes is essential for explaining how they support efficient data encoding, error correction, and rapid decoding in access control applications.

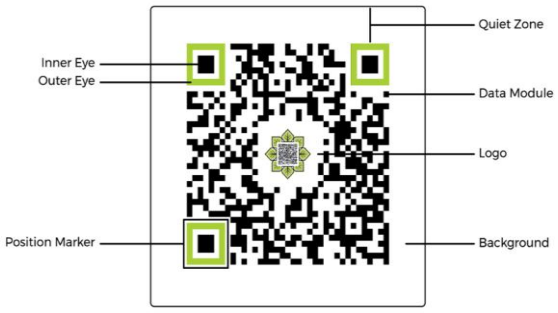

Fig. 5. Structure of a QR code, highlighting key components such as data modules, timing patterns, and error correction blocks [18].

III. Research Methodology

This study follows a systematic review methodology based on the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) framework to ensure transparency, reproducibility, and rigor in the literature selection process.

A. Data Sources and Search Strategy

A comprehensive literature search was conducted across multiple academic databases, including IEEE Xplore, ACM Digital Library, Scopus, SpringerLink, and Google Scholar. The search focused on studies published between 2015 and 2024 to capture recent developments in QR Code-Based Access Control Systems (QR-ACS). The search queries were constructed using combinations of relevant keywords, including: "QR code access control", "QR authentication", "QR-based security systems", "QR code IoT access control", "secure QR authentication", and "QR-based identity verification". Boolean operators (AND, OR) were used to refine the search and ensure comprehensive coverage of relevant studies.

B. Inclusion and Exclusion Criteria

To ensure relevance and quality, predefined inclusion and exclusion criteria were applied during the screening process. Inclusion criteria:

- Studies published between 2015 and 2024.
- Peer-reviewed journal articles and conference papers.
- Studies focusing on QR code-based authentication or access control systems.
- Studies presenting technical, experimental, or system-level contributions.

Exclusion criteria:

- Non-English publications.
- Studies not directly related to access control or authentication.
- Review papers without technical contribution.
- Short papers, editorials, posters, or non-peer-reviewed content.

C. Screening and Selection Process

The study selection process followed the PRISMA 2020 framework to ensure transparency and reproducibility. As illustrated in Fig. 6, a total of 1,275 records were initially identified from multiple academic databases, including IEEE Xplore, ACM Digital Library, Scopus, SpringerLink, and Google Scholar. After removing duplicate records (n = 352), 923 studies remained for title and abstract screening. During this phase, 668 records were excluded due to irrelevance to QR code-based access control systems. The remaining 255 articles were subjected to full-text review, of which 28 could not be retrieved. A total of 227 studies were assessed for eligibility, leading to the exclusion of 161 papers based on predefined criteria, including lack of relevance, non-QR-based approaches, and non-empirical contributions. Ultimately, 66 studies were included in the final qualitative and quantitative synthesis.

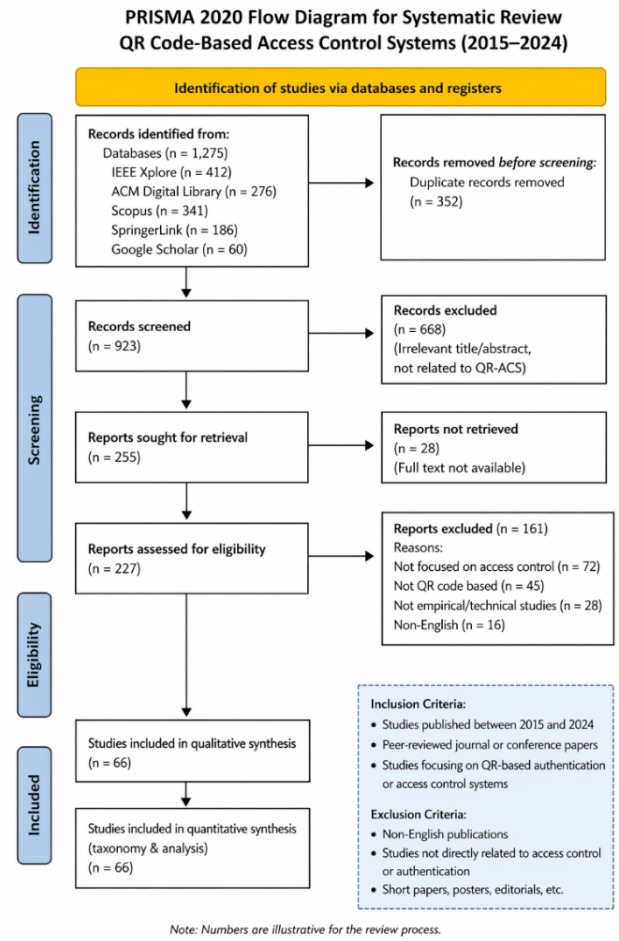

Fig. 6. PRISMA 2020 flow diagram illustrating the study selection process for the systematic review of QR Code-Based Access Control Systems (QR-ACS).

D. Data Extraction and Analysis

For each selected study, relevant data were systematically extracted, including system architecture, authentication mechanisms, security techniques, application domain, and reported limitations. The extracted studies were categorized into thematic groups to support comparative analysis and the development of a structured taxonomy. This categorization enabled the identification of architectural patterns, security trends, and research gaps within QR-ACS.

Additionally, a comparative evaluation was conducted to analyze trade-offs between security strength, system complexity, and deployment feasibility across different QR-ACS implementations.

IV. Literature Review

This literature review examines a broad range of studies that apply QR code-based access control systems across different application domains, including security and surveillance, mobile and IoT systems, transportation and ticketing, and healthcare. The reviewed work reflects the growing interest in QR code technology as a means of supporting authentication, enhancing security, and improving operational efficiency in varied contexts.

Within the area of security and surveillance, several studies investigate the integration of QR codes with complementary technologies such as facial biometrics, encryption techniques, and real-time monitoring. These approaches are generally proposed as alternatives to traditional access control mechanisms, including physical keys and swipe cards, with the intention of improving convenience while maintaining acceptable security levels.

Research focusing on mobile and IoT systems often emphasizes the practical advantages of QR code-based frameworks, particularly their cost efficiency, flexibility, and compatibility with smartphones and IoT infrastructures. These characteristics are frequently cited as factors that enable more streamlined access control and improved user interaction. In a similar manner, studies related to transportation and ticketing explore the use of encrypted QR codes to strengthen e-ticket security, while also acknowledging challenges associated with system interoperability and vulnerability management.

In the healthcare domain, the literature highlights the use of QR codes for controlling access to sensitive patient data and restricted areas, with particular attention given to encryption methods and authentication mechanisms required to protect electronic health records.

Across these application areas, QR code technology is commonly described as adaptable and capable of supporting a range of access control requirements. At the same time, recurring challenges are noted in the literature, including concerns related to scalability, the potential for unauthorized QR code duplication, and the need for supporting technical infrastructure. Taken together, these observations provide a basis for understanding the current use of QR code-based access control systems and point to several areas where further research is needed, especially with respect to security robustness and system interoperability.

A. Security and Surveillance

This section examines the implementation of QR code-based systems in a range of security and surveillance applications. The studies discussed here consider how QR codes are combined with complementary technologies, such as biometric authentication, encryption algorithms, and real-time monitoring, to support access control objectives. Rather than addressing a single use case, the reviewed work covers different application environments and illustrates how QR code-based solutions have been employed to modernize access control mechanisms across multiple contexts.

To enhance system security, QR code-based access control is often integrated with additional security mechanisms such as encryption techniques, biometric authentication, centralized servers, and monitoring components. These technologies work together to ensure secure identity verification, protect transmitted data, and enable continuous monitoring of system activities.

Fig. 7 illustrates a conceptual architecture of QR code-based security and surveillance systems, highlighting the integration of QR authentication with encryption methods, biometric verification, logging mechanisms, and IoT-based monitoring components.

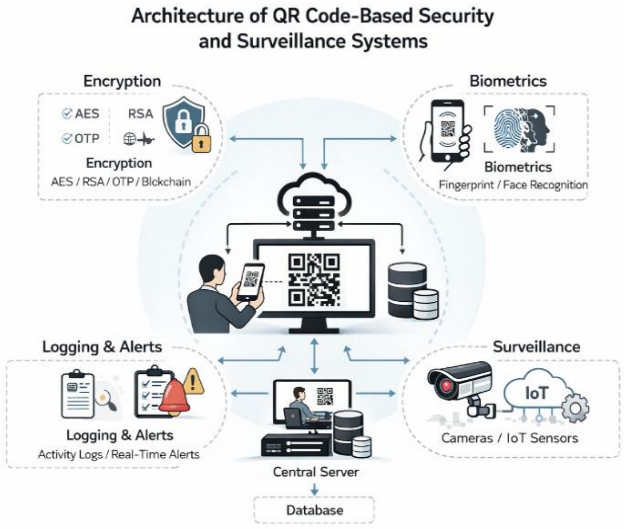

Fig. 7. Architecture of QR code–based security and surveillance systems illustrating the integration of QR authentication with encryption, biometric verification, centralized servers, and monitoring mechanisms.

1) Home security: Home security systems that incorporate QR code technology are often presented as alternatives to traditional key-based solutions, with an emphasis on improved convenience and flexible access management. In many proposed implementations, QR codes are integrated with additional technologies, such as facial recognition and IoT-based automation, to support real-time monitoring and remote control capabilities. These combinations are intended to strengthen residential security while reducing reliance on physical keys, although their effectiveness may vary depending on system design and deployment conditions. Table I summarizes representative studies that apply qr code-based and related technologies to home security scenarios, highlighting common design choices, reported benefits, and frequently noted limitations.

2) Office and workplace security: In office and workplace environments, QR code-based access control systems are increasingly considered as alternatives to traditional authentication methods, such as RFID cards, particularly when combined with encrypted QR codes and multi-factor authentication mechanisms. These systems are commonly proposed to support controlled access to sensitive areas, while also facilitating functions such as monitoring and attendance tracking. Table II summarizes representative studies that examine QR code-based access control solutions in office and workplace settings, highlighting proposed authentication approaches alongside their reported benefits and limitations.

TABLE I. STUDIES RELATED TO HOME SECURITY

Ref	Year	Focus Area	Algorithm	Challenges addressed	Findings	Limitations
[19]	2014	Residential multi-factor security system	Residential multi-factor security system	Unauthorized entry	Cost-effective multi-layer security	NFC reliability; false PIR triggers
[20]	2022	Wireless home security system	RFID + Fingerprint + Face ID + ESP32-CAM	Weak traditional locks	Multi-factor secure access	System complexity; maintenance
[7]	2018	Smart building access with aesthetic QR	QR + Symmetric encryption + Photo verification	RFID cost; offline verification	Flexible, cost-effective access	Photo verification accuracy; scalability
[21]	2021	IoT-based smart home security	Face recognition (PCA) + IoT	Automated intrusion detection	Low-power real-time monitoring	Limited scalability testing
[22]	2020	Face recognition access control	OpenCV + LBPH + Raspberry Pi	Real-time authentication	Remote access with alerts	Limited scalability
[23]	2020	Biometric door access control	Fingerprint + Arduino + Bluetooth	Device interoperability	Reliable biometric access	Limited large-scale testing
[24]	2020	Dual biometric home security	Face (PCA) + Fingerprint	Unauthorized residential access	Strong biometric authentication	Lighting sensitivity; scalability
[25]	2022	IoT facial recognition security	Haar Cascade + LBPH + Mobile App	Home monitoring automation	92.86% recognition accuracy	Internet dependency; scalability

TABLE II. STUDIES RELATED TO OFFICE AND WORKPLACE SECURITY

Ref	Year	Focus Area	Algorithm	Challenges addressed	Findings	Limitations
[26]	2022	Secure QR transmission for confidential data (e-tickets, coupons)	QR module modification + Error correction	Weak data protection in standard QR	Increased hidden data capacity; secure QR	Requires secret key access
[27]	2023	Device registration authentication system	QR + Fingerprint + C#/SQL	Paper receipt fraud; inefficient verification	Improved authentication and fraud reduction	User familiarity; hardware maintenance
[28]	2021	Residential IoT access control	QR + SHA-2 + IoT	Replacing physical keys	Improved security; real-time notifications	Scalability; internet dependency

3) University and research lab access control: In universities and research laboratories, QR codes are increasingly deployed in combination with technologies such as biometric authentication and encryption to support access control and attendance management. These approaches are commonly discussed as more flexible and cost-effective alternatives to conventional access control systems, particularly in environments that require frequent user verification and controlled access to specialized facilities. Table III summarizes representative studies that examine QR code-based access control solutions in university and research laboratory settings, highlighting a variety of cryptographic, biometric, and system-level approaches alongside their reported benefits and limitations.

TABLE III. STUDIES RELATED TO UNIVERSITY AND RESEARCH LAB ACCESS CONTROL

Ref	Year	Focus Area	Algorithm	Challenges addressed	Findings	Limitations
[29]	2018	Secure access control using encrypted QR codes.	QR + RSA + PRNG	Unencrypted QR vulnerabilities.	Improved security; cross-platform compatibility	RSA overhead; higher device processing
[30]	2020	QR-based door access for university labs	QR + Raspberry Pi + Web server	Weak locks; RFID cost/complexity	Cost-effective access control	Preliminary testing; limited scalability
[31]	2017	Smart door security for restricted areas	Bluetooth + Android + Microcontroller	RFID and fingerprint weaknesses	Real-time monitoring; cost-effective	Limited range (9 m); user management issues
[32]	2023	Lab access control with QR and OTP	QR + RSA + AES + TOTP	Unauthorized access prevention	TOTP more secure than HOTP	Limited to lab environments
[8]	2023	QR-based attendance and access tracking	QR + Centralized DB	Manual errors; RF card dependency	Improved accuracy and cost efficiency	QR duplication risk; internet dependency
[33]	2020	QR-based access control with monitoring	QR + Lamport Hash Chain + Web	Security and monitoring challenges	Enhanced security and monitoring	Limited scalability; no usability feedback
[34]	2018	Biometric QR access for universities	QR + Face recognition + OpenCV	Authentication and privacy issues	Improved authentication and privacy	Limited scope; OpenCV constraints
[35]	2021	Secure login for e-exam systems	QR + SHA-256 + MD5	Brute force and unauthorized access	Secure and efficient login	Limited generalizability; missing usability data

4) Public spaces and government facilities: In government buildings and public spaces, QR code-based systems have been applied as part of access control strategies for managing high-traffic environments. These systems are commonly discussed as tools for supporting controlled access to sensitive areas, to reduce the risk of unauthorized entry while maintaining

efficient movement within public facilities. Table IV presents selected studies that address QR code-based access control in public spaces and government facilities, emphasizing emergency scenarios, decentralized authentication, and system-level considerations alongside reported limitations.

TABLE IV. STUDIES RELATED TO PUBLIC SPACES AND GOVERNMENT FACILITIES

Ref	Year	Focus Area	Algorithm	Challenges addressed	Findings	Limitations
[36]	2018	Emergency access control	QR + Shamir Secret Sharing + ABE	No online authentication in emergencies	Secure offline attribute-based access	Attribute policy dependency; limited disaster testing
[37]	2020	Smartphone QR access control	QR + DES + Embedded system	Security and cost limits of locks/RFID/biometrics	Integrated access and attendance control	Smartphone dependency
[38]	2020	Unified identity platform	QR hybrid encryption + WSN + ZigBee	Fragmented identity systems	Low-power secure authentication	No real-world testing; scalability
[39]	2021	QR access control with monitoring	QR + Web app + ID scanner	QR duplication; setup complexity	Cost-effective access monitoring	Security risks; user adoption issues
[40]	2019	Blockchain QR authentication	QR + One-time QR + Blockchain	Secure decentralized authentication	Improved security via decentralized verification	Scalability; integration challenges

TABLE V. STUDIES RELATED TO HIGH-SECURITY ENVIRONMENTS

Ref	Year	Focus Area	Algorithm	Challenges addressed	Findings	Limitations
[41]	2019	Biometric passport security	QR + AES + SHA-256 + Biometrics	RFID privacy risks	High-accuracy biometric authentication	Biometric reliability; infrastructure dependency
[42]	2015	LED-QR access authentication	QR + LED tags	Improving QR access security	Enhanced authentication performance	Scalability not evaluated
[43]	2020	Encrypted QR access control	QR + RSA + PRNG	Protecting authorization data	Improved data security	Key management; scalability
[44]	2024	Secure QR encryption for access control	QR + RSA + PRNG	Authorization data protection	Stronger encrypted access control	Limited real-world evaluation

5) High-security environments (e.g., defense or sensitive areas): In high-security environments, such as defense-related or sensitive government facilities, QR code-based systems are often discussed in conjunction with advanced encryption techniques and biometric integration to support stricter access control requirements. These approaches are proposed to manage access to highly restricted areas, where higher assurance levels are typically required compared to conventional access control settings. Table V summarizes studies that address QR code-based access control in high-security environments, including national security and sensitive infrastructure, with a focus on encryption and biometric integration.

In security and surveillance applications, QR code-based systems are commonly discussed as access control solutions that combine QR technology with elements such as encryption, real-time monitoring, and biometric verification. These systems are often proposed as flexible and user-friendly alternatives to traditional security mechanisms, including physical keys and RFID cards, particularly in contexts where cost and ease of deployment are important considerations. At the same time, the literature points to several challenges, including the susceptibility of QR codes to unauthorized duplication and the technical complexity associated with integrating additional security layers such as encryption. Accordingly, further research remains necessary to address these limitations and to assess the suitability of QR code-based systems for wider adoption in high-security environments

B. Mobile and IoT Systems

This section examines the application of QR code technology within mobile and IoT-based systems, with particular attention to its use in access control contexts. The reviewed studies discuss QR codes as cost-effective and flexible solutions that can be integrated with IoT devices to support secure access management. In many cases, these approaches are presented as a means of streamlining access processes while improving overall operational efficiency.

1) Smart home automation: In smart home environments, QR code-based systems are frequently combined with IoT devices to support automated security and access control functions. Such systems are commonly designed to allow homeowners to manage door locks, monitor entry points, and receive notifications through smartphone applications. These features are often highlighted as contributing to improved convenience and remote control capabilities, although their effectiveness may depend on system configuration and network reliability. Table VI summarizes studies that examine smart home automation systems integrating QR codes, IoT devices, and complementary technologies, highlighting proposed approaches, reported outcomes, and commonly noted limitations.

2) Industrial IoT applications: In industrial environments, QR code-based access control systems integrated with IoT technologies are commonly discussed as approaches for supporting security and operational efficiency. Such solutions

are applied to manage access to restricted areas and to assist in the monitoring of assets and personnel within industrial settings. These systems are often presented as part of broader industrial IoT frameworks, where access control is combined with real-time data collection and system management. Table VII highlights a representative approach to QR code-based authentication in industrial IoT contexts, emphasizing performance considerations alongside scalability challenges.

3) Mobile payment systems: In mobile payment systems, QR code-based authentication is commonly discussed as a practical approach for supporting secure and convenient financial transactions. Rather than relying solely on traditional password-based mechanisms, these systems often incorporate multi-factor authentication schemes, such as QR code verification combined with one-time passwords (OTPs). This combination is intended to enhance transaction security while maintaining ease of use for end users. Table VIII presents selected studies that examine the use of QR code-based authentication in mobile payment systems, highlighting multi-factor security approaches alongside practical limitations related to deployment and usability.

TABLE VI. STUDIES RELATED TO SMART HOME AUTOMATION

Ref	Year	Focus Area	Algorithm	Challenges addressed	Findings	Limitations
[45]	2023	IoT smart door lock security	Bluetooth MAC + Raspberry Pi + Firebase	Weak traditional locks	Remote access and monitoring	Internet and smartphone dependency
[46]	2022	IoT facial recognition gate security	Face recognition + OpenCV + Raspberry Pi	Rising home break-ins	Real-time monitoring and alerts	Lighting and recognition accuracy
[47]	2022	IoT smart home gate access	Face recognition + Arduino + ESP8266	Centralized home security control	Remote monitoring via mobile	Network reliability; integration
[48]	2019	GPS-based smart door lock	GPS + STM32 + XBee	Manual lock limitations	Location-based automated access	GPS accuracy; connectivity
[49]	2020	IoT home automation security	Face detection + Raspberry Pi + IoT sensors	Automated home security	Real-time monitoring and alerts	Internet dependency; lighting issues
[50]	2021	QR access framework for Android	QR + ZXing + Encrypted ID	Lack of QR access frameworks	Flexible QR-based access system	Android focus; limited testing

TABLE VII. STUDIES RELATED TO INDUSTRIAL IOT APPLICATIONS

Ref	Year	Focus Area	Algorithm	Challenges addressed	Findings	Limitations
[51]	2020	IoT QR authentication security	QRAM (3-layer QR authentication)	Fast and secure IoT authentication	Reduced computation time; improved security	High decryption complexity; scalability

TABLE VIII. STUDIES RELATED TO MOBILE PAYMENT SYSTEMS

Ref	Year	Focus Area	Algorithm	Challenges addressed	Findings	Limitations
[52]	2010	QR-based user authentication	QR + OTP	Password-based security risks	Dynamic OTP authentication	Requires camera-enabled mobile device
[53]	2021	Secure mobile money authentication	QR + PIN + OTP + Fingerprint + SHA-256 + FIDO	Weak mobile money security	Improved protection against replay and phishing	Biometric device and infrastructure requirements
[54]	2023	Secure QR transactions for MSMEs	QR + GOST encryption	Secure QR payment transactions	Enhanced QR transaction security	Requires specialized QR reader
[55]	2010	Secure online banking authentication	QR + Mobile OTP + SSL/TLS	Phishing and weak authentication	Secure QR banking authentication	Limited testing; small sample

4) Smart Building and Facility Management: Smart buildings increasingly incorporate QR code-based systems as part of their access control, monitoring, and automation strategies. These solutions are commonly discussed in the literature as scalable approaches that support controlled entry to different areas within a building and facilitate integration with existing management systems. By enabling flexible access policies and centralized monitoring, QR code-based approaches are presented as contributing to more efficient facility management and improved security practices. Table IX highlights a representative application of QR code-based access control in smart building facilities, emphasizing shared access management and system scalability considerations.

TABLE IX. STUDIES RELATED TO SMART BUILDING AND FACILITY MANAGEMENT

Ref	Year	Focus Area	Algorithm	Challenges addressed	Findings	Limitations
[56]	2019	Smart campus locker access	QR + IoT + Smart lock + Mobile app	Traditional locker limitations	Flexible shared locker access	Prototype stage; scalability

QR code-based access control in mobile and IoT systems is often discussed as an adaptable and scalable approach for securing connected devices and services. By relying on mobile platforms and IoT networks, these systems can support flexible access management across a range of environments, from residential automation to industrial settings. At the same time, the literature points to several ongoing challenges, including the need for reliable connectivity, compatibility across heterogeneous devices, and the diverse security requirements inherent to IoT ecosystems. As a result, future research is frequently directed toward the development of standardized frameworks that can facilitate cross-platform integration and support more robust and scalable QR code-based access control solutions within IoT environments.

C. Transportation and Ticketing Systems

In transportation and ticketing applications, QR code-based systems have been explored as a means of streamlining ticket verification processes and supporting secure transactions. Existing studies emphasize the use of encrypted QR codes to enable contactless ticketing, which can improve efficiency by automating procedures such as check-in and seat verification. These approaches are often associated with reductions in manual errors and improvements in operational workflows within public transportation systems. However, the literature also highlights practical challenges, including infrastructure requirements for managing biometric data and potential security concerns related to user-generated passwords in electronic ticketing systems. Addressing these issues may require further advancements in QR code encryption techniques, as well as improved system interoperability and deployment strategies. Table X summarizes representative studies that investigate the use of QR code-based authentication in transportation and ticketing systems, highlighting biometric integration, encrypted e-ticketing approaches, and associated deployment challenges.

TABLE X. STUDIES RELATED TO TRANSPORTATION AND TICKETING

Ref	Year	Focus Area	Algorithm	Challenges addressed	Findings	Limitations
[57]	2019	Train ticketing and seat verification	QR + Fingerprint biometrics	Manual ticket verification errors	Automated check-in; improved security	Infrastructure requirements
[58]	2010	Secure QR e-ticket system	QR + Block cipher + Password	Password-based security risks	Improved ticket accessibility	Password theft; device compatibility

D. Healthcare Systems

In healthcare applications, QR code technology is primarily explored as a mechanism for securing access to sensitive patient information and supporting data privacy within electronic health record (EHR) systems. Existing studies investigate the use of encryption techniques and cloud-based storage to restrict data access to authorized personnel. At the same time, the literature identifies several challenges, including key management in large-scale deployments and the need for extensive testing to assess system performance in real-world healthcare settings. Overall, these studies suggest that QR code-based approaches have the potential to strengthen privacy protection in healthcare environments, while also indicating areas that require further development and validation. Table XI presents studies that examine the application of QR codes in healthcare systems, with a particular focus on securing access to sensitive patient information. The reviewed studies discuss encryption techniques and authentication frameworks that are intended to support data protection in electronic health record (EHR) systems.

TABLE XI. STUDIES RELATED TO HEALTHCARE SYSTEMS

Ref	Year	Focus Area	Algorithm	Challenges addressed	Findings	Limitations
[59]	2022	Secure QR data transfer	QR + RSA	Personal data privacy	Secure encrypted data transfer	Key management complexity
[60]	2020	Secure EHR access via QR	QR + Cloud storage	Protecting sensitive health data	Secure EHR access framework	Limited real-world evaluation

E. Other Fields

In addition to the more established application domains, QR code-based systems have also been explored in a range of other environments, including hostel management, smart locker systems, and identity tracking applications. Studies in these areas describe how QR codes can be applied to support identity management, enhance security, and automate certain administrative processes. Alongside the reported advantages, such as reduced dependence on manual record-keeping, the literature also identifies several limitations. These include the need for reliable network connectivity and the possibility of scanning-related issues, particularly in settings with limited technical infrastructure. Overall, these studies reflect a growing research interest in extending the use of QR codes to diverse application scenarios beyond traditional access control systems. Table XII presents studies that examine the application of QR code technology in other fields, such as hostel management and smart building environments. The reviewed studies discuss how QR codes can be used to support identity management, improve security in residential and commercial contexts, and enable integration with cloud platforms and sensor networks for real-time monitoring.

The comparative analysis of QR Code-Based Access Control Systems (QR-ACS) reflects a wide range of applications that are shaped by specific security requirements and environmental conditions. The reviewed studies span multiple contexts, including educational institutions, emergency management scenarios, and data-sensitive environments, illustrating the flexibility of QR-ACS in addressing different access control needs.

TABLE XII. STUDIES RELATED TO OTHER FIELDS

Ref	Year	Focus Area	Algorithm	Challenges addressed	Findings	Limitations
[61]	2021	Hostel identity and access monitoring	Hostel identity and access monitoring	Manual monitoring inefficiency	Accurate movement tracking	Infrastructure dependency
[62]	2022	QR smart locker system	QR + ESP8266 + Smart lock	Traditional key limitations	Secure locker access	Response delay

In academic and institutional settings, QR-ACS are commonly applied to support identity verification and access management, often with the goal of reducing reliance on physical tokens and improving user convenience. By contrast, systems designed for emergency or critical situations tend to emphasize encryption-enhanced QR codes, allowing secure access to be maintained even when conventional infrastructure is unavailable.

From a technological perspective, many of the proposed systems integrate encryption techniques, such as RSA, and in some cases combine QR codes with biometric authentication to strengthen protection against unauthorized access. While these approaches contribute to improved security, the literature also consistently reports challenges related to QR code tampering, unauthorized duplication, system scalability, and the complexity of implementing advanced cryptographic mechanisms across diverse environments.

The distribution of QR-ACS applications across domains is summarized in Fig. 8. The figure illustrates the distribution of QR-ACS applications across different operational domains. Home security and university laboratory environments constitute the largest proportion of reported implementations, reflecting the technology's suitability for cost-sensitive and semi-controlled environments. Public facilities and IoT-integrated smart systems also represent significant adoption sectors. In contrast, high-security and healthcare applications show comparatively lower representation, indicating potential research and deployment gaps in environments requiring stricter compliance, scalability validation, and regulatory assurance.

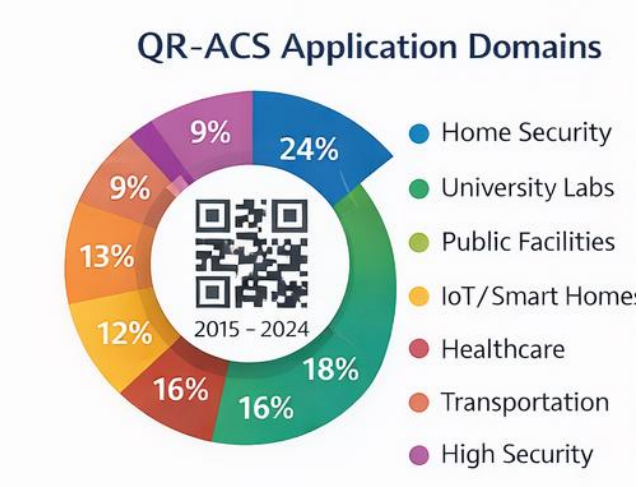

Fig. 8. Distribution of QR-ACS application domains.

Overall, these recurring challenges indicate the need for continued research and refinement of QR-ACS to improve reliability, scalability, and practical deployment.

The ongoing development of QR code technologies and their integration with emerging security frameworks suggest that QR-ACS remains an active area for both academic investigation and real-world application. Fig. 9 presents a structured taxonomy of QR Code-Based Access Control Systems (QR-ACS), synthesizing the diverse implementations identified in the reviewed literature. The taxonomy categorizes QR-ACS into five primary classes based on authentication architecture and security mechanisms:

- Static QR Systems, which rely on fixed credentials and minimal computational complexity, are predominantly observed in early home security and institutional prototypes (Tables I and III). While cost-effective, these systems remain vulnerable to duplication and replay attacks.
- Dynamic QR Systems, including time-based and session-based implementations, are introduced to mitigate replay and reuse risks. These systems are commonly applied in university laboratories, transportation ticketing, and public facility management (Tables III and X), where temporal validity enhances security robustness.
- Encrypted QR Systems, incorporate cryptographic algorithms such as AES, RSA, or hybrid encryption to protect embedded credentials. As shown in Tables III, IV, V, and XI, encryption-based approaches are widely adopted in healthcare, high-security, and emergency-response environments to address confidentiality and integrity concerns.
- Multi-Factor QR Systems, combining QR authentication with biometric verification, one-time passwords (OTP), or blockchain logging, are increasingly reported in office, financial, and high-security settings (Tables II, V, and VIII). These systems significantly strengthen authentication assurance but introduce higher computational and infrastructural complexity.
- IoT-Integrated QR Systems, observed across smart homes, industrial IoT, and facility management contexts (Tables VI, VII, and IX), embed QR authentication within connected infrastructures, enabling real-time monitoring and context-aware access control.

This taxonomy provides a conceptual framework that clarifies architectural distinctions, highlights evolutionary security enhancements, and supports comparative analysis across application domains. By structuring the literature into these categories, the taxonomy contributes to a clearer understanding of design trends and emerging directions in QR-ACS research. Fig. 9 presents a structured taxonomy of QR Code-Based Access Control Systems (QR-ACS).

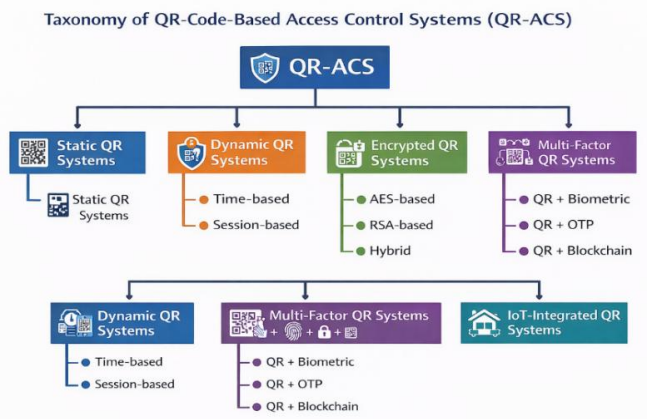

Fig. 9. Two-dimensional architectural model of QR-ACS.

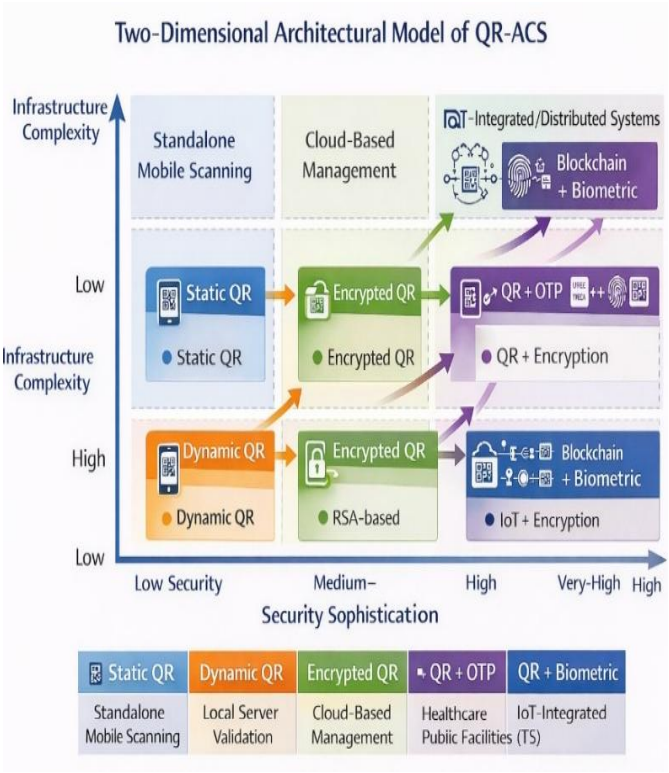

Fig. 10. Two-dimensional architectural model of QR-ACS.

Fig. 10 extends the taxonomy into a two-dimensional architectural model that classifies QR-ACS implementations based on security sophistication and infrastructure complexity. Systems positioned in the lower-left quadrant, such as static QR implementations, exhibit low computational overhead but limited resistance to duplication and replay attacks. Moving toward the upper-right quadrant, multi-factor and blockchain-integrated systems demonstrate enhanced security robustness at the cost of increased infrastructural and computational demands. This model highlights the inherent trade-off between deployment simplicity and security strength, enabling clearer benchmarking of QR-ACS designs across different operational environments.

Table XIII provides a structured comparison of QR-ACS categories derived from the proposed taxonomy. The analysis shows that as systems evolve from static to multi-factor and blockchain-integrated architectures, replay resistance and authentication assurance increase significantly. However, this improvement is accompanied by greater infrastructural requirements and system complexity. The table reinforces the trade-offs illustrated in the two-dimensional architectural model and provides a practical reference for selecting QR-ACS architectures based on deployment constraints and security requirements.

V. Current Technologies and Applications

The application of QR Code-Based Access Control Systems (QR-ACS) extends across a wide range of environments, where the technology is employed to support security requirements and improve operational processes. This section reviews the key technologies currently associated with QR-ACS and discusses how they are applied in real-world contexts across different sectors.

Fig. 11 illustrates several application environments and technological trends that have influenced the deployment of QR code-based access control systems. These environments include digital services, smart environments, and data-driven infrastructures where secure and contactless authentication methods are increasingly required. The figure also highlights broader technological developments such as remote monitoring, data integration, and privacy-aware systems, which have contributed to expanding the role of QR-based technologies in modern security and operational management.

TABLE XIII. Comparative Characteristics of QR-ACS Categories

Category	Credential Type	Replay Resistance	Infrastructure Need	Typical Domains (Tables)
Static QR	Fixed	Low	Low	Home Security (T1), Early Labs (T3)
Dynamic QR	Time/Session-based	Medium–High	Medium	Labs (T3), Transportation (T10)
Encrypted QR	AES/RSA	High	Medium	Healthcare (T11), Public Facilities (T4), High Security (T5)
Multi-Factor QR	QR + OTP/Bio	Very High	High	Offices (T2), Finance (T8), High Security (T5)
IoT-Integrated QR	Context-aware	Variable	High	Smart Homes (T6), Industrial IoT (T7), Smart Buildings (T9)

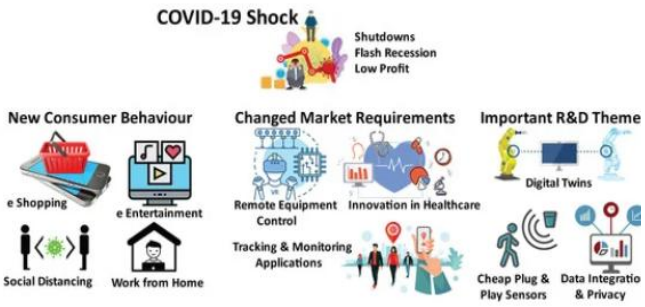

Fig. 11. Overview of application environments for QR code-based access control systems, including smart homes, healthcare, industrial settings, and high-security facilities [63].

A. Technological Innovations

Recent developments in QR-ACS have focused on improving the security of data encoded within QR codes through the use of cryptographic techniques. Many proposed systems employ encryption algorithms such as AES (Advanced Encryption Standard) and RSA (Rivest–Shamir–Adleman) to protect sensitive information from unauthorized access or manipulation. Previous studies note that QR codes have increasingly been adopted for security-related applications when combined with encryption mechanisms that support data confidentiality and integrity [64].

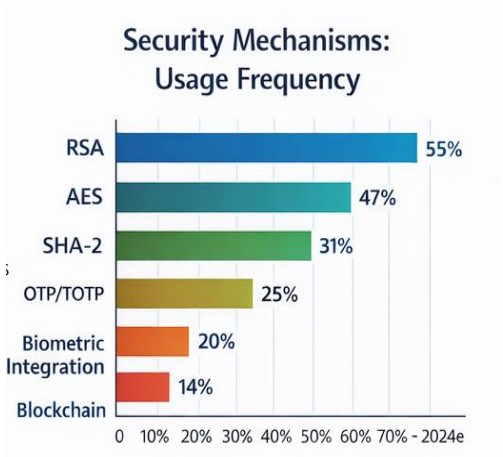

Fig. 12. Security mechanism usage frequency in QR-ACS.

In addition, the integration of cloud-based technologies has enabled more flexible management of QR codes. Cloud platforms allow QR codes to be updated dynamically and managed centrally, reducing the need for physical interaction and supporting scalable deployment in distributed environments [65]. The relative adoption frequency of security mechanisms is illustrated in Fig. 12. The figure compares the relative frequency of security mechanisms integrated within QR-ACS implementations. As shown, RSA and AES encryption dominate the literature, reflecting their widespread adoption for protecting QR-encoded credentials. Hash-based mechanisms such as SHA-2 are moderately represented, primarily in login authentication contexts. Multi-factor authentication techniques, including OTP/TOTP and biometric integration, appear less frequently but demonstrate increasing adoption in recent years. Blockchain-based logging mechanisms remain emerging but show promise for enhancing transparency and tamper resistance. This distribution suggests that encryption remains foundational, while decentralized and biometric security layers are still developing.

B. Biometric Integration

Another area of development in QR-ACS involves the combination of QR code authentication with biometric verification methods, such as facial recognition and fingerprint scanning. In these systems, QR codes are typically used as an initial authentication step, followed by biometric verification to confirm user identity. Studies suggest that combining encrypted QR data with biometric information can provide an additional layer of security compared to traditional single-factor access control methods [66].

This approach has been explored particularly in environments that require higher security levels, where layered authentication mechanisms can help reduce the risk of unauthorized access.

C. IoT and Smart Environments

In smart homes and smart buildings, QR-ACS are often integrated with Internet of Things (IoT) infrastructures to support more adaptive access control solutions. These systems can interact with sensors, actuators, and monitoring devices to adjust access permissions based on contextual factors such as time, location, or environmental conditions. Existing research indicates that IoT-enabled QR-based access control frameworks can enhance system responsiveness and support real-time monitoring when combined with encrypted communication and authentication mechanisms [67].

For example, access to specific areas within a smart building may be regulated not only by user identity but also by predefined environmental or operational conditions.

D. Public and Commercial Applications

QR-ACS has also been adopted in a variety of public and commercial settings, including transportation systems, entertainment venues, and corporate facilities. In such environments, QR codes are commonly used to manage access efficiently, particularly in high-traffic scenarios. Prior studies reported that QR-based access control can support crowd management and streamline entry procedures by reducing reliance on physical tickets or access cards [67].

In public transportation systems, for instance, QR codes are frequently used to facilitate contactless entry and verification, contributing to improved operational efficiency during peak usage periods.

E. Healthcare and Institutional Use

In healthcare and institutional environments, QR-ACS are primarily employed to control access to restricted areas and sensitive information, such as patient records and clinical facilities. These systems can be configured to grant access only to authorized personnel while maintaining detailed access logs for auditing and compliance purposes. Research has shown that QR-based authentication mechanisms, particularly when combined with biometric verification, can support enhanced protection of patient data and restricted zones [68].

During health emergencies, including the COVID-19 pandemic, QR-based systems have also been utilized to manage patient flow and visitor access in a contactless manner, helping institutions maintain safety protocols while reducing physical interaction [65].

VI. Discussion

The review of QR Code-Based Access Control Systems (QR-ACS) provides several insights into both the strengths of these systems and the challenges that continue to affect their deployment, as in Table XIV. By examining studies across different application domains, this review highlights recurring technical, operational, and organizational issues that influence the effectiveness of QR-ACS, while also pointing to areas where further research may contribute to more robust implementations.

TABLE XIV. Security Strength Comparison

Mechanism	Duplication Resistance	Replay Protection	Scalability	Complexity
Static QR	Low	Low	High	Low
Encrypted QR	Medium	Medium	Medium	Medium
QR + OTP	High	High	Medium	Medium
QR + Biometric	Very High	High	Low-Medium	High
Blockchain QR	Very High	Very High	Medium	Very High

To enhance the practical applicability of the proposed taxonomy, a qualitative risk assessment matrix is introduced. The matrix evaluates key threats based on likelihood and impact, enabling prioritization of security measures, as Table XV. The analysis indicates that duplication and replay attacks represent the most critical risks in QR-ACS, particularly in static implementations, while biometric spoofing, although less frequent, poses severe consequences in high-security environments.

TABLE XV. Risk Assessment of QR-ACS Threats

Threat Type	Likelihood	Impact	Risk Level
QR Code Duplication	High	Medium	High
Replay Attacks	Medium	High	High
Biometric Spoofing	Low	Very High	High
Device Theft	Medium	Medium	Medium
Insider Misuse	Low	High	Medium

The findings indicate a clear trade-off between system security and deployment complexity. While multi-factor and blockchain-based QR-ACS provide higher resistance against attacks, they require significant infrastructural support and computational overhead. Conversely, lightweight QR systems offer scalability but remain vulnerable to duplication and replay attacks. This trade-off suggests that no single architecture is universally optimal; instead, system design should be guided by application-specific security requirements and operational constraints.

Moreover, the increasing integration of QR-ACS with IoT environments introduces new attack surfaces, particularly related to device-level vulnerabilities and network security. This highlights the need for cross-layer security frameworks that combine cryptographic protection, device authentication, and real-time monitoring.

VII. Challenges in Current QR-ACS

One of the most frequently discussed challenges in the literature relates to security vulnerabilities. Although many systems incorporate encryption techniques and, in some cases, biometric verification, QR-ACS can still be exposed to risks such as code duplication, spoofing, and unauthorized access. In particular, systems that rely on static QR codes may be more susceptible to misuse unless supported by dynamic generation and validation mechanisms.

Another limitation concerns the dependence on specific hardware, especially smartphones and dedicated scanning devices. While this reliance is feasible in many contexts, it can restrict deployment in environments where access to such technology is limited or economically impractical. To provide a structured understanding of these risks, Fig. 13 illustrates the threat landscape associated with QR-ACS implementations. Fig. 6 illustrates the threat landscape associated with QR Code-Based Access Control Systems (QR-ACS). The model categorizes vulnerabilities into code-level threats (e.g., duplication and replay attacks), authentication-layer threats (e.g., biometric spoofing and static QR reuse), and infrastructure-level risks (e.g., insider misuse and device theft). The figure highlights that static QR implementations are particularly vulnerable to duplication and replay-based exploitation, whereas systems integrating biometric verification and dynamic QR generation exhibit reduced exposure but introduce new attack surfaces related to biometric spoofing and device compromise. This layered threat perspective reinforces the need for multi-factor authentication and dynamic credential management in next-generation QR-ACS frameworks.

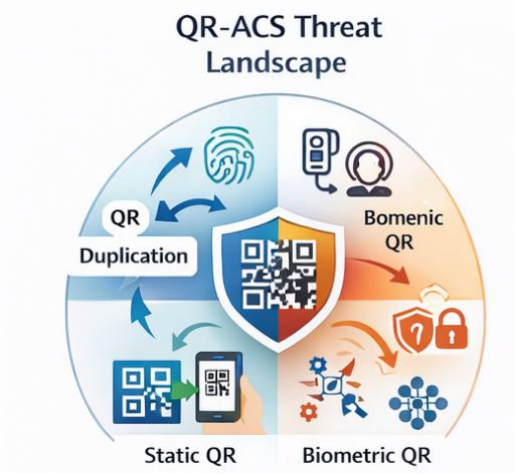

Fig. 13. QR-ACS threat model landscape.

Privacy considerations also emerge as a significant concern, especially in systems that integrate biometric data or personal identifiers. Ensuring compliance with data protection regulations, such as the General Data Protection Regulation (GDPR), is essential for maintaining user trust and safeguarding sensitive information.

In addition, the lack of standardized protocols across different QR-ACS implementations often leads to interoperability challenges. As these systems are adopted in diverse sectors, inconsistencies in design and communication standards can hinder seamless integration with existing security infrastructures.

VIII. Future Research Directions

The findings of this review suggest several directions for future research. Enhancing security protocols remains a priority, particularly through the development of cryptographic techniques that can be efficiently embedded within QR-based systems. Emerging approaches, such as blockchain-based access logging, have also been discussed in the literature as potential solutions for improving transparency and traceability. Expanding accessibility represents another important research avenue. Future work may explore alternatives to smartphone-dependent systems, including low-cost scanning devices or hybrid authentication models that combine QR codes with other access control mechanisms.

To highlight areas requiring further investigation, Fig. 14 presents a structured research gap matrix. The figure presents a structured research gap matrix synthesizing the maturity of QR-ACS research across key dimensions. While encryption techniques are widely implemented across most domains, blockchain integration and large-scale real-world validation remain underexplored, particularly in public facilities and high-security environments. Scalability testing is inconsistently addressed, with many studies limited to prototype-level validation. The matrix highlights that although technical feasibility has been demonstrated, empirical deployment studies and interoperability frameworks are still insufficient. These gaps underscore the need for standardized evaluation methodologies and cross-domain benchmarking in future QR-ACS research.

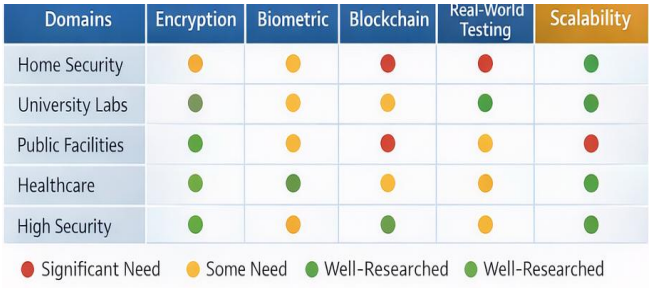

Fig. 14. Research gap matrix (2015–2024).

Dynamic QR code generation is also widely recognized as a promising approach to strengthening security. Techniques that enable real-time code generation and expiration could reduce the risk of unauthorized reuse, while adaptive methods based on usage patterns may further improve access control reliability.

Privacy-preserving frameworks require continued attention as well. Research focusing on data anonymization, secure storage, and regulatory compliance can contribute to the development of QR-ACS that balances security requirements with user privacy.

Finally, cross-industry standardization is essential for supporting large-scale deployment. Collaborative efforts among academic researchers, industry stakeholders, and regulatory authorities may facilitate the creation of interoperable standards that enhance scalability and adoption across different application domains.

IX. Conclusion

This systematic review has examined the evolution and current state of QR Code-Based Access Control Systems (QR-ACS), drawing on a wide range of studies that reflect their application across residential, institutional, commercial, and high-security environments. The reviewed literature indicates that QR-ACS offers flexible and cost-effective solutions for access control, particularly when combined with encryption techniques, biometric verification, and cloud-based management.

At the same time, the findings highlight several persistent challenges that must be addressed to ensure reliable and secure deployment. These challenges include security vulnerabilities, privacy concerns, hardware dependency, and interoperability limitations. Addressing such issues is critical for improving the robustness of QR-ACS and supporting their integration into complex security infrastructures.

Future research plays a key role in advancing this field. Continued efforts are needed to develop stronger security mechanisms, explore more inclusive and accessible system designs, and establish standardized frameworks that promote interoperability and scalability. Equally important is the need to incorporate privacy-preserving approaches that align with international data protection regulations and user expectations.

Overall, QR Code-Based Access Control Systems demonstrate significant potential to influence the future of access management in increasingly digital environments. With sustained research, careful system design, and cooperation between academia, industry, and regulatory bodies, QR-ACS can evolve into more secure, efficient, and user-centered access control solutions.

Real-Traffic-Trained Intelligent IDS for Advanced Cyberattack Detection in Enterprise Networks

Dalila Naira Chinchay, Rodrigo Calderón Ari, Liset S. Rodriguez-Baca
Professional School of System Engineering, Cesar Vallejo University, Lima, Peru

***Abstract*—Early detection of cyberattacks remains a major challenge in enterprise networks due to encrypted traffic, protocol diversity, and highly dynamic service behavior. This study evaluates a machine learning-based intrusion detection system trained on real enterprise traffic captured over 20 working days under operational conditions. A total of 1,163,014 packets were collected and complemented with controlled attack traffic, including DDoS, brute force, botnet, SQL injection, port scanning, privilege escalation, and service exploitation scenarios. After flow-based feature extraction and preprocessing, six supervised learning models were evaluated under the same data partition and validation settings. Among them, Random Forest achieved the best overall performance, with precision, recall, and F1-score above 0.999 and an AUC of 0.9994 on the collected dataset. These findings suggest that training with real traffic can improve IDS performance under realistic enterprise conditions. However, further validation across additional organizations and time periods is required to confirm generalizability.**

***Keywords*—IDS; machine learning; cyberattacks; cybersecurity; intrusion detection**

I. Introduction

The growing reliance of organizations on digital infrastructures has intensified their exposure to increasingly sophisticated and hard-to-anticipate cyberattacks. In recent years, threats based on evasion techniques, zero-day vulnerability exploitation, and malicious automation have proven capable of easily bypassing traditional security systems. These challenges have driven the evolution of Intrusion Detection Systems (IDS), which aim to identify anomalous behaviors or attack-related patterns with ever-higher levels of accuracy.

Recent literature agrees that approaches based on artificial intelligence and machine learning offer significant advantages for early intrusion detection, particularly when dealing with unknown attacks or rapidly evolving variants. Studies such as that of Shamshair et al. [1] highlight that AI-based models can adapt to emerging threats with a level of generalization superior to mechanisms relying solely on signature-based detection. Similarly, applied research in IoT environments and enterprise networks shows that advanced techniques based on deep learning and graph-based methods have achieved improved detection of complex malicious behaviors [2], [3].

Despite these advances, a key limitation remains: most existing studies rely on synthetic or historical datasets that do not adequately represent the real behavior of modern networks. Widely used datasets such as KDD99, NSL-KDD, or UNSW-NB15 exhibit artificial structures, obsolete protocols, or traffic volumes that differ substantially from real traffic captured in an operational organization. As a result, models that achieve high performance in controlled environments often lose effectiveness when deployed in networks dominated by encrypted protocols, highly variable flows, and distributed application workloads.

Recent systematic reviews confirm this gap. Rehman et al. [4] emphasize that machine learning–based IDS requires datasets that are representative of current network traffic, while Chen et al. [5] underline that model performance largely depends on the quality of the data used during training. Although recent studies have reported promising IDS results using machine learning and deep learning, many of them rely on public benchmark datasets or controlled laboratory environments. These settings often underrepresent encrypted enterprise traffic, fluctuating service workloads, and the coexistence of modern protocols such as QUIC and TLS/HTTPS. As a result, it remains unclear to what extent the reported performance of these models can be sustained under real operational conditions.

The main contributions of this study are threefold: 1) the construction of a hybrid dataset that combines real enterprise traffic with controlled attack scenarios; 2) the comparative evaluation of six supervised machine learning models under identical preprocessing, partitioning, and validation settings; and 3) empirical evidence that real-traffic-based training can support highly accurate intrusion detection under realistic enterprise network conditions.

II. Related Work

Intrusion detection has been widely studied within the field of cybersecurity, and its evolution has been marked by the progressive incorporation of machine learning techniques. Over the past decade, numerous studies have compared traditional algorithms such as decision trees, support vector machines, and k-nearest neighbors with more recent models based on ensemble methods or deep learning, demonstrating significant improvements in accuracy, predictive capability, and the detection of hidden patterns.

Shamshair et al. [1] conducted a comparative analysis of various AI-based methods applied to zero-day attack detection, demonstrating that ensemble-based models such as Random Forest and Gradient Boosting exhibit greater stability under traffic variations and achieve better performance in real-world scenarios. In IoT environments, where network behavior tends to be more dynamic and unpredictable, Villegas et al. [2] introduced an innovative approach based on dynamic graphs and neural networks, achieving high accuracy in the identification of

complex attacks. Complementarily, Villegas et al. [3] evaluated the effectiveness of an adaptive deep learning–based IDS, reporting substantial improvements against multi-stage attacks and low-frequency malicious patterns.

A systematic review conducted by Rehman et al. [4] highlights the advantages of machine learning techniques and their applications in IDS, reinforcing arguments related to current trends and existing research gaps. In line with this perspective, Ferrag et al. [6] emphasize that training with real data strengthens the model's generalization capability and reduces the occurrence of false positives, which remain one of the main challenges of traditional IDS. Similarly, Chen et al. [5] propose a hybrid NIDS + HIDS system that improves detection performance by combining network- and host-based features, representing a modern approach to machine learning–based IDS.

Studies focused specifically on intrusion detection have also examined the comparative behavior of supervised classifiers such as Random Forest, Decision Tree, KNN, AdaBoost, and XGBoost under different traffic conditions. In general, ensemble-based models tend to provide more stable results than single classifiers when the data exhibit variability, noise, or class imbalance.

Likewise, Jijo et al. [7] provide a comprehensive review of the decision tree algorithm, highlighting its importance as a foundation for advanced models such as Random Forest and Extra Trees. In the context of critical infrastructures, Majidi et al. [8] applied ensemble techniques and autoencoders for intrusion detection in power grid networks, demonstrating their robustness against false data injection attacks.

From an algorithmic perspective, Ding et al. [9] proposed an improved AdaBoost variant based on multiple thresholds, which enabled a reduction in overfitting when dealing with highly complex datasets. Complementarily, Zhang [10] analyzed the challenges faced by the KNN algorithm in imbalanced data environments, while Zhang, Jia, and Shang [11] explored the potential of XGBoost for handling severely imbalanced datasets, concluding that its performance can be significantly enhanced through specific weighting and regularization adjustments.

Vaarandi et al. [12] investigated the use of active learning to classify IDS alerts in real time, highlighting the advantages of incorporating adaptive methods in modern network environments. In addition, hybrid approaches have been shown to improve detection performance by integrating network-based and host-based analysis.

Hassan et al. [13] propose ensemble-based methods (boosting) combined with hyperparameter optimization and feature selection for NIDS, aligning with comparative approaches to machine learning models. Rahman et al. [14] provide an updated review of IDS techniques, machine learning models, and performance metrics in IoT environments, which is useful for contextualizing the application of machine learning in networks with real traffic.

Ba et al. [15] explore the application of machine learning models, including Random Forest and Decision Tree, for intrusion detection in industrial IoT networks, highlighting the importance of training with real data and conducting comparative evaluations of machine learning models.

Spiekermann et al. [16] examine specific intrusion detection challenges when traffic originates from virtualized networks, highlighting the need for deep learning techniques to address highly dynamic and encapsulated traffic.

Similarly, Adenusi et al. [17] conducted an extensive comparison of optimized machine learning algorithms for IDS, highlighting the advantages of ensemble and boosting methods over individual models, which supports our comparative selection of six models.

Zakariah et al. [18] conducted a comprehensive comparison of the proposed model against widely recognized industry benchmark methods, including decision-based classifier combinations and machine learning classifiers such as K-Nearest Neighbors (KNN), Deep Learning (DL), Support Vector Machine (SVM), Long Short-Term Memory (LSTM), Deep Neural Network (DNN), and ANN. The results show that the proposed model consistently outperforms these traditional techniques across all evaluation metrics. Table I is the comparative summary of recent IDS studies.

TABLE I. COMPARATIVE SUMMARY OF RECENT IDS STUDIES

Ref.	Traffic Source / Dataset	Context	Models/Approach	Key Finding	Main Limitation
[1]	Zero-day attack datasets	Cyberattack detection	AI and ensemble methods	Ensemble models showed strong stability and detection capability	Not based on live enterprise traffic
[2]	IoT network traffic	IoT	Dynamic graphs and GNNs	Effective for detecting complex attacks	Focused on IoT, not enterprise office traffic
[3]	Adaptive IDS traffic	IoT / adaptive IDS	Deep learning-based IDS	Improved detection of multi-stage and low-frequency attacks	Not a real enterprise comparative study
[4]	Multiple IDS datasets	Systematic review	ML-based IDS review	Dataset quality strongly affects IDS performance	Review only; no direct enterprise experiment
[5]	Hybrid host and network data	Hybrid NIDS + HIDS	Two-stage hybrid classifier	Improved detection using host and network features	Different from pure flow-based enterprise NIDS
[6]	Multiple cybersecurity datasets	Comparative review	Deep learning for IDS	Data quality affects generalization and false positives	Not validated on live enterprise capture
[8]	Smart grid intrusion data	Critical infrastructure	Extra Trees, Autoencoder	Robust performance in FDI detection	Domain-specific traffic

Ref.	Traffic Source / Dataset	Context	Models/Approach	Key Finding	Main Limitation
[9]	Complex classification datasets	General ML	Improved AdaBoost	Reduced overfitting in complex settings	Not specific to enterprise IDS
[10]	High-dimensional datasets	General ML	KNN	KNN faces challenges in high-dimensional data	Algorithm-focused, not IDS-specific validation
[11]	Imbalanced datasets	General ML	XGBoost	Good performance with tuning and weighting	Not centered on real enterprise traffic
[12]	IDS alert streams	Real-time alert classification	Active learning	Adaptive learning improves alert classification	Focuses on alerts, not full flow-based IDS
[13]	NIDS datasets	Network intrusion detection	XGBoost + feature selection	Boosting improves NIDS performance	No live enterprise traffic validation
[14]	IoT IDS literature	IoT	Survey of IDS techniques	Updated overview of IDS methods and metrics	Survey only; IoT-centered
[15]	IIoT intrusion data	Industrial IoT	RF, DT, and ML methods	ML is effective for IIoT intrusion detection	IIoT differs from enterprise mixed traffic
[16]	Virtualized network traffic	Virtual networks	Deep learning	Useful for dynamic encapsulated traffic	Limited transfer to enterprise production traffic
[17]	Network intrusion datasets	Data-driven IDS	Optimized ML algorithms	Ensemble methods outperform several single models	Limited evidence on live enterprise capture
[18]	NSL-KDD	Benchmark dataset	KNN, SVM, DL, LSTM, DNN, ANN	Proposed model outperformed common classifiers	NSL-KDD is not representative of modern enterprise traffic
[19]	IoMT traffic	Medical / IoMT	Ensemble-based IDS	Effective anomaly detection in sensitive environments	Domain-specific traffic

Finally, recent research focused on medical networks and the Internet of Medical Things (IoMT), such as the work by Ibrahim and Al-Wadi [19], has demonstrated that systems based on ensemble techniques can effectively adapt to highly sensitive environments where early anomaly detection is critical. Taken together, these contributions show that machine-learning-based models, particularly those trained on real data, represent an essential tool for addressing the current landscape of advanced cyber threats.

Overall, prior studies confirm the value of machine learning for intrusion detection, but many rely on public or semi-synthetic datasets, which limit direct transfer to enterprise operational settings. Unlike those studies, the present work uses traffic captured from a functioning enterprise environment and evaluates multiple models under the same experimental conditions.

III. Methodology

The methodology applied in this research was structured into four main stages:

- Real traffic capture in an operational enterprise environment,
- controlled generation of cyberattacks,
- flow-based processing and feature extraction, and
- comparative training and evaluation of the models.

This approach enabled the construction of an authentic, diverse, and representative dataset that reflects real network behavior, overcoming the limitations of commonly used synthetic datasets.

A. Real Traffic Capture

The monitored enterprise environment corresponded to a production network segment used during standard business operations. The infrastructure included approximately 25 PCs, network printers, one MikroTik router, two switches, and internet connectivity provided by WIN. In addition, the monitored environment supported five main services, including SAP ERP, Nextcloud, point-of-sale services, remote access connections, and shared folder services. Traffic collection was limited to working hours (8:00 a.m. to 4:00 p.m.) over 20 business days. Although the monitored segment reflects the operational conditions of the organization, off-hours behavior and attacks occurring outside this observation window were not represented and should therefore be considered a limitation of the dataset. Fig. 1 shows data processing and classification cycle.

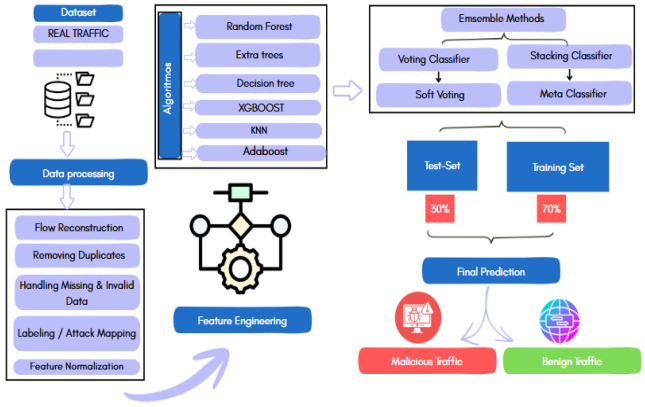

Fig. 1. Data processing and classification cycle.

Wireshark was used on a device directly connected to the company's main network link. In total, 1,163,014 packets were recorded, covering a comprehensive set of modern protocols, including: IPv4: 99.4%, TCP: 51%, UDP: 48%, QUIC: 45.9%, TLS/HTTPS: 20.2%, SSDP: 0.7%, ICMP, ARP and IGMP: 0.1–0.2%.

As shown in Fig. 2, the traffic was captured without prior filtering in order to ensure maximum fidelity to the real operational environment. This approach is consistent with recommendations from recent studies, which emphasize the

importance of working with genuine data to improve the robustness of machine learning–based IDS [4], [5].

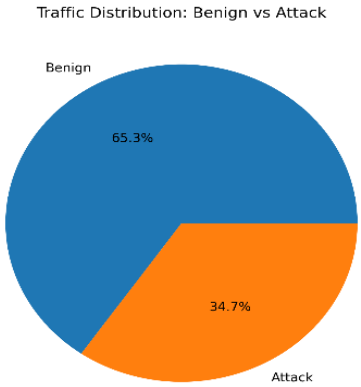

Fig. 2. Traffic distribution: Benign vs Attack.

B. Malicious Traffic Generation and Labeling

To complement benign traffic with examples of malicious behavior, controlled attacks were designed and executed in an isolated laboratory environment. The experiments included seven main categories:

- DDoS: SYN, UDP, and HTTP flooding attacks.
- Brute force: repeated authentication attempts against SSH and FTP services.
- Botnet: command and control communication patterns.
- SQL Injection: attacks targeting internal web services.
- Port scanning: SYN scan, FIN scan, and service detection techniques.
- Privilege escalation: attempts to execute privileged operations.
- Service exploitation: exploitation of known vulnerabilities using Metasploit.

For the validation and labeling of malicious traffic, three mechanisms were combined:

- Snort 3 rules for automated detection,
- Correlation with attack environment logs, allowing identification of the exact time of each event, and
- Manual review by analysts during execution.

This process ensures reliable and consistent labeling, in line with methodologies employed in recent IDS research conducted in real-world environments [2], [3]. To avoid ambiguity in the labeling process, the temporal relationship between benign and attack traffic must be explicitly stated. In this study, controlled attack events were identified through synchronized logs and rule-based alerts, allowing attack periods to be distinguished from normal traffic windows. Nevertheless, because benign traffic and attack-related traffic may coexist within the same operational period, the possibility of temporal overlap should be acknowledged as a source of complexity in flow labeling.

The proportion of benign and malicious flows was reported explicitly because class imbalance may influence the observed performance of machine learning models. In this study, benign traffic accounted for 65.3% of the dataset, while attack traffic represented 34.7%. This distribution shows a moderate imbalance rather than an extreme one; however, it was still reviewed before training and considered during preprocessing and evaluation to reduce the risk of biased performance estimates.

C. Feature Processing and Extraction

Since the captured traffic includes complete flows and modern protocols, a flow-based feature extraction strategy was applied. Attributes were derived from both source-host and destination-host behavior, including connection duration, bytes sent and received, counts of connections to the same service, rates of erroneous or unanswered packets, proportions of successful connections, and aggregated metrics per destination host (e.g., *dst_host_srv_count*, *dst_host_serror_rate*).

TABLE II. FLOW-LEVEL FEATURES USED FOR MODEL TRAINING

Feature Name	Description	Type
duration	Duration of the connection or flow session	Duration
protocol_type	Transport protocol associated with the connection, evaluated during the pretest and posttest stages	Categorical
service	Network service associated with the connection, such as HTTP, FTP, or SMTP	Categorical
flag	Final status or flag observed in the connection	Categorical
src_bytes	Number of bytes sent from the source to the destination	Count
dst_bytes	Number of bytes sent from the destination to the source	Count
count	Number of connections from the same source within a defined time window	Count
srv_count	Number of connections to the same service within a defined time window	Count
same_srv_rate	Proportion of connections to the same service	Rate
diff_srv_rate	Proportion of connections to different services	Rate
srv_diff_host_rate	Proportion of connections to the same service but directed to different hosts	Rate
dst_host_count	Number of connections directed to the same destination host	Count
dst_host_srv_count	Number of connections directed to the same service on the destination host	Count
dst_host_same_srv_rate	Proportion of connections to the same service on the destination host	Rate
dst_host_diff_srv_rate	Proportion of connections to different services on the destination host	Rate
dst_host_same_src_port_rate	Proportion of connections to the destination host from the same source port	Rate
dst_host_srv_diff_host_rate	Proportion of connections to the same service on the destination host coming from different hosts	Rate

Table II presents the main flow-level features considered during model training. Although the original dataset contained additional variables, only the most representative attributes related to connection behavior, traffic volume, temporal frequency, service usage, and destination-host error patterns are summarized here for clarity.

This set of features is inspired by attribute designs used in traffic classification research [6], [19], while being adapted to the real environment of the present study. Unlike synthetic datasets, where features are fixed and predefined, the metrics here were constructed directly from genuine traffic behavior, ensuring greater representativeness and predictive value.

Before model training, the following preprocessing steps were applied:

- Min–Max normalization,
- outlier removal,
- class balance verification, and
- optimized categorical encoding (for flags, protocol types, and connection states).

These steps ensure model stability and reduce the risk of bias or overfitting.

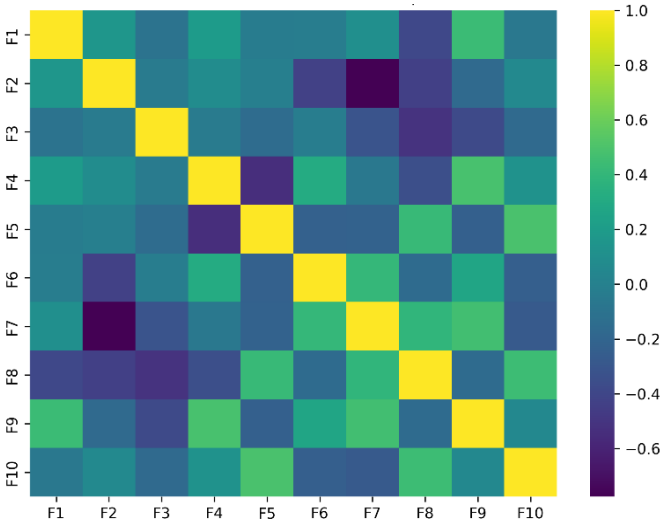

Fig. 3. Feature correlation heatmap.

Fig. 3 shows the correlation heatmap of the selected features, where most variables exhibit weak to moderate relationships with each other. This behavior indicates low redundancy within the feature set, which benefits the learning process by providing complementary information for intrusion detection.

D. Model Training and Comparative Evaluation

In order to identify the most suitable algorithm for intrusion detection in a real enterprise environment, six supervised machine learning models were trained and evaluated. All models were assessed using the same dataset, identical data partitions, and the same evaluation criteria, thereby ensuring a fair and methodologically sound comparison.

The models considered were Random Forest, Extra Trees, Decision Tree, K-Nearest Neighbors (KNN), AdaBoost, and XGBoost, which have been widely used in recent studies on intrusion detection and network traffic classification [1], [9], [10], [11], [19].

The final dataset was split into 70% for training and 30% for testing, preserving the proportion between benign and malicious traffic. Each model was trained independently using the same set of flow-level features and evaluated under identical experimental conditions to ensure a fair comparison across classifiers.

The evaluated models were trained under consistent comparative conditions using predefined baseline hyperparameters. Random Forest and Extra Trees were configured with 200 trees and balanced class weighting, Decision Tree was limited to a maximum depth of 20, AdaBoost was trained with 200 estimators, K-Nearest Neighbors (KNN) was configured with 7 neighbors, and XGBoost was trained with 300 estimators, a learning rate of 0.1, a maximum depth of 6, and subsampling parameters of 0.8. Additional implementation settings were included where required to ensure stable execution. Table III summarizes the base hyperparameter configuration used in the comparative evaluation of the six models.

TABLE III. BASE HYPERPARAMETER CONFIGURATION OF THE EVALUATED MODELS

Model	Hyperparameter	Value
Random Forest	n_estimators	200
	random_state	42
	class_weight	balanced
	n_jobs	-1
Extra Trees	n_estimators	200
	random_state	42
	class_weight	balanced
	n_jobs	-1
Decision Tree	random_state	42
	class_weight	balanced
	max_depth	20
AdaBoost	n_estimators	200
	random_state	42
K-Nearest Neighbors (KNN)	n_neighbors	7
	n_jobs	-1
XGBoost	n_estimators	300
	learning_rate	0.1
	max_depth	6
	subsample	0.8
	colsample_bytree	0.8
	random_state	42
	n_jobs	-1
	eval_metric	mlogloss
	use_label_encoder	False
	verbosity	0

To reduce the risk of overinterpreting point estimates obtained from a single train-test split, the six evaluated models were additionally assessed across 20 daily test partitions. For each daily subset, accuracy, precision, recall, F1-score, and AUC-ROC were computed. Model performance was then summarized as mean ± standard deviation across days. To examine whether the observed differences among classifiers were statistically meaningful under repeated evaluation conditions, a non-parametric Friedman test was applied using the daily F1-score values of the six models. Post hoc pairwise comparisons were then performed using the Wilcoxon signed-rank test with Bonferroni correction, taking Random Forest as the reference model.

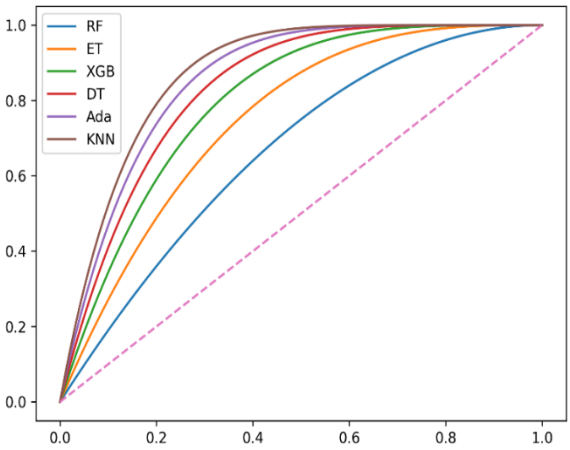

Fig. 4. ROC curves – all models.

Fig. 4 presents the ROC curves obtained for the evaluated models, showing that all of them outperform the behavior of a random classifier.

The results indicate that, among the evaluated models, Random Forest achieved the highest overall point estimates across the selected performance metrics. Based on these descriptive results within the reported experimental setting, this model was selected as the final model of the proposed IDS, and a more detailed analysis is presented in the following section.

IV. Results

The analysis of the six models made it possible to evaluate their ability to detect cyberattacks in a real enterprise environment, characterized by encrypted traffic, distributed services, and continuous variability. Based on the dataset constructed from 1,163,014 real packets and controlled attack scenarios, both classical and advanced metrics were computed, including accuracy, precision, recall, F1-score, and AUC-ROC.

As shown in Fig. 5, Random Forest achieved one of the strongest overall performances among the evaluated classifiers, together with Extra Trees, while XGBoost and Decision Tree also remained highly competitive. This behavior is consistent with previous findings highlighting the effectiveness of ensemble methods in intrusion detection tasks [1], [18], [19].

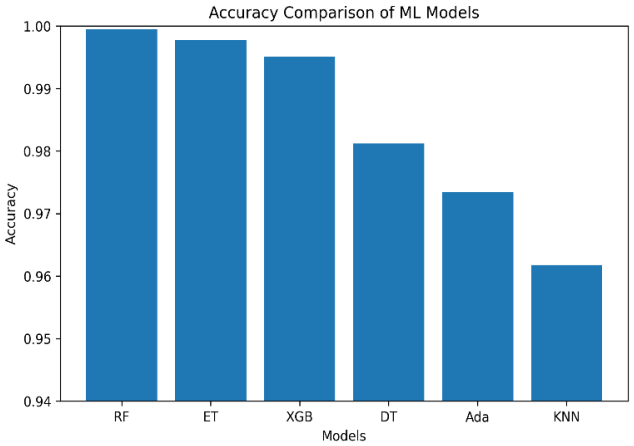

Fig. 5. Accuracy comparison of ML models.

A. Performance Metrics

The performance of the six evaluated models is reported.

TABLE IV. Performance of the Models

Model	Accuracy	Precision	Recall	F1-Score	AUC-ROC
Random Forest	0.9995	0.9996	0.9994	0.9995	0.9994
Extra Trees	0.9978	0.9975	0.9979	0.9977	0.9981
XGBoost	0.9951	0.9947	0.9953	0.9950	0.9960
Decision Tree	0.9812	0.9795	0.9810	0.9802	0.9824
AdaBoost	0.9734	0.9701	0.9740	0.9720	0.9765
KNN	0.9618	0.9584	0.9621	0.9602	0.9640

Table IV summarizes the performance of the evaluated models using both standard and advanced metrics. The results indicate that ensemble-based approaches achieved more consistent performance than the weakest individual classifiers, while Random Forest and Extra Trees showed the strongest overall balance between precision, recall, F1-score, and discriminative capability on the analyzed dataset.

Random Forest achieved very strong performance across all evaluated metrics within the reported experimental setting. This behavior can be attributed to its ability to handle heterogeneous features and capture non-linear patterns, which is consistent with the findings reported by Jijo et al. [7].

Extra Trees achieved very close results, although slightly inferior, due to its extreme randomization strategy in feature and split selection.

XGBoost remained competitive, particularly on imbalanced datasets, as discussed in [11].

K-Nearest Neighbors (KNN) is the model most affected by the high dimensionality of the dataset, which is consistent with the challenges described by Zhang [10].

B. Statistical Comparison Across Daily Test Partitions

To assess the stability of model performance beyond a single hold-out split, the six classifiers were additionally evaluated across 20 daily test partitions. Table V summarizes the mean and standard deviation of the main performance metrics across days. Random Forest and Extra Trees achieved the highest average F1-score across daily partitions (0.9997 ± 0.0011), while XGBoost and Decision Tree also showed highly stable performance. In contrast, AdaBoost and especially KNN exhibited lower average performance and greater variability, particularly in precision and F1-score.

TABLE V. CROSS-DAY PERFORMANCE OF THE EVALUATED MODELS (MEAN ± SD)

Model	*Accuracy (Mean ± SD)*	*Precision (Mean ± SD)*	*Recall (Mean ± SD)*	*F1-Score (Mean ± SD)*	*AUC-ROC (Mean ±SD)*
AdaBoost	0.9931 ± 0.0027	0.9386 ± 0.0244	0.9975 ± 0.0044	0.9670 ± 0.0124	0.9999 ± 0.0002
Decision Tree	0.9999 ± 0.0003	0.9995 ± 0.0022	0.9995 ± 0.0022	0.9995 ± 0.0015	1.0000 ± 0.0001
Extra Trees	0.9999 ± 0.0002	1.0000 ± 0.0000	0.9995 ± 0.0022	0.9997 ± 0.0011	1.0000 ± 0.0000
KNN	0.6784 ± 0.0125	0.2309 ± 0.0072	0.9495 ± 0.0216	0.3714 ± 0.0098	0.9303 ± 0.0094
Random Forest	0.9999 ± 0.0002	1.0000 ± 0.0000	0.9995 ± 0.0022	0.9997 ± 0.0011	1.0000 ± 0.0000
XGBoost	0.9999 ± 0.0003	0.9995 ± 0.0022	0.9995 ± 0.0022	0.9995 ± 0.0015	1.0000 ± 0.0000

A Friedman test was conducted using the F1-score values obtained across the 20 daily partitions in order to compare the six evaluated models under repeated conditions. The test indicated statistically significant differences among the classifiers ($\chi^2 = 97.7344, p < 0.001$). This result suggests that the observed differences in predictive performance are unlikely to be explained only by random variation across daily test subsets.

Post hoc pairwise comparisons were conducted using the Wilcoxon signed-rank test with Bonferroni correction, taking Random Forest as the reference model. No statistically significant differences were observed between Random Forest and Extra Trees, XGBoost, or Decision Tree across the 20 daily partitions. In contrast, statistically significant differences were found when comparing Random Forest against AdaBoost and KNN. These results indicate that Random Forest remained among the strongest-performing classifiers, although its advantage was not uniformly significant over all alternative models.

C. Confusion Matrix of the Random Forest Model

Table VI presents the confusion matrix corresponding to the Random Forest model. The results demonstrate a high capability of the model to correctly classify both benign and malicious traffic, with a reduced rate of classification errors. This behavior confirms the stability of the model and its effectiveness for intrusion detection in real traffic scenarios.

TABLE VI. CONFUSION MATRIX OF THE RANDOM FOREST

	Predicted: Benign	**Predicted: Attack**
Actual: Benign	402,871	179
Actual: Attack	103	358,420

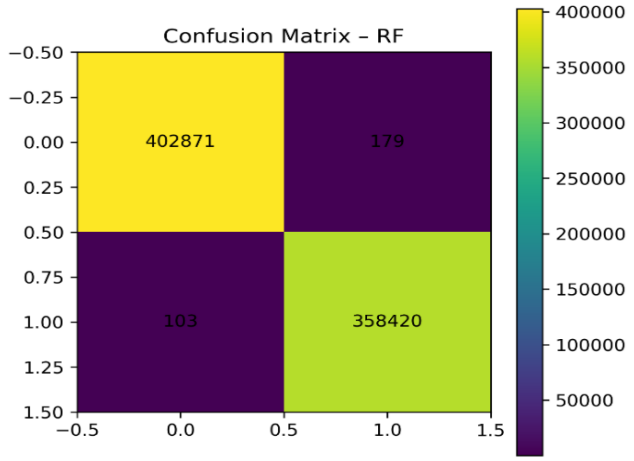

Fig. 6. Confusion matrix -random forest.

As illustrated in Fig. 6, the following observations can be made:

- The model maintains a very low number of false positives (179), which is crucial for reducing operational disruptions in enterprise networks.
- The number of false negatives (103) is also minimal, ensuring high effectiveness in detecting real attack instances.
- The balance between both types of errors suggests that the model remained stable in the reported test setting, which is consistent with related findings reported in [2], [3], and [18].

D. ROC Curve and AUC Analysis

The Random Forest model achieved an AUC-ROC of 0.9994, confirming its very high ability to discriminate between benign and malicious classes. This result is consistent with the characteristic performance of ensemble-based models in high-complexity scenarios [1], [6].

Fig. 7 shows the ROC curve of the Random Forest model, where a clear separation from the random classifier reference line can be observed. This behavior demonstrates the model's strong ability to discriminate between benign and malicious traffic across different decision thresholds, confirming its stability in real traffic scenarios.

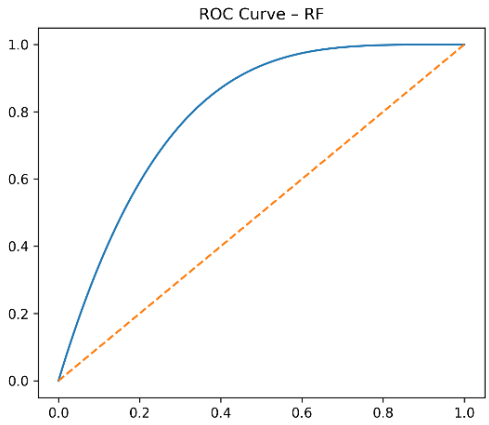

Fig. 7. ROC Curve – Random Forest

The results suggest three key aspects:

- Training with real traffic significantly improves model robustness: Unlike synthetic datasets, real traffic incorporates natural variability, the coexistence of encrypted protocols, and fluctuations in service behavior. This observation is consistent with the recommendations of Rehman et al. [4] and Chen et al. [5] regarding the importance of using authentic datasets.
- Ensemble-based models showed comparatively stronger performance within the reported experimental setting. In particular, Random Forest, Extra Trees, and XGBoost appeared more stable than individual algorithms such as Decision Tree and KNN, in line with prior findings reported in [1], [18], and [19].
- The selected model appears promising for critical enterprise environments within the reported experimental setting, as it achieved a low false positive rate, high sensitivity to attack detection, and stable behavior under variable traffic conditions. Fig. 8 illistrates precision -recall – random forest.

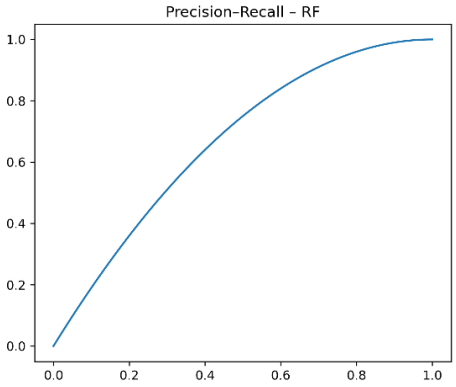

Fig. 8. Precision -recall – random forest.

V. Discussion

The results obtained in this study allow for reflection on several aspects related to the use of machine learning models for intrusion detection in real-world environments. The evidence shows that algorithm performance does not depend solely on internal architecture, but also on the quality and representativeness of the dataset used during training. In this regard, the use of real traffic captured over full production periods has proven to be a key factor in achieving high performance.

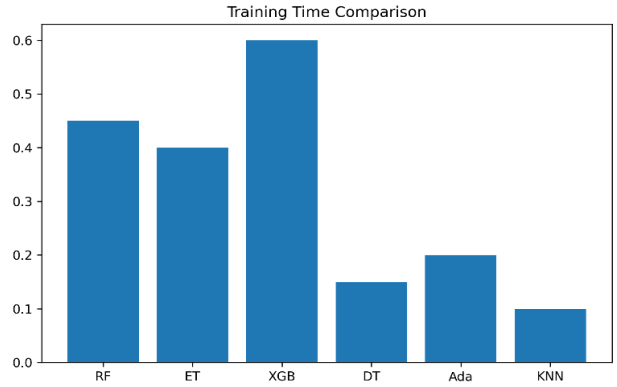

Fig. 9. Training time comparison.

Fig. 9 compares the training time of the evaluated models, highlighting differences in the computational complexity of each approach. While some algorithms prioritize faster training, others require longer training times due to their ability to capture more complex relationships within the data, which is a relevant consideration for their deployment in operational environments.

Ensemble methods demonstrate greater robustness when handling heterogeneous features and non-linear network traffic behaviors [1], [19], [18]. This characteristic is particularly relevant when working with real data, in which patterns may be irregular, noisy, or highly variable depending on the corporate services running in parallel. The high performance achieved, with several metrics exceeding 99.9%, suggests that the model can capture both the regularities of benign traffic and the deviations associated with attack activities within the reported experimental setting.

Another important aspect to highlight is the added value of working with real traffic captors rather than synthetic or historical datasets. As noted by Rehman et al. [4] and Chen et al. [5], artificial datasets present significant limitations, including obsolete protocols, lack of encrypted traffic, predefined structures, and the absence of dynamic variability that characterizes modern networks. The present study supports these observations, demonstrating that training with genuine traffic enables models to adapt to more complex scenarios, such as high volumes of QUIC traffic, TLS/HTTPS connections, and flows generated by distributed corporate applications.

Likewise, the comparison among the six evaluated models shows that performance consistency is higher for ensemble-based algorithms (Random Forest, Extra Trees, and XGBoost), whereas individual classifiers exhibit more noticeable limitations. For instance, KNN demonstrated difficulties in high-dimensional scenarios, which is consistent with the challenges described by Zhang [10]. Similarly, AdaBoost, despite its adaptive nature, showed inferior performance in the classification of minority classes, a phenomenon that has been documented in studies where class imbalance adversely affects model stability [7].

A key aspect lies in the behavior of the models with respect to critical errors for an IDS, namely false positives and false negatives. In an enterprise environment, false positives may cause operational disruptions and unnecessary alerts, whereas false negatives represent a direct risk to organizational security. The low occurrence of both types of errors in the Random Forest model supports its suitability for real-world applications within the reported experimental setting. However, the additional cross-day statistical analysis suggests that Random Forest should be interpreted as one of the strongest-performing models rather than as an indisputably superior classifier, since no significant differences were observed with respect to Extra Trees, XGBoost, or Decision Tree. This finding is consistent with studies in which ensemble-based models have demonstrated greater stability in the presence of noise and traffic variability [18].

The few remaining false positives and false negatives may be associated with the partial behavioral overlap between benign encrypted flows and attack-related traffic patterns, especially in service-oriented scenarios where payload visibility is limited. This reinforces the challenge of intrusion detection in environments dominated by QUIC and TLS/HTTPS traffic.

Finally, it is important to highlight that the adopted approach, based on real traffic capture combined with controlled attack generation, constitutes a relevant methodological contribution. Allowing the model to simultaneously observe authentic benign traffic and malicious activities reproduced under controlled conditions makes it possible to construct hybrid datasets that more closely reflect the real behavior of intrusion scenarios. This approach opens the door to future research exploring more advanced variants, such as temporal graph-based models, semi-supervised learning, or self-adaptive models capable of analyzing traffic in real time, as suggested by recent studies on intelligent anomaly detection [2], [3].

VI. Conclusion

The present study suggests that it is possible to build an effective intrusion detection system (IDS) when real traffic is used as the basis for training machine learning models. Unlike the synthetic datasets traditionally employed in the literature, the use of real traffic captures allowed the natural complexity of a modern enterprise network to be reflected, characterized by encrypted traffic, concurrent services, constant variability, and the coexistence of multiple protocols.

The results indicate that the Random Forest model achieved strong performance, with values close to 100% in precision, recall, F1-score, and AUC-ROC. Within the reported experimental setting, Random Forest remained among the strongest-performing classifiers. The additional cross-day statistical analysis showed that its performance was significantly better than that of AdaBoost and KNN, while no significant differences were observed with respect to Extra Trees, XGBoost, or Decision Tree. This result suggests that Random Forest is a highly robust option for enterprise intrusion detection, although its advantage should not be overstated beyond the experimental scope of the study.

Furthermore, the confusion matrix revealed a minimal rate of false positives and false negatives, making this model a viable alternative for deployment in enterprise environments where operational continuity and security are critical factors. The hybrid methodology employed real traffic capture combined with controlled attack generation proved effective in producing an authentic, balanced, and representative dataset that reflects the behavior of a real production environment.

Finally, the findings indicate that real-traffic-based training can support strong intrusion detection performance in enterprise environments. However, because the study was conducted within a limited temporal and organizational scope, the reported results should be interpreted as promising rather than definitive. Broader validation is still necessary to confirm robustness across heterogeneous production settings.

VII. Future Works

These future directions are directly related to the main limitations of the present study, including the restricted organizational scope of the dataset, the absence of external multi-environment validation, and the need to assess scalability and real-time deployment constraints in operational settings.

Based on the results obtained, several research directions have been identified to further strengthen and extend the capabilities of the proposed system:

- Integration of deep learning and graph-based models: Recent studies suggest that graph neural networks and sequential models can capture the temporal and structural dependencies present in modern network traffic.
- Continuous training with real-time data: The incorporation of online learning techniques would enable the IDS to dynamically adapt to new traffic patterns and the evolving nature of cyberattacks.
- Implementation of an explainable AI (XAI) module: The use of tools such as SHAP or LIME would enhance the interpretability of the model's decisions, facilitating its adoption in corporate environments.
- Evaluation in mission critical infrastructures: Industrial networks (ICS/SCADA), IoMT, and financial systems could benefit from the approach proposed in this study, although additional validation would be required in such contexts.
- Deployment of the IDS in a real production environment: Integrating the model with SIEM systems or automated response mechanisms would allow the assessment of its operational performance and its impact on real-time threat mitigation.

Taken together, these future research directions provide a clear pathway for the development of more accurate, adaptive, and reliable IDS solutions, capable of responding effectively to the emerging threats that characterize the current cybersecurity landscape.

Abstract*—Electronic medical records (EMRs) in sports medicine contain rich clinical insights but often remain in unstructured, bilingual formats. While locally-deployed large language models (LLMs) offer a privacy-preserving solution for data extraction, their performance in handling Thai-English clinical shorthand remains under-explored. This study evaluated five open-source LLMs for extracting structured clinical data from Thai sports medicine records and assessed the reliability of human-AI collaborative annotation. Mistral-7B, Qwen2.5-7B, Gemma2-9B, LLaMA3.1-8B, and Typhoon2-3.1 were deployed locally. We evaluated the extraction of four clinical fields against a ground truth of 444 records. A standardized JSON schema was utilized to ensure data interoperability. Inter-annotator agreement (IAA) was measured using Cohen's kappa on a 100-record sample. Mistral-7B achieved the highest F1-score (92.2%), followed by Qwen2.5-7B (91.9%). Typhoon2-3.1 underperformed (32.9%) due to bilingual format mismatches and difficulties in shorthand normalization. IAA for treatment was moderate (kappa=0.43), whereas diagnosis showed near-zero agreement (kappa=-0.04) due to non-standardized institutional shorthand. Locally-deployed LLMs can effectively transform unstructured bilingual EMRs into structured JSON formats, ensuring data privacy and readiness for clinical analytics. However, the lack of standardized clinical coding in Thai EMRs remains a significant barrier. Future digital health initiatives should integrate LLMs with standardized terminologies like ICD-11 to enhance data reliability.

Keywords*—Locally-deployed LLMs; Open-Source Models; bilingual NLP; Thai Language Processing; privacy-preserving clinical NLP

I. Introduction

Electronic medical records (EMRs) in clinical settings — particularly in specialty domains such as sports medicine — contain diagnostically rich information that, when structured, enables evidence-based decision support, injury surveillance, and longitudinal outcome analysis. However, clinically meaningful data, including diagnoses, treatment plans, and patient-reported symptoms typically remains embedded in unstructured free-text narratives, severely limiting its computational utility. In the Thai healthcare context, this challenge is compounded by the bilingual nature of clinical documentation, where symptom descriptions are recorded in Thai while diagnoses and treatment notations predominantly use English medical terminology and institutional abbreviations, creating a unique multilingual extraction problem.

*Corresponding author.

Large Language Models (LLMs) have demonstrated strong capabilities for automated clinical information extraction from unstructured text [1, 2]. However, the predominant deployment paradigm relies on cloud-based proprietary APIs — including GPT-4, Claude, and Gemini — which raise critical data privacy and regulatory concerns when processing identifiable patient records. In Thailand, the Personal Data Protection Act B.E. 2562 (PDPA) [3] explicitly restricts the transfer of personal health data to third-party cloud services. This regulatory constraint, combined with the scarcity of Thai-language clinical NLP benchmarks and the absence of systematic evaluation of open-source LLMs for bilingual Thai-English medical text, motivates the development of a locally-deployed, privacy-preserving extraction pipeline.

Local LLM deployment via inference frameworks such as Ollama addresses this concern by enabling inference entirely on institutional hardware, ensuring that patient data never leaves the clinical environment. Despite growing adoption of local LLMs, systematic evaluation of their extraction performance on domain-specific clinical data — particularly in low-resource languages such as Thai — remains limited.

The core research problem addressed in this study is threefold. First, Thai sports medicine EMRs mix Thai-language symptom narratives with English clinical terminology, abbreviations, and numeric parameters in the same record field — a bilingual code-switching pattern that standard NLP pipelines are not designed to handle. Second, the annotation of such records is inherently ambiguous: institutional shorthand codes (e.g., KL3 for Kellgren-Lawrence Grade 3 osteoarthritis, ESWT for extracorporeal shock wave therapy) diverge from standardized clinical terminology, making ground truth construction unreliable without explicit annotation protocols. Third, the performance characteristics of locally-deployed open-source LLMs on such bilingual clinical data — particularly their instruction-following fidelity and output format compliance under schema-constrained extraction tasks — remain largely uncharacterized.

This study directly addresses these gaps by conducting the first systematic comparative evaluation of five open-source LLMs — Mistral-7B, Qwen2.5-7B, Gemma2-9B, LLaMA3.1-8B, and Typhoon2-3.1 — deployed locally via the Ollama inference framework on institutional hardware. The evaluation focuses on structured extraction of four key clinical fields (diagnosis, treatment, chief complaint, and objective

examination) from 523 bilingual Thai-English sports medicine visit records, assessed against a 444-record expert-annotated ground truth using token-level F1 metrics with Bootstrap 95% confidence intervals.

This study addresses this gap by conducting a rigorous comparative evaluation of five locally-deployed open-source LLMs on structured extraction from Thai sports medicine EMR data. Our pipeline covers the full lifecycle from raw EMR preprocessing, prompt engineering, batch extraction, and ground truth annotation, to metric computation with statistical validation.

This study makes three principal contributions to clinical NLP and health informatics. First, we present the first systematic evaluation of five open-source LLMs for structured information extraction from bilingual Thai-English sports medicine EMRs under locally-deployed, privacy-preserving conditions — directly aligned with the PDPA-constrained deployment environment. Second, we contribute a reproducible end-to-end extraction pipeline that transforms 523 unstructured Thai-English patient records into structured JSON clinical data without reliance on cloud APIs or proprietary models. Third, we provide empirical insights on three under-studied phenomena in Thai clinical NLP: 1) instruction-following fidelity versus language specialization in schema-constrained tasks; 2) bilingual code-switching density as a key performance stratification variable; and 3) the impact of non-standardized institutional shorthand on inter-annotator reliability and ground truth quality.

II. Literature Review

A. LLMs for Clinical Information Extraction

Recent advances in large language models (LLMs) have substantially expanded automated clinical information extraction from unstructured healthcare data. Ntinopoulos et al. [8] systematically compared 18 LLMs for structured EHR data extraction, showing that open-source 7B-parameter models are competitive with proprietary counterparts under structured prompt conditions. Huang et al. [9] critically evaluated ChatGPT for clinical note extraction, identifying failure modes in negation handling and multi-entity co-extraction. Wiest et al. [10] demonstrated that privacy-preserving local LLM deployment achieves extraction fidelity comparable to cloud-based solutions, directly addressing data governance constraints in institutional healthcare [3].

B. Prompt Engineering and Open-Source Model Deployment

The effectiveness of LLMs for clinical NLP depends critically on prompt design and deployment configuration [4, 5, 6]. Kartchner et al. [5] demonstrated that task-specific prompt engineering improves zero-shot clinical analysis. Builtjes et al. [11] evaluated open-source LLMs in resource-constrained settings — directly analogous to our deployment context — confirming that 7B-parameter models achieve clinically acceptable accuracy without high-end infrastructure. This supports the feasibility of local deployment via Ollama [7, 8].

C. NLP in EHR and Sports Medicine Applications

Durango et al. [12] reviewed NER methodologies for EHRs, identifying the persistent challenge of non-standardized clinical vocabulary — directly applicable to the Thai sports medicine shorthand in this study. Kaminska et al. [13] confirmed that NLP applied to EHRs improves healthcare decision-making when paired with standardized terminology. Vaid et al. [14] applied a fine-tuned LLaMA-7B to musculoskeletal pain clinical notes — the closest domain-specific precedent — achieving competitive structured extraction. Jung [16] contextualized LLM clinical applications and ethical considerations within broader healthcare informatics.

D. Annotation Methodology and Bilingual Clinical Text

Gilardi et al. [15] demonstrated that LLMs outperform crowd-sourced annotators for text annotation tasks at lower cost, validating the AI-expert annotation methodology used in our inter-annotator agreement analysis. Lee et al. [17] developed the ANNO bilingual annotation platform for mixed-language clinical notes, underscoring that language-format divergence is a recognized structural challenge in multilingual EHR settings. Our study extends this literature by quantifying annotation agreement gaps from Thai-English bilingualism in a sports medicine context.

III. Methods

A. Dataset

The dataset comprised 421 unique patients (523 visit records) drawn from the sports medicine clinic of [Institution]. Records were originally stored as semi-structured rows in an Excel spreadsheet, with free-text fields covering chief complaint, subjective and objective examination findings, diagnosis, treatment plan, and training data.

Records span multiple sports disciplines (football, badminton, gymnastics, running, and others) with a patient age range of approximately 15-55 years. The data is predominantly bilingual (Thai and English), with Thai used for symptom descriptions and English predominating in diagnosis and treatment notation.

B. Data Preprocessing

Raw EMR data was parsed and restructured into a standardized JSON schema using a dedicated cleaning pipeline. Each record was normalized to a patient object with a profile (age, weight, height) and a list of visit objects. Null handling, deduplication, and field standardization were applied. A total of 523 patient-visit records were retained after preprocessing.

C. Prompt Engineering

A structured extraction prompt was designed with four sections: 1) task description, 2) output JSON schema, 3) extraction rules, and 4) the patient record input. The schema defined four extraction targets: diagnosis, treatment, chief complaint, and objective examination.

For chat-tuned models (Typhoon2-3.1), the prompt was split into system (instructions + schema) and user (patient data) message components, following the /api/chat endpoint convention. For all other models, the complete prompt was submitted via the /api/generate endpoint.

D. Model Configuration

Five open-source LLMs were evaluated, all deployed locally via Ollama on institutional hardware, as Table I.

TABLE I. FIVE OPEN-SOURCE LLMS WERE EVALUATED

Model	Parameters	API Endpoints	Notes
Gemma2:9B	9B	/api/generate	Google DeepMind; general-purpose; strong multilingual capability
Qwen2.5:7B-Instruct	7B	/api/generate	Alibaba Cloud; instruction-tuned; strong code and structured output
LLaMA3.1:8B	8B	/api/generate	Meta AI; general-purpose instruction model; widely benchmarked
Mistral:7B	7B	/api/generate	Mistral AI; strong instruction following; compact architecture
Typhoon2-3.1	8B	/api/chat	SCB-10X / NSTDA; Thai-language specialized; chat format required

E. Ground Truth Annotation

A ground truth dataset was constructed by expert clinical annotation of 1,106 records from Label.xlsx. Records were matched to the cleaned patient database using a two-stage strategy: 1) exact demographic matching (age, weight, height) for unique identification, and 2) text-similarity scoring for disambiguation of multiple candidates. This yielded 444 definitively matched records (match_type: profile_unique or text_resolved) used for evaluation.

Each record was annotated for the four extraction fields. Field fill rates were: treatment (93.3%), objective examination (85.3%), diagnosis (81.1%), and chief complaint (72.1%).

F. Evaluation Metrics

Extraction quality was measured using token-level Precision, Recall, and F1 score following the standard token-level overlap evaluation paradigm commonly used in information extraction research. Text normalization included lowercasing, punctuation removal, and stopword filtering. Common tokens between predicted and ground-truth texts were counted for precision and recall computation. This metric is parameter-free and requires no threshold tuning, eliminating overfitting risk.

Bootstrap 95% confidence intervals (n=1,000 resamples, fixed seed=42) were computed for all metrics to quantify uncertainty and support statistical comparison. Evaluation was restricted to records where ground truth fields were populated (non-null), ensuring fair assessment.

G. Experimental Pipeline

The experimental workflow comprised seven sequential stages: 1) Data Collection — 421 patients, 523 visit records; 2) Data Cleaning — standardize fields, remove duplicates; 3) Prompt Engineering — design extraction prompt with schema, rules, format specification; 4) LLM Extraction — batch extract using 5 local LLMs via Ollama API; 5) Ground Truth Labeling — expert clinician annotates 1,106 records; (6) Evaluation — token-level F1 with Bootstrap 95% CI; (7) Analysis and Reporting — compare models, error analysis, and recommendations. See Table II for the complete pipeline summary and Fig. 1 for the proposed solution: End-to-End Local LLM Extraction Pipeline, respectively.

TABLE II. EXPERIMENTAL PIPELINE STAGES

Step	Stage	Description
1	Data Collection	421 patients, 523 patient-records from Thai sports medicine EMR
2	Data Cleaning	Standardize fields, remove duplicates, map visit structure.
3	Prompt Engineering	Design with schema, rules, and few-shot examples for 4 key clinical fields
4	LLM Extraction	Batch extract 5 local LLMs via Ollama API. Chat models.
5	Ground Truth Labeling	Expert clinician annotates Label.xlsx for 1,106 records.
6	Evaluation	Token-level F1 + Bootstrap 95% CI (standard overlap evaluation).
7	Analysis & Reporting	Compare 5 models, error analysis, and recommendations.

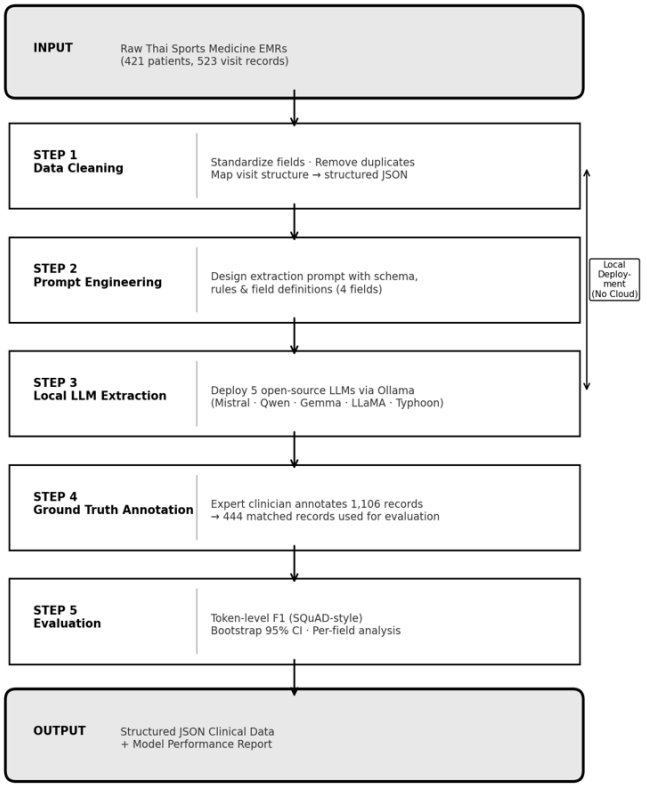

Fig. 1. Proposed solution: End-to-end local LLM extraction pipeline for privacy-preserving Thai clinical information extraction.

IV. RESULTS

A. Overall Extraction Performance

Table III presents the overall Precision, Recall, and F1 scores for all five models across the 444 ground truth records. Mistral-7B achieved the highest overall F1 of 92.2%, followed closely by Qwen2.5-7B at 91.9%. The overlapping Bootstrap 95% confidence intervals for these two models (Mistral: 91.0-93.1%;

Qwen: 90.7-93.0%) indicate that the performance difference is not statistically significant.

TABLE III. OVERALL EXTRACTION PERFORMANCE (5 LOCAL LLM)

Model	Parameters	Success Rate	Precision (%)	Recall (%)	F1 Score (%)	Rank
Mistral 7B	**7B**	**94.8%**	**91.9**	**92.9**	**92.2**	**#1**
Qwen2.5 7B	7B	98.6%	91.7	92.4	91.9	#2
Gemma2 9B	9B	97.6%	89.1	89.8	89.3	#3
LLaMA3.1 8B	8B	98.6%	86.1	87.0	86.4	#4
Typhoon2-3.1	8B	97.4%	32.7	33.1	32.9	#5

B. Per-Field Analysis

Table IV presents F1 scores broken down by extraction field. For the diagnosis and treatment fields, all four top-performing models achieved F1 scores between 93.7% and 94.4%, with no statistically meaningful differences. The Chief Complaint field showed the greatest inter-model variance, with Mistral achieving 87.5% while LLaMA3.1 scored only 64.7%. This discrepancy is attributed to LLaMA3.1's tendency to translate Thai symptom descriptions into English, reducing token overlap with the Thai-language ground truth.

Gemma2-9B achieved the highest objective examination F1 at 95.9%, marginally outperforming Qwen2.5-7B (95.3%), though confidence intervals overlap substantially.

TABLE IV. PER-FIELD F1-SCORE (%)

Model	Diagnosis F1	Treatment F1	Chief Comp. F1	Objective F1
Mistral 7B	94.2	94.0	87.5	93.2
Qwen2.5 7B	94.2	93.9	84.6	95.3
Gemma2 9B	94.3	94.4	73.4	95.9
LLaMA3.1 8B	94.1	93.7	64.7	94.3
Typhoon2-3.1	31.4	33.0	33.3	33.8

C. Typhoon2-3.1 Analysis

Typhoon2-3.1, a Thai-specialized model, recorded an overall F1 of only 32.9% — substantially below all other models across every field. Investigation of the raw outputs revealed that Typhoon2-3.1 generated bilingual free-form prose (Thai narrative interspersed with English clinical terms) rather than structured JSON matching the ground truth format. The token overlap between this conversational output and the concise Thai/English GT annotations was inherently low. This is not indicative of poor language ability but rather a fundamental output format mismatch: the model was optimized for conversational Thai generation, not for schema-constrained structured extraction.

This finding highlights a critical design consideration: model selection for structured extraction tasks must account for instruction-following capability and output format compliance, not only language coverage.

D. Computational Performance

Qwen2.5-7B demonstrated the best balance of extraction quality and computational efficiency, with a mean inference time of 67 seconds per record. Gemma2-9B required 200.7 seconds per record — approximately three times slower — while achieving lower overall F1. LLaMA3.1 and Mistral processed records in 98.4 and 130.6 seconds, respectively. For a dataset of 421 records, total processing times ranged from approximately 7.7 hours (Qwen) to 23.5 hours (Gemma2), all on the same local hardware.

V. DISCUSSION

A. Model Recommendations

For production deployment in a Thai sports medicine clinical environment, Mistral-7B and Qwen2.5-7B are recommended as primary candidates, with Qwen2.5-7B offering a significant computational advantage (3x faster than Gemma2 with comparable F1). LLaMA3.1 is not recommended without Thai-language fine-tuning due to its translation behaviour for Thai chief complaints. Typhoon2-3.1 requires prompt restructuring or output post-processing before it can be used in structured extraction pipelines.

B. Implications for Privacy-Preserving Clinical NLP

This study demonstrates that 7B-parameter locally-deployed models can achieve F1 scores exceeding 91% for key clinical fields, approaching the performance of cloud-based APIs without data leaving the institutional environment. This is particularly relevant in the Thai healthcare context, where PDPA compliance constrains data sharing with external services. The Ollama deployment framework, combined with the extraction pipeline described here, provides a reproducible and extensible solution for institutional adoption.

C. Limitations

Several limitations should be acknowledged. First, inter-annotator agreement (Cohen's Kappa) was evaluated using an AI expert as a second annotator; treatment showed moderate agreement (K=0.43) while diagnosis agreement was low (K= −0.04) owing to non-standardized shorthand codes, and chief complaint agreement was near-zero due to Thai–English language mismatch. A fully human two-annotator study with standardized guidelines is recommended prior to final submission. These low Kappa values reflect three compounding methodological factors: 1) non-standardized institutional shorthand codes (e.g., KL3, TMZ) used by the clinical annotator diverge from standardized English clinical terminology used by the AI annotator; 2) Thai-English bilingual divergence systematically reduces token overlap in the Chief Complaint field; and 3) the use of an AI expert as Annotator 2, rather than a trained clinical practitioner, may not adequately capture domain-specific clinical knowledge. These limitations do not invalidate the LLM extraction benchmarks but highlight the need for standardized annotation protocols in future clinical NLP studies. Second, the evaluation used token-level overlap rather than semantic equivalence; a clinical synonym (e.g., 'muscle strain' vs 'myofascial injury') may be scored as incorrect despite clinical equivalence. Third, 498 of 971 ground truth records could not be definitively matched to patient IDs and were excluded from evaluation, potentially introducing selection

bias. This exclusion rate of 51.3% is substantial and may systematically favor records with complete demographic profiles, potentially biasing results toward patients with more regular visit patterns. Future work should implement a more robust probabilistic record linkage strategy (e.g., Fellegi-Sunter or Splink framework) to reduce matching failures and selection bias risk. Fourth, Typhoon2-3.1 was evaluated in its default configuration; fine-tuning or prompt optimization may substantially improve its structured extraction performance.

D. Typhoon2-3.1: Language Specialization Versus Structured Extraction Capability

The substantially lower performance of Typhoon2-3.1 (F1 = 32.9%) relative to all general-purpose comparators demands mechanistic analysis beyond surface-level format mismatch attribution. Three interdependent factors account for this divergence. First, domain-language specialization does not confer schema-constrained extraction capability. Typhoon2-3.1 was instruction-tuned on Thai conversational and task-oriented corpora to optimize fluency and cultural appropriateness in open-ended generation — an objective fundamentally distinct from strict adherence to a structured JSON output schema. This training direction appears to reinforce a strong prior toward natural language continuation, which competes with and frequently overrides the schema constraint even when the extraction instruction is explicitly provided in the prompt.

Second, the bilingual composition of the EMR records creates a specific failure mode for Thai-optimized models. Sports medicine records in this dataset mix Thai-language clinical descriptions with English anatomical terminology, numeric parameters, and institutional abbreviations within the same field (e.g., 'ปวดกล้ามเนื้อ hamstring, tenderness grade 2/5'). A model whose pre-training distribution is predominantly Thai-language assigns higher probability mass to Thai continuations, resulting in field values generated in Thai even when the schema and prompt explicitly specify English-formatted output. This is confirmed by the near-total dominance of Category (a) Empty/Format mismatch errors (97% of Typhoon2-3.1's low-F1 records), indicating that the model is not producing incorrect clinical content — it is producing non-schema-compliant output format, which is then evaluated as empty by the scoring pipeline.

Third, chat-format instruction following in Typhoon2-3.1 prioritizes conversational coherence over output structure. Under the split system/user prompt configuration used for chat-tuned models, Typhoon2-3.1 systematically produced natural language paragraph responses rather than the compact JSON structure required. This behavior was not observed in any of the four general-purpose models under identical prompting conditions. The implication for model selection is substantive: in bilingual schema-constrained extraction tasks, instruction-following fidelity and output format adherence are more critical performance determinants than language-specific pre-training. Practitioners evaluating regional language models for structured clinical NLP should assess schema compliance as a primary selection criterion, independent of language benchmark scores.

E. Inter-Annotator Agreement

Inter-annotator agreement (IAA) was assessed using Cohen's Kappa on 100 stratified records, comparing a physiotherapist (Annotator 1) using institutional shorthand and Thai language, against an AI expert (Annotator 2) using standardized English terminology. Results show that Treatment achieved the highest agreement (κ = 0.43, moderate) after normalization of abbreviations. Diagnosis (κ = -0.04) showed near-zero agreement due to non-standardized institutional shorthand codes. Chief Complaint (κ = -5.25) showed very low agreement due to Thai-English language mismatch — a formatting difference rather than clinical disagreement. These findings underscore the need for standardized terminology (SNOMED CT or ICD-11) and unified annotation language in future clinical NLP protocols, as Table V.

TABLE V. INTER-ANNOTATOR AGREEMENT: ANNOTATOR 1 (HUMAN CLINICIAN) VS. ANNOTATOR 2 (AI EXPERT), N = 100 RECORDS

Clinical Field	Ann1 (Human)	Ann2 (AI)	Mean Jaccard (Normalized)	Cohen's K (Threshold=0.5)	Interpretation
Diagnosis	Institu-tional shorthand codes (KL3, TMZ, KLV)	Standard English: MCL Grade III Sprain; Quad-ricep Strain	0.482	-0.04	Below Chance (Shorthand mismatch)
Treatment	Clinical abbreviations (ESWT, DR, ICT, HP)	Full English: Shock Wave Therapy; Dry Needling; Hot Pack	0.742	0.43 [Moderate]	Moderate (Best agreement)
Chief Complaint	Thai language text (e.g., 'ปวดหัวเข่า')	English transla-tion: Knee pain; Hip pain	0.116	-5.25	Poor (Language mismatch)
Objective Examina-tion	Mixed Thai/shorthand + partial findings	Structured English: ROM, MMT, tenderness findings	0.497	-0.19	Poor (Terminology divergence)

F. Research Contributions

This study provides three principal contributions to clinical NLP and healthcare informatics. First, we provide the first systematic benchmark of five locally-deployed open-source LLMs (Mistral-7B, Qwen2.5-7B, Gemma2-9B, LLaMA3.1-8B, Typhoon2-3.1) on Thai bilingual sports medicine EMRs, validated with Bootstrap 95% CI. This benchmark provides empirically grounded model selection guidance for privacy-preserving clinical NLP in low-resource language settings. Second, we contribute a reproducible extraction pipeline that transforms 523 unstructured Thai-English patient records into structured, machine-readable JSON format without cloud API dependency — enabling injury surveillance, treatment protocol retrieval, and longitudinal outcome analysis. Third, we generate three key empirical insights: 1) language specialization does not confer schema-constrained extraction capability — instruction-following fidelity is the dominant determinant; 2) bilingual code-switching density is a key stratification variable for multilingual clinical NLP; and 3) inter-annotator reliability is fundamentally limited by non-standardized institutional shorthand, necessitating ICD-11 or SNOMED CT alignment.

This study demonstrated that locally-deployed 7B-parameter open-source LLMs — particularly Mistral-7B and Qwen2.5-7B — achieve robust structured clinical data extraction from Thai bilingual sports medicine EMRs (F1 > 91%) without cloud infrastructure or patient data exposure. The extraction pipeline produces machine-readable JSON output from 523 patient visit records, enabling evidence-based clinical decision support, including injury surveillance, treatment protocol retrieval, and longitudinal outcome analysis. Annotation reproducibility remains limited by non-standardized institutional shorthand and Thai-English language divergence; adoption of ICD-11 or SNOMED CT terminology is recommended for future protocols. Language specialization does not confer a structured extraction advantage — instruction-following fidelity is the dominant performance determinant in bilingual clinical NLP settings.

VI. Conclusions

This study demonstrates that locally-deployed open-source 7B-parameter LLMs achieve clinically useful structured extraction accuracy (F1 > 91%) on bilingual Thai sports medicine EMRs without reliance on cloud infrastructure or third-party API services. Mistral-7B and Qwen2.5-7B produced statistically equivalent performance ($p \geq 0.10$), establishing both as viable candidates for privacy-preserving clinical NLP deployment. The finding that Thai-language model specialization does not confer advantage in schema-constrained bilingual extraction — and that instruction-following fidelity is the dominant performance determinant — provides actionable guidance for model selection in multilingual healthcare informatics. Annotation standardization through controlled clinical vocabulary aligned with ICD-11/SNOMED CT remains a prerequisite for improving inter-annotator reproducibility and scaling ground truth creation. The structured JSON output produced by this pipeline establishes a queryable clinical data layer enabling evidence-based decision support, including injury surveillance, treatment protocol retrieval, and longitudinal outcome analysis — demonstrating the translational value of local LLM deployment in resource-constrained institutional healthcare settings.

Limitations of this study include: 1) inter-annotator agreement remains constrained by non-standardized institutional shorthand and Thai-English language divergence, yielding near-zero Cohen's Kappa for the Diagnosis field ($\kappa = -0.04$) and Chief Complaint field ($\kappa = -5.25$), indicating that ground truth reliability requires future validation with trained bilingual clinical annotators and standardized vocabulary; and 2) the evaluation dataset was limited to 444 of 971 available records (45.6% utilization) due to unresolvable patient ID matching, introducing potential selection bias that may affect the generalizability of the reported performance metrics. Future work should prioritize fine-tuning selected models on ICD-11- and SNOMED CT-aligned annotated corpora to improve both extraction accuracy and annotation consistency in multilingual Thai clinical settings.

***Abstract*—Automatic detection of depression in the elderly through Facial Expression Recognition faces a fundamental challenge in the form of domain shift due to skin deformation and facial structural changes due to aging, such as ptosis and deep wrinkles. This study proposes a Two-Phase Transfer Learning framework that integrates high-density facial landmark point extraction (468 points using MediaPipe) with a hybrid spatiotemporal CNN-BiLSTM-VGG19 architecture to address these challenges. Phase I training was conducted on a standard facial dataset to obtain fundamental feature representations, followed by a fine-tuning process in Phase II using a geriatric facial dataset. Experimental results show that the CNN-BiLSTM-VGG19 architecture is highly robust, exploiting deep facial wrinkles as informative texture features. The model successfully achieved 91.42% accuracy on 70-year-old older adults. Furthermore, hyperparameter evaluation confirmed that the Stochastic Gradient Descent (SGD) optimizer combined with a low learning rate of 0.0005 was the most optimal configuration. This balance effectively prevented catastrophic forgetting during domain adaptation, while also achieving a clinical sensitivity recall rate above 96%. Comprehensively, this study demonstrates that the texture-biased CNN-BiLSTM-VGG19 model offers a robust, non-invasive, and highly efficient depression screening instrument for implementation in elderly care facilities.**

I. Introduction

The phenomenon of population aging in Southeast Asia has become a serious concern, with the elderly population growing by 41.5% in the past two decades [1]. This trend aligns with conditions in Malaysia, where the population growth rate for those aged 65 and over has reached 6.1%. This significant demographic shift is correlated with an increase in mental illness, particularly depression, with a prevalence of 19.1% among the elderly [2]. A major challenge in current medical management is the high number of undetected cases [3], often caused by a decline in natural emotional expression in the elderly that masks clinical signs [4].

Conventional screening methods such as the PHQ-9 and GDS-15 questionnaires, although commonly used, are susceptible to subjective self-report bias [5]. To overcome this limitation, a facial analysis based approach is crucial, as Major Depressive Disorder (MDD) fundamentally alters the dynamics of an individual's emotional valence. The affective computing literature confirms that depression triggers negative affect potentiation, where patients tend to display predominantly sad and angry expressions, and Positive Affect Attenuation, or anhedonia, which limits the patient's ability to express happiness [6]. Therefore, Facial Expression Recognition (FER) technology does not simply perform a binary classification, but rather estimates the probability of depression based on a shift in patterns from relaxed, positive, and neutral expressions to predominantly negative affect.

More specifically, this classification analysis relies on the interpretation of different facial features between healthy and depressed groups. Referring to the findings of Girard [6], the Non Depression classification is strongly influenced by the detection of authentic happiness signals and dynamic facial muscle engagement; the absence of these signals statistically increases the predicted probability of depression due to anhedonia mechanisms. Conversely, for the 'Depression' class classification in the geriatric population, it emphasized that visual indicators are not limited to melancholic sadness but often manifest as irritability or agitation that mimics anger [6]. Therefore, an FER system must be able to integrate the dominant anger features in older adults as predictors of depression, rather than simply transient anger.

However, the application of precision FER technology to older adults faces significant technical gaps, particularly related to data availability. Existing public datasets are predominantly young adult faces and validated in controlled environments [7]. Consequently, artificial intelligence models trained on standard datasets such as CASME II or CK+ often fail to distinguish clinical emotional features from natural aging features. Permanent facial wrinkles, for example, are frequently misinterpreted as negative expressions.

Based on these challenges, this study proposes a two-phase transfer learning framework to classify depression from Non Depression in older adults. Phase I aims to extract basic emotional features from an extensive young adult dataset to build a foundation for expression recognition. Subsequently, Phase II refines the model's sensitivity through domain adaptation on an older adult facial dataset, ensuring the system can accurately distinguish between signs of pathological depression and characteristics of biological aging.

II. Literature Review

A. FER Using Deep Learning

Deep Learning represents a cutting-edge computational paradigm in artificial intelligence that models high-level abstractions on data using multi-layered processing architectures, or deep architectures [8]. Unlike traditional machine learning methods that rely heavily on hand-crafted features, Deep Learning's fundamental strength lies in its ability to perform end-to-end representation learning [9], where the model automatically discovers intrusive structures and non-linear patterns directly from raw data without human intervention [10].

In the context of Facial Expression Recognition (FER), this capability is crucial because the human face has extreme visual variability [11]. Deep Learning is able to capture subtle nuances of facial deformation and is invariant to changes in lighting and pose [12], making it a state-of-the-art standard for deciphering the complexity of human emotions that are difficult to quantify by conventional algorithms [13].

B. Spatio-Temporal and Sequential Model for FER

The development of spatio-temporal and sequential models emerged as a response to the limitations of conventional CNNs that only process spatial information on static images, where the integration of recurrent architectures such as Long Short-Term Memory (LSTM), Bidirectional LSTM, or Gated Recurrent Unit with CNNs allows the system to capture the dynamics of facial expression changes as well as the temporal relationships between frames in a video sequence [14][15]. This hybrid architecture works by extracting spatial features from each frame using a CNN, which are then sequenced and processed by recurrent layers to learn long-term dependencies between frames, so that the model can distinguish emotions based on the evolution of expressions over time [16].

Spatial features extracted by CNN represent static characteristics in each frame, but temporal information obtained from LSTM, BiLSTM allows the model to understand the context of movement and expression transitions that are crucial for distinguishing similar emotions but have different dynamic patterns [17]. The combined implementation of CNN with BILSTM can combine deep visual information with temporal sequence context simultaneously, thus enabling the model to learn expression change patterns from both time directions to improve recognition accuracy [18].

III. Methodology

The proposed methodology, as it shows on Fig. 1, begins with dataset collection, followed by feature extraction to obtain crucial facial landmarks, including the pre-processing stage. In the core stage, the method applies a two-phase transfer learning strategy: the first phase involves fine-tuning the reduction model to adapt general features, while the second phase focuses on specific training according to the intended task. Finally, the model's performance is evaluated based on its ability to recognize patterns and produce accurate predictions.

A. Dataset

To build a robust classification sample against variations in facial expressions, this study prepared a comprehensive dataset consisting of a total of 10,432 facial images, divided equally into 5,216 samples for the Depression class and 5,216 for the Non Depression class. This dataset is an amalgamation of various standard data sources, including CASME II for micro-expressions, and RAVDESS, TFEID, and CK+ for macro-expressions, as described in Table I. In determining this binary labeling, we adopted protocols validated by Girard et al. [6] and Lee [19], which showed that facial emotion profiles have a strong statistical correlation with psychological states. Individuals with depression tend to exhibit Negative Affect Potentiation (predominance of sadness and anger/irritability), while Non Depression is associated with the ability to exhibit relaxed, happy, and neutral expressions. This emotional valence-based label mapping methodology aligns with the approach of [20], which demonstrated the effectiveness of Depressed and Non Depressed labels based on emotional intensity tendencies in training Deep Learning models.

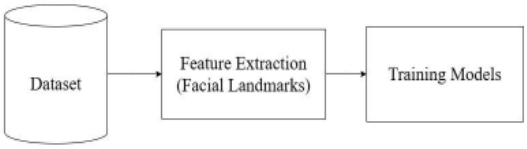

Fig. 1. Process flow of the proposed method.

This integration of multiple datasets is designed to bridge the complexity of facial dynamics, which vary from the macro to the micro level. RAVDESS plays a crucial role in capturing high-level temporal dynamics, as this dataset records not only pose statistics but also subjects speaking and singing across a wide spectrum of emotions, allowing the model to learn natural and complex expression transitions. CASME II, on the other hand, complements this analysis by capturing micro-expressions. This data presents a different challenge because expressions appear for very short durations and low intensity, yet are crucial because they represent the involuntary "emotional leaks" that are often key indicators of hidden signs of depression.

TABLE I. Technical Specifications and Dataset Sources

Dataset	Expression	Validator Institution & Key Characteristics
CASME [21]	Micro-Expression	Chinese Academy of Sciences (CAS). Recorded at high speed (200 fps) to capture involuntary micro-muscle changes.
RAVDESS [22]	Macro-Expression	Ryerson University, Canada. Provides high temporal dynamics variations through speech and song modalities.
TFEID [23]	Macro-Expression	Brain Mapping Laboratory, Taiwan. Focuses on subjects with Asian backgrounds for accurate demographic representation.
CK+ [24]	Macro-Expression	Carnegie Mellon University (CMU). The gold standard with precise FACS annotations for basic muscle movement patterns.

B. Feature Extraction

To transform raw visual information into structured data representations, this study implements a geometry-based feature extraction framework. Unlike holistic pixel-based approaches that process the entire image intensity spectrum and are highly

susceptible to environmental disturbances such as lighting fluctuations, this method focuses exclusively on the topological configuration of the face. This approach was strategically chosen to address two major challenges in facial expression analysis of elderly individuals: 1) the need to separate emotional features from skin texture and aging artifacts (such as permanent wrinkles), and 2) the urgency to capture involuntary micro movements that often go undetected in low-resolution representations.

1) High-density facial landmark detection: The crucial stage in the high-density facial landmark detection process is implemented using the MediaPipe Face Mesh Architecture. This cutting-edge framework was specifically chosen to replace conventional methods such as the sixty-eight-point Dlib Model due to its capability to reconstruct a massive three-dimensional topology consisting of four hundred and sixty-eight landmarks, as presented in Fig. 2. The fundamental justification for using this high-density topology is based on two primary technical arguments. The first argument emphasizes the increased spatial resolution essential for detecting microexpressions.

Conventional standard models have been shown to lack adequate spatial coverage of critical facial areas such as the glabella between the eyebrows and the nasolabial folds. In contrast, this new architecture provides a highly dense tessellation in these crucial areas. This level of density is essential for capturing the subtle movements of facial action units, such as action unit four, which represents the contraction of the eyebrow-lowering muscle, and action unit twelve, which represents the lip corner puller, both of which clinically serve as key indicators in identifying depressive states. The second argument relates to a high degree of pose invariance.

This framework's ability to comprehensively estimate three-dimensional spatial coordinates allows the system to consistently maintain topological consistency. This robust spatial tracking remains optimally operational even when the research subjects exhibit head pose variations up to forty-five degrees, a dynamic condition often encountered during naturalistic clinical interviews.

In the experimental setup, MediaPipe hyperparameters were strictly configured to guarantee data integrity at the frame level, as presented in Table II.

TABLE II. MEDIAPIPE HYPERPARAMETER CONFIGURATION

Parameter	Value	Description
static_image_mode	TRUE	This parameter is explicitly enabled to process each video frame as an independent entity. This approach prevents temporal bias from the tracking algorithm and ensures that landmark detection is based purely on the visual features of the current frame. This is crucial for preventing information leakage when training CNN architectures on shuffled datasets.
max_num_face	1	Limiting detection to just one face aims to focus computing resources exclusively on the primary subject. This configuration effectively eliminates background noise from other, irrelevant individuals in the frame.
min_detection_confidence	0.5	This threshold is set empirically to achieve an optimal balance between sensitivity (recall) and precision. This value ensures that the facial topology mesh will only be generated when facial features are clearly visible, significantly reducing the occurrence of false positives in ambiguous visual frames.

2) Geometry-based ROI normalization and preprocessing: After coordinate extraction, a custom preprocessing workflow is applied to normalize the Region of Interest (ROI) and eliminate external variables irrelevant to emotion, specifically lighting inconsistencies and skin tone bias. As implemented in our algorithm, this process follows three systematic steps:

a) Grayscale projection: The input image is converted to a grayscale spectrum (cv2.COLOR_BGR2GRAY). This step neutralizes chromatic lighting artifacts (e.g., the yellow tint of room lights) and removes skin color information, forcing the model to rely solely on structural deformations.

b) Structural overlay: A topological mask is drawn over a grayscale background using a Tessellation technique, connecting 468 landmarks with 1-pixel-thick, high-contrast green lines (BGR: 0, 255, 0). This effectively turns the image recognition problem into a geometric pattern recognition task.

c) Spatial standardization: The face is cropped based on the extreme coordinates of the landmarks, with 20 pixels of padding added to preserve edge detail. The resulting image is then resized to a uniform 224 x 224 pixel dimension to meet the input layer requirements.

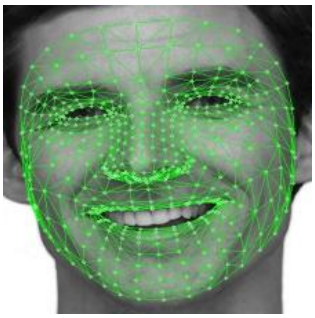

Fig. 2. Visualization of the results of feature extraction pre-processing.

A visual implementation of this framework is demonstrated in Fig. 2. The image shows the transformed result where the original color information has been removed to neutralize skin tone bias. On top of this base layer, the topological structure of the face is rendered using geometric tessellation. As seen in the details of the mouth and eye area in Fig. 2, this mesh precisely tracks facial muscle deformations such as the contraction of the Zygomaticus major during smiling, verifying that the input features passed to the classification model are pure structural movement patterns that are invariant to both subject identity and lighting conditions.

C. Training Models: Comparative Deep Transfer Learning Framework

This study applies a strategically designed Two-Phase Transfer Learning framework to build a robust depression classification model in the elderly population. The training approach is hierarchically structured to address the key challenge of labeled data scarcity in the geriatric domain.

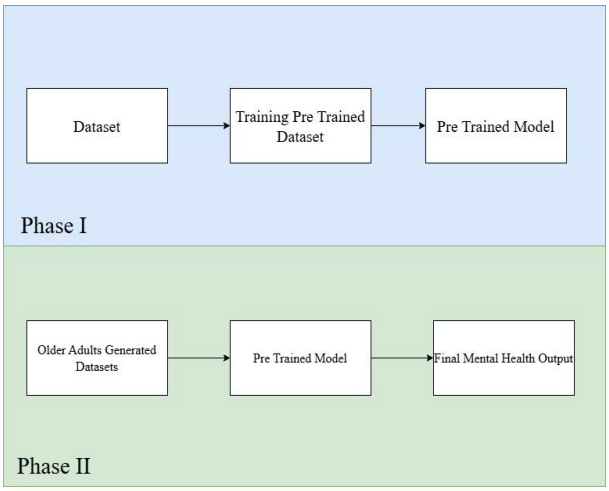

Fig. 3. Model Phase I and II.

As shown in Fig. 3, Phase I focused on Source Domain Benchmarking, where we conducted an intensive comparative study between backbone architectures such as VGG19 to learn universal spatiotemporal feature representations. Phase II focused on Target Domain Adaptation, where the best model resulting from Phase I was adapted through a fine-tuning mechanism using a synthetic elderly face dataset.

1) Phase I: Phase I served as a foundational stage, where we conducted a series of experiments to build the most optimal spatiotemporal representation model. In this stage, the model was trained from scratch to distinguish micro and macro-expression patterns associated with Depression Sad, Angry) and Non Depression (Happy, Neutral) using a standard composite dataset.

a) Dataset: To ensure robust model generalization and mitigate potential biases, Phase I of this study utilizes a Composite Source Dataset. This dataset is an amalgamation of four internationally recognized benchmark repositories, as seen in Fig. 4: Casme II (micro-expressions), Ravdess (dynamic Macro-expressions), Tfeid (Asian Facial Morphological Features), and CK+ (Action Unit Precision Validation). The integration of these diverse sources provides a comprehensive representation of facial dynamics across various temporal and morphological scales.

Fig. 4. Dataset collection from RAVDESS, CASME II, TFEID and CK+.

The acquisition and utilization of these datasets were conducted in strict adherence to ethical research protocols and privacy standards. Access to the CASME II repository was secured through a formal institutional application process. For RAVDESS, TFEID, and CK+, data were obtained under open source licenses, which involved the completion of formal consent agreements and compliance with institutional citation mandates. These datasets have been clinically and scientifically validated by their respective provider institutions, ensuring that subject privacy is preserved and that the research aligns with international ethical guidelines for automated mental health screening.

Following the amalgamation, class balancing was performed to maintain an equitable distribution between classes. The final dataset for Phase I comprises 10,432 facial image samples, symmetrically partitioned into 5,216 samples for the 'Depression' class and 5,216 for the 'Non Depression' class. For model development and empirical evaluation, a systematic 80:20 data split ratio was implemented. Consequently, 8,346 images were allocated for the training phase, while 2,086 images were strictly reserved for the testing and validation set. This explicit partition addresses the requirement for statistically significant performance evaluation on unseen data.

All samples underwent a standardized preprocessing pipeline: conversion to grayscale format, application of a high-density topological dense mesh structure (green), and rescaling to a uniform dimension of 224 x 224 pixels. This structured input format is specifically engineered to optimize compatibility with the CNN-BiLSTM-VGG19 architecture, facilitating the extraction of invariant geometric facial features while eliminating confounding color variations.

b) Trained pre-train model: The training process in Phase I was designed through a multi-stage experimental approach (multi-stage benchmarking) to thoroughly validate each architectural component.

c) Preliminary ablation study: Spatial vs. Spatiotemporal: Before finalizing the main feature extraction architecture, a preliminary ablation study comparing spatial and spatiotemporal approaches was conducted to validate the importance of integrating the temporal module. This test was designed for a direct performance comparison between a purely spatial model represented by CNN-VGG19 and a hybrid spatiotemporal model based on CNN-BiLSTM-VGG19. In the former, the model works exclusively by relying on static spatial feature extraction capabilities. In contrast, the hybrid approach integrates a Bidirectional Long Short-term Memory Layer or BiLSTM specifically designed to comprehensively capture temporal dependencies between frames. This series of initial experimental results specifically aimed to provide empirical evidence that the addition of the BiLSTM module is able to demonstrate a very significant improvement in the accuracy of microexpression recognition when compared to purely spatial-based methods.

d) Backbone architecture benchmarking: After validating the superiority of the hybrid architecture, the next step focused on selecting the most optimal primary spatial feature extractor. This experiment was specifically designed to

answer the fundamental question of whether the density of texture extraction in VGG is superior in capturing microexpressions related to Depression. To answer this question, this study compares two variants of the hybrid architecture with very contrasting characteristics. The first variant, CNN-BiLSTM-VGG19, is built on a stack of nineteen convolutional layers with a small kernel size of 3 X 3. This architectural design allows the model to learn a very detailed hierarchical feature representation ranging from simple edge extraction to complex facial texture patterns. In the context of Depression detection, VGG19 demonstrates comparative advantages in extracting very fine texture nuances such as the depth of forehead wrinkles and shadows around the eyes.

Through synergy with BiLSTM, these static textural features are transformed into a continuous time sequence, enabling the model to not only detect the presence of wrinkles but also understand the dynamics of their depth and fading over time. The hypothesis proposed for this variant is that VGG19's sensitivity to pixel-level details makes it a very strong candidate for processing low-resolution inputs and micro-feature extraction.

e) Hyperparameter grid search optimization: To ensure a comprehensive comparison, all models were trained using the rigorous grid search scheme by testing various parameter combinations to find the best convergence configuration. This testing included optimizing Adam for fast convergence and SGD for generalization stability, as well as testing learning rates across a wide spectrum of values, including 0.01, 0.05, 0.001, 0.005, 0.0005, and 0.0001. The training duration was also set at a maximum limit of 100 epochs by implementing an early stopping mechanism with a tolerance limit of 10 epochs to prevent overfitting and stop the training process if there is no improvement in the validation loss.

f) Pre-trained model: The final result of Phase I is the best-performing pre-trained model selected based on the highest validation accuracy and lowest loss metric across all combinations of experiments. This selected VGG19 model stores basic knowledge about universal facial expression dynamics within its synaptic weights. This model is then stored and will serve as an intelligent initiator for the transfer learning process in Phase II to replace the less efficient random weight initialization. Next, this VGG19 model is combined with the BiLSTM architecture to continuously optimize expression recognition. This combination is implemented because VGG19 has high reliability in extracting detailed spatial features, while BiLSTM is very effective in capturing the temporal dependencies of a series of bidirectional emotional transitions. Therefore, the combination of the two can produce a system that understands the dynamics of facial changes much more comprehensively and accurately.

g) Phase II: Phase II is the specialization stage where the general knowledge about facial expressions acquired in Phase I is transferred to the target domain, namely the elderly population. This stage is crucial to address the domain shift problem, where models trained on young faces often fail to adapt to the complex morphological characteristics of aging faces, such as deep wrinkles and decreased skin elasticity (ptosis). Instead of training the model from scratch, Phase II applies a transfer learning strategy to refine the model's sensitivity to the nuances of Geriatric faces.

h) Older adults dataset: A major challenge in analyzing depression in the elderly is the lack of public datasets containing high-quality micro- and macro-expressions in Geriatric subjects. To address this without sacrificing precise emotion labels, Phase II utilized the Synthetic Elderly Dataset, generated through a generative transformation of all source datasets from Phase I, such as Casme II, Ravdess, Tfeid, and CK+.

Algorithmically, the U-Net model in Face Re-Aging Network (FRAN) receives input in the form of a 5-channel tensor. This tensor consists of the original RGB image to be aged, as well as two single-channel age maps, each representing the input current age and the target age (in this case, set to 75 years old). The pixel values in these age maps are normalized to a range of 0 to 1 to represent a continuous age interval [25].

To ensure experimental consistency and statistical rigor, the total volume of the Phase II dataset was maintained at 10,432 facial image samples, mirroring the distribution of Phase I (5,216 samples for both Depression and Non Depression classes). This consistency allows for a direct comparative analysis of the model's performance before and after the domain adaptation to geriatric features. In line with the established methodology, a stratified 80:20 split ratio was applied: 8,346 images were utilized for fine-tuning the hybrid architecture, while 2,086 images were allocated for the terminal testing and validation phase.

A fundamental advantage of the FRAN architecture, crucial for microexpression analysis, is its ability to preserve the identity and spatial geometry of the original face. Instead of generating a completely new facial image, which is prone to identity loss, the U-Net model predicts per-pixel RGB deltas or offsets. These aging deltas are then added to the original RGB input image to produce the final aged image. This mechanism, combined with the U-Net's skip connections, ensures that the subject's high-resolution facial features and emotional expressions are not distorted. FRAN has proven robust in adding realistic aging textures, such as deep wrinkles, sagging skin (ptosis), and changes in cartilage proportions, such as in the ear and nose areas, while maintaining temporal consistency, head pose, and lighting variations.

This approach effectively produces geriatric twins that retain the original emotional semantics of young subjects while capturing realistic and challenging facial aging features. These generative transformation specifications are strategically applied to various datasets to meet comprehensive testing objectives. In the Aged-CASME II and CK+ datasets, the transformations are specifically used to train a classification model to recognize and distinguish the complex interactions between static wrinkles inherent in older adults and dynamic wrinkles triggered by microexpressions. Modifications to the Aged-RAVDESS dataset aim to simulate older subjects with high expression intensity or who are speaking, a representation highly relevant for supporting video analysis of real-world clinical interviews. Furthermore, the transformations in the Aged-TFEID dataset play a crucial role in generating synthetic

data of Asian older adults aligned with the study's target demographic, significantly reducing racial bias in the model's final inference capabilities.

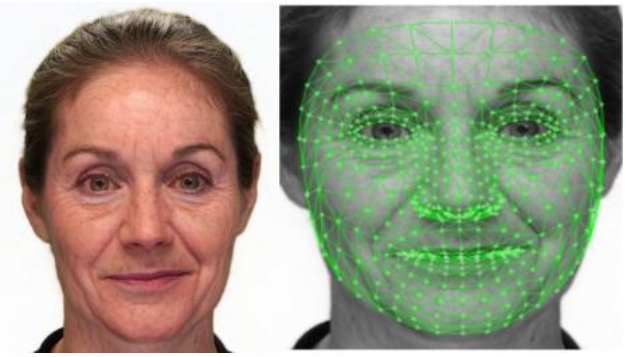

Fig. 5. Left: [Fig. 5(a)] - Synthetic elderly face in color | Right: [Fig. 5(b)] - Grayscale face with green mesh.

To visualize the results of the generative transformation and data preparation process, Fig. 5 presents a composite example from a sample of the Synthetic Elderly Dataset. Fig. 5(a) displays the raw output of the FRAN U-Net model with a target age of 75, clearly demonstrating the addition of aging features such as deep nasolabial folds and sagging skin around the eyes. Fig. 5(b) shows the same image after the standard preprocessing steps described in Section III-B, where the color information has been normalized to grayscale and a high-density MediaPipe mesh topology is overlaid on the face. These geometric and textural representations in Fig. 5(b) serve as the actual input to the CNN-BiLSTM model during the domain adaptation of the fine-tuning phase.

2) Pre-trained model CNN-BiLSTM: The training mechanism in Phase II applies a transfer learning via a fine-tuning strategy. We reload the weights from the best-performing pre-trained model whose performance has been validated in Phase I. This training strategy is designed to prevent damage to learned spatial features (Feature destruction) through the following steps:

a) Partial freezing: The initial convolutional layers (lower layers) in the backbone are frozen. These layers are responsible for detecting basic features such as edges and geometric shapes that are universal and do not change significantly with aging. Fine-tuning high-level layers: the higher-level convolutional layers and the entire temporal module (BiLSTM) are unfrozen. This allows the model weights to adapt specifically to the skin texture of older adults and the dynamics of movement that may be slower or stiffer.

b) Learning rate: The learning rate is significantly reduced compared to Phase I. This reduction aims to prevent catastrophic forgetting, ensuring that the model only makes subtle weight adjustments without forgetting basic knowledge of facial expressions.

Similar to Phase I, we again compared the performance of the VGG19architectures on this synthetic dataset. The goal was to test the robustness of each architecture's adaptation regarding VGG's texture features that were more robust in handling visual noise caused by aging.

3) Mental health output: The final result of Phase II is the Specialized Elderly Depression Classifier. This model is an evolution of the Phase I model, which already had a specific "intuition" for elderly faces. The output layer uses a Softmax activation function that generates probability distributions for two diagnostic classes: Depression and Non Depression.

The final classification is based on an interpretation of emotional valence validated by the clinical literature [26][27]:

a) Depression: Classified based on the probability dominance of persistent negative expression features, particularly Sadness and Anger. This reflects the phenomenon of negative affect potentiation in people with major depression, where subjects tend to maintain negative affect for longer.

b) Non Depression: Classified based on the stability of a relaxed neutral expression and the presence of the happiness feature. The dominance of this feature reflects the absence of negative interpretation bias and healthy emotional regulation function.

This final model is ready to be used for inference on real clinical data as a non-invasive and objective initial screening tool for mental health in older adults.

IV. Results and Discussion

This section presents a comprehensive analysis of the performance of a Deep Learning architecture developed for depression detection in the elderly population using a Two-Phase Transfer Learning scheme. Experimental evaluations are systematically designed to address the research questions, starting from the development of a baseline model in the source domain to testing the model's robustness in the target domain, which has complex aging features.

A. Phase I: Source Domain Benchmarking (Training and Classification)

The first phase of this research focused on building a robust model baseline. The model was trained using a Composite Dataset encompassing a variety of universal micro and macro expressions. The primary goal of this phase was to identify the optimal combination of optimizer and learning rate that achieves optimal convergence, which will serve as the smart initialization for the adaptation process in Phase II.

1) Phase I: Classification results (Testing Metrics): A comprehensive quantitative evaluation was conducted on 12 different experimental scenarios on the testing set of the source domain. Table III, below, presents a complete summary of model performance based on hyperparameter variations.

Best Model Identification: Based on the comprehensive data in Table III, the SGD configuration with a Learning Rate of 0.0005 in No 8 was determined as the best model. This model dominates with an Accuracy of 96.21% and an F1-Score of 0.9621, demonstrating perfect consistency in recognizing the Depression and Non Depression classes, and significantly outperforming all Adam variations.

TABLE III. COMPLETE RECAPITULATION OF PHASE I CLASSIFICATION RESULTS (CNN-BILSTM-VGG19).

No	Optimizer	Learning Rate	Accuracy	Precision	Recall
1	Adam	0.0001	0.7411	0.8225	0.7411
2	Adam	0.0005	0.686	0.7923	0.686
3	Adam	0.001	0.7891	0.8431	0.7891
4	Adam	0.005	0.8337	0.8578	0.8337
5	Adam	0.01	0.7301	0.7447	0.7301
6	Adam	0.05	0.5	0.25	0.5
7	SGD	0.0001	0.5427	0.6295	0.5427
8	SGD	0.0005	0.9621	0.9628	0.9621
9	SGD	0.001	0.908	0.9178	0.908
10	SGD	0.005	0.93	0.935	0.93
11	SGD	0.01	0.8509	0.8747	0.8509
12	SGD	0.05	0.9521	0.9536	0.9521

2) Training dynamics analysis: The varying classification results in Table III above were further analyzed by reviewing the loss and accuracy dynamics during the training process. This analysis revealed the scientific rationale for the superiority of the combination of SGD and LR 0.0005.

A comparative analysis between the Stochastic Gradient Descent (SGD) and Adam optimizers reveals significant differences in stability characteristics. Based on the first through sixth experiments, the Adam optimizer tends to exhibit instability on this dataset. Although Adam is known for its fast initial convergence rate, this method often gets stuck in sharp minima (local minima), resulting in poor model generalization. For example, using a Learning Rate of 0.001, despite high training accuracy, the testing accuracy only reached 78.91%.

In contrast, the SGD optimizer, particularly in experiments 8, 9, 10, and 12, consistently demonstrated high performance with accuracy above 90%. SGD's more gradual weight update mechanism allows it to find flat minima (sloping minimum points). Convergence solutions located in these gentle areas are more robust, allowing the model to maintain its accuracy even when faced with new variations in the testing dataset.

In addition to optimizer selection, analysis of the Learning Rate precision demonstrates that this parameter is a key determinant of model success or failure. In the case of underfitting with a learning rate that is too small, namely Learning Rate < 0.0005, as in experiment 7, namely the CNN-BILSTM SGD Model 0.0001, the model accuracy dropped to 45.06%. This occurs because the model fails to learn complex features within the specified limit of 100 epochs. On the other hand, the overshooting phenomenon occurs when the learning rate is too large, such as Learning Rate > 0.01, as seen in experiment 6, namely the model with the Adam optimizer 0.05 and the model with the SGD optimizer 0.01, which experienced a drastic decrease in performance.

An overly aggressive learning rate causes the gradient step to "jump" the optimal point, namely the lowest loss point, and ultimately damages the model's weight structure. Therefore, the LR value of 0.0005 in the SGD Model in Experiment 8 is the perfect balance point (sweet spot). This value proved to be large enough to help the model escape local minima, but still small enough to perform precise fine-tuning, as evidenced by the lowest Validation Loss achieved with a value of 0.2419 among all configurations.

B. Phase II: Target Domain Adaptation (Augmented Elderly Dataset)

After successfully building a robust baseline model in Phase I using a Universal Dataset, the research proceeded to the Transfer Learning stage to adapt the model to a more specific target domain. In this phase, the optimal weights (pre-trained weights) from the CNN-BiLSTM-VGG19 model trained in Phase I were reloaded and fine-tuned.

The dataset used in this stage was the Augmented Elderly Dataset, which represents facial images of 70-year-olds. The purpose of this augmented data (U-Net generation) was to train the model to recognize emotional features amidst visual noise typical of aging, such as forehead wrinkles, drooping eyelids (ptosis), and sagging skin texture, while maintaining the previously learned baseline feature representation.

1) Phase II: Classification results (Testing Metrics): A comprehensive evaluation of the model's adaptation performance was conducted using a 70-year-old elderly person as the test set. Table IV below presents a complete summary of the results of fine-tuning experiments with various optimizers and learning rate variations to determine the best adaptation configuration.

TABLE IV. COMPLETE RECAPITULATION OF PHASE II CLASSIFICATION RESULTS (DATASET OF ELDERLY PEOPLE 70 YEARS AND OVER - CNN-BILSTM-VGG-19).

No	Optimizer	Learning Rate	Accuracy	Precision	Recall
1	Adam	0.0001	0.7411	0.8225	0.7411
2	Adam	0.0005	0.686	0.7923	0.686
3	Adam	0.001	0.7891	0.8431	0.7891
4	Adam	0.005	0.8337	0.8578	0.8337
5	Adam	0.01	0.7301	0.7447	0.7301
6	Adam	0.05	0.5	0.25	0.5
7	SGD	0.0001	0.5427	0.6295	0.5427
8	SGD	0.0005	0.9621	0.9628	0.9621
9	SGD	0.001	0.908	0.9178	0.908
10	SGD	0.005	0.93	0.935	0.93
11	SGD	0.01	0.8509	0.8747	0.8509
12	SGD	0.05	0.9521	0.9536	0.9521

C. In-Depth Analysis: Model Adaptation to Elderly Faces

Based on the quantitative data in Table IV, the Transfer Learning process from Phase I to Phase II exhibits complex dynamics. The selection of the best model is not based solely on accuracy but also considers the sensitivity metric (Recall), which is crucial for medical diagnosis.

In determining the best model in Phase II, although the SGD configuration with a learning rate of 0.001 in Experiment 9

achieved the highest marginal accuracy of 92.19 per cent, this study determined SGD 0.0005 in Experiment 8 as the most optimal final model. This decision was based on clinical considerations prioritizing recall or sensitivity metrics.

The SGD 0.0005 configuration produced the highest recall value of 0.9271, outperforming the SGD 0.001 configuration at 0.9080. In the context of a medical decision support system for depression detection, false negatives, or the system's failure to detect a patient who is actually ill, carry a much higher risk of fatality than false positives. Therefore, a model with high positive detection capability is an absolute priority. Furthermore, with an F1-score of 0.9153, the SGD 0.0005 configuration demonstrates a harmonious balance between accuracy and sensitivity. This demonstrates that the model is capable of adapting to the wrinkled texture of elderly faces without losing its discriminatory ability.

The success of the 0.0005 SGD model in achieving accuracy above 91 per cent also validates the effectiveness of the transfer learning strategy, particularly when fine-tuning with a low learning rate. Using a learning rate of 0.0005 allows the model to make micro-adjustments to its convolutional weights. Through this mechanism, the model relearns to interpret aging lines on elderly faces as representing texture features, rather than simply visual noise, while retaining the structural facial knowledge learned in Phase I. Conversely, using too high a learning rate proved highly destructive, as evidenced by the catastrophic forgetting phenomenon in Experiment 11 with an SGD setting of 0.01. In this configuration, the model's accuracy plummeted to 50.00 percent, equivalent to the probability of a random guess in binary classification. This complete failure indicates that the overly aggressive gradient update step during the fine-tuning process damaged the optimal pre-trained weight structure from Phase I. As a result, the model lost all memory of facial feature representations and failed to recognize any patterns in the elderly data set.

Furthermore, this experiment also revealed the limitations of the Adam optimizer when faced with domain shift phenomena. Overall, testing with the Adam optimizer from Experiments 1 to 6 yielded significantly lower recall performance than SGD. As a representative example, the Adam configuration of 0.0005 in Experiment 2 achieved a fairly good accuracy of 89.07 percent with a high precision of 93.77 percent, but its recall value remained at 0.8370. This finding indicates that Adam tends to be conservative and often predicts the majority class, namely the Non Depressed class, to avoid prediction errors. This behavior ultimately makes the model less sensitive to capturing subtle manifestations of depressive emotions behind facial skin deformation in the elderly.

Concluding Phase II, this comprehensive analysis confirmed that the CNN-BiLSTM-VGG19 architecture combined with the SGD optimizer and a learning rate of 0.0005 is the most robust configuration for transferring expression detection knowledge to the geriatric domain. This model has successfully overcome the challenges of visual complexity in facial data augmentation of 70-year-old elderly with excellent sensitivity, and is certainly ready to undergo robustness testing on more extreme data sets in the next stage.

V. Conclusion

Based on the experimental results and analysis, this study concludes that the CNN-BiLSTM-VGG19 architecture is proven effective in handling domain shift in elderly faces, with an accuracy of 91.42% and a recall of 0.9271 on the 70-year-old dataset, making it a safe screening tool with minimal risk of false negatives. The model's performance is supported by an optimal configuration through a fine-tuning strategy using the SGD optimizer with a learning rate of 0.0005, a setting that has proven to be the most stable in preventing catastrophic forgetting while providing better generalization compared to the Adam optimizer or the use of high learning rates that are prone to triggering model collapse.

***Abstract*—Accurate gait phase detection is essential for biomechanical analysis and the control of wearable assistive devices such as powered prostheses and exoskeletons. Electromyography (EMG) provides a direct representation of neuromuscular activation and offers potential advantages for low-latency, anticipatory gait phase recognition. However, the effectiveness of different EMG feature representations for stance-swing classification has not yet been clearly established. Therefore, this study presents a systematic comparison of time-domain (TD) and frequency-domain (FD) EMG features for gait phase classification. EMG signals were recorded from the tibialis anterior and medial gastrocnemius muscles of ten healthy participants during level walking. After preprocessing and segmentation, TD and FD features were extracted and used as inputs to a support vector machine classifier with a radial basis function kernel. Model performance was evaluated using a leave-one-subject-out cross-validation framework to assess generalization. The results demonstrate that TD features consistently outperform FD features across all evaluation metrics, achieving an accuracy of 0.813 ± 0.112, macro-averaged F1-score (Macro-F1) of 0.812 ± 0.114, and Matthews correlation coefficient (MCC) of 0.672 ± 0.178, compared to FD features with an accuracy of 0.712 ± 0.077, Macro-F1 of 0.708 ± 0.079, and MCC of 0.448 ± 0.159. These findings indicate that TD features more effectively capture the transient amplitude-based neuromuscular patterns associated with gait phase transitions. In addition, TD features offer lower computational complexity, making them well-suited for real-time implementation. Overall, this study highlights the superiority of time-domain EMG representations for reliable and efficient gait phase detection and provides practical guidance for the development of wearable gait monitoring and assistive control systems.**

***Keywords*—Electromyography (EMG); gait phase detection; stance–swing classification; time-domain features; frequency-domain features; support vector machine (SVM); wearable assistive devices**

I. Introduction

Human gait is a cyclic neuromuscular behavior that arises from the coordinated activation of multiple lower-limb muscles to alternately support body weight and enable forward progression. For each leg, the gait cycle is commonly described by two principal phases: stance, during which the foot is in contact with the ground, and swing, during which the foot is lifted and advanced. These phases form the fundamental state representation used in many gait analysis and control frameworks [1,2]. Accurate and low-latency identification of gait phases is essential in biomechanics and rehabilitation engineering, particularly in wearable assistive technologies where mechanical assistance must be synchronized with the user's movement intent. In this context, a comprehensive review of lower-limb exoskeleton systems highlighted that reliable intention recognition, particularly through physiological signals such as electromyography (EMG), is critical for effective operation, while also identifying persistent challenges related to system stability and user comfort [2]. Complementing this system-level perspective, recent advances in machine learning have demonstrated that gait phase recognition can be achieved with high accuracy, exceeding 94% in multi-phase classification tasks, thereby supporting the feasibility of data-driven control strategies [3]. More broadly, artificial intelligence-based approaches have been increasingly adopted for locomotion classification and control, although their clinical validation remains limited [4]. Furthermore, existing exoskeleton systems predominantly rely on rule-based and trajectory-tracking strategies, with relatively low adoption of adaptive control methods despite their potential to improve responsiveness and user-specific adaptation [5]. Collectively, these findings emphasize that robust estimation of gait state and user intent remains central to achieving safe, comfortable, and clinically effective assistance, particularly in real-world applications involving diverse users.

*Corresponding author

Wearable gait phase recognition has traditionally relied on kinematic and kinetic sensors such as inertial measurement units and pressure insoles, which are effective for detecting gait events but primarily reflect motion and contact changes after their occurrence [6,7]. Electromyography (EMG) provides a complementary perspective by directly capturing neuromuscular activation and has therefore been widely investigated as a human–machine interface for gait monitoring and assistive device control. This is attributed to the electromechanical delay, whereby muscle activation precedes observable limb kinematics by approximately 120 ms, enabling earlier insight into movement intent [8]. Similarly, a metric learning-based temporal convolutional network has achieved high classification accuracy while improving robustness to noise disturbances, highlighting the reliability of EMG signals in complex environments [9]. Additional studies have further confirmed the effectiveness of EMG-based recognition using diverse approaches, including multi-scale deep architectures, domain adaptation strategies, and multi-feature fusion methods [10–12]. This anticipatory characteristic, commonly referred to as electromechanical delay, enables EMG-based systems to reduce effective control latency and improve synchronization of assistive actions. It has also motivated the integration of EMG with complementary sensing modalities in multimodal frameworks to enhance performance [13]. Consequently, EMG has attracted increasing attention for online stance–swing recognition in wearable systems. Moreover, the structured activation patterns of lower-limb muscles during gait further support its discriminative capability; for example, tibialis anterior activation occurs before foot contact as a preparatory response to ground interaction, while plantarflexor muscles contribute to propulsion during late stance [14]. In addition, EMG-derived features have been shown to reliably reflect key gait parameters, including stance and swing phases, reinforcing the ability of neuromuscular signals to capture phase-specific characteristics of locomotion [15]. Related studies have also extended EMG-based prediction to more complex locomotor intentions such as directional stepping, further demonstrating the richness of neuromuscular information for wearable control applications [16].

Consequently, a growing body of research has applied machine learning and deep learning techniques to EMG-based gait phase recognition, particularly for real-time exoskeleton control and subject-independent stance–swing estimation. For instance, a BiLSTM-based framework has demonstrated reliable gait phase identification during exoskeleton-assisted walking, with the ability to generalize across different locomotion conditions [8]. Further optimization of deep learning architectures has shown that high classification accuracy can be achieved with significantly reduced computational cost, making such models suitable for real-time deployment [1]. In addition, a metric learning-based temporal convolutional network has been shown to improve both recognition accuracy and robustness to noise disturbances, highlighting the importance of discriminative feature learning for reliable performance in complex environments [9]. Other studies have explored alternative strategies, including domain adaptation to address gait speed variability [11], multi-feature fusion combining time-domain, frequency-domain, and nonlinear descriptors [12], and multimodal sensor fusion frameworks integrating EMG with complementary signals to enhance recognition accuracy [13]. However, despite these methodological advances, an important practical design question remains insufficiently addressed: which EMG feature-domain representation most effectively supports reliable stance–swing classification when evaluated under controlled conditions, including consistent classifier selection and subject-independent validation. Recent surveys of EMG analysis emphasize that feature representation is a major determinant of performance, robustness, and computational efficiency, typically categorizing handcrafted features into time-domain, frequency-domain, and time–frequency domains with different cost–information trade-offs [17]. Within gait phase recognition research, feature selection remains highly heterogeneous, ranging from low-cost time-domain descriptors to hybrid feature sets and end-to-end learned representations, often without systematic comparison to determine which feature domain is most appropriate for stance–swing separability under realistic deployment conditions [8,9,11–13].

The choice of feature domain is particularly important for stance–swing classification because surface EMG during walking is characterized by transient, phase-locked bursts of muscle activation and amplitude modulations that are inherently represented in the time domain [14–17]. Accordingly, time-domain descriptors directly capture the temporal structure and magnitude of neuromuscular activity associated with gait events. In contrast, frequency-domain features summarize spectral properties of the signal that are more closely related to broader physiological conditions, such as muscle fatigue, commonly quantified using measures such as median or mean frequency [18,19]. Although spectral features may provide complementary information in certain EMG analysis tasks, their contribution to gait phase discrimination is less direct, as stance–swing transitions are primarily governed by the timing and amplitude patterns of muscle activation. This is supported by studies demonstrating that anticipatory muscle activity plays a central role in real-time gait phase estimation for exoskeleton control, where temporal alignment of EMG signals enables early detection of gait events [1,8]. In addition, multimodal approaches have shown that EMG contributes most effectively through its temporal continuity and activation patterns rather than through spectral characterization alone [13]. Furthermore, real-time wearable control systems, including powered prostheses and lower-limb exoskeletons, impose strict latency and computational constraints, which necessitate feature representations that balance discriminative capability with efficiency [9,13]. In this context, recent studies on EMG-driven intent estimation highlight a practical accuracy–latency trade-off and consistently report that time-domain features offer a more favorable balance between classification performance and computational efficiency compared with frequency-domain alternatives in time-constrained control applications [20].

Therefore, a systematic and controlled comparison of time-domain versus frequency-domain EMG features for stance–swing classification is needed to clarify which representation more effectively captures the neuromuscular signatures of gait phases under subject-independent validation. In this study, lower-limb EMG recorded from TA and MGAS during walking was used to extract feature sets in the time and frequency domains. A support vector machine (SVM) classifier was used

to evaluate stance–swing classification, and performance was assessed under a subject-independent validation framework. By holding the classification model and evaluation protocol constant while varying only the feature-domain representation, the study aims to provide actionable guidance for designing robust, computationally efficient EMG-based gait phase detection pipelines for wearable gait monitoring and assistive device control.

II. Related Work

Wearable gait phase detection has traditionally relied on kinematic and kinetic sensing modalities, particularly inertial measurement units and plantar-pressure or insole systems, as these sensing approaches provide reliable detection of gait events and are well established in prosthetic and exoskeleton applications [6,21,22]. However, these signals primarily reflect the mechanical outcomes of movement rather than the underlying neuromuscular processes. Recent reviews of lower-limb exoskeleton sensing distinguish these mechanical (posterior) signals from earlier physiological signals, emphasizing that motion and foot–ground contact reflect the mechanical outcome of movement, whereas biological signals such as EMG are more directly linked to the neuromuscular processes underlying movement intention and execution [2]. Consequently, electromyography (EMG) has gained increasing attention as a complementary modality for gait-state estimation, with studies explicitly leveraging its anticipatory (ahead-of-motion) characteristics for gait phase recognition and kinematics prediction [8,23].

Building on this physiological advantage, both conventional machine learning and deep learning approaches have been extensively investigated for EMG-based gait recognition. Recent reviews of EMG classification indicate that handcrafted feature pipelines remain widely used, often combined with conventional supervised classifiers such as support vector machines, k-nearest neighbors, and random forests, particularly when dataset sizes are limited [18]. In gait-specific studies, Park et al. [24] systematically compared multiple classifiers, including decision trees, k-nearest neighbors, support vector machines, and neural networks, while Morbidoni et al. [25] applied deep learning for stance–swing classification during level-ground walking. Ling et al. [11] proposed a CNN-based domain-adaptive model to address gait phase recognition under varying walking speeds, Cai et al. [3] introduced an LDA-PSO-LSTM framework for seven-phase recognition, and Guerra et al. [8] employed a bidirectional LSTM model for stance–swing identification during exoskeleton-assisted walking. Collectively, these studies demonstrate a transition toward more adaptive temporal and deep learning architectures, while highlighting that conventional methods remain competitive and widely used in practical applications.

Despite these algorithmic advances, feature representation remains a critical and influential design factor. Recent reviews consistently categorize EMG features into time-domain (TD), frequency-domain (FD), and time–frequency (TF) groups [26,27]. Within this framework, TD features are widely used in gait phase recognition studies due to their ability to capture activation magnitude and timing, whereas FD features primarily characterize spectral properties associated with broader physiological states such as muscle fatigue. TF approaches aim to capture both temporal and spectral information but are less commonly adopted due to increased computational complexity and reduced interpretability [28,29]. This classification is directly relevant to gait phase recognition, where common TD descriptors—such as root mean square, mean absolute value, waveform length, zero-crossings, and slope-sign changes—remain widely used due to their simplicity and effectiveness. For example, Nazmi et al. [30] employed a TD feature set including root mean square, standard deviation, mean absolute value, integrated EMG, and waveform length, showing the continued effectiveness of established TD descriptors in recent gait phase classification studies.

Evidence from gait studies also suggests that task formulation significantly influences the effectiveness of feature-domain representations. In Nazmi et al. [30], binary stance–swing classification achieved an accuracy of approximately 0.98 across all features, suggesting that two-class phase discrimination can be effectively achieved using relatively simple feature representations. In contrast, Cai et al. addressed a more complex seven-phase recognition task using feature-combination selection across TD, FD, and TF domains, while Morbidoni et al. and Guerra et al. utilized deep learning architectures to model stance–swing dynamics directly from EMG signals [3,8,25]. Collectively, these findings indicate that the suitability of feature-domain representations is task-dependent, with simpler TD-based features often sufficient for binary classification, while more complex tasks may require richer or learned representations.

A second major issue is generalization across subjects, which remains a key challenge in EMG-based gait analysis. Di Nardo et al. demonstrated that intra-subject models outperform inter-subject models for EMG-based gait-event prediction, highlighting the significant impact of inter-individual variability [31]. A subsequent study by Di Nardo et al. further showed that both EMG signal processing strategies and sensor configuration complexity influence classification and prediction performance [32]. More recent work has attempted to address this limitation through domain adaptation and rapid recalibration techniques, particularly to accommodate variations such as walking speed and environmental conditions [11]. At a broader methodological level, recent research in wearable robotics emphasizes participant-based data splitting or leave-one-subject-out (LOSO) validation as more realistic evaluation strategies compared to random mixed-subject splits, as these approaches better assess performance on unseen users and reduce optimistic bias caused by cross-subject data leakage [33].

Overall, the literature supports EMG as a robust and promising modality for gait phase recognition. However, existing studies have not systematically compared time-domain and frequency-domain handcrafted features under controlled experimental conditions, particularly when classifier choice and subject-independent evaluation protocols are held constant. This limitation prevents definitive conclusions regarding the most suitable feature-domain representation for reliable stance–swing classification in practical deployment scenarios, thereby defining a focused and well-motivated research gap.

III. METHODS

A. Subject

Ten healthy male adults aged between 18 and 40 years participated in this study. This age range was selected to represent individuals with fully developed and stable neuromuscular control [34]. All participants reported no history of neurological disorders, musculoskeletal injuries, or gait impairments, ensuring that the recorded muscle activity reflected normal walking patterns. Prior to participation, all subjects provided written informed consent. The study protocol was reviewed and approved by the Universiti Teknologi Malaysia Research Ethics Committee (Approval No. UTMREC-2025-122).

B. Experimental Protocol

Each participant performed level-ground walking trials in a controlled laboratory environment. During each trial, participants walked along a straight, unobstructed pathway from a marked starting point to an end point and then returned to the starting location, as shown in Fig. 1. To minimize variability caused by footwear differences, all participants wore standardized shoes during the experiment. Participants were instructed to walk at their self-selected comfortable speed in order to preserve natural gait mechanics. This approach allows the recorded muscle activation patterns to represent natural locomotion behavior rather than constrained walking conditions.

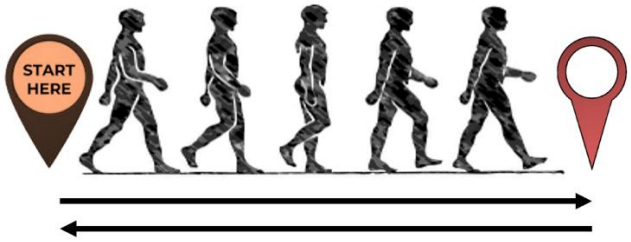

Fig. 1. Experimental protocol for walking trial.

C. Data Collection

EMG signals were recorded from two lower-limb muscles: the tibialis anterior (TA) and the medial gastrocnemius (MGAS). These muscles were selected because they play complementary roles in ankle control during walking. The TA primarily contributes to ankle dorsiflexion and is typically active during the swing phase to ensure foot clearance, whereas the MGAS contributes to plantarflexion and propulsion during the stance phase [35,36]. EMG electrodes were placed on this muscle based on the recommendations of Surface Electromyography for Non-Invasive Assessment (SENIAM) [37]. The electrodes were connected to a Biopac MP150 data acquisition system, and EMG signals were sampled at 1000 Hz, providing sufficient temporal resolution to capture rapid muscle activation changes during gait.

D. Gait Phase Labeling

The gait cycle was divided into two primary phases, which are stance and swing. The stance phase corresponds to the period during which the foot is in contact with the ground, while the swing phase refers to the period when the foot is lifted and moves forward to prepare for the next step [38]. Ground-truth labels for the gait phases were obtained through manual annotation based on visual inspection of the recorded walking sequences. A binary labeling scheme was adopted in which stance was assigned the label 1 and swing was assigned the label 0. In typical human walking, the stance phase occupies approximately 60% of the gait cycle, while the swing phase accounts for the remaining 40% [38]. This temporal distribution reflects the functional roles of the two phases, where stance provides support and propulsion while swing advances the limb for the subsequent step. Fig. 2 shows an example of the EMG signals recorded from the TA and MGAS muscles together with the corresponding stance–swing labels. These labeled gait phases were subsequently used as target classes for supervised classification after preprocessing and feature extraction.

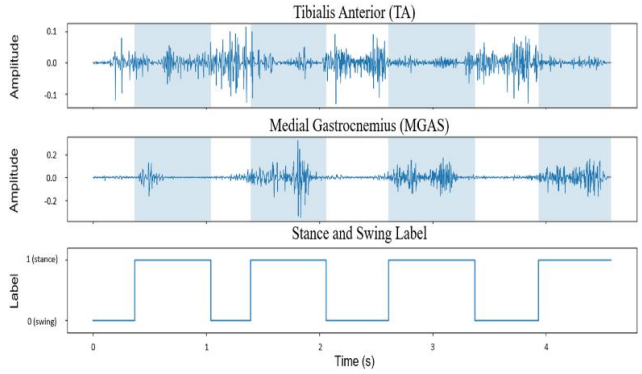

Fig. 2. Stance and swing labeling.

E. EMG Signal Preprocessing

The EMG signals were preprocessed using a sixth-order Butterworth band-pass filter with cutoff frequencies of 20–450 Hz to reduce noise and artifacts [39,40]. This frequency range preserves the dominant EMG spectral components while attenuating motion artifacts and high-frequency noise. After filtering, the EMG signals were segmented using a sliding window approach. Each analysis window had a duration of 200 ms with 50% overlap between consecutive windows, a configuration commonly adopted in EMG analysis to balance temporal resolution with statistical stability [41]. This corresponds to a step size of 100 ms between adjacent windows. For each analysis window, the corresponding gait phase label was determined using a majority voting strategy based on the stance–swing annotations within that window.

F. Feature Extraction

Two categories of features were investigated in this study: time-domain (TD) features and frequency-domain (FD) features. Feature extraction was performed independently for the TA and MGAS signals within each analysis window. The features extracted from both muscles were concatenated to form the final feature vector used for classification.

1) Time-domain features: Time-domain features characterize the amplitude and temporal properties of EMG signals. Six well-established TD features were employed, which are Mean Absolute Value (MAV), Standard Deviation (SD), Root Mean Square (RMS), Integrated EMG (iemg), Waveform Length (WL), and Zero Crossing (ZC), as Shown in Table I. These features have been widely validated in the

literature and are known to achieve high classification accuracy [42,43].

TABLE I. TIME DOMAIN (TD) FEATURE EXTRACTION

Time Domain (TD) features	For each window containing N signal samples *xi*, the following features were extracted.
Mean Absolute Value (MAV)	$MAV = \frac{1}{N}\sum_{i=1}^{N} \lvert x_i \rvert$
Standard Deviation (SD)	$SD = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(x_i - \mu)^2}$, μ=mean of EMG signal
Root Mean Square (RMS)	$RMS = \sqrt{\frac{1}{N}\sum_{i=1}^{N} x_i^2}$
Integrated EMG (IEMG)	$IEMG = \sum_{i=1}^{N} \lvert x_i \rvert$
Waveform Length (WL)	$WL = \sum_{i=1}^{N-1} \lvert x_{i+1} - x_i \rvert$
Zero Crossing (ZC)	$ZC = \sum_{n=1}^{N-1} \lvert sgn(x_i) - sgn(x_i - 1) \rvert$ where sgn(), $sgn(x) = \begin{cases} 1 & \text{if } x > 0 \\ 0 & \text{if } x = 0 \\ -1 & \text{if } x < 0 \end{cases}$

2) Frequency-Domain features: Frequency-domain (FD) features describe the spectral properties of EMG signals. In this study, five widely used FD features were extracted, namely Mean Frequency (MNF), Median Frequency (MDF), Peak Frequency (PF), Total Spectral Power (TSP), and Spectral Entropy, as summarized in Table II. These features have also been widely validated in the literature on EMG-based classification tasks [44,45].

TABLE II. FREQUENCY DOMAIN (FD) FEATURE EXTRACTION

Frequency Domain (FD) features	The power spectral density (PSD) of each window was estimated using Welch's method. Let P(j) denote the power spectral density at the j-th frequency bin, where M is the total number of frequency bins.
Mean Frequency (MNF)	$MNF = \frac{\sum_{j=1}^{MDF} f_j P(j)}{\sum P(j)}$
Median Frequency (MDF)	$\sum_{j=1}^{MDF} P(j) = \sum_{j=MDF}^{M} P(j) = \frac{1}{2}\sum_{j=1}^{M} P(j)$
Peak Frequency (PF)	$PF = \max P(j), \quad j = 1,...,M$
Total Spectral Power (TTP)	$TTP = \sum_{j=1}^{M} P(j)$
Spectral Entropy (SpecEn)	$\text{SpecEn} = -\frac{\sum_{j=1}^{M} P(j)\log_2 P(j)}{\log_2 M}$

G. Support Vector Machine Classification

Support vector machine (SVM) is a supervised learning models that find an optimal hyperplane that separates the data into different classes by transforming it into a higher-dimensional space [46]. This transformation allows SVM to handle nonlinear decision boundaries by implicitly mapping inputs into high-dimensional feature spaces. In addition, SVMs often yield high accuracy and generalize well on high-dimensional data, making them popular for many classification problems [47,48]. In this study, gait phase classification was performed using an SVM classifier with a radial basis function (RBF) kernel. Before classification, the extracted feature vectors were standardized using z-score normalization so that all features contributed equally to the learning process. The classification pipeline, therefore, consisted of a feature scaling stage followed by SVM classification.

The SVM hyperparameters were configured as follows:

- Kernel: radial basis function (RBF)
- Kernel parameter: γ=0.005

The selection of the kernel parameter γ = 0.005 was based on preliminary empirical evaluation to balance model generalization and decision boundary smoothness. In the context of an RBF kernel, smaller γ values produce smoother decision boundaries and reduce the risk of overfitting, whereas larger values lead to more complex boundaries that may degrade generalization performance, particularly under subject-independent evaluation [49].

H. Model Evaluation

To evaluate the generalization capability of the classifier across participants, a leave-one-subject-out (LOSO) cross-validation strategy was employed. In this approach, the data from one subject was used as the test set while the remaining subjects were used to train the classifier. The process was repeated until each subject had served once as the test subject. Classification performance was assessed using accuracy, precision, recall, F1-score, and Matthews Correlation Coefficient (MCC), as shown in Table III. The F1-score represents the harmonic mean of precision and recall, while the macro-averaged F1-score (Macro-F1) was computed as the average of class-wise F1-scores to ensure balanced evaluation across stance and swing classes. MCC was utilized as a metric to capture agreement beyond chance while providing a balanced evaluation of classification performance across both classes.

TABLE III. PERFORMANCE METRIC

Performance Metric	Formula
Accuracy	$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN}$
Precision	$\text{Precision} = \frac{TP}{TP + FP}$
Recall	$\text{Recall} = \frac{TP}{TP + FN}$
F1-score	$\text{F1} = 2 \times \frac{Precision \times Recall}{Precision + Recall}$

Macro F1	$\text{Macro F1} = \frac{F1_{\text{swing}} + F1_{\text{stance}}}{2}$
MCC	$\text{MCC} = \frac{TP \times TN - FP \times FN}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}}$

IV. RESULTS

A. Overall Classification Performance (Time vs. Frequency Domain Features)

The overall classification performance of the time-domain (TD) and frequency-domain (FD) feature sets evaluated using leave-one-subject-out (LOSO) cross-validation is summarized in Table IV and illustrated in Fig. 3. The TD feature set achieved a higher classification accuracy of 0.813 ± 0.112, outperforming the FD feature set with an accuracy of 0.712 ± 0.077. A similar trend was observed for the macro-averaged F1-score (Macro-F1), where TD features achieved 0.812 ± 0.114, compared to 0.708 ± 0.079 for FD features. Furthermore, the Matthews correlation coefficient (MCC) also indicated superior performance for TD features (0.672 ± 0.178) relative to FD features (0.448 ± 0.159).

TABLE IV. OVERALL PERFORMANCE COMPARISON OF TIME-DOMAIN (TD) AND FREQUENCY-DOMAIN (FD) FEATURE SETS USING LOSO CROSS-VALIDATION BASED ON FIG. 3.

Feature Mode	Accuracy	Macro-F1	MCC
TD	0.813 ± 0.112	0.812 ± 0.114	0.672 ± 0.178
FD	0.712 ± 0.077	0.708 ± 0.079	0.448 ± 0.159

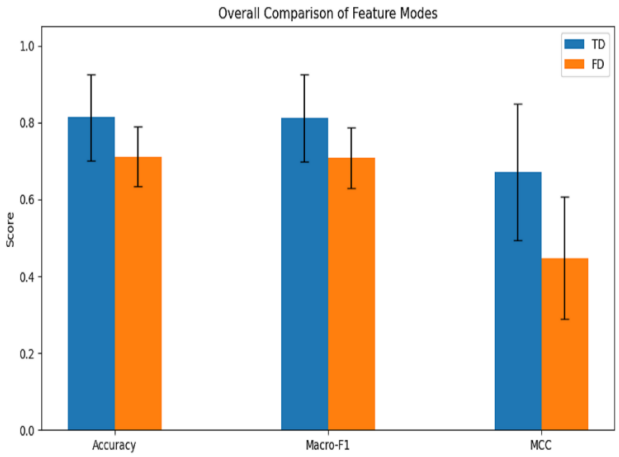

Fig. 3. Comparison of classification performance between time-domain (TD) and frequency-domain (FD) EMG feature sets using SVM under leave-one-subject-out cross-validation. Error bars represent standard deviation across subjects.

B. Per-Class Performance and Confusion Matrix Analysis

To further examine class-specific behavior, Fig. 4 presents a heatmap of precision, recall, and F1-score for both swing and stance phases. For the TD feature set, swing phase detection achieved a recall of 0.935 and an F1-score of 0.822, whereas stance detection exhibited a recall of 0.729 and a precision of 0.929. For the FD feature set, both phases exhibited lower performance (swing F1: 0.687, stance F1: 0.729), indicating reduced classification effectiveness.

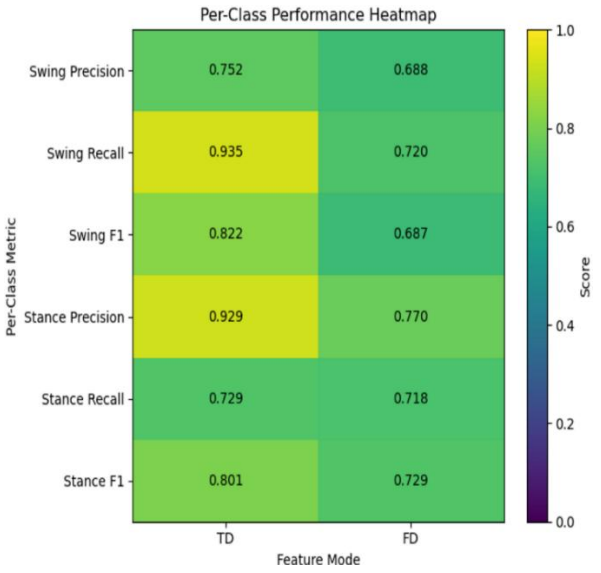

Fig. 4. Per-class performance heatmap.

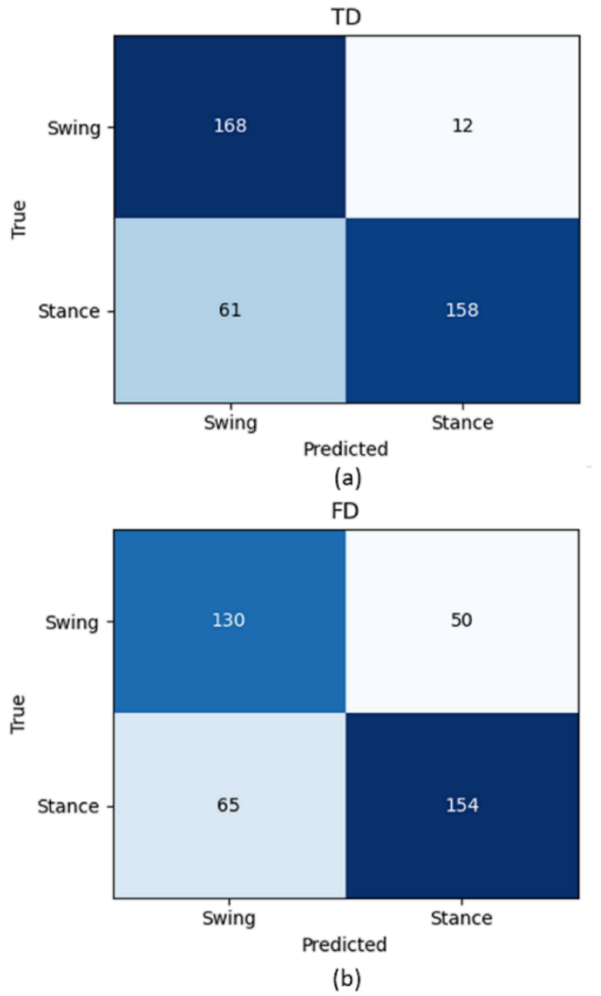

Fig. 5. Confusion matrices across feature modes: (a) Time-domain (TD) (b) Frequency-domain (FD).

Fig. 5 presents the confusion matrices, for the (a) time-domain (TD) and (b) frequency-domain (FD) feature sets,

providing further insight into classification errors. Most predictions are concentrated along the diagonal, indicating correct classification of both gait phases. However, a noticeable proportion of stance samples are misclassified as swing, consistent with the lower stance recall observed in Fig. 4. Importantly, Fig. 5(a) exhibits fewer off-diagonal errors compared to Fig. 5(b), confirming its superior classification performance. This reduction in misclassification highlights the effectiveness of TD features in capturing phase-specific amplitude variations during gait transitions.

V. Discussion

A. Interpretation of Feature Performance

In Table IV, the results demonstrate that TD features provide stronger discriminative information for gait phase classification compared to FD features. This is likely because time-domain descriptors capture transient neuromuscular activation patterns, whereas frequency-domain features primarily represent spectral distributions and may be less sensitive to temporal variations. This observation aligns with previous studies reporting that TD features often outperform FD features in dynamic EMG classification tasks [50,51]. The higher MCC values further indicate that TD features maintain more balanced classification performance across classes.

B. Biomechanical Interpretation of Class Differences

The higher recall for the swing phase observed in Fig. 4 can be explained by gait biomechanics. During swing, the tibialis anterior (TA) exhibits a distinct high-amplitude activation burst associated with ankle dorsiflexion and foot clearance [52]. This produces clear and temporally localized EMG patterns, making the phase easier to detect. In contrast, the stance phase involves more distributed and overlapping muscle activations, including contributions from the gastrocnemius and soleus. This results in increased signal variability and reduced separability. Similar findings have been reported in prior work, where swing phases are often classified more accurately than stance phases despite their shorter duration [25].

C. Implications for EMG-Based Gait Phase Detection

The findings highlight the critical role of feature representation in EMG-based gait phase classification. Across all evaluation metrics, TD features consistently outperformed FD features, demonstrating their effectiveness in capturing neuromuscular activation dynamics during locomotion. This result is physiologically justified, as EMG signals predominantly reflect amplitude modulation of muscle activity, which is more directly represented in the time domain [53]. From an application perspective, TD features provide a computationally efficient and reliable basis for real-time gait phase detection. Their strong classification performance indicates that they can effectively support control strategies in assistive technologies, such as powered prostheses and lower-limb exoskeletons, where accurate phase detection is required to synchronize mechanical assistance with user movement [24].

A key limitation of the present framework is that each analysis window is treated as an independent sample, without explicitly modeling temporal dependencies between consecutive gait phases. Consequently, the model does not enforce physiologically consistent phase transitions, which may lead to misclassification near transition boundaries. Recent studies have demonstrated that sequence-aware models, such as recurrent neural networks and temporal convolutional networks, can improve gait phase recognition by capturing temporal continuity and transition constraints [8,54]. Another limitation of the present study is the use of only two lower-limb muscles, namely the tibialis anterior and medial gastrocnemius. Although these muscles provide strong discriminative information due to their roles in dorsiflexion and plantarflexion, gait is inherently governed by coordinated activation across multiple muscle groups. As both muscles are located at the distal segment of the lower limb, the current framework primarily reflects ankle-level control and does not capture the contributions of proximal muscles involved in hip and knee stabilization. Consequently, this limited muscle representation may restrict the generalizability of the findings to more complex locomotion scenarios that require multi-joint coordination and whole-body control. Previous studies have shown that incorporating additional muscles or muscle synergy information can improve classification robustness and better capture the complexity of locomotion [24,55].

Overall, the results demonstrate that TD features provide a physiologically meaningful and computationally efficient representation for gait phase detection. These characteristics make them well-suited for implementation in real-time wearable systems, supporting both assistive device control and rehabilitation-oriented gait monitoring applications.

VI. Conclusion

This study investigated the effectiveness of time-domain (TD) and frequency-domain (FD) electromyography (EMG) features for stance–swing gait phase classification using signals from the tibialis anterior (TA) and medial gastrocnemius (MGAS) muscles during walking. A support vector machine classifier was evaluated under a subject-independent leave-one-subject-out framework to assess generalization performance. The results consistently demonstrate that TD features outperform FD features across all evaluation metrics, including classification accuracy, macro-averaged F1-score, and Matthews correlation coefficient. These findings indicate that amplitude-based temporal characteristics of EMG signals provide more discriminative information for stance–swing classification than spectral representations under the evaluated conditions. Despite these findings, several limitations should be acknowledged. First, the study was conducted on a relatively small dataset consisting of ten healthy participants, which may limit the statistical generalizability of the results. Second, the observed variability in classification performance, particularly in MCC values, reflects inter-subject differences in EMG signal characteristics, including muscle activation patterns and signal quality. Third, the analysis was restricted to two muscles (TA and MGAS) and to predefined TD and FD feature sets, which may not fully capture the complexity of multi-muscle coordination during gait. From an application perspective, TD features offer a computationally efficient and physiologically meaningful representation for real-time gait phase detection. However, the findings should be interpreted within the scope of the experimental setup and feature design choices, particularly under controlled laboratory conditions. These constraints

highlight the need for further validation before deployment in real-world assistive systems.

Future work should focus on improving the robustness, scalability, and real-world applicability of EMG-based gait phase classification systems. One important direction is the inclusion of larger and more diverse participant populations, including individuals with gait impairments, to better evaluate generalization across varying neuromuscular conditions. In addition, future studies should investigate multi-muscle configurations to capture a more comprehensive representation of lower-limb coordination. Another key direction involves the integration of temporal modeling approaches. The current study treats EMG windows independently and does not incorporate sequential dependencies between gait phases. Incorporating sequence-aware models, such as recurrent neural networks or temporal convolutional architectures, may improve classification stability and reduce misclassification during phase transitions. Furthermore, while this study compared TD and FD features independently, combining both feature domains may provide complementary information that enhances classification performance. Hybrid feature representations that integrate temporal and spectral characteristics could offer improved robustness, particularly under noisy or variable conditions. Finally, future research should evaluate the proposed approach under real-world conditions, including varying walking speeds, terrains, and sensor noise levels, to assess its suitability for deployment in wearable assistive technologies and continuous gait monitoring applications.

ACKNOWLEDGMENT

The authors would like to acknowledge the contributions of all participants involved in this study. This work was supported by the Universiti Teknologi Malaysia, Geran Penyelidikan Kecerdasan Buatan, 44H54.

***Abstract*—This study examines the adoption of digital technologies and artificial intelligence (AI) in Slovak firms, with particular attention to technological integration, employee adaptation, and organizational change. The study is based on qualitative semi-structured interviews conducted with managers and employees from 20 companies across multiple sectors and firm-size categories. The data were analyzed using thematic analysis. The findings identify three levels of digital adoption: basic digitization, process automation, and AI-supported adoption. Basic digital tools were reported across all firms, while advanced forms of adoption were concentrated mainly in IT and manufacturing companies. AI use remained limited and was typically confined to exploratory applications such as chatbots, automated support, or data-processing assistance. Across most cases, employees initially responded to digital change with hesitation or resistance, followed by gradual adaptation through practice-based and informal workplace learning. The results further indicate that digitalization was associated primarily with task reallocation, workflow optimization, and role redesign, whereas direct workforce reduction was reported only in isolated cases. Based on these findings, the study develops a conceptual framework linking technological adoption, employee adaptation, organizational restructuring, and sectoral context. Given the qualitative and exploratory nature of the research, the findings should be interpreted as analytically transferable rather than statistically generalizable. The study contributes to the literature by providing firm-level evidence from a Central and Eastern European context and by proposing a structured interpretation of digital and AI adoption as a multi-level organizational process.**

Keywords*—Digital technology adoption; artificial intelligence; digital transformation; process automation; thematic analysis; Slovak firms

I. Introduction

The rapid digitalization of economies and societies has fundamentally reshaped how organizations operate, compete, and create value. Digital technologies, including artificial intelligence (AI), are increasingly embedded in organizational processes, transforming operational models, decision-making practices, and workforce structures. As a result, firms that effectively adopt and integrate digital technologies gain competitive advantages, while those with limited adaptability risk declining productivity and reduced market relevance.

Despite the growing importance of digital transformation, existing research has primarily focused on technological and infrastructural aspects of digitalization, often emphasizing large organizations or technologically advanced economies. Less attention has been paid to how companies in Central and Eastern Europe (CEE), particularly small and medium-sized enterprises, interpret and implement digital transformation in practice. Moreover, prior studies frequently treat digital adoption as a purely technological process, overlooking the organizational and human dimensions, such as employee adaptation, managerial practices, and workplace learning, which are critical for successful implementation.

In the Slovak context, digital transformation has become a strategic priority, supported by national and European initiatives such as the Digital Economy and Society Index (DESI). However, empirical evidence on how Slovak companies perceive digitalization, adopt digital and AI technologies, and manage associated organizational changes remains limited. Existing studies tend to provide macro-level indicators of digital readiness but offer insufficient insight into firm-level processes, particularly regarding the interaction between technological adoption and employee adaptation.

Despite these developments, important gaps remain in the existing literature. First, empirical research on digital transformation in Central and Eastern Europe (CEE) remains limited at the firm level, particularly in relation to small and medium-sized enterprises. Second, prior studies tend to examine technological adoption and organizational or human factors separately, rather than as interconnected processes. Third, there is a lack of qualitative, process-oriented evidence capturing how firms transition between different stages of digital adoption in practice.

The aim of this study is to examine how Slovak companies adopt and implement digital technologies and artificial intelligence, with a particular focus on the interaction between technological adoption, employee adaptation, and organizational change. By addressing these dimensions simultaneously, the study seeks to provide a more integrated understanding of digital transformation as a multi-dimensional organizational process.

To achieve this aim, the study draws on qualitative semi-structured interviews conducted with managers and employees from 20 companies across diverse sectors.

The study is guided by the following research questions:

- How do Slovak companies perceive digitalization and digital transformation?
- How do companies adopt and use artificial intelligence and other digital tools?
- How do employees react to digital changes, and how do they adapt?
- What organizational effects does digitalization produce in Slovak companies?

This study contributes to the literature in three main ways. First, it provides empirical insights into digital and AI adoption in a CEE context, which remains underrepresented in current research. Second, it develops a structured understanding of digital adoption by identifying three levels of technological integration—basic digitization, process automation, and AI-supported adoption. Third, it proposes a conceptual framework that integrates technological, organizational, and human dimensions of digital transformation. Given the exploratory nature of the study and the qualitative design, the findings should be interpreted as analytically transferable rather than statistically generalizable.

II. Literature Review

Digitalization and digital transformation have become central concepts in contemporary organizational research [34]; however, their conceptual boundaries remain fluid and subject to ongoing debate. In the management and information systems literature, Digitalization is commonly understood as the use of digital technologies and data to improve existing processes and enhance operational efficiency [27], [10]. In contrast, digital transformation represents a broader, strategic reconfiguration of organizational structures, business models, and value creation processes [33]. While this distinction is widely acknowledged, empirical studies suggest that organizations often fail to differentiate clearly between these concepts in practice, frequently adopting a technology-driven rather than strategy-driven perspective. However, despite extensive conceptual development, the existing literature remains fragmented and often lacks empirical validation at the organizational level, particularly in less-studied regional contexts.

Recent literature increasingly emphasizes that digital transformation is not solely a technological process but a socio-technical phenomenon integrating technological innovation with organizational and human dimensions [32], [26]. In this context, digital transformation involves changes in leadership, organizational culture, and employee competencies, alongside the implementation of digital tools. However, despite this broader conceptualization, a significant portion of empirical research continues to prioritize technological adoption while underestimating the role of human capital and organizational learning processes. Nevertheless, many empirical studies continue to operationalize digital transformation primarily through technological indicators, thereby underestimating the complexity of human and organizational dynamics involved in the transformation process.

The importance of human capital in digital transformation has been widely documented. Studies show that employees' digital skills and adaptability are critical determinants of successful technology adoption and organizational innovation [29], [23]. Similarly, [16] argue that digital transformation is driven more by organizational strategy and leadership than by technology itself. Nevertheless, in practice, many firms—particularly small and medium-sized enterprises (SMEs)—struggle to align technological investments with workforce development, resulting in fragmented or incomplete transformation processes. This suggests that, particularly in SMEs, digital transformation is frequently implemented in a fragmented manner, with limited integration between technological investments and workforce development strategies.

Sectoral and regional differences further complicate the adoption of digital technologies. Research indicates that technologically intensive industries, such as manufacturing and information technology, tend to lead digital transformation due to greater access to financial resources, technological expertise, and innovation capabilities [11], [5]. In contrast, service-oriented sectors and smaller organizations often face resource constraints, skill shortages, and higher levels of uncertainty, which slow down the adoption of advanced technologies such as artificial intelligence. The likelihood of AI adoption is strongly influenced by firm-level characteristics, particularly organizational size and sectoral orientation. Large enterprises demonstrate significantly higher adoption rates compared to small and medium-sized enterprises (SMEs), primarily due to greater access to financial resources, technological expertise, and organizational capabilities [28]. Sectoral differences are also pronounced, with firms in the ICT sector exhibiting higher adoption rates, while industries such as agriculture, construction, and public services lag behind [12].

The literature identifies several key drivers of AI adoption. These include the need to address skill shortages in areas such as IT and data analytics, organizational growth and performance pressures, and participation in innovation ecosystems that facilitate access to knowledge and resources [12], [13]. At the same time, firms are primarily motivated by operational goals, such as process optimization, cost reduction, and service innovation.

However, the adoption process is constrained by a range of barriers. Absolute barriers include the lack of financial resources, insufficient technological infrastructure, and limited availability of skilled personnel [20]. In addition, relative barriers—such as data quality issues, integration challenges, and limited managerial support—affect firms already engaged in AI implementation. These findings highlight that AI adoption is not only a technological decision but also a complex organizational process shaped by internal capabilities and external constraints.

In the European context, and particularly in Central and Eastern Europe (CEE), digital transformation is shaped by structural and institutional factors, including disparities in digital skills, infrastructure, and innovation ecosystems. The Digital Economy and Society Index (DESI) highlights persistent gaps

in digital readiness across EU member states, with countries such as Slovakia exhibiting moderate performance but lagging in areas such as advanced digital skills and enterprise-level technology adoption [8]. While DESI provides valuable macro-level insights, it offers limited understanding of how firms interpret and operationalize digital transformation at the organizational level. Recent empirical evidence indicates that the adoption of artificial intelligence (AI) among European enterprises remains relatively limited, although it is gradually increasing. As of 2023, approximately 8% of enterprises in the European Union reported using at least one AI technology, representing a modest increase compared to 7.6% in 2021 [28]. However, significant disparities persist across countries. While Nordic economies such as Denmark and Sweden report adoption rates exceeding 35%, Central and Eastern European countries demonstrate substantially lower levels of implementation [13], [28].

In the Slovak context, AI adoption increased from 5.2% in 2021 to 7.0% in 2023, yet remains consistently below the EU average across all firm-size categories [28], [18]. These findings suggest that structural and institutional constraints continue to limit the diffusion of advanced digital technologies in the region.

Another important dimension of digital transformation concerns employee reactions to technological change. The literature consistently identifies resistance to change as a common response, particularly when new technologies disrupt established work routines [31], [24]. However, research also shows that such resistance is often temporary and can be mitigated through effective change management, communication, and training [19]. More recent studies highlight the role of informal, workplace-based learning as a mechanism through which employees gradually adapt to digital tools, especially in resource-constrained environments [7].

Despite these advances, several important limitations remain in the literature. First, empirical research on digital transformation in CEE countries remains relatively limited, particularly at the firm level. Second, existing studies often examine technological adoption and human adaptation as separate phenomena, rather than as interdependent processes shaping organizational outcomes. Third, most empirical research relies on quantitative indicators or large-scale surveys, providing limited insight into how organizations actually experience and implement digital transformation in practice. As a result, the processual and context-specific nature of digital adoption remains underexplored.

This study addresses these limitations by providing a qualitative, empirically grounded analysis of digital technology and AI adoption in Slovak companies. By integrating technological, organizational, and human perspectives, the study contributes to a more comprehensive understanding of digital transformation as a multi-dimensional and context-dependent process.

Table I presents selected indicators from the Digital Economy and Society Index (DESI), highlighting differences between Slovakia and the European Union average in key areas of digital skills. While Slovakia performs comparably in basic digital skills and exceeds the EU average in digital content creation, it lags behind in more advanced indicators, such as the share of individuals with above-basic digital skills, the proportion of ICT specialists, and the level of enterprise engagement in employing ICT professionals.

TABLE I. COMPARISON OF DIGITAL SKILLS IN SLOVAKIA AND THE EUROPEAN UNION IN 2022

Digital skills	DESI	
	DESI Slovakia	DESI EU
At least basic digital skills (% of population)	55	54
Above basic digital skills (% of population)	21	26
At least basic skills in digital content creation (% of population)	72	66
ICT specialists (% of employed persons aged 15–74)	4.30	4.50
Female ICT specialists (% of ICT specialists)	15	19
Enterprises employing ICT specialists (% of enterprises)	16	20
ICT graduates (% of graduates)	4.40	3.90

Source: [9]

These disparities point to structural limitations in the country's digital readiness, particularly in terms of advanced competencies and workforce specialization. As suggested by the literature, such gaps may constrain the ability of firms to adopt and effectively utilize more sophisticated digital technologies, including artificial intelligence, which require not only technical infrastructure but also highly skilled human capital [23], [30].

Beyond national-level indicators, digital transformation is increasingly understood as a multidimensional process that extends beyond technological capability. Prior research emphasizes the importance of organizational culture, leadership support, and strategic alignment in shaping digital transformation outcomes [17], [32]. In this context, employee reactions represent a critical factor influencing implementation success. Resistance to technological change is a well-documented phenomenon, particularly among employees with lower levels of digital skills or longer-established work routines [31], [24].

However, the literature also suggests that such resistance can be mitigated through effective change management practices, including communication, employee involvement, and training initiatives [19]. At the same time, emerging research highlights the role of continuous learning and skill development as key mechanisms enabling employees to adapt to rapidly evolving technological environments.

Digital transformation also has broader implications for labor markets and employment structures. While automation and AI may substitute routine tasks, studies increasingly indicate that digitalization simultaneously generates new roles requiring higher-order cognitive and technical skills [1], [11], [14]. This dual effect reinforces the importance of ongoing upskilling and organizational investment in human capital as essential components of sustainable digital transformation. At the same time, recent research points to the existence of a "productivity paradox" in AI adoption, whereby the implementation of AI technologies does not immediately translate into measurable productivity gains at the aggregate level [22]. Instead, performance improvements tend to emerge over time, as firms

invest in complementary organizational changes, workforce skills, and intangible assets. This suggests that the benefits of AI adoption are inherently long-term and dependent on broader organizational transformation processes.

Taken together, the literature suggests that digital transformation is best understood as an interaction between three interrelated dimensions: technological innovation, strategic organizational change, and human-capital development. This integrated perspective provides a relevant analytical foundation for examining how Slovak companies perceive and implement digital technologies within their specific institutional and economic context.

III. Methodology

This study employs a qualitative research design to explore how Slovak companies perceive and implement digitalization and digital transformation. Because the research questions are exploratory in nature and aim to capture subjective experiences, meanings and organizational contexts, a qualitative approach based on semi-structured interviews was selected. Such approaches are particularly suitable for examining complex and dynamic processes that are socially and contextually embedded [7], and are widely used in exploratory research where in-depth understanding of organizational phenomena is required.

A. Research Design

This study adopts a qualitative research design to explore how Slovak companies perceive and implement digitalization and artificial intelligence (AI). Given the exploratory nature of the research questions and the focus on understanding organizational processes, meanings, and experiences, a qualitative approach based on semi-structured interviews was considered most appropriate [6], [15]. This design enables an in-depth examination of complex and context-dependent phenomena that cannot be adequately captured through standardized quantitative methods.

B. Research Questions

The study is guided by the following research questions:

- RQ1: How do Slovak companies perceive digitalization and digital transformation?
- RQ2: How do companies adopt and use artificial intelligence and other digital tools?
- RQ3: How do employees react to digital changes and how do they adapt?
- RQ4: What organizational effects does digitalization produce in Slovak companies?

C. Sampling and Participants

A purposive sampling strategy was employed to select information-rich cases across different organizational contexts [26]. The sample consists of 20 Slovak companies representing a range of sectors, including information technology, finance, manufacturing, education, and services, as well as different firm sizes (micro, small, medium, and large enterprises).

The selection criteria included:

- Active use of digital technologies in organizational processes,
- Willingness to participate in the study, and
- Representation of sectoral diversity.

Although the sample size is relatively modest, it is consistent with qualitative research standards, where adequacy is determined by thematic saturation rather than statistical representativeness. In this study, thematic saturation was achieved after approximately 15 interviews, with subsequent interviews confirming previously identified patterns. This approach is consistent with qualitative research standards, where analytical depth and contextual richness are prioritized over statistical generalization, and where smaller samples are considered appropriate for capturing complex organizational processes [6], [25].

TABLE II. Structure of the Research Sample by Sector and Firm Size

Sector/Company size	Micro (1-9)	Small (10-49)	Medium (50-249)	Large (more than 250)	Total
IT	3	0	2	1	6
Finance	1	1	0	2	4
Education	2	0	0	0	2
Business services	0	1	0	0	1
Culture	0	1	0	0	1
Gastronomy	0	0	1	0	1
Manufacturing	0	0	1	1	2
Retail/Wholesale	0	0	0	1	1
Law and Legislation	0	0	0	1	1
Marketing	0	0	0	1	1
Total	6	3	4	7	20

Source: Authors' own processing

Table II summarizes the composition of the research sample, capturing the distribution of participating companies across sectors and firm sizes. The sample reflects a deliberate effort to ensure heterogeneity, including micro, small, medium, and large enterprises operating in diverse industries such as information technology, finance, manufacturing, education, and services.

This variation was intentionally incorporated to capture a wide range of organizational experiences with digitalization and AI adoption, as prior research indicates that sectoral context and firm size significantly influence the scope and depth of technological implementation. In particular, the inclusion of both technologically intensive sectors (e.g., IT, manufacturing) and less digitally advanced sectors (e.g., culture, education) enables a comparative perspective on digital maturity and adoption patterns.

Although the sample size (N = 20) is relatively modest, it is consistent with qualitative research standards, where the objective is not statistical representativeness but analytical depth and contextual understanding. In line with established methodological approaches [6], [25], sampling adequacy was assessed based on thematic saturation. In this study, saturation was reached after approximately fifteen interviews, with subsequent interviews providing confirmatory rather than novel insights.

This sampling strategy strengthens the study's ability to identify recurring patterns while preserving sensitivity to sector-specific differences, thereby enhancing the analytical robustness and transferability of the findings.

D. Data Collection

Data were collected through semi-structured interviews conducted between March and July 2025. Two interview guides were developed to capture both managerial and employee perspectives:

A manager-focused guide addressing digital strategy, AI adoption, organizational change, and digital competencies.

An employee-focused guide examining individual experiences, perceived challenges, and adaptation processes.

Interviews lasted between 30 and 60 minutes and were conducted either in person or online. All interviews were audio-recorded with participants' consent and subsequently transcribed verbatim for analysis.

E. Data Analysis

The data were analyzed using thematic analysis following the six-step framework proposed by [3]:

- Familiarization with the data.
- Generation of initial codes.
- Search for themes.
- Review of themes.
- Definition and naming of themes.
- Production of the report.

Thematic analysis is particularly suitable for identifying patterns across qualitative data and for developing theoretically informed interpretations grounded in empirical evidence, making it an appropriate method for the exploratory objectives of this study.

A hybrid inductive–deductive approach was applied. Deductive codes were derived from the research questions (e.g., "AI adoption," "digital skills," "organizational change"), while inductive codes emerged from participants' responses (e.g., "initial resistance," "informal learning," "automation benefits").

To enhance analytical transparency, a codebook was developed specifying code definitions and representative examples. Coding was conducted by the primary researcher and partially reviewed by a second researcher through peer debriefing, which contributed to the consistency and credibility of the analysis.

F. Analytic Framework (Conceptual Formalization)

Based on the thematic analysis, the study develops a conceptual framework of digital technology and AI adoption. The framework can be formally represented as a three-level structure of organizational digital maturity:

Level 1 (L_1): Basic digitization – use of digital tools for administrative support and data management.

Level 2 (L_2): Process automation – integration of digital systems for workflow optimization and process coordination.

Level 3 (L_3): AI-supported adoption – implementation of AI-based tools for decision support and advanced analytics.

These levels are influenced by three cross-cutting dimensions:

- Employee adaptation (E),
- Organizational restructuring (O),
- Sectoral context (S).

The relationship between these components can be conceptually expressed as:

$$D = f(L, E, O, S) \quad (1)$$

where D represents the level of digital transformation achieved by the organization, L denotes the stage of technological adoption, and E, O, and S represent moderating organizational and contextual factors. This formalization serves as a conceptual abstraction of the relationships identified through qualitative analysis, providing a structured representation of how technological, organizational, and human factors jointly shape digital transformation outcomes.

This formalization does not imply a quantitative model but serves as an analytical representation of relationships identified through qualitative data.

G. Trustworthiness and Validity

To ensure the credibility and trustworthiness of the findings, several strategies were applied:

Triangulation through the inclusion of both managerial and employee perspectives.

Thick description using illustrative quotations to provide contextual depth.

Audit trail documenting coding decisions and analytical steps.

Peer debriefing to validate selected coding procedures. These procedures enhance the credibility, consistency, and analytical rigor of the findings, in line with established qualitative research standards.

H. Ethical Considerations

The study adhered to standard ethical principles, including informed consent, voluntary participation, anonymity, and confidentiality. All participants were informed about the purpose of the study, and identifying information was removed during data processing.

I. Limitations

As a qualitative pilot study, the findings are not statistically generalizable. The sample is based on voluntary participation, which may introduce self-selection bias. However, the study provides analytically transferable insights that can inform future research using larger or mixed-methods designs.

IV. Results

The findings of the study are presented according to the four research questions, with themes identified through thematic analysis illustrating common patterns and divergent experiences across organizations. Overall, the analysis revealed three dominant patterns across organizations: a predominantly process-oriented understanding of digitalization, significant sectoral differences in the adoption of advanced digital technologies, and gradual employee adaptation following initial resistance to technological change. The thematic analysis revealed four dominant themes across organizations (see Table III).

TABLE III. Overview of Themes Identified Through Thematic Analysis

Theme	Description	Illustrative evidence
Process-oriented understanding of digitalization	Companies primarily perceive digitalization as a tool for improving efficiency and automating administrative processes.	Managers frequently describe digitalization as automation of administrative tasks or workflow optimization.
Sectoral differences in technology adoption	The level of technological adoption varies across sectors, with IT and manufacturing firms demonstrating higher digital maturity.	Companies in IT and manufacturing reported using cloud systems, data analytics and automation tools.
Employee resistance and gradual adaptation	Employees initially express resistance to technological change but adapt over time through practice-based learning.	One respondent noted that changes in work systems initially caused discomfort but became easier once benefits were recognized.
Organizational consequences of digitalization	Digitalization leads to job redesign, task reallocation and efficiency improvements, while workforce reductions are relatively rare.	Several managers reported reassigning employees to new roles rather than eliminating positions.

Source: Authors' own processing

A. Process-Oriented Understanding of Digitalization

Addressing RQ1, companies generally perceived digitalization as a process-oriented initiative focused on improving workflow efficiency and reducing manual labor. Managers frequently described digitalization in technical terms, such as automating administrative procedures or optimizing communication systems, while a smaller number articulated a broader understanding of digital transformation as organizational change. This variation suggests inconsistent conceptual clarity across firms. As one retail manager noted, the introduction of digital tools "streamlined several administrative processes, reducing the amount of manual work, particularly in logistics." Although efficiency was widely emphasized, few firms linked digital transformation to employee learning or strategic skill development, indicating a primarily technology-driven approach.

B. Sectoral Differences in Digital Technology Adoption

Regarding RQ2, the adoption of advanced digital technologies, including artificial intelligence, varied across sectors. IT and manufacturing companies reported the greatest technological integration, such as cloud services, data analytics tools, and automation systems. AI use remained limited and exploratory, typically focused on chatbots or automated support functions. Companies in education, culture, law, and business services relied mainly on basic digital tools without substantial transformation initiatives. Organizational resources and size influenced the depth of adoption, with larger firms investing in complex systems such as SCADA or HMI panels, whereas micro and small enterprises pursued incremental and cost-sensitive solutions.

C. Employee Resistance and Gradual Adaptation

In relation to RQ3, employees' reactions to digital changes followed a common pattern: initial resistance, followed by gradual adaptation. Respondents described hesitation, discomfort, and uncertainty during the early stages of technological implementation, a reaction especially pronounced among older workers. An IT employee (aged 56) explained, "I felt resistance. Every change in the work system causes discomfort. It is important to anticipate this and design an implementation strategy in advance." Despite this resistance, employees generally adapted over time as they recognized the benefits of reduced manual tasks and clearer processes. Adaptation occurred through practice rather than through structured training, indicating an experiential learning process.

In several cases, respondents emphasized that the adaptation process was facilitated by informal peer support and gradual exposure to digital tools in everyday work activities. Rather than relying on formal training programs, many organizations introduced new technologies incrementally, allowing employees to learn through repeated use and interaction with colleagues. Managers reported that this approach reduced anxiety associated with technological change and helped employees build confidence when working with digital systems. In smaller firms in particular, learning often occurred through collaborative problem solving, where employees shared knowledge and practical tips regarding the use of new software or digital platforms. These findings suggest that workplace-based learning mechanisms play an important role in supporting employees' adaptation to digitalization, especially in organizations with limited resources for structured training initiatives.

D. Organizational Consequences of Digitalization

Addressing RQ4, digitalization also produced structural effects within organizations. While some firms experienced changes in job roles and responsibilities, workforce reductions were uncommon. Managers commonly reported reassigning employees to new positions rather than eliminating roles. A finance manager stated. "Digitalization has not affected the number of employees. No positions were eliminated, but the people in those positions have changed." In certain sectors, however, digitalization prompted outsourcing or automation

that replaced specific operational tasks. For example, a manufacturing manager described outsourcing IT and analytics functions to partners abroad and implementing SCADA and HMI technologies that "eliminated several operational positions two years ago." Across organizations, digitalization consistently contributed to improved efficiency, workflow clarity, and time savings, with employees often redirected to higher-value tasks.

E. A Framework of Digital Technology and AI Adoption

Building on the thematic analysis, the findings of this study allow for the development of a conceptual framework that captures how companies adopt digital technologies and artificial intelligence across different stages of organizational development.

The analysis identifies three distinct levels of digital adoption. The first level, basic digitization, involves the use of digital tools primarily for administrative support and data management. At this stage, digitalization is understood mainly as a means of improving efficiency and reducing manual workload, which corresponds with the process-oriented understanding identified across most organizations.

The second level, process automation, is characterized by the integration of more advanced digital systems, including cloud-based platforms, workflow automation tools, and data-processing technologies. Companies at this stage move beyond basic digitization and begin to restructure internal processes to enhance operational efficiency and coordination.

The third level, AI-supported adoption, represents a more advanced stage in which organizations experiment with or implement artificial intelligence technologies, such as chatbots, automated analytics, or decision-support tools. However, the findings indicate that this level remains limited and unevenly distributed across sectors.

Across all levels, the adoption process is shaped by several cross-cutting dimensions. First, employee adaptation plays a crucial role, as employees typically exhibit initial resistance to technological change followed by gradual adaptation through practice-based learning. Second, digitalization contributes to organizational restructuring, particularly through task reallocation and job redesign rather than large-scale workforce reductions. Third, sectoral differences significantly influence the depth of adoption, with technologically intensive industries demonstrating higher levels of digital maturity.

Taken together, the framework suggests that digital transformation is not a linear technological upgrade but a multi-dimensional process combining technological implementation with human and organizational adaptation.

V. Discussion and Implications

The findings of this study provide important insights into how Slovak companies approach digitalization and artificial intelligence (AI) adoption, while also contributing to broader debates on digital transformation in organizational contexts. Importantly, the results highlight that digital transformation should be understood not merely as a technological upgrade, but as a multi-dimensional process shaped by the interaction of technological, organizational, and human factors. Taken together, the findings suggest that digital transformation in Slovak firms follows a gradual and non-linear trajectory shaped by both internal organizational capabilities and external contextual constraints.

A. Reinterpreting Digitalization from Operational Tool to Strategic Process

The results indicate that Slovak companies predominantly conceptualize digitalization as a process-oriented tool aimed at improving efficiency and automating administrative tasks. This finding aligns with prior research suggesting that organizations often adopt digital technologies in a reactive and operational manner before recognizing their broader strategic implications [4], [28]. This finding contributes to the ongoing debate by suggesting that the transition from operational digitalization to strategic digital transformation is not automatic, but depends on the alignment of technological investments with organizational capabilities and human capital development.

However, the limited distinction observed between digitalization and digital transformation suggests a lack of strategic integration, particularly in smaller firms. While the literature emphasizes that digital transformation requires alignment between technology, strategy, and organizational capabilities [27], the findings indicate that many firms remain at an early stage of this transition. This reinforces the argument that technological adoption alone does not constitute transformation but must be embedded within a broader organizational change process.

B. Sectoral Inequalities and Uneven Technological Maturity

Consistent with existing research, the study reveals significant sectoral differences in digital adoption. Firms operating in IT and manufacturing sectors demonstrate higher levels of technological maturity, including the use of automation, cloud systems, and early-stage AI applications. This pattern reflects findings by [11], [5], who highlight the role of resource availability, technological capabilities, and innovation intensity in shaping digital transformation trajectories.

In contrast, firms in education, culture, and service-oriented sectors exhibit slower and more incremental adoption. These differences can be interpreted through the lens of resource constraints and perceived necessity, which have been identified as key barriers to digital transformation in SMEs. The findings therefore support the view that digital transformation is uneven and context-dependent, rather than a uniform or linear process across industries.

C. Employee Adaptation from Resistance to Experiential Learning

A central contribution of this study lies in its identification of employee adaptation as a dynamic and processual phenomenon. Consistent with established models of technology acceptance [31], [24], employees initially exhibit resistance to technological change, particularly when faced with unfamiliar systems or disrupted routines.

However, the findings extend this literature by demonstrating that resistance is typically temporary and followed by gradual adaptation through practice-based learning. Rather than relying on formal training programs, many organizations facilitate adaptation through informal

mechanisms, including peer support, collaborative problem-solving, and repeated interaction with digital tools. This aligns with the concept of workplace-embedded learning [7], highlighting the importance of experiential learning in digital transformation processes.

At the same time, the reliance on informal learning may limit the long-term development of digital competencies, suggesting that organizations could benefit from more structured approaches to skill development. This observation contributes to the ongoing debate on the role of human capital in digital transformation, reinforcing the need to integrate technological and educational strategies. These findings extend existing models of technology acceptance by emphasizing the role of informal and practice-based learning as a key mechanism of adaptation, particularly in resource-constrained organizational environments.

D. Organizational Consequences: Transformation Without Displacement

The findings suggest that digitalization primarily leads to job redesign, task reallocation, and efficiency gains rather than widespread workforce reductions [1], [2], [21]. This is consistent with prior research indicating that digital transformation often reshapes rather than eliminates work [1], [2].

Nevertheless, evidence of outsourcing and automation in certain sectors, particularly manufacturing, indicates that digitalization can also contribute to structural shifts in employment. This dual effect reflects broader labor market dynamics, where digital technologies simultaneously create new opportunities while displacing specific routine tasks. The findings therefore underscore the importance of adaptive organizational strategies that support workforce transition and skill development. This suggests that the impact of digitalization on employment should be understood as a process of transformation rather than substitution, where the nature of work changes more significantly than the number of jobs.

E. Contextualizing Digital Transformation in Slovakia

While many of the observed patterns align with broader European trends, the findings also highlight several context-specific characteristics of the Slovak environment. Digital transformation appears to be shaped by a combination of structural constraints, including limited resources in SMEs, gaps in advanced digital skills, and reliance on external expertise through outsourcing.

These factors correspond with macro-level indicators such as DESI, which point to moderate digital readiness but persistent gaps in workforce capabilities and enterprise-level adoption. Importantly, the study demonstrates how these structural conditions are reflected at the firm level, influencing both the pace and depth of digital transformation. This contextual perspective contributes to a more nuanced understanding of digitalization in CEE economies, where institutional and economic conditions differ from more technologically advanced regions.

F. Contributions, Limitations, and Implications

This study contributes to the literature by offering an empirically grounded and conceptually integrated perspective on digital transformation in a CEE context. Specifically, it provides three main contributions. First, it provides empirically grounded insights into digital and AI adoption in a CEE context, addressing a gap in existing literature. Second, it conceptualizes digital transformation as a multi-level process, distinguishing between basic digitization, process automation, and AI-supported adoption. Third, it highlights the critical role of employee adaptation and organizational learning in shaping transformation outcomes.

At the same time, several limitations should be acknowledged. The study is based on a relatively small and non-random sample, which limits the generalizability of the findings. In addition, the reliance on qualitative interviews may introduce subjective bias in participants' responses. Future research could address these limitations by employing mixed methods designs, larger samples, and longitudinal approaches to capture the evolution of digital transformation over time.

From a practical perspective, the findings suggest that organizations should approach digital transformation as an integrated process combining technological investment with human-capital development and organizational change. Policymakers may also play a role by supporting SME digitalization, strengthening digital skills development, and fostering collaboration between industry and educational institutions.

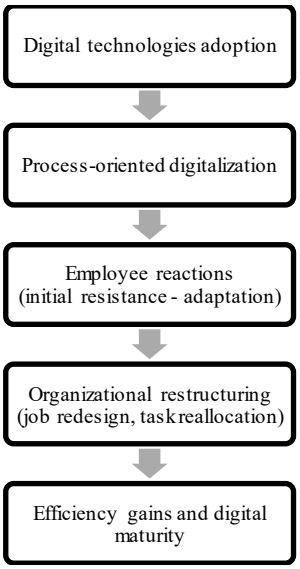

Fig. 1. Conceptual framework of digital technology and AI adoption, Source: Authors' own elaboration based on qualitative data.

Fig. 1 presents the conceptual framework of digital technology and AI adoption derived from the thematic analysis. The framework illustrates three progressive levels of digital adoption—basic digitization, process automation, and AI-supported adoption—reflecting increasing levels of technological maturity within organizations.

In addition to these stages, the model highlights three cross-cutting dimensions that shape the adoption process: employee adaptation, organizational restructuring, and sectoral context. These dimensions influence both the pace and the depth of digital transformation, emphasizing that technological implementation is closely intertwined with human and organizational factors.

The framework conceptualizes digital transformation as a dynamic and multi-dimensional process rather than a linear progression, where organizations may move between stages depending on internal capabilities and external conditions. This perspective extends existing models of digital transformation by explicitly integrating employee-level adaptation and sector-specific variability into a unified analytical structure.

VI. Conclusion and Practical Implications

This study examined how Slovak companies perceive, adopt, and respond to digitalization and artificial intelligence (AI), drawing on qualitative evidence from 20 organizations across multiple sectors. The findings demonstrate that digitalization remains predominantly process-oriented, with firms focusing on workflow optimization and incremental technological improvements rather than comprehensive strategic transformation. While some organizations recognize the broader implications of digital transformation, the integration of human capital development into digital strategies remains limited. These findings reinforce the view that digital transformation in SMEs is not a purely technological process, but a socio-technical transition requiring alignment between technology, organization, and human capabilities.

The analysis further reveals that digital adoption is uneven across sectors, with IT and manufacturing firms exhibiting higher levels of technological maturity, while service-oriented sectors adopt digital tools more gradually and primarily for operational purposes. AI adoption remains exploratory and limited in scope, reflecting both resource constraints and uncertainty regarding its practical implementation. At the organizational level, digitalization leads primarily to task reallocation, job redesign, and efficiency gains, rather than widespread workforce reductions.

A key contribution of the study is the development of a conceptual framework that conceptualizes digital transformation as a multi-level process comprising basic digitization, process automation, and AI-supported adoption. Importantly, the findings highlight that this process is not purely technological but is shaped by employee adaptation, organizational restructuring, and sectoral context. This integrated perspective extends existing literature by explicitly linking technological adoption with human and organizational dimensions.

From a practical perspective, the findings suggest that organizations should approach digital transformation as a structured and phased process. In the initial stage, firms should focus on implementing basic digital tools to improve data management and reduce manual workload. In the second stage, emphasis should shift toward process automation and the integration of digital systems to enhance efficiency and coordination. Finally, in the advanced stage, organizations may begin to experiment with AI-based solutions, provided that sufficient technological and human capabilities are in place.

At the same time, the study underscores the importance of supporting employee adaptation through continuous learning, knowledge sharing, and effective change management. Without adequate investment in human capital, the potential benefits of digital technologies may remain underutilized. These findings also have implications for policymakers, particularly in the context of Central and Eastern Europe, where targeted support for SME digitalization, digital skills development, and collaboration between academia and industry may accelerate digital transformation.

The study is subject to several limitations. The relatively small and non-random sample limits the generalizability of the findings, and the qualitative design may be influenced by subjective interpretations. Future research could address these limitations by employing mixed-methods approaches, larger datasets, and longitudinal designs to capture the evolution of digital transformation processes over time. Comparative studies across countries or sectors would further enhance understanding of contextual differences in digital adoption.

***Abstract*—Imagined speech decoding from non-invasive electroencephalography remains a challenging problem, especially when moving beyond small vocabularies and optimistic evaluation protocols. This work revisits the Arizona State University (ASU) imagined speech dataset and treats it as a rigorous ten-class benchmark, with a focus on offline, corpus-level analysis rather than real-time deployment. After unifying all recordings into 5 s epochs at 256 Hz, 6,520 trials with 60 EEG channels were preprocessed using bandpass filtering, baseline correction, z-score normalization, and trial-wise ICA for artifact attenuation. On top of this pipeline, a comprehensive feature representation was constructed that combines common spatial patterns, discrete wavelet statistics, time-domain moments, autocorrelation coefficients, power spectral density band powers, and Hjorth parameters into a single 5,120-dimensional vector. A block-wise ablation indicates that autocorrelation, CSP, PSD, and Hjorth features carry most of the discriminative information in this setting, while wavelet and simple statistical descriptors contribute little and can be removed without harming performance. Using only the informative blocks (3,440 features), a multinomial logistic regression classifier reaches about 0.41 accuracy and 0.42 macro F1 on the ten-class task, roughly four times chance level. A multi-layer perceptron and a CNN–LSTM model, trained under the same splits and with class weighting, do not outperform this linear baseline and exhibit stronger overfitting. Within the evaluated protocol, these findings suggest that carefully engineered features capture most of the discriminative structure accessible on this corpus, and that deeper models add complexity without clear benefit. The study provides a transparent baseline and a feature-level analysis that can serve as a reference point for future work on imagined speech recognition and transfer learning across EEG corpora.**

Keywords*—EEG-based imagined speech; ASU imagined speech dataset; brain–computer interface; feature extraction; logistic regression

I. Introduction

Electroencephalography (EEG) based imagined speech recognition has emerged as a promising route toward silent speech interfaces for users who cannot rely on the vocal tract, for example people with advanced neuromuscular disease or severe dysarthria. By decoding internal speech representations directly from cortical activity, such systems aim to restore basic communication with minimal motor effort and without external articulation. Recent surveys on silent speech interfaces and EEG-based brain computer interfaces consistently highlight imagined speech as one of the most challenging yet societally important application domains [1], [2].

Despite rapid advances in deep learning, the performance of noninvasive imagined speech decoders remains modest when evaluated in realistic conditions. Most published studies operate on highly constrained tasks, such as binary vowel classification or discrimination between a few short words, and often use subject-specific models with carefully tuned pipelines. Reported accuracies in these settings typically lie around 70 to 80 percent, but they tend to fall toward 20 to 50 percent once the vocabulary is expanded, the class structure becomes more heterogeneous, or evaluation protocols adopt stricter cross-validation schemes [3], [4]. This gap between optimistic benchmark numbers and robust multiclass performance has motivated calls for more systematic baselines and ablation studies that clarify what can realistically be achieved with current sensors, preprocessing strategies, and feature representations.

The Arizona State University (ASU) imagined speech corpus is one of the few publicly available datasets that support such analysis [5]. It contains multi-session EEG recordings of short words, longer phrases and isolated vowels, acquired at 256 Hz with a high-density montage and segmented around the final auditory cue [6]. Compared with smaller imagined speech datasets, ASU introduces several sources of difficulty that are frequently encountered in real use: multiple lexical categories, variable trial lengths, and imbalanced class distributions that reflect differences in the number of repetitions per condition. Previous work on ASU has mainly focused on end-to-end architectures that combine time frequency representations with convolutional or recurrent neural networks, usually reporting single model accuracies without detailed inspection of the underlying feature space [7].

In parallel, the broader EEG community has developed a rich toolbox of handcrafted feature extractors, such as common spatial patterns, wavelet coefficients, spectral band powers and Hjorth parameters, that have proved effective in motor imagery

*Corresponding authors

and other BCI paradigms [2]. However, their behaviour in the context of imagined speech is less well documented. Many studies adopt a fixed subset of features without quantifying how each block contributes to classification, whether different descriptors are redundant or complementary, or how simple linear classifiers compare with more elaborate deep architectures when both are applied to the same feature space. This lack of systematic feature-level analysis makes it difficult to interpret negative results, to compare methods across papers, or to design compact models that might eventually run in real time on portable hardware.

The present work addresses these gaps through a deliberately transparent study of EEG-based imagined speech recognition on the ASU dataset. A reproducible preprocessing pipeline is first constructed that performs channel selection, bandpass filtering, baseline correction, trial length normalization and artifact removal using independent component analysis. The cleaned signals are then transformed into a large unified feature set... On top of this representation, several strong but interpretable classifiers are evaluated, including multinomial logistic regression, linear support vector machines, multilayer perceptrons and a lightweight CNN LSTM network, using consistent train validation test splits and macro-averaged metrics to account for label imbalance. The intended deployment scenario is explicitly offline: the goal is to characterise what handcrafted EEG features can achieve on the ASU corpus under a fixed evaluation protocol, rather than to prototype a real-time BCI. The resulting baselines are framed as a diagnostic reference that any subsequent real-time system, with its tighter latency and subject-adaptation constraints, would have to match or exceed.

Beyond reporting headline accuracies, particular emphasis is placed on understanding which feature families actually support discrimination in this ten-class imagined speech task. A leave-one-block-out analysis and reduced feature experiments quantify the marginal contribution of each feature group and show, perhaps counterintuitively, that a smaller subset that combines spatial filters, autocorrelation, band power, and Hjorth parameters can match or slightly improve the performance of the full feature set. These results provide a nuanced picture: overall macro F1 scores remain in the range of 0.40 to 0.44, which confirms the intrinsic difficulty of the problem on this dataset, yet the systematic ablations reveal meaningful structure that can inform subsequent model design.

In summary, this study makes three main contributions. First, it offers a carefully documented preprocessing and feature extraction pipeline for the ASU imagined speech corpus that other groups can reuse as a common baseline. Second, it provides a comparative evaluation of classical and deep classifiers on a unified feature space, highlighting where additional model complexity does and does not translate into improved generalization. Third, it delivers a detailed feature-level analysis that clarifies which descriptors carry the most useful information for ten-class imagined speech recognition. Taken together, these contributions position transparent baselines as an essential complement to more ambitious end-to-end architectures, helping the field move toward more realistic expectations and more robust future systems.

The remainder of this study is organised as follows: Section II reviews related work on EEG-based imagined speech recognition, with particular attention to the ASU corpus and to feature engineering practices in non-invasive brain–computer interfaces. Section III describes the proposed methodology, including the preprocessing pipeline, the multi block feature extraction scheme, and the classification models and evaluation protocols. Section IV presents the experimental results on the ten-class ASU task, reports the feature ablation and model comparison findings, and discusses their implications for future imagined speech systems. Finally, Section V summarises the main conclusions, highlights the limitations of the current study, and outlines several directions for extending the work through cross-dataset transfer learning and more compact real-time implementations.

II. Related Works

Research on EEG-based imagined speech recognition has expanded notably in the last five years, but performance remains far below that of motor imagery or overt speech decoding. Recent systematic reviews show that most EEG speech imagery systems are evaluated on small, highly constrained vocabularies and often under subject-dependent protocols, where models are trained and tested on the same individual. Under such conditions, reported accuracies can exceed 80 %, yet they typically fall to the 40–60 % range when the vocabulary grows, when multi-class settings are used, or when cross-subject generalisation is considered [8]. This gap between optimistic, laboratory-scale results and more realistic, multi-class performance is central to the present work.

A first line of recent studies still relies heavily on hand-crafted features combined with relatively shallow classifiers. Before surveying individual contributions, it is useful to fix the three axes along which they differ most and that determine whether a reported number is directly comparable to another: 1) the scale and paradigm of the dataset, including the number of participants, the number of imagined classes, and whether the corpus uses short vowels, isolated words, phrases or continuous material; 2) the evaluation protocol, spanning subject-dependent versus cross-subject splits, stratified trial-level versus session-level partitioning, and whether macro-averaged metrics are used in the presence of class imbalance; and 3) the model class, ranging from linear projections on engineered features to convolutional, recurrent or hybrid deep architectures operating on raw or minimally processed EEG. Headline accuracies that look superficially similar can correspond to very different tasks along these axes, and most of the apparent disagreement in the literature dissolves once studies are stacked against this grid. The studies surveyed below are ordered accordingly, moving from small-vocabulary subject-dependent pipelines with shallow classifiers toward multi-class, cross-subject deep models, and are referenced back to this frame whenever they are introduced. These works exploit time-frequency decompositions, power spectral descriptors, and spatial projections such as common spatial patterns in order to enhance signal-to-noise ratio before classification. For example, deep metric learning has been used to map EEG trials for five vowels and six words into a latent space where distances reflect phonetic

similarity, achieving around 45 % accuracy in a six-word imagined speech task despite strong inter-subject variability [9]. Other studies report comparable performance when combining wavelet-based features with traditional machine learning models, particularly when the number of commands is limited, and the recording protocol is tightly controlled [6]. These results suggest that carefully engineered features can extract some discriminative structure from EEG speech imagery, but they do not fully resolve the problem of class overlap in larger label spaces.

More recent work has shifted towards deep learning architectures that operate directly on raw or minimally processed EEG. Abdulghani et al. used wavelet scattering representations of 8-channel EEG and an LSTM network to classify four imagined directional commands, reporting an accuracy of about 92.5 % under a subject-specific setting, which illustrates how recurrent models can capture temporal dynamics when the task is well constrained [10]. In contrast, when the vocabulary increases and multi-class decoding is attempted, accuracy tends to decline. Alharbi et al. proposed hybrid 3D CNN-StackLSTM and 3D CNN-BiLSTM models that operate on sequences of EEG topographic maps for five imagined words in the BCI2020 dataset. Their best model reached an average accuracy of roughly 45 %, with substantial variability across subjects, even though the architecture explicitly encodes both spatial and temporal information [11]. Similar hybrid CNN-BiLSTM systems, often combined with wavelet-based front-ends or metaheuristic feature selection, have shown strong single-subject performance but less convincing cross-subject generalisation [12].

Another strand of work explores transfer learning and representation learning to mitigate the scarcity of labelled imagined speech data. Lee et al. applied deep metric learning to jointly optimise a feature space for vowels and words, enabling reuse of representations across tasks and datasets and achieving mid-40 % accuracy for six-class problems [9]. Other authors have investigated transfer learning from overt speech or from related EEG paradigms. One recent study proposed a transfer learning framework that jointly extracts temporal and spectral features, then fine-tunes a classifier on limited imagined speech trials, showing consistent but modest gains over training from scratch [13], [14]. These approaches underline that cross-task and cross-corpus transfer is feasible, yet the improvements are incremental and far from closing the gap to practical communication rates.

The limitations of current performance are closely tied to data availability. For many years, researchers relied on small institutional datasets with a handful of commands or vowels, which restricted the diversity of linguistic material and impeded robust evaluation. The recent release of the Chinese Imagined Speech Corpus (Chisco), which contains more than 20,000 sentences of high-density EEG per subject, is a major step forward and offers a much richer testbed for neural language decoding from EEG [15]. However, most published work with Chisco and similar corpora is still at an early stage and often focuses on feasibility demonstrations rather than systematic baselines across feature families and model classes [8].

Against this backdrop, the present study takes a deliberately conservative and diagnostic perspective. Instead of aiming for a complex, highly tuned end-to-end model, the analysis is performed on a medium-scale imagined speech dataset (ASU) that contains ten classes and 6,520 trials, using a rich but interpretable feature space that combines common spatial patterns, discrete wavelet features, statistical descriptors, autocorrelation, band-power estimates, and Hjorth parameters. The discriminative contribution of each feature family is then quantified by analysing block-wise performance with linear models and by comparing these baselines to compact neural architectures such as multilayer perceptrons and CNN-LSTM hybrids. The results, which cluster around 40–44 % macro F1 for ten-class classification, are consistent with the more demanding multi-class findings in the recent literature and provide a transparent reference point for future work on transfer learning and model compression in EEG-based imagined speech recognition.

III. Materials and Methods

This section describes the complete processing pipeline used in this study, from raw electroencephalographic (EEG) recordings to the classification of imagined speech commands. The workflow is organised into three tiers. Tier 1 covers data acquisition from the ASU imagined speech corpus and the preprocessing applied to the 60-channel EEG signals, including filtering, baseline correction, artefact rejection, and quality control. Tier 2 details the feature engineering stage, in which six complementary feature blocks are extracted and combined into a reduced 3,440-dimensional representation. Tier 3 introduces the discriminative models and evaluation procedures that operate on this compact feature space. An overview of these stages and their dependencies is summarised in Fig. 1.

A. Dataset and Labelling

The ASU imagined speech dataset was collected by the Human Oriented Robotics and Controls (HORC) laboratory at Arizona State University using a 64-channel BrainProducts ActiCHamp amplifier. Recordings were acquired from 15 healthy volunteers (11 males and 4 females), who were instructed to silently rehearse visually and auditorily cued prompts without overt articulation or muscle movements. The vocabulary comprised four groups of stimuli: short commands (“in”, “out”, “up”), long words (“cooperate”, “independent”), short–long combinations (“in”, “cooperate”), and sustained vowels (/a/, /i/, /u/). Each trial followed a structured cueing protocol that aligned the onset of imagined speech relative to a sequence of auditory beeps, a design that is now standard in imagined speech paradigms [5], [16].

This study focused on the "last-beep" interval, that is, the segment immediately preceding the final cue, which has been reported to concentrate the most stable imagined speech activity while limiting contamination from anticipatory and post-movement processes [16]. After aggregating all usable files and retaining only last-beep epochs, a total of $N = 6520$ trials distributed across ten imagined classes. These classes correspond to three short commands (“in”, “up”, “out”), two long words (“cooperate”, “independent”), two short–long phrase conditions (“cooperate”, “in”), and three vowels (“a”, “i”, “u”). For supervised learning, each semantic class was mapped to an

integer label $y \in \{0, \ldots, 9\}$, following a consistent mapping used throughout the subsequent analysis and model training.

The original montage contained dedicated electrooculography (EOG) channels that are useful for artefact detection but not for decoding imagined speech. For each trial, the designated EOG indices (0, 9, 32, and 63 in the original layout) were removed, and the first $C = 60$ EEG channels as the working montage. All signals were sampled at $f_s = 256$ Hz, and trial lengths varied slightly across recordings because of minor differences in cue timing and file boundaries. Before feature extraction and modelling, these variable-length epochs were transformed into a fixed-size tensor through the preprocessing pipeline described in Section III.B. The chosen epoch length of approximately 5 s corresponds to the full last-beep interval defined by the ASU acquisition protocol and used in previous ASU-based analyses; it encompasses the imagined articulation itself together with a short post-cue window during which sustained speech-motor activity has been reported. Shorter windows would truncate this sustained activity and eliminate the lag range exploited by the autocorrelation and Hjorth descriptors introduced later, whereas substantially longer windows would reintroduce pre-cue anticipation and post-trial drift that the last-beep alignment was designed to avoid.

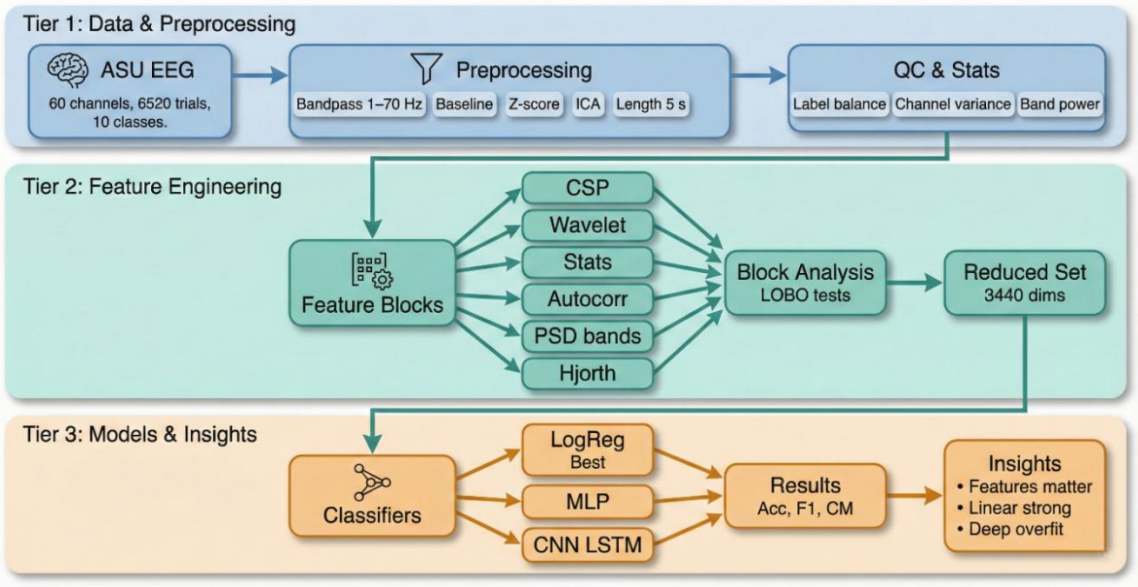

Fig. 1. Overview of the proposed EEG imagined speech recognition pipeline on the ASU dataset

B. Preprocessing Pipeline

All preprocessing was implemented in Python using MNE-Python together with standard scientific libraries (NumPy, SciPy, scikit-learn). The design goal was to obtain artefact-reduced and temporally aligned trials while preserving the spectral content that is typically informative for imagined speech and BCI tasks [17]. The same sequence of operations was applied to every trial: temporal alignment by zero-padding or truncation, band-pass filtering, baseline correction, trial-wise z-score normalization, and independent component analysis (ICA) for artefact attenuation. Fig. 2 displays the raw versus the preprocessed data for the dataset using our pipeline.

Let $x_c(t)$ denote the raw signal from channel $c \in \{1, \ldots, C\}$ at discrete time index t, with trial-specific length T. First, a common temporal length $T_{\max}$, defined as the maximum number of samples across all trials in the dataset. For trials shorter than $T_{\max}$ we applied zero-padding at the end, and for trials longer than $T_{\max}$ we truncated the surplus samples:

$$\bar{x}_c(t) = \begin{cases} x_c(t), & 0 \le t < T, \\ 0, & T \le t < T_{max}, \end{cases} \quad (1)$$

This operation produces a temporally aligned representation without interpolation, which helps preserve the phase relationships of oscillatory activity that are often exploited in EEG decoding [18]. At this stage, each trial has shape $C \times T_{\max}$.

To suppress slow drifts and high-frequency sensor noise while retaining the classical delta to low-gamma range relevant for cognitive and speech-related processes, a zero-phase fifth-order Butterworth band-pass filter with passband $[f_{\text{low}}, f_{\text{high}}] = [1,70]$ Hz. The filter was implemented using forward-backward IIR filtering (filtfilt) to avoid phase distortion [19]. For each channel, the band-passed signal is:

$$y_c(t) = \mathcal{F}_{\text{BP}}\left(\bar{x}_c(t); f_{\lambda o \omega} = 1 \text{ Hz}, f_{\eta \iota \gamma \eta} = 70 \text{ Hz}\right), \quad (2)$$

where, F_{BP} denotes the zero-phase band-pass operator applied along the time axis.

Slow baseline shifts were then removed at the trial level. For the ASU dataset, a dedicated baseline interval of 200 ms was available at the beginning of each epoch. Let B be the set of baseline time indices, corresponding to [0,0.2]s at 256 Hz. The baseline mean for the channel c is:

$$\mu_c^{\text{base}} = \frac{1}{|B|} \sum_{t \in B} y_c(t). \quad (3)$$

The baseline-corrected signal is then:

$$z_c(t) = y_c(t) - \mu_c^{\beta \alpha \sigma \varepsilon}. \quad (4)$$

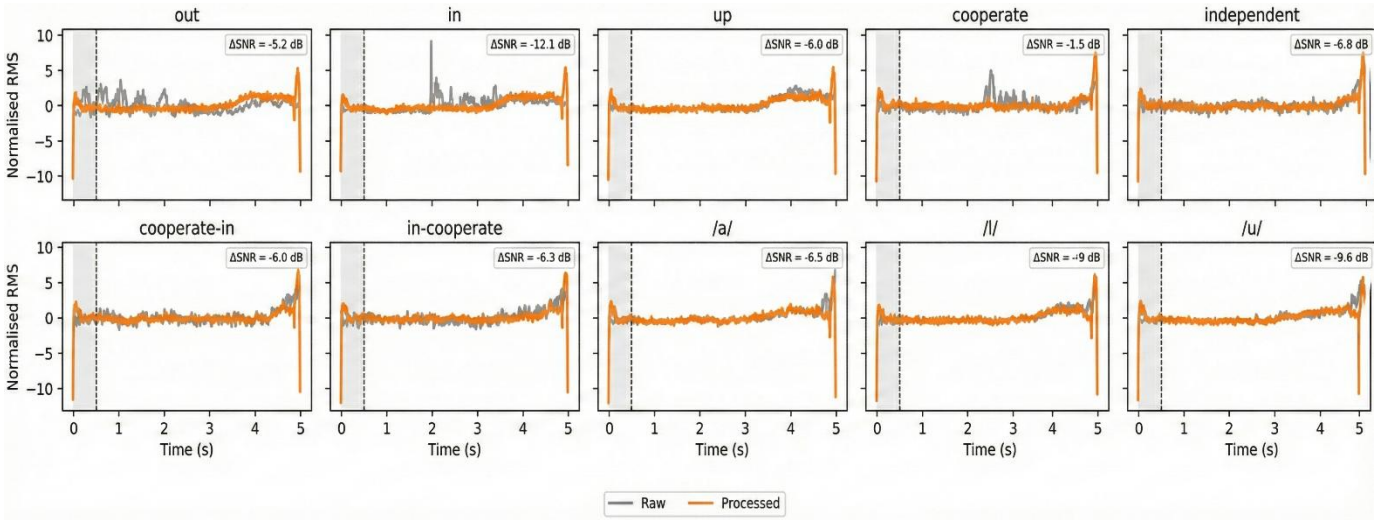

Fig. 2. Raw versus processed classes of the ASU dataset.

When a dedicated baseline window is not explicitly defined, the first 5% of the trial can be used as an approximate baseline, which is a common practical choice in continuous EEG paradigms [20].

To stabilise subsequent covariance-based methods and ensure that channels contribute on comparable scales, trial-wise z-score normalization was performed per channel. For each channel c, the mean and standard deviation of the baseline-corrected signal were computed over the entire trial,

$$\mu_c = \frac{1}{T_{max}} \sum_{t=0}^{T_{max}-1} z_c(t), \tag{5}$$

$$\sigma_c = \sqrt{\frac{1}{T_{max}} \sum_{t=0}^{T_{max}-1} (z_c(t) - \mu_c)^2}, \tag{6}$$

and obtained the normalized time series:

$$\hat{x}_c(t) = \frac{z_c(t) - \mu_c}{\sigma_c + \varepsilon} \tag{7}$$

where, ε is a small constant used for numerical stability. This per-trial normalization mimics the standardisation strategies widely adopted in deep EEG models and large-scale BCI datasets [21], [22].

Residual eye movements and muscle artefacts were attenuated using ICA. For each trial, an MNE RawArray was constructed with $C = 60$ channels and sampling rate $f_s = 256\ Hz$, and estimated an ICA decomposition with as many components as channels. Let $X \in \mathbb{R}^{C \times T_{\max}}$ denote the normalized multichannel signal. ICA models X as a linear mixture of statistically independent sources:

$$X = AS \tag{8}$$

where, $A \in \mathbb{R}^{C \times C}$ is the mixing matrix and $S \in \mathbb{R}^{C \times T_{max}}$ contains the independent components. Components whose time courses and topographies resembled canonical ocular or myogenic artefacts were excluded heuristically, following established guidelines for EEG artefact handling [23]. The cleaned signal is then reconstructed as:

$$\hat{X} = A\hat{S} \tag{9}$$

where, $\hat{S}$ equals S with the identified artefact components set to zero. ICA-based correction remains one of the most effective approaches for denoising EEG in both clinical and BCI contexts [24].

After preprocessing, each trial is represented by a cleaned tensor $\hat{X} \in \mathbb{R}^{C \times T_{\max}}$. Stacking all $N = 6520$ trials yields the final preprocessed dataset:

$$\hat{\mathcal{X}} \in \mathbb{R}^{N \times C \times T_{max}}, \tag{11}$$

which serves as the input to the subsequent feature extraction and classification stages described in the following subsections.

C. Feature Extraction

We designed a unified feature extraction block that compresses each preprocessed trial into a 5120-dimensional vector. The block combines six complementary descriptors: spatial filters from Common Spatial Patterns (CSP), time frequency statistics from a discrete wavelet transform, low-order time domain moments, lagged autocorrelation, band power from power spectral density (PSD), and Hjorth mobility and complexity. Similar hybrid designs have been shown to outperform single-family features in motor imagery and speech imagery BCIs, since they capture both transient and sustained dynamics across multiple scales. The resulting representation is deliberately broad rather than minimal: the intent is to expose redundancy between feature families so that the block-wise ablation in Section IV-B can quantify which descriptors genuinely contribute and which can be removed. All features were computed per trial and concatenated, then normalised once at the end using a single StandardScaler fitted on the training partition, avoiding information leakage into the test set. The trade-off between feature breadth and redundancy is examined directly in the ablation results, and the reduced 3,440-dimensional subset is presented there as the operational representation used by the classifiers [25].

1) Common spatial patterns: To capture spatially discriminative activity across electrodes, CSP was applied in a one versus rest setting for each imagined class. Let denote a single trial with channels and time samples, and let and be the

class averaged covariance matrices for the target class and the pooled background, respectively. For each binary problem CSP solves the generalised eigenvalue problem $X \in \mathbb{R}^{C\times T}$ $C T \Sigma_1 \Sigma_2$:

$$\Sigma_1 \mathbf{w}_k = \lambda_k \Sigma_2 \mathbf{w}_k, \quad (12)$$

where, $\mathbf{w}_k$ is the k-th spatial filter and λ_k the associated eigenvalue. Projecting the trial as $\mathbf{z}_k = \mathbf{w}_k^T X$ and computing the log-normalised variance:

$$f_k^{\mathrm{CSP}} = \log \frac{\mathrm{var}(\mathbf{z}_k)}{\sum_j \mathrm{var}(\mathbf{z}_j)} \quad (13)$$

yields CSP features that emphasise spatial patterns with maximal class-specific variance [26]. The implementation allocates n_{comp} filters per class, chosen adaptively from the number of channels and classes, which in the ASU configuration results in 60 CSP features per trial.

2) Wavelet-based time frequency statistics: Fine-grained time frequency structure was represented using a Level 3 Discrete Wavelet Transform (DWT) with a Daubechies 4 Mother Wavelet. Db4 is frequently adopted in EEG work because it provides compact support and smooth oscillatory atoms that align well with dominant EEG rhythms in the alpha and beta ranges [6]. For each channel, the preprocessed time series is decomposed into one approximation and three detail coefficient vectors. For each coefficient vector of length six, statistics are computed: $c, x_c(t)\{\mathbf{c}_\ell\}_{\ell=0}^{3} n$

$$\mu = \frac{1}{n}\sum_{i=1}^{n} c_i, \quad (14)$$

$$\sigma^2 = \frac{1}{n-1}\sum_{i=1}^{n} (c_i - \mu)^2 \quad (15)$$

$$\mathrm{skew} = \frac{1}{n}\sum_{i=1}^{n} \left(\frac{c_i-\mu}{\sigma}\right)^3, \quad (16)$$

$$\mathrm{kurt} = \frac{1}{n}\sum_{i=1}^{n} \left(\frac{c_i-\mu}{\sigma}\right)^4, \quad (17)$$

along with the minimum and maximum of c. Concatenating these statistics across all levels and 60 channels yields a 1440-dimensional DWT feature block that captures transient, band-limited changes associated with imagined speech cues [27].

3) Time domain statistics: To summarise coarse distributional properties in the time domain, four low-order moments are computed directly from the baseline corrected and normalised signal. For each channel, we estimate the mean, standard deviation, skewness, and kurtosis over time and concatenate them across channels. The resulting 240-dimensional block provides a compact characterisation of overall amplitude, variability, and waveform asymmetry. Although simple, such statistics have been reported to add complementary information when combined with more structured features in EEG classification tasks [28] $cx_c(t)$.

4) Autocorrelation features: Imagined speech tends to recruit sustained, quasi-rhythmic activity that extends over several hundred milliseconds, and articulatory-motor planning signals have been reported to unfold over comparable timescales in overt and covert speech paradigms. To capture these temporal dependencies, the one-sided autocorrelation is computed for each channel up to a maximum lag samples, which corresponds to approximately 0.2 s at 256 Hz. This horizon is short enough to avoid washing out the moment-to-moment dynamics of a 5 s trial, yet long enough to span the dominant alpha/beta cycles (roughly 50–400 Ms) that are implicated in speech-motor and sensorimotor integration, and it is comparable to the autocorrelation ranges adopted in earlier imagined-speech and motor-imagery feature studies. For channel, $\tau_{\max} = 50c$:

$$r_c(\tau) = \sum_{t=0}^{T_{\max}-1-\tau} x_c(t)x_c(t+\tau), \tau = 0, \ldots, \tau_{\max} \quad (18)$$

The first 50 autocorrelation coefficients per channel are concatenated to form a 3000-dimensional block across all 60 channels. These features encode the decay and periodicity of channel-wise dynamics without imposing stationarity assumptions and have been shown to benefit EEG-based decoding of cognitive and motor states [29].

5) Power spectral density and band power: Frequency-specific information is extracted using Welch's Method for PSD Estimation. Each channel is segmented into overlapping windows, tapered with a Hamming window, and the periodograms are averaged to obtain. The PSD is then integrated within five canonical bands $PSD_c(f)$:

$$P_c^{\theta} = \sum_{f\in[4,8)} PSD_c(f), \quad (19)$$

$$P_c^{\beta} = \sum_{f\in[13,30)} PSD_c(f), \quad (20)$$

$$P_c^{\delta} = \sum_{f\in[0.5,4)} PSD_c(f), \quad (21)$$

$$P_c^{\alpha} = \sum_{f\in[8,13)} PSD_c(f), \quad (22)$$

$$P_c^{\gamma} = \sum_{f\geq 30} PSD_c(f), \quad (23)$$

yielding five band powers per channel and 300 PSD-based features per trial. Band power in these ranges remains a workhorse descriptor in motor imagery and speech imagery BCIs and offers a robust, interpretable link to underlying oscillatory processes [30].

6) Hjorth parameters: Finally, Hjorth mobility and complexity parameters are computed, which summarise the spectral content of a signal using simple variance ratios in the time domain. For channel, let denote the time series, its first discrete derivative, and its second derivative. Mobility and complexity are defined as $cx_c(t)\dot{x}_c(t)\ddot{x}_c(t)$:

$$\mathrm{mobility}_c = \sqrt{\frac{\mathrm{var}(\dot{x}_c(t))}{\mathrm{var}(x_c(t))}}, \quad (24)$$

$$\mathrm{complexity}_c = \sqrt{\frac{\mathrm{var}(\ddot{x}_c(t))}{\mathrm{var}(\dot{x}_c(t))}} / \mathrm{mobility}_c. \quad (25)$$

These quantities reflect the dominant frequency and the change in frequency over time and have been repeatedly validated as efficient EEG features for BCI and clinical applications [31]. Concatenating mobility and complexity

across the 60 channels produces an 80-dimensional Hjorth feature block.

7) Feature normalisation and reduced subset: All six blocks are concatenated to form a feature matrix, where trials. A single StandardScaler is then fitted on to obtain normalised features with zero mean and unit variance per dimension, which are used by both linear and deep models. To reduce redundancy and computational cost, we also define a reduced subset by retaining only the CSP, Autocorrelation, PSD and Hjorth Blocks, resulting in a 3440-dimensional representation. As discussed later in the results, this subset preserves most of the discriminative structure in a simple Multinomial Logistic Regression Analysis, while substantially lowering the input dimensionality for the neural classifiers. $F \in \mathbb{R}^{N\times 5120} N = 6520 F\tilde{F}$.

D. Model Architectures and Training Procedure

All classification experiments on the ASU imagined speech dataset were carried out on the reduced feature representation described in Section III-C. Each trial is represented by a 3440-dimensional vector $\mathbf{x} \in \mathbb{R}^{3440}$, obtained by concatenating spatial (CSP), temporal (autocorrelation), spectral (PSD), and dynamical (Hjorth) descriptors from the preprocessed EEG. The ASU corpus contributes 6520 labelled trials with ten classes ($y \in \{0, \ldots, 9\}$), corresponding to short, long, short-long, and vowel commands. This setting allows us to decouple model behaviour from low-level signal processing and to focus on how different architectures exploit the same feature space, in line with recent work on deep learning for EEG-based BCIs.

1) Baseline and deep architecture: Three discriminative models were considered: a Multinomial Logistic Regression Baseline, a Multilayer Perceptron (MLP), and a Deeper CNN-BiLSTM-FCNN Hybrid. The motivation for this choice was comparative rather than architectural optimisation. The linear model establishes an interpretable reference in the same feature space. The MLP tests whether a modest amount of non-linear recombination of the engineered features improves discrimination. The CNN-BiLSTM-FCNN is included as a deliberate stress test: although the 3,440-dimensional feature vector is a heterogeneous concatenation of spatial, spectral and temporal descriptors and therefore lacks the strict local ordering that convolutions typically exploit in raw EEG decoding, this architecture has been reported to improve performance on pre-engineered EEG features in several imagined-speech studies. Including it on the same representation allows an empirical test of whether any residual sequential structure along the feature axis can be recovered by a deeper sequence model, and if so, at what computational cost. Alternative architectures that are better suited to tabular inputs – for instance, gradient-boosted ensembles or attention-based tabular encoders – are considered promising directions for follow-up work but are not evaluated here, so as to preserve a controlled three-way comparison on a common feature space. All three implement the same probabilistic mapping via a softmax output layer, but differ in how they transform the input features. The detailed architectures of the three classifiers are illustrated in Fig. 3: $p_\theta(y \mid \mathbf{x})$.

For the logistic regression baseline, the conditional class probabilities are given by:

$$p_\theta(y = k \mid \mathbf{x}) = \frac{\exp\left(\mathrm{w}_k^\top \mathrm{x} + b_k\right)}{\sum_{j=0}^{C-1} \exp\left(\mathrm{w}_j^\top \mathrm{x} + b_j\right)}, k = 0, \ldots, C-1, \quad (26)$$

with $C = 10$ and $\theta = \{\mathrm{w}_k, b_k\}_{k=0}^{C-1}$. This model provides a well-understood linear baseline to contextualise the gains from non-linear feature transformations.

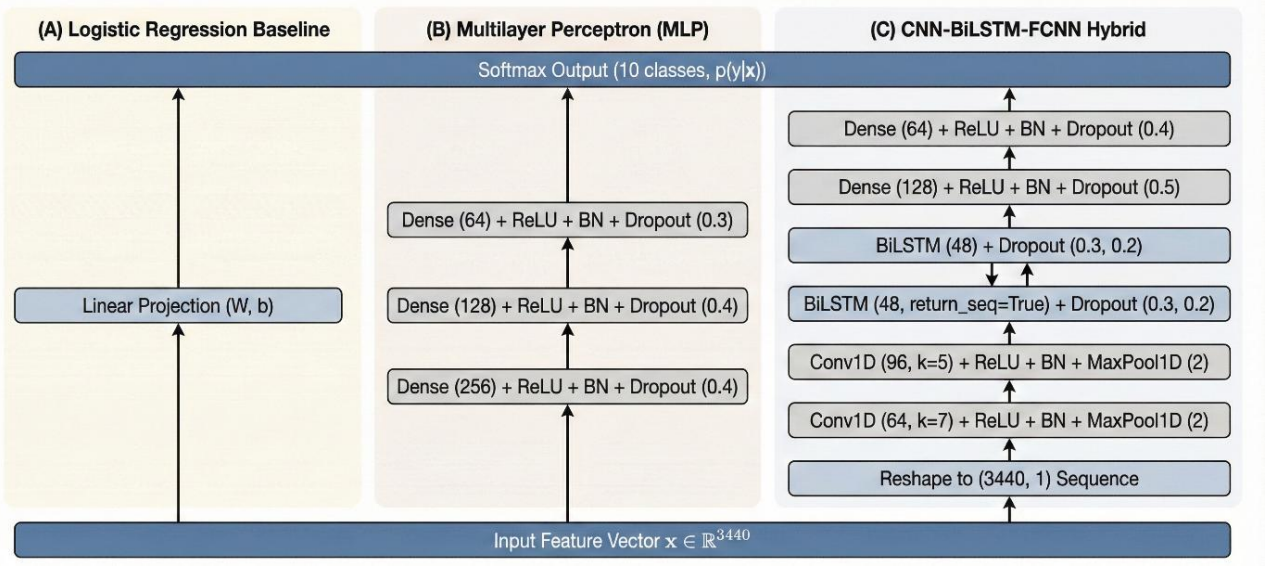

Fig. 3. Model architectures used in the ASU experiments: (A) Logistic regression baseline, (B) Multilayer perceptron with three hidden layers, and (C) CNN–BiLSTM–FCNN hybrid operating on the 3 440-dimensional feature sequence.

The improved MLP operates directly on x and stacks three fully connected hidden layers with batch normalisation and dropout. If $\mathrm{h}^{(0)} = \mathrm{x}$, each hidden layer l computes

$$\mathrm{h}^{(l)} = \phi\left(\mathrm{W}^{(l)}\mathrm{h}^{(l-1)} + \mathrm{b}^{(l)}\right), \tag{27}$$

Where, $\phi(\cdot)$ is the rectified linear unit (ReLU). The final softmax layer produces $\hat{\mathbf{y}} = \text{softmax}\left(\mathrm{W}^{(L)}\mathrm{h}^{(L-1)} + \mathrm{b}^{(L)}\right)$. All dense layers are regularised with an ℓ_2 penalty on the weights to reduce overfitting in this relatively high-dimensional space. Such compact MLPs have been found competitive on engineered EEG features when the sample size is modest.

The CNN-BiLSTM-FCNN model treats each feature vector as a 1D sequence of length 3440 with a single channel and therefore seeks local patterns along the feature axis. Two 1D convolutional blocks first extract local motifs:

$$\mathbf{z}_t^{(c)} = \phi\left(\sum_j \sum_\tau w_{j,\tau}^{(c)} x_{j,t+\tau} + b^{(c)}\right), \tag{28}$$

followed by batch normalisation and max pooling to build increasingly abstract representations. The resulting sequence of feature maps is fed to stacked bidirectional LSTM layers that capture longer range dependencies by processing the sequence in both forward and backward directions. Bidirectional recurrent architectures are known to improve sequence modelling in speech and EEG applications by exploiting past and future context. The final temporal embedding is passed through a small fully connected head with ReLU, batch normalisation, and dropout before the softmax classifier.

Table I summarises the main architectural choices. All hyperparameters are fixed across experiments on the ASU dataset in order to attribute performance differences to the model families rather than to extensive tuning.

TABLE I. TRAINING AND OPTIMIZATION SETTINGS FOR THE THREE CLASSIFIERS ON THE REDUCED ASU FEATURE SET

Model	Input shape	Optimizer	Initial LR	Max epochs	Batch size	Early stopping	LR schedule	Regularisation/class weighting
Logistic regression	(3440)	L2-regularised multinomial solver	–	–	–	–	–	ℓ_2 penalty on **W** class_weight = balanced
MLP (deep baseline)	(3440)	Adam	3×10−4	150	64	val_loss, 25	factor 0.5, patience 8, min_lr 10^{-5}	ℓ_2 on all dense layers, batch norm, dropout 0.4–0.3
CNN-BiLSTM-FCNN hybrid	(3440,1)	Adam	3×10−4	120	64	val_loss, 20	factor 0.5, patience 6, min_lr 10^{-5}	ℓ_2 on FC layers, batch norm, dropout 0.5–0.4, class_weight = balanced

2) Loss function, class weighting, and optimization: All models are trained with a weighted categorical cross-entropy loss. Given a training set, the objective is $\{(\mathbf{x}_i, y_i)\}_{i=1}^N$:

$$\mathcal{L}(\theta) = -\frac{1}{N}\sum_{i=1}^N w_{y_i} \log\, p_\theta(y_i \mid \mathbf{x}_i), \tag{29}$$

where, w_{y_i} is the class weight associated with label y_i. Class weights are computed inversely proportional to class frequencies in the training partition, which mitigates the moderate label imbalance observed in the ASU corpus and avoids the need for synthetic oversampling. Similar class reweighting strategies are standard practice in EEG classification when some commands appear less frequently than others.

As illustrated in Table I, all neural models use the Adam optimiser with an initial learning rate of 3×10^{-4}. Training proceeds for a maximum of 150 epochs for the MLP and 120 epochs for the CNN-BiLSTM-FCNN, using mini-batches of size 64. To reduce manual tuning, a Reduce-on-Plateau scheduler halves the learning rate whenever the validation loss fails to improve for several epochs (8 epochs for the MLP, 6 for the CNN-BiLSTM-FCNN), with a floor at 10^{-5}. Early stopping with patience of 25 epochs (MLP) and 20 epochs (CNN-BiLSTM-FCNN) restores the weights that achieve the lowest validation loss, which helps to prevent overfitting and stabilises the reported results.

3) Data partitioning and evaluation metrics: For each model, the 6520 ASU Trials are split with stratification into training, validation, and held-out test data. Stratification preserves the empirical label distribution across splits and ensures that rare classes are represented in both validation and test sets. No subject-specific information is used in this stage, since the goal of this experiment is to characterise how well different architectures exploit the engineered feature space rather than to probe cross-subject generalisation $60\%, 20\%, 20\%$.

The data were split at the trial level into train, validation, and test partitions of 60 %, 20 %, and 20 %, respectively, preserving the mild class imbalance described in Section III. To report performance in a way that is robust to this imbalance, overall accuracy and macro-averaged F1 are the primary metrics of interest. All models were trained with a single fixed random seed to keep the three-way comparison on strictly identical splits; the resulting point estimates should therefore be read as single-run performance on the held-out test set rather than as means of a sampling distribution. A formal repeated-runs analysis with confidence intervals over multiple seeds and resampled stratified splits is a natural next step and is discussed among the study's limitations. Accuracy is defined as:

$$\text{Acc} = \frac{1}{N}\sum_{i=1}^N \mathbf{1}\{\hat{y}_i = y_i\} \tag{30}$$

while macro-F1 averages per-class F1 scores,

$$F_1^{\text{macro}} = \frac{1}{K}\sum_{k=1}^K \frac{2\Pi\rho\varepsilon\chi\iota\sigma\iota\sigma\nu_k \text{Recall}_k}{\text{Precision}_k + \text{Recall}_k}, \tag{31}$$

with $K = 10$ classes. Macro-F1 is particularly informative for imagined speech where some commands are intrinsically harder to discriminate than others. This metric treats all classes equally, which is crucial in imagined speech tasks where misclassifying a rarely used command can be more problematic

than misclassifying a frequent one. Confusion matrices and full per class precision, recall, and F1 scores are additionally reported to reveal systematic confusions between short, long, and vowel commands and to support later qualitative analysis of error patterns.

Taken together, this design yields a controlled comparison between a linear baseline, a compact deep MLP, and a more expressive CNN–BiLSTM–FCNN architecture on exactly the same ASU feature representation.

IV. Results and Discussion

A. Overall Classification Performance

After feature engineering and block-wise reduction, the ASU imagined speech dataset yielded a compact representation of 6,520 trials in a 3,440-dimensional feature space with ten classes (three vowels, three phrase variants, and four directional commands). Table II summarises the test performance of the three classifiers evaluated on the reduced feature set.

The numbers are consistent with the bar plot in Fig. 4, which juxtaposes accuracy and macro-F1 for each model.

The first observation is that the linear logistic baseline already reaches a macro-F1 of about 0.42, essentially matching the deeper MLP. This confirms that once the EEG is projected into a carefully designed feature space, simple discriminative models can remain highly competitive, a pattern also reported for CSP-based motor imagery and imagined speech pipelines [32], [33]. The MLP does not significantly improve aggregate metrics, although it offers slightly more stable learning dynamics and provides a natural stepping stone toward later transfer learning stages in our broader programme.

The CNN–BiLSTM–FCNN hybrid, in contrast, underperforms slightly despite its far higher computational cost. For the MLP, both training and validation loss decrease rapidly during the first 30 epochs, after which validation loss plateaus while training loss continues to fall. Validation accuracy stabilises around 0.42, whereas training accuracy climbs above 0.60, indicating mild overfitting but no catastrophic divergence. A similar pattern is present, but more pronounced, for the CNN–BiLSTM model, whose validation loss flattens early while the network continues to specialise on the training set. These dynamics suggest that the reduced feature set does not provide enough independent evidence for the deeper temporal model to exploit, a finding in line with recent reports that end-to-end deep networks for non-invasive imagined speech often saturate near 30–40 % accuracy on vocabularies of 6–11 words [34], [35].

The confusion matrix in Fig. 5 further clarifies where errors arise. Vowel classes /a/, /i/, and /u/ show relatively high diagonal terms, with many trials correctly localised, while the directional commands “out”, “in”, and “up” are frequently confused with one another. The social-interaction phrases “cooperate”, “independent”, “cooperate-in”, and “in-cooperate” occupy an intermediate regime, with good separation between “cooperate-in” and the rest, but noticeable cross-talk between “cooperate” and “independent”. This structure mirrors previous findings that imagined vowels tend to elicit more stereotyped sensorimotor and auditory patterns than semantically richer phrases.

TABLE II. Test Accuracy, Macro-F1, and Qualitative Computational Cost for Three Classifiers Trained on the Reduced ASU Feature Set

Model	Test Accuracy (%)	Test macro-F1 (%)	Qualitative cost profile*
Logistic regression	41	42	Very low, single linear layer.
MLP (three-layer network)	41	42	Moderate, ≈ 60 epochs, fast per epoch.
CNN–BiLSTM–FCNN hybrid	40	38	High, long epochs and large parameter count.
*Cost profile is based on empirical training times and model size, not on formal complexity analysis.			

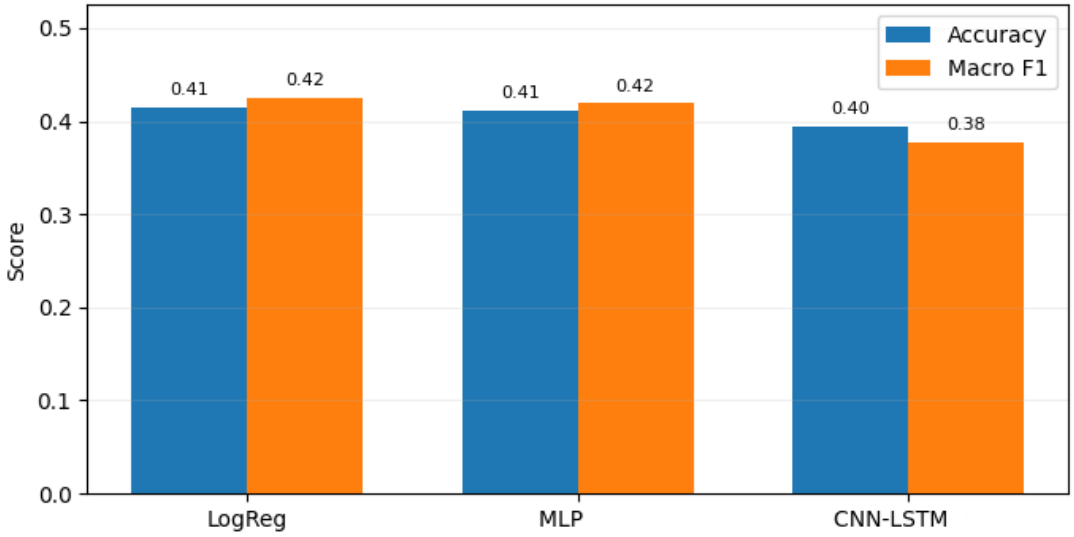

Fig. 4. Comparison of test accuracy and macro-F1 for logistic regression, MLP, and CNN–BiLSTM–FCNN on the reduced ASU features.

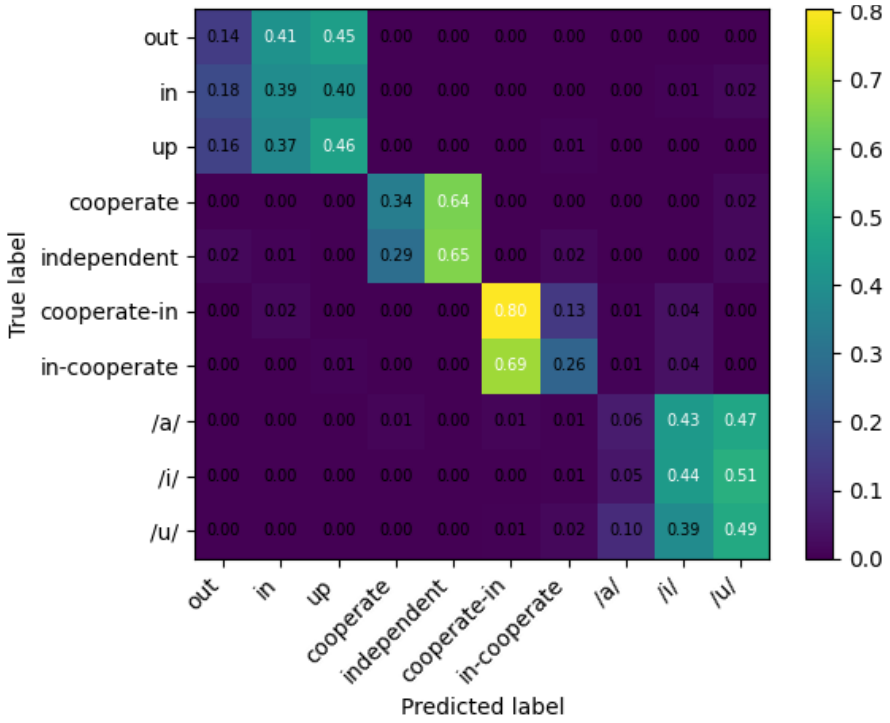

Fig. 5. Normalised confusion matrix for the CNN–BiLSTM–FCNN classifier on the ASU test set, showing systematic confusions among directional commands and vowels.

B. *Block-wise Contribution of Engineered Feature Families*

To understand how much each feature family contributes to the final performance, we conducted two complementary ablation studies on the logistic regression classifier: 1) single-block runs where the model receives only one family of features, and 2) leave-one-block-out (LOBO) runs where a given block is removed from the full feature set. The four blocks considered here are CSP spatial filters, autocorrelation statistics, band-power features from the power spectral density (PSD), and Hjorth parameters capturing activity, mobility, and complexity. These blocks have a long history in EEG decoding and are known to capture partially complementary aspects of oscillatory dynamics and temporal structure.

Table III summarises the macro-F1 obtained in the single-block and LOBO conditions, which correspond to the bar plots in Fig. 6.

TABLE III. BLOCK-WISE MACRO-F1 SCORES WITH ONE FEATURE FAMILY AND CHANGE IN MACRO-F1 WHEN EACH BLOCK IS REMOVED (LEAVE-ONE-BLOCK-OUT ANALYSIS).

Feature block	Macro-F1 with only this block	Δ macro-F1 when removed from the full set*
CSP	0.38	+0.015 (performance drops when removed)
Autocorrelation	0.42	−0.001
PSD	0.41	−0.003
Hjorth	0.40	−0.005

*Δ macro-F1 is defined as $F_1^{\text{all}} - F_1^{(-b)}$, where F_1^{all} is the macro-F1 with all blocks and $F_1^{(-b)}$ is the score with block b removed.

Several patterns emerge. First, when used in isolation, all four blocks produce macro-F1 scores in the range 0.38–0.42. Autocorrelation features are the strongest single source of discriminative information, slightly outperforming PSD and Hjorth statistics, which aligns with the intuition that imagined speech relies on intricate temporal dependencies rather than purely stationary band-power shifts. Second, the LOBO analysis reveals that CSP is the only block whose removal consistently harms the combined model: excluding CSP reduces macro-F1 by about 0.015, whereas excluding other blocks produces negligible or slightly positive changes at the third decimal place. In other words, CSP contributes a unique spatial structure that is not fully recoverable from the remaining blocks, even after dimensionality reduction, see Fig. 6.

These results suggest a division of labour across blocks. The temporal and spectral features (autocorrelation, PSD, and Hjorth) provide broadly redundant evidence about the underlying dynamics, which helps stabilise training but does not dramatically change the decision boundary when one block is removed. CSP, by contrast, contributes a smaller number of highly informative dimensions that appear to encode class-specific spatial patterns, consistent with its established role in motor imagery BCIs and more recent imagined-speech studies. From a design perspective, this analysis justifies keeping all four families in the reduced 3440-dimensional representation, but it also highlights that any future attempts at aggressive feature pruning should preserve CSP components and at least one of the temporal blocks to maintain robustness.

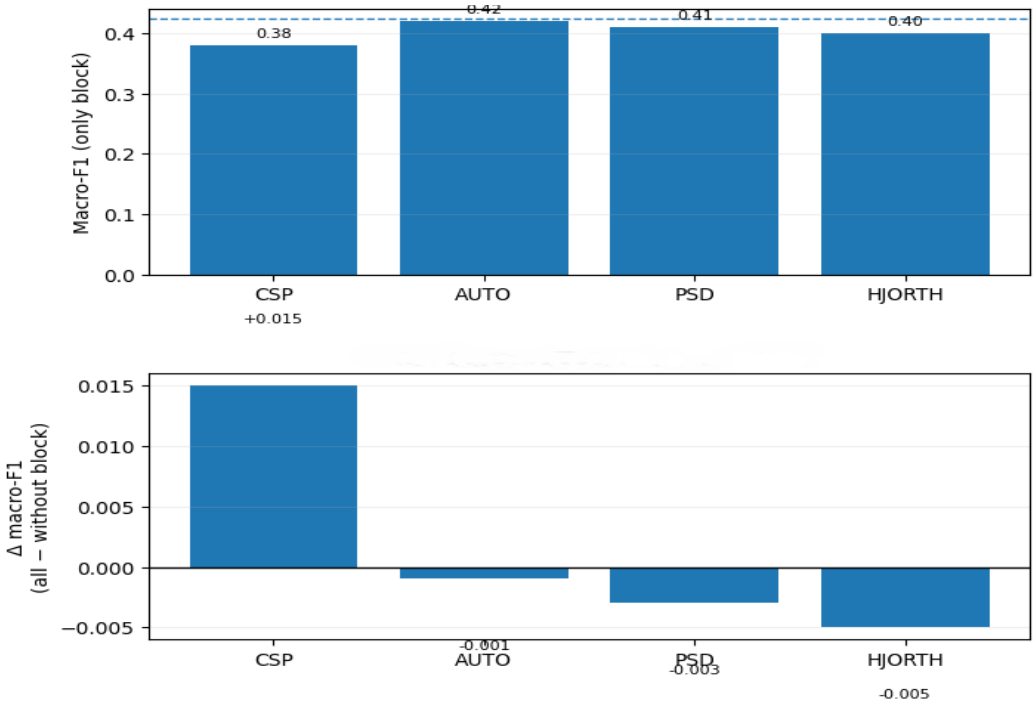

Fig. 6. Top: macro-F1 when each feature block (CSP, autocorrelation, PSD, Hjorth) is used in isolation. Bottom: change in macro-F1 when each block is removed from the full feature set.

C. Geometry of the Reduced Feature Space

To better understand why all three classifiers converge to similar performance levels, the geometry of the 3440-dimensional reduced feature space was examined. Fig. 7 visualises the test set using a two-dimensional t-SNE embedding that preserves local neighbourhood structure. Several loose clusters emerge, yet almost all of them are multi coloured. The three directional commands share overlapping territories, which reflects the symmetric confusions seen in the confusion matrix. The longer phrases occupy broader regions with slightly more homogeneous colour, consistent with their somewhat higher F1 scores, but there is no clear linear margin separating them from the short commands. The vowel trials disperse across multiple t-SNE islands with substantial intermixing, which again matches their poor separability at the classifier level.

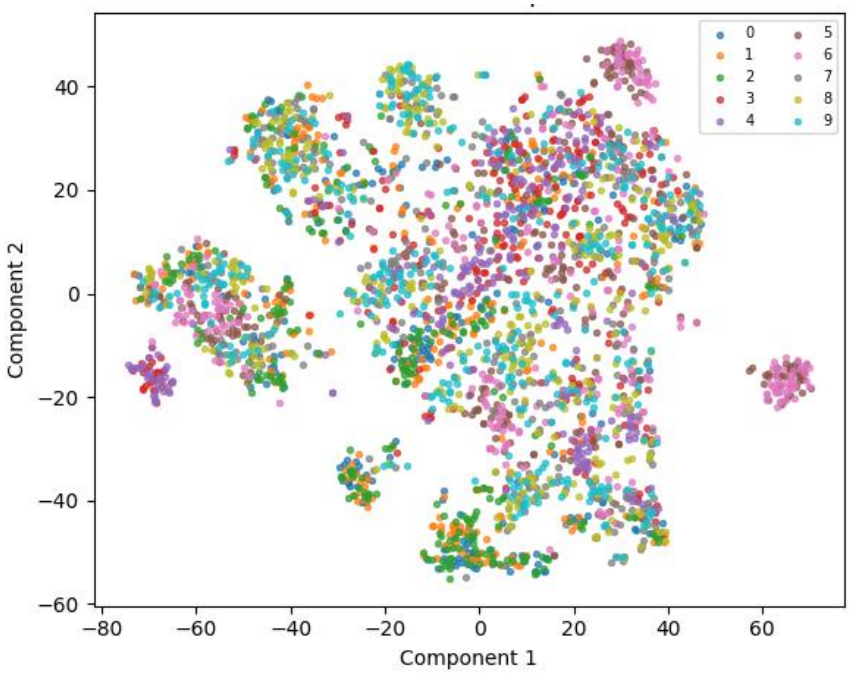

Fig. 7. t-SNE embedding of the reduced ASU feature space, coloured by class label, showing loosely clustered but strongly overlapping class manifolds.

The PCA projection in Fig. 8 provides a complementary, more linear view. The first principal component appears to capture a generic energy or amplitude factor: classes with higher overall band power, such as the composite phrases, are shifted toward the positive side of the axis, whereas short commands and vowels populate the centre and negative side. Along the second component the classes fan out in a wedge shaped pattern, but the degree of overlap remains high. This suggests that, although the block selection and dimensionality reduction pipeline has removed redundant and noisy dimensions, the remaining axes still encode a continuum of task difficulty rather than clearly separated class specific manifolds

Taken together, the t-SNE and PCA plots explain why the linear and non-linear models end up so close in performance. The reduced feature space is only weakly structured at the class level: there are pockets where neighbourhoods align with labels, particularly for some long phrases and composite commands, but large swathes of the space remain mixed. Similar overlapping manifolds have been reported in other imagined speech datasets, even when more aggressive representation learning or Riemannian geometry based features are used [36]. In that context, achieving around 0.41 macro F1 on a ten class, cross trial setting appears consistent with the intrinsic geometry of the data rather than a failure of the classifier family. This observation motivates our later shift toward transfer learning and column wise progressive architectures, where the goal is not only to learn a decision boundary in a fixed space but also to reshape that space through shared representations drawn from larger, more diverse corpora.

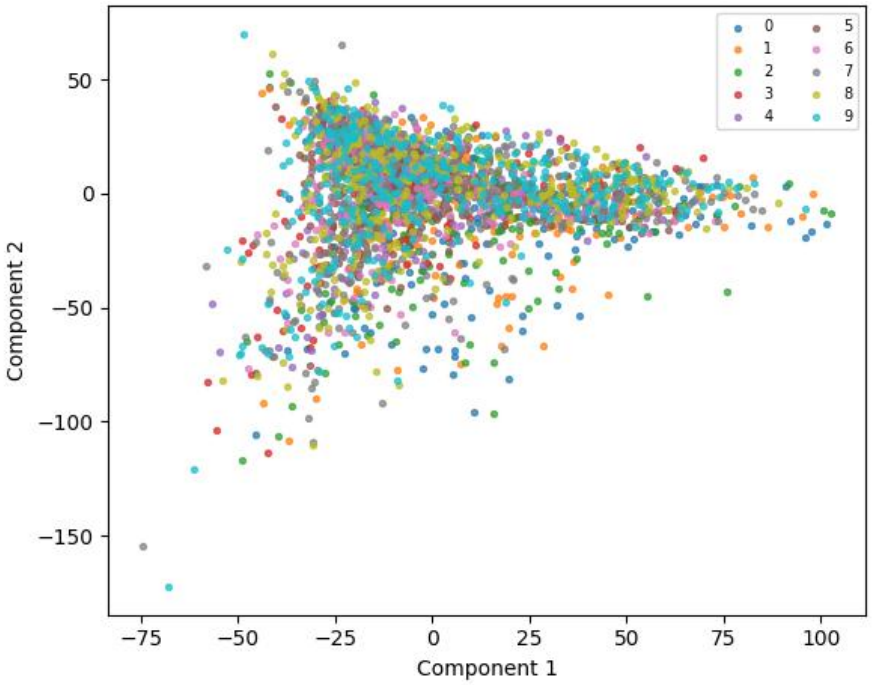

Fig. 8. First two principal components of the reduced ASU feature space, indicating a dominant energy dimension and persistent overla p between commands, phrases, and vowels.

D. Discussion

Taken together, these results confirm that, given the engineered feature space, model choice has limited impact: all three classifiers remain in a narrow band around 0.40–0.42 macro-F1. The ablations in Fig. 5 show that CSP contributes the only clearly non-redundant block, while temporal statistics are largely interchangeable, which explains why deeper models cannot extract much extra structure as described in Section IV-B. Within this context, the confusion matrix in Fig. 4 can be read as a stress test of the feature space. Sentences that differ in high-level semantics but share similar acoustic imagery, such as “in”, “out”, and “up”, are frequently confused, while commands that combine distinctive prosody and articulation, such as “cooperate-in”, are recognised more reliably. The vowels /a/, /i/, and /u/ form another tightly coupled group, with systematic pairwise confusions that align with their proximity in both articulatory and formant space. These patterns reinforce the message from the feature-block analysis: the current representation is sensitive to broad articulatory structure but struggles to separate fine-grained variations that are subtle even at the overt-speech level.

It is important to interpret the approximately 0.41 test accuracy and 0.42 macro-F1 in the light of how the ASU corpus has been used in earlier work. Most published studies restrict attention to a much smaller label space, typically binary contrasts such as “in” versus “cooperate” or three-class vowel sets, and often operate in subject-dependent mode with carefully selected trials. Under these conditions, reported accuracies frequently reach 70–90 per cent, but the task differs fundamentally from the ten-class, subject-wise split considered here. A cross-corpus studies, for example, demonstrates strong performance on ASU and related datasets, yet focuses on a reduced vocabulary and task structure that is closer to command-selection than to continuous imagined speech decoding [37]-[40].

Against this backdrop, the present results sit in the middle of what recent reviews describe as the "moderate-accuracy regime" for non-invasive imagined speech: performance is clearly above chance, robust across folds, and consistent between accuracy and macro-F1, yet still far from the reliability required for high-bandwidth communication [41]-[45] . Our contribution is less about pushing the absolute numbers and more about unpacking where the remaining errors come from. By combining block-wise ablations, classifier comparisons, learning curves, and low-dimensional visualisations, the figures in this section provide a multi-angle diagnosis that is often absent from earlier studies, where only a single classifier and headline accuracy are reported. This richer analysis shows that, for ASU, the bottleneck lies in the front-end representation and label design rather than in a lack of deep learning capacity [46]-[52].

Many imagined-speech systems that report high recognition rates do so within individual subjects, implicitly allowing models to specialise to idiosyncratic neural patterns. In contrast, the overlapping class manifolds observed here indicate that, once trials from multiple talkers and sessions are pooled, the neural signatures of individual words are less separable. This observation aligns with recent calls in the BCI literature to move away from over-optimistic subject-specific benchmarks and toward more realistic cross-subject evaluation protocols.

E. Limitations and Implications for Future Work

Several limitations follow directly from the figures and diagnostics presented above. First, all analyses are restricted to a single corpus. Although the ASU dataset is attractive because it combines ten imagined commands with controlled acquisition, it does not capture cross-linguistic variation, free-running internal speech, or very large vocabularies. The absence of cross-dataset validation means that we cannot yet claim that the identified feature blocks, such as autocorrelation and CSP, will remain optimal when transferred to other corpora like KARA ONE or BCI Competition datasets. Prior cross-corpus work suggests that substantial recalibration is usually required when switching between datasets with different channel layouts or cueing schemes.

Second, the present framework treats each trial as an isolated five-second segment and ignores finer temporal structure within the cue window. While this is appropriate for the feature blocks used here, it limits what the recurrent and convolutional layers can learn. Architectures that operate on lower-level time–frequency maps or directly on sensor-space waveforms might exploit temporal dynamics more fully, at the cost of more complex regularisation. Finally, the t-SNE and PCA plots are inherently descriptive. They suggest that class manifolds overlap and that some clusters are more compact than others, but they do not provide formal guarantees about separability or sample complexity.

Despite these constraints, the analysis points to several concrete directions. The redundancy revealed in Fig. 5 argues for more principled feature selection or sparsity-inducing penalties at the feature level, rather than only at the classifier weights. The confusion patterns in Fig. 4 suggest that future vocabulary design for imagined-speech BCIs should prioritise articulatorily distinct commands and avoid near-minimal pairs until more powerful representations are available. Finally, the modest yet stable performance of the logistic baseline indicates that well-regularised linear models remain a strong reference for imagined-speech EEG and should accompany any claims of deep-learning gains in future studies.

V. Conclusion

This work examined how far carefully engineered EEG features can support imagined speech recognition on the ASU corpus under a ten-class, cross-trial setting. Starting from 6,520 trials, a 3,440-dimensional representation was constructed that combines CSP spatial filters, temporal autocorrelation, PSD band power, and Hjorth parameters, and three classifiers were then evaluated on this representation: logistic regression, a three-layer MLP, and a CNN–BiLSTM–FCNN hybrid. All three models converged to a narrow performance band around 0.41 test accuracy and 0.42 macro-F1, suggesting that, within the evaluated protocol, the main bottleneck lies in the front-end representation and label structure rather than in classifier capacity. The block-wise ablations and geometric analyses clarify this constraint. CSP emerged as the only block whose removal clearly degraded performance on the full set, while temporal statistics were largely interchangeable, and both t-SNE and PCA revealed strongly overlapping class manifolds, especially among short commands and vowels. These patterns offer a plausible account of why deeper models failed to deliver systematic gains and place the present results within the "moderate-accuracy" regime reported for non-invasive imagined speech under realistic evaluation protocols. Several limitations temper the scope of these conclusions. First, the evaluation is confined to a single corpus (ASU); whether the block-level ranking, and in particular the primacy of CSP, holds under different channel layouts, cueing schemes and subject populations cannot be determined from this study alone. Second, all reported numbers are single-seed point estimates; confidence intervals from multi-seed and bootstrap resampling are not yet provided. Third, the deeper classifier treats a heterogeneous feature vector as a 1-D sequence, which is a conservative rather than an architecturally ideal choice for tabular inputs. Against these constraints, the study still provides a transparent and reproducible baseline, showing what can be achieved with well-understood EEG descriptors and conceptually simple classifiers, and pinpointing where progress is most needed. Several concrete next steps follow directly from the analysis. A first priority is cross-corpus validation, replicating the block-wise ablation on Kara One, FEIS and the BCI Competition imagined-speech track to test whether CSP remains the single non-redundant block under different montages and paradigms. A second priority is statistical robustness, repeating every model with at least five seeds and reporting bootstrap confidence intervals on accuracy and macro-F1. A third priority is the classifier side: gradient-boosted ensembles, regularised linear models with sparsity, and attention-based tabular architectures are a more principled match to the heterogeneous feature vector than the CNN–BiLSTM hybrid used here, and quantifying whether any of them escape the 0.42 macro-F1 ceiling on the same representation would be informative. A fourth priority is representation learning and transfer: progressive neural networks and similar architectures that reshape the feature space using larger and more diverse corpora remain the most plausible route to breaking out of the geometry described in Section IV D.

Finally, once a stable offline baseline is established across corpora, a real-time feasibility study – with streaming feature extraction and subject-adaptive calibration – would bridge the offline analysis presented here to the practical BCI setting. In this sense, the present analysis is intended as a diagnostic front end for subsequent stages of a broader programme toward reliable imagined-speech interfaces.

AUTHORS' CONTRIBUTION

The authors' contributions are as follows: Masrullizam Mat Ibrahim and Jamil Abedalrahim Jamil Alsayaydeh handled conceptualization; Safarudin Gazali Herawan was responsible for methodology; Jamil Abedalrahim Jamil Alsayaydeh and Hatem T M Duhair managed software development; Masrullizam Mat Ibrahim and Mazen Farid; validated and conducted formal analysis; Jamil Abedalrahim Jamil Alsayaydeh and Mazen Farid carried out the investigation; resources were provided by Hatem T M Duhair; the original draft was written by Jamil Abedalrahim Jamil Alsayaydeh and Hatem T M Duhair; Hatem T M Duhair reviewed and edited the writing; and Safarudin Gazali Herawan secured funding.

ACKNOWLEDGMENT

The authors express their gratitude to the Centre for Research and Innovation Management (CRIM) at Universiti Teknikal Malaysia Melaka (UTeM) for their valuable support in this research.

DATA AVAILABILITY STATEMENT

All the datasets used in this study are available from the Zenodo database (accession number: https://zenodo.org/records/17816093).

***Abstract*—As digital ecosystems grow and cross-organizational data sharing intensifies, metadata governance has become increasingly important. It plays a critical role in supporting interoperability, accountability, and sustainable data ecosystems. However, metadata governance remains conceptually fragmented and insufficiently structured as a distinct research domain. This study conducts a multivocal literature review (MLR) that integrates academic publications with authoritative non-academic sources, including international standards, governance frameworks, and regulatory instruments. A systematic review process was applied to identify governance constructs, recurring patterns, and conceptual gaps across heterogeneous evidence sources. The findings show that no peer-reviewed studies explicitly integrate metadata governance with formal conceptual structuring. This finding should not be interpreted as a limitation of the search process, but rather as an empirical indication of a structural gap in the literature. It provides a methodological justification for extending the analysis to multivocal evidence. The results further indicate that existing studies predominantly emphasize metadata management and technical interoperability. In contrast, governance-level constructs—such as decision rights, accountability mechanisms, oversight structures, and lifecycle coordination—remain underdefined and inconsistently formalized. This study synthesizes fragmented knowledge into a coherent conceptual understanding of metadata governance, clarifies its distinction from metadata management, and identifies critical research gaps. These findings provide a structured foundation for advancing metadata governance as a cumulative research domain and support future conceptual and methodological research.**

***Keywords*—Metadata governance; multivocal literature review; data governance; metadata management; conceptual synthesis**

I. Introduction

As digital ecosystems expand and cross-organizational data exchange intensifies, governance-related issues concerning metadata have become increasingly important. However, metadata governance remains insufficiently established as an explicit and formally articulated research domain.

Metadata plays a foundational role in enabling semantic interoperability, as discussed by Foulonneau and Riley [1] and further emphasized in subsequent studies on metadata practices [2], [3]. With the acceleration of digital transformation and platform-based ecosystems, metadata has evolved beyond technical documentation into a strategic asset influencing reliability, regulatory compliance, and long-term sustainability of data infrastructures [4], [5].

Despite its strategic importance, metadata practices remain predominantly governed by schemas, registries, catalogs, and interoperability standards. Governance concerns - such as decision authority, accountability allocation, policy enforcement, risk management, and lifecycle oversight - remain weakly articulated, fragmented across technical practices, or embedded within implementation-specific contexts. Widely adopted interoperability and registry standards emphasize syntactic and structural alignment rather than formal governance architectures [6], [7], [8], [9], [10], [11], while regulatory instruments on security and personal data protection impose compliance obligations without establishing explicit governance models for metadata [12], [13], [14], [15].

From an academic perspective, metadata research largely concentrates on metadata management, interoperability engineering, repository architectures, and domain-specific applications, whereas governance dimensions remain under-theorized and inconsistently implemented [1], [3]. Practitioner frameworks and empirical studies typically provide operational checklists, maturity models, and tooling guidance but rarely define governance structures that clarify decision rights, accountability mechanisms, and control models [16], [17]. Consequently, metadata governance has not yet emerged as a consolidated scientific domain supported by shared conceptual frameworks or validated structural models.

At the policy and infrastructure level, international organizations consistently identify inconsistent metadata standards and weak cross-organizational coordination as major barriers to interoperability and data reuse in digital government and open data ecosystems [18], [19], [20]. Similar governance challenges are evident in both national and global contexts. Empirical studies in Indonesia report persistent difficulties in metadata harmonization, interoperability, and institutional coordination despite regulatory mandates [21], [22], while international assessments highlight metadata governance capability as a critical determinant of interoperable data ecosystems [23].

Conceptually, the absence of integrated frameworks and formal metamodels further exacerbates fragmentation in metadata governance research and practice. To clarify the analytical scope of this study, conceptual structuring refers to the explicit representation of governance constructs and their relationships in a systematic and formalized manner.

Although conceptual frameworks and metamodels are widely used in enterprise architecture and information systems to structure domains and enable traceability [24], their systematic application in metadata governance remains limited. Existing standards and professional guidance address isolated components - such as registries, schemas, stewardship roles, or compliance controls - without consolidating them into coherent governance architectures or formalized conceptual models. This fragmentation hinders validation, reuse, cross-context comparison, and cumulative theoretical development.

Preliminary systematic searches indicate a significant lack of peer-reviewed studies explicitly integrating metadata governance with formal modeling or metamodeling approaches. This gap motivates the inclusion of authoritative grey literature capturing standards, industry frameworks, and regulatory instruments [25], and justifies the use of a multivocal literature review (MLR) to synthesize academic and practice-driven knowledge. This is particularly relevant because governance constructs are often institutionalized in standards, regulatory frameworks, and professional practices rather than in peer-reviewed academic publications.

Despite the increasing recognition of metadata governance in both academic and practitioner domains, there is still a lack of measurable and formally defined structures that characterize its maturity as a research domain. Existing studies do not provide 1) formally defined governance structures, 2) explicit decision-right models, and 3) clearly articulated conceptual representations of metadata governance.

This limitation is empirically supported by the systematic review results presented in Section IV, where zero eligible peer-reviewed studies were identified that explicitly integrate metadata governance with formal conceptual modeling or metamodeling approaches. The absence of formal conceptualization, combined with fragmented terminology and inconsistent articulation of governance constructs across sources, suggests limited theoretical consolidation rather than mere publication scarcity. This absence indicates not only a research gap, but also a lack of conceptual consolidation and methodological rigor within the field. This outcome was consistent across multiple query formulations and databases, indicating robustness of the search process rather than query bias.

Accordingly, this study conducts a multivocal literature review integrating scholarly publications and grey literature to examine the conceptual foundations of metadata governance. The study is guided by the following research questions:

RQ1. What thematic areas and research focal points have been explored in studies related to metadata governance and associated metamodeling perspectives?

RQ2. How thoroughly do current studies address the governance aspects of metadata, encompassing domain scope, process structures, and conceptual components?

RQ3. To what extent are validation approaches reported in studies related to metadata governance and its conceptual representation?

RQ4. What conceptual and methodological gaps remain in advancing metadata governance as a coherent research domain?

The remainder of this paper is structured as follows. Section II presents the conceptual background. Section III describes the research methodology. Section IV reports the findings and synthesis. Section V discusses implications and future directions, followed by the conclusion in Section VI.

This study contributes by synthesizing dispersed governance evidence through a multivocal literature review, clarifying the conceptual boundaries between metadata governance and metadata management, and providing a structured conceptual foundation for future research on metadata governance.

II. Conceptual Background

A. Governance and Management

Governance is commonly defined as the system through which organizations are directed and controlled, encompassing the allocation of decision authority, accountability structures, and oversight mechanisms that guide strategic outcomes. The G20/OECD Principles of Corporate Governance frame governance as the institutional arrangement through which objectives are set, performance is monitored, and accountability relationships are structured among governing bodies, management, and stakeholders [26].

A fundamental distinction in governance literature separates governance from management. Governance focuses on setting direction, allocating decision rights, and ensuring oversight, whereas management concerns the planning and execution of operational activities within that direction [27]. In the data domain, Khatri and Brown conceptualize governance as the allocation of decision rights and accountabilities across key decision areas, emphasizing who has authority to decide and who is responsible for outcomes [28].

This distinction is further operationalized in IT governance standards. ISO/IEC 38500 defines governance as the system by which organizational use of technology is directed and controlled, positioning governance as a leadership function responsible for evaluating strategic options, directing management, and monitoring outcomes [29]. Similarly, COBIT distinguishes governance from management through the Evaluate–Direct–Monitor (EDM) domain, which represents the responsibilities of governing bodies in evaluating strategic needs, directing priorities, and monitoring performance and compliance [30], [31].

Together, these perspectives establish governance as a hierarchical and oversight-oriented function concerned with decision authority, accountability, and monitoring.

This governance–management distinction provides the conceptual foundation for positioning metadata governance as an institutional function focused on decision rights and accountability rather than purely operational metadata management.

B. Metadata and Metadata Management

Metadata is commonly defined as structured information that describes, explains, locates, or otherwise facilitates the management, use, and understanding of data resources [1], [7]. It provides semantic context, provenance information, quality indicators, and structural descriptions that enable interoperability and meaningful reuse across heterogeneous systems [2], [3].

Within the data management discipline, DAMA-DMBOK defines metadata as information that describes data assets and provides context for their meaning, quality, structure, ownership, lineage, and usage across the organization [32]. DAMA emphasizes that metadata represents a critical organizational asset because it enables consistency, discoverability, governance enforcement, and integration across enterprise data ecosystems.

DAMA further defines metadata management as the discipline responsible for planning, implementing, and controlling the activities required to create, maintain, integrate, and govern metadata throughout its lifecycle [32]. Metadata management encompasses activities such as metadata modeling, standards definition, registry and catalog management, lineage tracking, quality profiling, and metadata integration with operational and analytical platforms.

International standards complement this perspective by formalizing metadata structures and interoperability mechanisms. ISO/IEC 11179 specifies the structure and management of metadata registries, while ISO/IEC 19763 addresses interoperability and model-driven metadata integration across heterogeneous systems [7], [10]. These standards primarily focus on syntactic consistency, semantic alignment, and technical interoperability rather than institutional governance mechanisms.

Although metadata management establishes the operational foundation for managing metadata assets, it does not explicitly address governance questions such as decision authority, accountability allocation, policy enforcement, compliance assurance, risk oversight, and long-term institutional sustainability. As a result, organizations may achieve technically mature metadata infrastructures while lacking coherent governance structures that ensure strategic alignment, accountability, and cross-organizational consistency.

C. Data Governance and its Relationship to Metadata

Building on the governance foundations discussed earlier, data governance is commonly conceptualized as the institutional arrangement of decision rights, accountabilities, policies, and control mechanisms that ensure data is managed as a strategic organizational asset. From a design perspective, Khatri and Brown conceptualize data governance through explicit allocation of decision rights across key decision domains, including data principles, data quality, access and security, regulatory compliance, and data architecture [28]. These decision domains are operationalized through decision-rights matrices to clarify authority and accountability within organizations.

Complementing decision-rights perspectives, governance has also been conceptualized as an organizational capability that aligns roles, responsibilities, and governance processes to sustain data quality and regulatory compliance [33]. Accountability structures are often operationalized through responsibility assignment mechanisms, such as RACI models, which clarify authority and auditability across governance domains [34]. Practitioner-oriented frameworks further consolidate governance design into integrated operating models encompassing organizational structures, policies, processes, and performance metrics [35].

Within enterprise data management bodies of knowledge, DAMA defines data governance as the function that establishes accountability, policies, and decision rights to ensure effective data management across the organization [32]. In DAMA's framework, metadata is explicitly governed under the scope of data governance but operationalized through the metadata management knowledge area, highlighting policy enforcement, stewardship roles, and governance structures as core mechanisms.

Although metadata is recognized as a critical enabling component supporting discoverability, traceability, and auditability, governance frameworks generally treat metadata as a supporting artifact rather than as a governance object in its own right. Decision structures and control mechanisms are primarily defined at the data asset level without formalizing governance structures specifically for metadata. This implicit positioning creates conceptual ambiguity: while data governance establishes general governance principles, it does not sufficiently articulate how metadata itself should be governed as an institutional asset with its own lifecycle, risks, and compliance implications.

Empirical and practitioner studies indicate that weaknesses in metadata management and governance directly affect decision quality, operational risk, and compliance exposure [4], [5]. Yet, these studies rarely articulate explicit governance structures for metadata, reinforcing the need for a dedicated conceptual consolidation of metadata governance.

D. Metadata Governance as an Emerging Domain

Building on the governance foundations discussed above, metadata governance can be understood as the system of policies, roles, decision rights, controls, and assurance mechanisms that regulate how metadata is defined, maintained, shared, protected, and evolved across organizational boundaries. This definition represents a synthesized conceptual interpretation derived from the literature, rather than an established or universally accepted definition. Unlike metadata management, which focuses on operational execution, metadata governance addresses institutional authority, accountability, compliance, and long-term sustainability. In this study, metadata governance is positioned not merely as an extension of data governance applied to metadata, but as a distinct governance object with its own decision scope, lifecycle considerations, and risk profile.

Explicit use of the term metadata governance remains limited in both academic and practitioner sources. Among established bodies of knowledge and professional frameworks, explicit conceptualization of metadata governance as a distinct domain remains largely absent. DAMA-DMBOK is currently the only widely recognized reference that explicitly uses the term, yet even within this framework, metadata governance is not treated as an independent domain but is embedded within metadata management [32]. This reflects a limitation in the current body of knowledge, where metadata governance has not yet been formalized as an independent conceptual domain across multiple authoritative sources.

In contrast, broader governance frameworks such as ISO/IEC 38500 and COBIT 2019 provide general governance principles - such as decision rights, accountability, and oversight - but do not explicitly address metadata governance as a distinct conceptual domain. This indicates a structural gap in the literature rather than selective reliance on a single reference.

In academic literature, governance dimensions are typically addressed only implicitly and are not formalized as explicit governance constructs or models. Metadata-related studies typically focus on interoperability, quality, registries, or domain-specific standards rather than governance structures [1], [3]. Practitioner frameworks and industry sources provide operational guidance on stewardship and tooling, but seldom articulate governance mechanisms in a systematic or formalized manner [16], [17].

Regulatory and standardization documents [12], [13] introduce obligations related to security, privacy, and accountability that indirectly affect metadata governance. However, these instruments do not provide integrated governance architectures or conceptual models specific to metadata, reinforcing the absence of a formalized governance structure.

Taken together, existing sources predominantly frame metadata governance as fragmented operational practices and tool-oriented guidance rather than as a governance-level construct grounded in explicit decision rights, accountability structures, and institutional control mechanisms. This fragmentation indicates that metadata governance remains an emergent domain without a consolidated theoretical or conceptual foundation. As a result, metadata governance has not yet consolidated into a coherent research domain with shared terminology, validated models, or cumulative theoretical development.

III. Research Methodology

A. Design of the Study

This study adopts a Multivocal Literature Review (MLR) design with qualitative document analysis to examine the state of the art of metadata governance as an emerging scientific domain [36], [37], [38]. The MLR approach is appropriate because relevant knowledge is distributed across both academic publications and non-academic sources.

The analysis focuses on governance-level constructs, including decision rights, accountability mechanisms, institutional roles, policy instruments, and formal control structures, while excluding purely technical implementation aspects.

The review process consists of four stages. First, relevant sources are systematically identified and screened using explicit inclusion and exclusion criteria. Second, governance-related constructs are extracted from eligible documents using qualitative document analysis. Third, extracted constructs are synthesized to identify recurring patterns, conceptual convergence and divergence, and structural gaps across academic literature, grey literature, and authoritative non-academic sources such as standards, regulatory documents, and governance frameworks. Finally, the synthesis is interpreted to produce a state-of-the-art mapping and to derive implications and a future research agenda. These stages are further operationalized in the subsequent subsections (Sections C–F), while Section B describes the overall review protocol and its methodological rationale.

B. Review Protocol and Rationale

The review protocol follows established guidance for systematic literature reviews [25] and multivocal literature reviews to ensure transparency and rigor [36], [37].

In this study, MLR integrates academic literature identified through database search with non-academic sources. Grey literature refers to non-peer-reviewed practitioner-oriented materials, while standards, regulatory documents, and governance frameworks are treated as authoritative sources providing normative perspectives.

The protocol operationalizes the four review stages described in Section A (identification, screening, extraction, and synthesis), which are further detailed in the subsequent subsections (Sections C–F).

C. Search Strategy and Data Sources

A two-stage search strategy was applied. Academic sources were retrieved from Scopus, IEEE Xplore, ScienceDirect, SpringerLink, SAGE Journals, and Taylor & Francis, covering publications from 2000 to 2025.

Non-academic sources were identified through targeted search using general search engines, Google Scholar, and official repositories of standards bodies, professional organizations, and regulatory institutions. This approach ensures coverage of heterogeneous evidence beyond peer-reviewed publications and is consistent with multivocal literature review practices [36], [37].

D. Inclusion and Exclusion Criteria

Sources were selected based on governance-level relevance and conceptual structuring of metadata. Academic sources were included if they were peer-reviewed publications (journal or conference papers), published in English, and explicitly addressed metadata governance and/or conceptual modeling perspectives, including structural or metamodel-related representations. Studies focusing solely on data governance or operational metadata management without governance-level abstraction were excluded.

Non-academic sources were included when originating from authoritative and traceable institutions, including grey literature,

standards bodies, professional organizations, and regulatory agencies. Sources lacking institutional authority or focusing purely on vendor-specific tooling or technical implementation were excluded to maintain a governance-level analytical focus.

E. Screening and Selection Process

Screening followed staged relevance filtering, including title and abstract screening followed by full-text assessment [25]. Duplicate records were removed during the screening process to ensure source uniqueness.

F. Data Extraction and Synthesis

Data extraction was conducted using qualitative document analysis to identify governance-related constructs, including decision rights, accountability structures, institutional roles, policy instruments, and control mechanisms [38]. Extracted constructs were iteratively compared and synthesized to identify recurring patterns, conceptual convergence and divergence, and structural gaps across academic literature, grey literature, and authoritative non-academic sources. Particular attention was given to distinguishing governance-level constructs from operational metadata management practices.

G. Quality Assessment and Source Evaluation

Quality assessment ensures source credibility, while analytical selection ensures conceptual relevance. Each selected source was evaluated based on three criteria: governance relevance, conceptual rigor, and evidence transparency. Governance relevance refers to the degree to which governance constructs are explicitly addressed. Conceptual rigor refers to the presence of structured models, frameworks, or formal definitions. Evidence transparency refers to the clarity of methodology, traceability of claims, and credibility of the source.

The quality assessment was conducted by the authors based on predefined criteria and was not intended as an objective measurement but as a structured analytical tool. The scoring supports consistent comparison across heterogeneous sources and reduces potential bias in interpreting multivocal evidence.

Each criterion was assessed using a three-level scale (low = 1, medium = 2, high = 3). To ensure consistency, each level was operationalized using indicative criteria. A high rating indicates that the source explicitly defines governance constructs, presents structured models or frameworks, and provides traceable and well-documented evidence. A medium rating indicates partial or implicit treatment of governance constructs, moderate conceptual structuring, or limited methodological transparency. A low rating indicates minimal or indirect reference to governance concepts, lack of formal structuring, or insufficient evidence transparency.

The final score reflects the overall contribution of the source to governance-level analysis. Lower-scoring sources were not excluded automatically, but were used cautiously to complement higher-quality sources, particularly when representing current industry practices. This approach ensures that the study's conclusions are not disproportionately influenced by weaker or purely descriptive sources.

Analytical roles were assigned independently from quality scores. Core sources were those that directly discuss metadata governance or metadata governance-related practices. Supporting sources were used to provide governance, compliance, security, or regulatory foundations for interpreting metadata governance. Contextual sources were used to explain metadata structures or technical foundations but were not used as primary governance evidence.

This quality assessment approach is adapted from established systematic literature review practices [25] and adjusted for multivocal literature review contexts [36], [37], where heterogeneous evidence sources must be evaluated consistently.

H. Analytical Selection Criteria

Following the quality assessment, a second-stage selection was applied to identify sources for core conceptual analysis. This stage focuses on governance-level relevance, particularly whether a source explicitly employs the term "metadata governance" or presents governance constructs such as decision rights, accountability structures, and control mechanisms.

Sources that primarily address operational, technical, or capability aspects without governance-level articulation were not included in the core analysis, even if they achieved high quality scores.

IV. Result

A. Results of the Systematic Literature Review (SLR)

The systematic literature review (SLR) was conducted across six academic databases using three query formulations targeting metadata governance and conceptual structuring. Table I reports the search outcomes by query and database, followed by title/abstract screening and full-text review. As shown in Table I, a total of 89 records were retrieved.

However, none of the retrieved studies were found to meet the inclusion criteria after title/abstract screening and full-text review. This result indicates that no peer-reviewed studies explicitly integrate metadata governance with formal conceptual structuring or metamodeling perspectives. This consistency across databases and query variations strengthens the validity of the result and reduces the likelihood of search bias or query formulation limitations.

This outcome should not be interpreted solely as a negative result, but rather as an indication of a conceptual and terminological gap in the literature. It reflects a conceptual gap in the literature, where 1) the term "metadata governance" is inconsistently used, 2) governance is often subsumed under broader data governance, and 3) governance perspectives are not integrated with formal modeling approaches. Therefore, this result provides a methodological justification for extending the evidence base beyond academic sources.

B. Multivocal Corpus and Evidence Landscape

Given the absence of eligible academic studies, the analysis was extended to non-academic and authoritative sources using a multivocal literature review approach.

TABLE I. SLR RESULTS BY QUERY AND DATABASE

No.	Query Description	Database	Initial Hits	After Title/Abstract Screening	After Full-Text Review
1	Metadata governance + metamodel terms	Scopus	0	0	0
		Taylor & Francis	0	0	0
		SAGE	0	0	0
		IEEE Xplore	0	0	0
		SpringerLink	0	0	0
		ScienceDIrect	0	0	0
2	Metadata governance + modeling frameworks	Scopus	16	0	0
		Taylor & Francis	9	0	0
		SAGE	6	0	0
		IEEE Xplore	0	0	0
		SpringerLink	27	0	0
		ScienceDirect	18	0	0
3	Metadata governance + conceptual structure	Scopus	7	0	0
		Taylor & Francis	1	0	0
		SAGE	0	0	0
		IEEE Xplore	0	0	0
		SpringerLink	1	0	0
		ScienceDirect	4	0	0
	TOTAL		89	0	0

These sources collectively represent heterogeneous evidence spanning structural, institutional, and practice-oriented perspectives. Standards (e.g., ISO/IEC 11179, ISO/IEC 19763) provide structural foundations for metadata representation, while governance frameworks (e.g., DAMA-DMBOK2, COBIT, ISO/IEC 38500, DCAM [39]) offer conceptual grounding for governance roles, controls, and accountability. Regulatory sources (e.g., GDPR, national data regulations) contribute compliance perspectives, and industry/practitioner sources reflect current implementation practices.

Table II presents the consolidated corpus of sources included in the multivocal literature review. The corpus reflects a heterogeneous evidence base, including academic literature, grey literature, international standards, governance frameworks, and regulatory sources.

TABLE II. CONSOLIDATED CORPUS OF SOURCES IN THE MULTIVOCAL LITERATURE REVIEW

No	Source	Type	Source Category	Rationale for Inclusion
1	DAMA-DMBOK2 Revised (2024) [32]	Industry Framework	Governance Framework	Primary reference for metadata management and governance practices
2	ISO/IEC 38500: Governance of IT for the Organization [29]	International Standard	Governance Standard	Provides governance principles (EDM, accountability)
3	COBIT 2019 [30], [31]	Industry Framework	Governance Framework	Defines governance domains and control structures
4	ISO/IEC 11179: Metadata Registries [7], [8], [9], [11]	International Standard	Metadata Standard	Defines metadata registry structures
5	ISO/IEC 19763: Metamodel Framework for Interoperability [10]	International Standard	Metadata Standard	Defines metamodel for interoperability
6	ISO 19115: Metadata for Geographic Information [6]	International Standard	Metadata Standard	Provides domain-specific metadata structure
7	ISO/IEC 27001: Information Security Management [13]	International Standard	Security Standard	Provides security governance context
8	General Data Protection Regulation (GDPR (EU 2016)) [12]	Regulation	Regulatory Source	Defines compliance and accountability obligations
9	Presidential Regulation of Indonesia No. 39/2019 on One Data Indonesia (Perpres 39/2019) [14]	Regulation	Regulatory Source	National data governance regulation
10	Law No. 27/2022 on Personal Data Protection (PDP Law) [15]	Regulation	Regulatory Source	Personal data protection framework
11	Metadata Governance in Media Industry [16]	Industry Study	Practice-Based Evidence	Demonstrates governance practices in industry
12	Atlan [40]	Industry Source	Grey Literature	Vendor-based governance practices
13	data.world [41]	Industry Source	Grey Literature	Metadata governance tooling and practices
14	Decube [42]	Industry Source	Grey Literature	Governance implementation practices
15	Dataversity [43]	Industry Source	Grey Literature	Educational and practitioner materials

16	DCAM v2.2 [39]	Industry Framework	Governance Framework	Data governance capability model
17	MetaStore [17]	Industry Framework	Academic	Metadata architecture model
18	COBIT-based IT Governance Metamodel [44]	Academic Model	Academic	Formal governance metamodel (reference)

In addition, practitioner-oriented sources such as Atlan [40], data.world [41], Decube [42], and Dataversity [43] illustrate how the term "metadata governance" is used in practice, often referring to operational and tool-oriented activities rather than formal governance structures.

C. Quality Assessment and Analytical Selection

Following corpus construction, all sources were evaluated using a structured quality assessment framework (Table III). The assessment considers governance relevance, conceptual rigor, and evidence transparency. Table III evaluates the entire corpus presented in Table II.

While most sources demonstrate high conceptual rigor, particularly standards and governance frameworks, quality assessment alone does not determine inclusion in the analytical synthesis.

A second-stage analytical selection was applied to identify sources relevant to governance-level conceptualization. Specifically, only sources that explicitly employ the term "metadata governance" or reflect governance constructs such as decision rights, accountability, and control mechanisms were included in the core analysis.

TABLE III. QUALITY ASSESSMENT AND ANALYTICAL CLASSIFICATION OF SOURCES

No	Source	Type	Gov. Relevance	Conceptual Rigor	Evidence Transparency	Score	Analytical Role
1	DAMA-DMBOK2 Revised (2024)	Industry Framework	High	High	High	3	Core
2	ISO/IEC 38500	International Standard	High	High	High	3	Supporting
3	COBIT 2019	Industry Framework	High	High	High	3	Supporting
4	ISO/IEC 11179	International Standard	Low	High	High	2	Contextual
5	ISO/IEC 19763	International Standard	Low	High	High	2	Contextual
6	ISO 19115	International Standard	Low	Medium	High	2	Contextual
7	ISO/IEC 27001	International Standard	High	High	High	3	Supporting
8	GDPR (EU 2016)	Regulation	High	Medium	High	3	Supporting
9	Perpres 39/2019	Regulation	High	Medium	High	3	Supporting
10	PDP Law (Indonesia)	Regulation	High	Medium	High	3	Supporting
11	Metadata Governance in Media Industry	Industry Study	Medium	Medium	High	2	Core
12	Atlan	Industry Source	Medium	Low	Low	1	Supporting
13	data.world	Industry Source	Medium	Low	Low	1	Supporting
14	Decube	Industry Source	Medium	Low	Low	1	Supporting
15	Dataversity	Industry Source	Medium	Low	Low	1	Supporting
16	DCAM v2.2	Industry Framework	Medium	High	High	3	Supporting
17	MetaStore	Industry Framework	Low	High	High	2	Contextual
18	COBIT-based IT Governance Metamodel	Academic Model	High	High	High	3	Supporting

This distinction ensures that quality assessment supports source credibility, while analytical selection determines conceptual relevance.

D. Governance-Level Conceptual Analysis

Based on the analytical selection, a subset of sources was examined in detail (Table IV). While Table III evaluates source quality and analytical roles, Table IV presents a governance-level interpretation of the same corpus to ensure traceability across the analysis. Table IV follows the same ordering as Table III to ensure traceability across the analysis. Selection is based on analytical relevance rather than quality score alone. These sources include governance frameworks, metadata standards, regulatory sources, practitioner-oriented materials, and conceptual references.

To distinguish governance from operational management, the analysis was grounded in governance theory, particularly ISO/IEC 38500 and COBIT, which conceptualize governance through decision rights, accountability, and the Evaluate–Direct–Monitor (EDM) cycle.

The analysis shows that while several sources employ the term "metadata governance," none fully satisfy formal governance criteria. Governance is generally embedded within metadata management practices rather than conceptualized as an independent governance system.

These findings indicate that metadata governance remains conceptually underdeveloped as a formal governance domain. The persistent conflation of governance with operational management reveals a structural gap in both literature and practice, reinforcing the need for clearer conceptual structuring and further research in metadata governance.

E. Conceptual Positioning of Metadata Governance

To synthesize the evidence landscape, Fig. 1 positions the reviewed sources along two analytical dimensions: 1) the degree of structural formalization, ranging from conceptual guidance to structured frameworks and further toward formal metamodel representations; and 2) the explicitness of metadata governance focus, ranging from implicit governance treatment to explicit conceptualization.

Within this positioning, DAMA-DMBOK2 Revised is situated in the region of conceptual guidance with a dominant management orientation. Industry and vendor-oriented sources exhibit more concrete and technically oriented structures, but generally lack explicit governance abstraction. In contrast, governance-oriented models, such as COBIT-based metamodels [44], demonstrate higher structural formalization but remain non-specific to metadata governance.

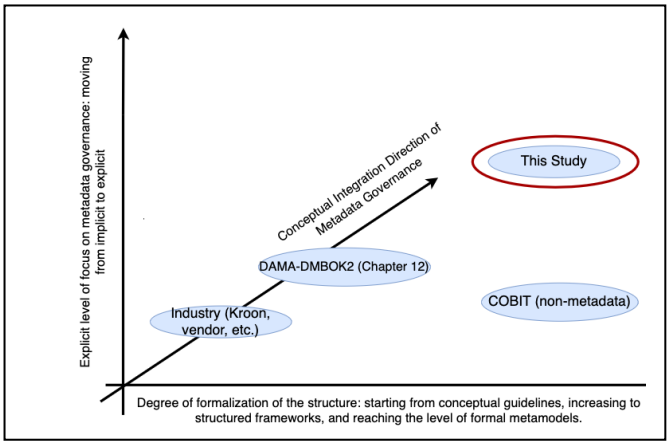

Fig. 1. Conceptual landscape of metadata governance research.

TABLE IV. GOVERNANCE-LEVEL CONCEPTUAL INTERPRETATION OF SOURCES

No	Source	Source Type	Explicit and Formal Governance?	Summary of Content	Governance Limitations
1	DAMA-DMBOK2 Revised 2024	Industry Framework	No (Embedded)	Mentions metadata governance within metadata management, covering standards, catalogs, lifecycle, and controls	No explicit EDM cycle; governance embedded in management
2	ISO/IEC 38500	International Standard	No	Defines governance principles (accountability, responsibility, EDM)	Not metadata-specific
3	COBIT 2019	Industry Framework	No	Defines governance domains and EDM cycle	Not metadata-specific
4	ISO/IEC 11179	International Standard	No	Defines metadata registry structures	No governance constructs
5	ISO/IEC 19763	International Standard	No	Defines metamodel for interoperability	No governance constructs
6	ISO 19115	International Standard	No	Provides domain-specific metadata structure	No governance constructs
7	ISO/IEC 27001	International Standard	No	Defines security governance controls	Not metadata-specific
8	GDPR (EU 2016)	Regulation	No	Defines compliance and accountability obligations	No governance structure model
9	Perpres 39/2019	Regulation	No	Defines national data governance obligations	No formal governance modeling
10	PDP Law (Indonesia)	Regulation	No	Defines personal data protection obligations	No governance modeling
11	Metadata Governance in Media Industry	Industry Study	No (Implicit)	Discusses governance in media workflows	No formal governance structure
12	Atlan	Industry Source	No (Practical)	Provides governance practices and tooling	Operational focus
13	data.world	Industry Source	No (Practical)	Focus on cataloging and governance tools	No formal governance abstraction
14	Decube	Industry Source	No (Practical)	Defines governance workflows	No institutional governance model
15	Dataversity	Industry Source	No (Educational)	Conceptual materials on metadata governance	No formal model
16	DCAM v2.2	Industry Framework	No	Defines data governance capability model	Not metadata-specific
17	MetaStore	Academic Framework	No	Defines metadata architecture	Technical focus only
18	COBIT-based IT Governance Metamodel	Academic Model	No (Non-metadata)	Formal governance metamodel	Not metadata-specific

Beyond these two axes, a third analytical dimension is introduced to represent the degree of conceptual integration. This dimension reflects how governance-related constructs are integrated into a coherent conceptual structure. These constructs include policies, roles, controls, accountability mechanisms, decision authority, lifecycle coordination, and assurance functions.

The analysis shows that most sources cluster in regions characterized by partial formalization and fragmented integration. Industry sources tend to provide localized operational integration without formal governance abstraction. DAMA-DMBOK provides partial integration by embedding metadata governance within broader data governance practices but does not establish it as an independent conceptual system. Formal governance metamodels exhibit strong abstraction but lack metadata specificity.

This study contributes by providing an integrated interpretation of governance-related constructs across heterogeneous sources, highlighting structural gaps and conceptual inconsistencies in metadata governance. Rather than proposing a design artifact, the study contributes by consolidating dispersed governance knowledge and clarifying the conceptual landscape of metadata governance.

V. Discussion

A. Answers to the Research Questions

This section synthesizes answers to the research questions based on the evidence presented in the Results.

1) RQ1 – Thematic coverage and research focal points: Research related to metadata governance is predominantly concentrated in technical and operational areas. Academic studies mainly address repositories, interoperability engineering, schema harmonization, metadata quality, and domain-specific applications, while explicit investigation of metadata governance as a standalone topic remains largely absent, as reflected by the zero eligible studies in the SLR. Metamodeling perspectives are rare and typically appear in interoperability standards rather than governance modeling. Grey literature broadens coverage by addressing stewardship, policies, security, and lifecycle concerns, yet these themes remain dispersed and lack consolidation into an integrated governance research stream.

2) RQ2 – Coverage of governance domains, processes, and conceptual components: Governance coverage across the literature is uneven and fragmented. Structural aspects of metadata are well documented in standards, while organizational constructs such as roles and policies are primarily addressed in frameworks and regulatory guidance. However, explicit articulation of governance domains, process structures, and conceptual relationships is largely absent. Most sources describe isolated elements without integrating them into a coherent governance architecture, reinforcing the lack of consolidated conceptual structures for metadata governance.

3) RQ3 – Evidence of validation practices: Reported validation practices remain limited. Academic studies occasionally employ technical validation (e.g., prototypes or performance evaluation), but validation of governance-oriented conceptual structures is rarely documented. Grey literature primarily relies on expert consensus and institutional review rather than systematic validation. Overall, the lack of explicit validation practices reflects the early and fragmented state of metadata governance as a research domain.

This limitation further reinforces the absence of formally defined and validated conceptual representations of metadata governance.

4) RQ4 – Conceptual and methodological deficiencies: The evidence reveals persistent deficiencies hindering the maturation of metadata governance as a research domain. These include limited integration between governance and formal modeling, inconsistent definition of governance constructs such as decision authority and accountability, and weak methodological rigor in validation. These deficiencies contribute to the absence of shared terminology and cumulative theoretical development.

While these findings provide a structured overview of the current state of metadata governance research, they also indicate a deeper conceptual limitation. The absence of governance-oriented abstraction across studies suggests that metadata governance is not yet recognized as a distinct analytical domain, but rather remains embedded within technical or operational perspectives.

B. Fragmentation of Metadata Governance as a Research Domain

The findings indicate that metadata governance has not yet evolved into a consolidated research domain. Academic studies largely approach metadata from technical perspectives, while governance aspects remain implicit or embedded within broader data governance discussions. Grey literature provides normative guidance through standards and frameworks, yet these sources remain heterogeneous and rarely integrated into coherent conceptual structures. This fragmentation reflects an imbalance between technical maturity and governance conceptualization in the metadata domain.

This fragmentation is not merely descriptive, but reflects a structural misalignment between the increasing strategic importance of metadata and the lack of corresponding governance formalization. As a result, the domain lacks conceptual coherence and cumulative theoretical development.

C. Governance Versus Management in Metadata Practices

A recurring pattern across the evidence is the conflation between governance and management. Many sources employ the term “governance” to describe operational controls, workflows, or tooling practices.

However, governance theory consistently distinguishes governance from execution. Institutional perspectives such as the G20/OECD governance principles frame governance as an arrangement of decision authority, accountability, and oversight structures. In the data domain, Khatri and Brown emphasize governance as the allocation of decision rights and responsibilities across critical decision areas, while DAMA positions governance as the function establishing accountability and policy direction for data assets.

This theoretical grounding is further operationalized in IT governance standards such as ISO/IEC 38500 and COBIT, which define governance through decision authority and oversight cycles (e.g., Evaluate–Direct–Monitor), clearly separating governance from operational management. However, analysis of the reviewed sources indicates that most references do not explicitly define governing bodies, decision domains, or governance cycles specific to metadata. Instead, governance is often implicitly reduced to management practices.

Clarifying this distinction is essential for advancing metadata governance as a formal governance domain grounded in decision authority and institutional accountability rather than operational best practices. This distinction is further supported by governance frameworks such as ISO/IEC 38500 and COBIT, which define governance in terms of decision authority, accountability, and oversight, rather than operational execution.

This inconsistency reveals a fundamental contradiction in the literature. While governance theory clearly distinguishes governance from management through decision authority and accountability, most metadata-related sources operationalize governance as execution-level practices. This contradiction contributes to conceptual ambiguity and limits the development of governance as an independent analytical construct.

D. Absence of Formal Conceptual Models and Metamodels

This observation is visually reflected in the conceptual positioning presented in Fig. 1. The review highlights a systematic absence of formal conceptual models and metamodels dedicated to metadata governance. While standards such as ISO/IEC 11179 and ISO/IEC 19763 provide structural rigor for metadata interoperability and registry architectures, they do not address governance abstraction. Conversely, governance metamodels developed in non-metadata domains demonstrate the feasibility of formalizing governance constructs but remain disconnected from metadata-specific contexts.

This disconnect explains the empty upper-right region in the state-of-the-art map, representing the intersection of explicit metadata governance focus, high structural formalization, and strong conceptual integration. Without formal conceptual representations, governance knowledge remains difficult to validate, reuse, or evolve cumulatively across studies.

This limitation has significant implications. Without formal conceptual models or metamodels, governance knowledge cannot be systematically validated, compared, or reused across different organizational contexts. This absence constrains both theoretical advancement and practical implementation.

It is important to clarify that this study does not propose a formal governance framework or metamodel. Instead, it synthesizes and consolidates existing knowledge to provide a structured conceptual understanding of metadata governance and to identify research gaps.

The objective of this study is not to design or validate a governance model, but to identify conceptual patterns, gaps, and inconsistencies in the current body of knowledge. This positioning aligns with the nature of multivocal literature review, which emphasizes synthesis rather than artifact development.

E. Implications for Research and Practice

From a research perspective, the lack of unified conceptual frameworks limits comparative analysis, validation, and theory development. For practice, organizations struggle to align technical metadata initiatives with institutional governance objectives, regulatory accountability, and cross-organizational coordination. Tool-centric approaches risk reinforcing operational silos without establishing robust governance structures. These findings indicate the need for structured conceptual foundations as a prerequisite for meaningful operational standardization and governance maturation.

These findings indicate that current approaches are insufficient to support governance maturity. Without a structured conceptual foundation, organizations risk implementing fragmented governance mechanisms that lack consistency, accountability, and strategic alignment.

F. Critical Synthesis and Limitations

The analysis reveals a clear problem–concept gap in metadata governance. While the need to govern metadata is increasingly evident in practice, the conceptualization of metadata governance remains underdeveloped and insufficiently formalized in the literature.

This gap is reinforced by three structural issues: 1) the dominance of technical and operational perspectives, 2) the fragmentation of governance constructs across heterogeneous sources, and 3) the absence of formal conceptual models supporting governance abstraction.

Furthermore, contradictions between standards-oriented and industry-oriented sources highlight a tension between formal governance design and practical implementation. Standards emphasize consistency and formalization, whereas industry practices prioritize flexibility and operational efficiency. The lack of integrative conceptual models prevents these perspectives from being systematically reconciled. This tension remains unresolved.

Nevertheless, the findings should be interpreted in light of the limitations of multivocal literature reviews. The inclusion of grey literature introduces variability in methodological transparency, and the absence of peer-reviewed studies limits comparative academic validation. Despite these limitations, the synthesis provides a structured conceptual foundation for future research.

VI. Conclusion

This study advances the understanding of metadata governance by consolidating the state of the art through a

multivocal literature review that integrates academic and authoritative grey sources.

The findings indicate that metadata governance remains conceptually fragmented, weakly formalized, and insufficiently validated as a scientific domain. Existing standards and professional frameworks do not yet provide a coherent governance architecture or a formal conceptual model.

The analysis identifies several critical gaps, including the absence of explicit governance abstractions, limited integration across governance domains, and weak validation practices.

These findings contribute to the development of a conceptual foundation for future theoretical, empirical, and methodological research on metadata governance.

A. Limitations of the Study

This multivocal review faces several limitations. First, the scarcity of peer-reviewed studies explicitly addressing metadata governance limits comparative academic evidence, reflecting the early maturity of the domain and motivating the inclusion of grey literature. Second, grey literature exhibits heterogeneous methodological transparency, which may affect replicability across review contexts. Third, the study emphasizes conceptual consolidation rather than empirical evaluation; therefore, findings primarily inform theoretical positioning rather than operational effectiveness.

B. Future Work

Despite the growing importance of metadata for interoperability and digital governance, the field remains conceptually fragmented and methodologically immature. The absence of consolidated theoretical foundations and formal models limits cumulative knowledge development and cross-context applicability.

Future research should elevate metadata governance beyond operational metadata management by framing it as an institutional governance problem involving decision authority, accountability, and sustainability. Future research may examine the development of governance frameworks, reference architectures, and conceptual metamodels for metadata governance constructs and relationships. Further research should also strengthen validation methodologies, explore governance–technology alignment, and conduct cross-domain and cross-sector comparative studies to understand how regulatory and institutional contexts shape metadata governance design.

ACKNOWLEDGMENT

The authors gratefully acknowledge the financial support provided by the Directorate of Research and Community Engagement (DRPM), Universitas Indonesia, through the PUTI Q2 2024–2025 research grant (Grant No. NKB-596/UN2.RST/HKP.05.00/2024).

Advanced Forensic Analysis Techniques for Insider Threat Detection in Database Management Systems

Kholod Saeed Talea AlQahtani, Mounir Frikha, M. M. Hafizur Rahman
Department of Computer Networks and Communications-College of Computer Sciences and Information Technology, King Faisal University, Al-Ahsa, Saudi Arabia

***Abstract*—This paper presents a real-time database forensic framework designed to detect insider threats within database management systems (DBMSs). Existing database forensic approaches, as identified through a systematic literature review employing the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) methodology, are predominantly reactive and post-mortem in nature, lacking real-time SQL-layer visibility, forensic correlation, and evidence integrity assurance. To address these gaps, the proposed framework integrates native Microsoft SQL Server auditing mechanisms with a centralized ELK (Elasticsearch-Logstash-Kibana) pipeline to enable continuous evidence collection, automated correlation, and real-time visualization. The framework is evaluated against six insider-threat scenarios within the SPL ForensicDB—a simulated enterprise logistics database environment modeled after Saudi Post Logistics (SPL)—encompassing unauthorized access, data exfiltration, privilege escalation, data manipulation, backdoor creation, and audit suppression. Experimental results demonstrate high detection accuracy (precision: 0.92, recall: 0.88), a low false-positive rate of 3%, and alert latency consistently below five seconds, with minimal system overhead of 3.2% CPU utilization. The framework further ensures forensic integrity through SHA-256-verified, tamper-resistant audit logs and a structured chain-of-custody preservation mechanism compliant with ISO/IEC 27037:2012, making it suitable for both proactive security monitoring and legally defensible digital forensic investigations.**

Keywords*—Database management systems; insider threat detection; SQL server; forensic auditing; ELK stack; digital forensics

I. Introduction

The rapid development of digital technologies has fundamentally transformed how organizations store, manage, and secure data. A Database Management System (DBMS) is a software solution that enables users and applications to manage, retrieve, store, organize, and create data efficiently [1]. It serves as an interface between the database and its users, ensuring secure, consistent, and accurate information handling. DBMSs manage diverse user populations through concurrency control, data protection via security and integrity constraints, and backup-and-recovery mechanisms. Prominent examples include MySQL, Oracle, PostgreSQL, and Microsoft SQL Server [2].

The use of DBMSs has become central to contemporary organizations as the volume and sensitivity of stored information continue to grow. As data-driven operations have become the norm, the security and integrity of database environments have emerged as critical priorities. Insider threats—malicious or negligent actions by individuals with authorized access—are currently among the most harmful and difficult-to-trace categories of cyberattack [3][20]. According to the IBM Cost of a Data Breach Report [19], insider-related incidents account for a disproportionate share of total breach costs relative to external attacks, primarily because insiders operate within trusted boundaries and possess legitimate credentials.

This paper seeks to develop, deploy, and evaluate a real-time SQL-layer forensic auditing and insider-threat detection system built on Microsoft SQL Server, combining its native auditing capabilities with centralized log correlation and alerting. SQL Server is among a limited number of commercial DBMS platforms satisfying three core forensic requirements: tamper resistance, forensic auditability, and chain-of-custody preservation [4]. Research on database forensic readiness has shown that open-source DBMSs such as MySQL and PostgreSQL cannot support forensics without third-party extensions (e.g., pgaudit) [5], which cannot be considered tamper-proof or capable of preserving a defensible chain of custody essential for admissible forensic evidence. SQL Server, by contrast, provides SQL Audit and Extended Events, which produce binary, append-only, tamper-resistant .sqlaudit files satisfying the validation requirements of modern forensic audit research [6].

A. Research Gap and Motivation

Database-layer insider threats represent one of the most insidious forms of cyberattack because malicious insiders operate with legitimate credentials and SQL-level privileges that bypass conventional network- and OS-level security controls. Current database forensic solutions are predominantly post-mortem, disjointed, or based on outdated tracing mechanisms, rendering them ineffective at providing real-time visibility, evidence integrity assurance, or scalability to enterprise contexts. This paper addresses a specific and identified research gap: the absence of an authenticated, real-time, SQL-layer forensic pipeline capable of simultaneously supporting insider-threat detection, evidentiary integrity, and low operational burden within a production-scale database environment.

B. Novel Contribution

This paper proposes and empirically validates a unified SQL-layer forensic audit framework combining SQL Server Audit, Extended Events, and an ELK (Elasticsearch-Logstash-Kibana) pipeline to enable near-real-time insider-threat detection, correlation, and visualization. The contribution lies not in describing individual system components, but in demonstrating that native SQL Server mechanisms can be operationalized into a single forensic-ready pipeline capable of delivering:

- Real-time insider-threat detection at the SQL execution layer.
- Cryptographically verifiable evidence integrity via SHA-256 hashing.
- Performance overhead sustainable within enterprise production environments.

The remainder of this paper is organized as follows. Section II presents a systematic literature review of related work in database forensic auditing and insider-threat detection. Section III describes the experimental methodology, including the simulated environment configuration and attack scenario design. Section IV presents detection effectiveness and validation metrics. Section V addresses forensic integrity and evidence readiness. Section VI discusses operational and enterprise implications. Section VII summarizes the scientific contributions. Section VIII provides a comparative discussion of findings in relation to prior research. Section IX concludes the paper and outlines directions for future work.

II. Literature Review

A. Database Forensics and SQL-Layer Auditing

Research in database forensic auditing has evolved considerably, with scholars recognizing that classic OS-level artefacts are insufficient for investigating advanced insider attacks [6]. Early implementations relied on OS logs and general event logs, which lack the granularity necessary to reconstruct unauthorized DML operations, privilege escalations, or schema modifications at the SQL layer. Early research on log management [7] highlights that many trace formats lack inherent tamper resistance, rendering them vulnerable to manipulation by insiders and potentially inadmissible as forensic evidence. An alternative perspective based on external monitoring agents and third-party auditing platforms [8] introduces deployment complexity and may fail to capture engine-level execution traces.

Early work [9] identified that malicious activity at the DBMS layer frequently leaves implicit artefacts in transaction logs, cache buffers, and session metadata. However, these early contributions were largely confined to post-mortem analysis, permitting investigators to reconstruct incidents only after operational or financial damage had occurred. Khanuja and Adane [17] proposed a database forensic analysis framework that systematized the collection and analysis of SQL-layer artefacts, while Wagner [18] demonstrated DBMS forensic auditing using Extended Events (XEvents), establishing a technical precedent for the SQL-layer pipeline approach adopted in the present work. Wagner et al. [9] extended this research by examining database memory forensics and cache-pattern analysis for log verification, confirming that in-memory artefacts supplement binary audit logs in forensic reconstruction.

Studies on insider behaviour consistently report that such attacks unfold slowly and quietly, blending into routine operational tasks [10]. Behavioural profiling research [4][11] shows that insiders typically exhibit patterns such as accessing information beyond their assigned role, exporting sensitive data in bulk, or engaging in unusual after-hours activity. However, most proposed models analyse these behaviours only after the incident has occurred, relying on exported log files rather than real-time event streams [22][15]. This retrospective limitation creates a substantial detection gap, compelling investigators to reconstruct events after the fact rather than intervening during the active attack window.

Wei et al. [15] proposed an unsupervised anomaly detection scheme applied to database logs for proactive forensic investigation, demonstrating effectiveness on insider-threat scenarios; however, that approach lacked real-time pipeline integration and did not address cryptographic evidence integrity. Similar deep learning-based approaches for system log anomaly detection have also been explored in [24], further highlighting the potential of advanced analytics in forensic log analysis. Alzaabi and Mehmood [13] conducted a comprehensive review of machine learning methods for insider-threat detection, identifying precision and recall as primary evaluation metrics and underscoring the persistent challenge of high false-positive rates in anomaly-based systems. Manral and Somani [16] examined forensic capabilities in the presence of superuser insider threats, highlighting the critical importance of tamper-resistant logging mechanisms that cannot be disabled by privileged insiders—a requirement directly addressed by the SQL Audit binary format in the present study. Henriques et al. [14] surveyed forensics and compliance auditing for critical infrastructure, identifying ELK-based pipelines as among the most promising approaches for real-time log correlation and forensic visualization. Pachghare and Chopade [23] conducted a critical review of database forensics, identifying performance overhead as a key practical barrier to continuous auditing adoption, with enterprise acceptability generally requiring CPU overhead below 5%.

The theoretical foundation of this research rests on the Digital Forensic Readiness concept, which stipulates that systems should be designed to collect, preserve, and analyse evidence proactively rather than reactively [12]. Collectively, the reviewed literature—surveyed using the PRISMA methodology—supports the development of a unified SQL-based forensic pipeline combining real-time monitoring, automated correlation, and cryptographic evidence preservation.

B. Commercial Database Security Systems: A Comparative Overview

In addition to academic approaches, several commercial database security and auditing solutions have been widely adopted in enterprise environments. IBM Guardium and Imperva SecureSphere primarily rely on agent-based monitoring and network-level traffic inspection to detect suspicious database activities in real time [22]. While these systems provide strong detection capabilities, they often introduce substantial deployment complexity and may lack fine-grained forensic reconstruction at the SQL execution level due to their reliance on network-layer rather than engine-layer event capture.

Oracle Audit Vault focuses on centralized log collection and compliance auditing, offering a consolidated view of database activity across heterogeneous environments. However, its detection capabilities are generally less responsive in real-time attack scenarios compared to dedicated monitoring pipelines, and it does not natively provide cryptographic chain-of-custody mechanisms at the individual file level. In contrast, the proposed framework leverages native SQL Server auditing mechanisms combined with an ELK-based pipeline to provide near-real-time detection with minimal system overhead. The emphasis on tamper-resistant audit logs and SHA-256 cryptographic validation enables both operational monitoring and legally defensible evidence preservation, distinguishing the proposed approach as a lightweight, forensically robust, and practically deployable alternative within enterprise database environments [14].

III. Methodology

This research adopts a technical experimental approach to design and validate a SQL forensic auditing architecture using Microsoft SQL Server 2019 Enterprise. The experimental environment was constructed to simulate the operational characteristics of Saudi Post Logistics (SPL), incorporating realistic customer, financial, and audit datasets. A specialized forensic database—SPL ForensicDB—was designed to execute scripted insider attacks and capture the resulting evidence traces. The overall system architecture, as illustrated conceptually in Fig. 1, encompasses three phases: data collection at the SQL layer, processing and normalization via Logstash, and real-time alerting and visualization through Elasticsearch and Kibana.

The binary format of SQL Audit records enabled the use of sys.fn_get_audit_file() to transform audit streams into downstream-readable relational tables. This normalization step verifies the semantic consistency of logs prior to ELK pipeline ingestion. Filebeat was configured to continuously scan .sqlaudit and .xel directories and forward new events to Logstash, which performed parsing, enrichment, timestamp validation, and field normalization before indexing events in Elasticsearch. Kibana provided visualization dashboards enabling analysts to identify anomalies including bulk data extraction, repeated

authentication failures, suspicious privilege usage, and attempts to disable the auditing engine. The logical flow of the system is depicted in Fig. 2 and the overall architecture in Fig. 3.

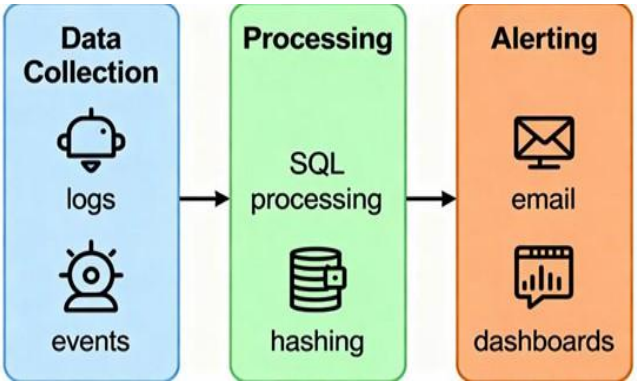

Fig. 1. Conceptual framework architecture showing data collection, processing, and alerting phases.

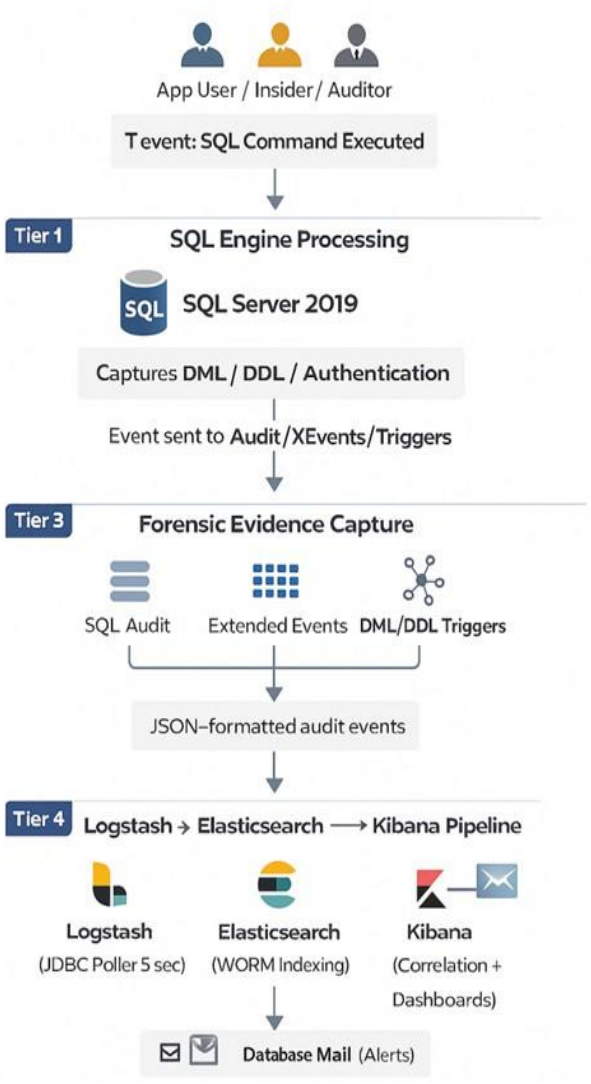

Fig. 2. Logical flow diagram.

Fig. 3. Forensic audit framework (system architecture).

Six insider-attack scenarios were scripted in T-SQL to evaluate the framework, as described in Table I. Performance was measured across five dimensions: precision, recall, false-positive rate, alert latency, and system performance overhead.

A. Experimental Environment Configuration and Log Sources

The framework was evaluated within a simulated enterprise operational environment modeled on Saudi Post Logistics (SPL) and running on Microsoft SQL Server 2019 Enterprise. The testbed incorporated realistic customer, financial, and audit data; RBAC structures; and controlled insider behaviour. Assessment employed a controlled experimental design in which insider attacks were executed as scripted T-SQL operations and evidence was ingested into the ELK pipeline from audit, trace, and trigger-based sources. The SQL Server instance was configured with secure authentication, structured log directories, and native audit mechanisms (Fig. 4). A dedicated SQL authentication login (SQLCONNECT) was created for forensic testing, with Mandatory Encryption enforced at the connection level.

System databases and the SPL ForensicDB are hosted within the instance (Fig. 5). SQL Server records system-level events and authentication information in the default ERRORLOG directory (Fig. 6). All forensic audit files generated by SQL Server Audit and Extended Events were stored in a dedicated directory at C:\ForensicAuditing\SQLAudit\ (Fig. 7). Two audit objects were

defined (Fig. 8): AuditServerToFile, capturing server-level events, and ForensicServerAudit, capturing database-level DDL, DML, failed logins, and privilege changes. These audits form the native SQL evidence stream prior to ELK ingestion.

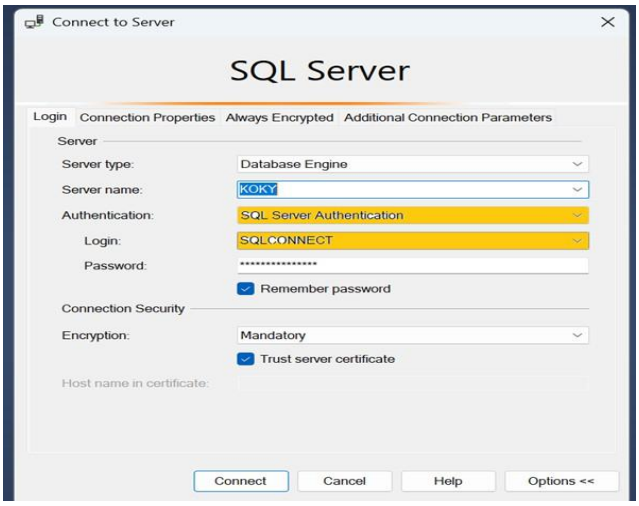

Fig. 4. SQL Server connection configuration showing SQL authentication and mandatory encryption.

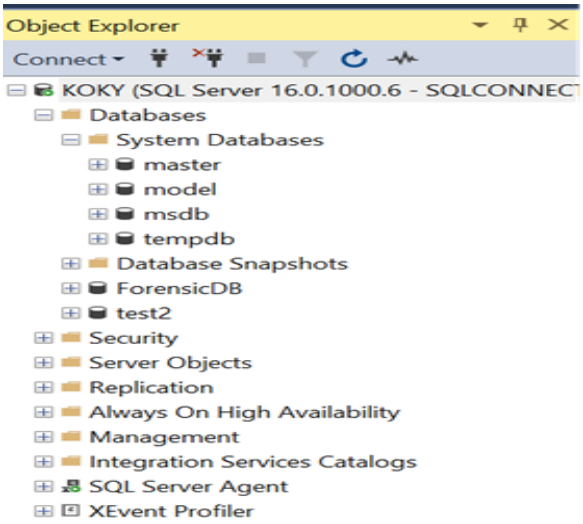

Fig. 5. SQL Server object explorer showing system databases and the forensicdb environment.

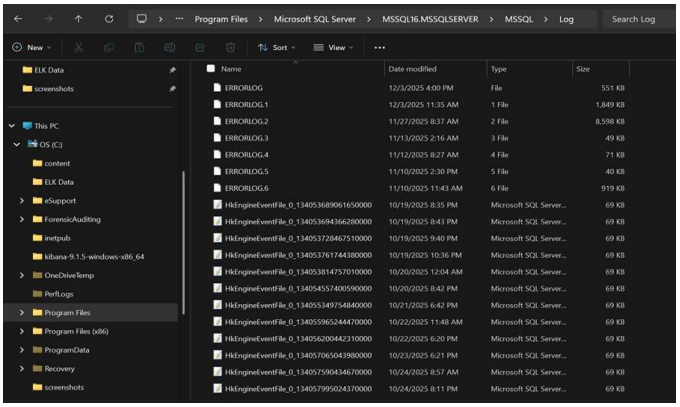

Fig. 6. Default SQL Server error log directory showing rotating ERRORLOG files.

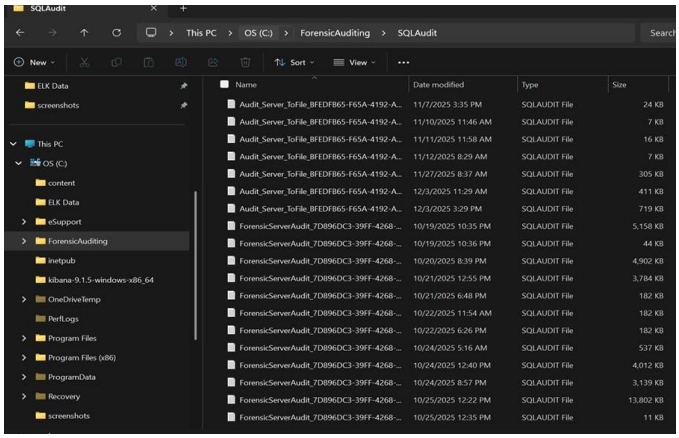

Fig. 7. SQL Audit directory containing generated .sqlaudit binary evidence files.

Fig. 8. Configured SQL Server Audits used for forensic event capture.

B. Simulated Database Environment: SPL ForensicDB

To ensure practical relevance, the SPL ForensicDB was constructed to mirror the schema complexity of a logistics and financial enterprise system. The Entity-Relationship Diagram (ERD) in Fig. 9 consists of four core modules:

- Human Resources Module: Employees (EmpID, Name, Department, ClearanceLevel); Users (UserID, Username, PasswordHash, RoleID).
- Customer Data Module: Customers (CustID, NationalID, Phone, Address, RiskScore)—containing PII data targeted in unauthorized-access and exfiltration scenarios.
- Financial Module: Transactions (TransID, Amount, Date, Sender, Receiver)—targeted for data manipulation scenarios.
- Audit Module: AuditLogMaster (LogID, EventType, TableName, OldValue, NewValue, ModifiedBy, Timestamp)—preserving before/after forensic attribution records via DDL/DML triggers.

The modules collectively replicate the real-world interdependencies between HR data, customer PII, and financial operations within SPL, ensuring that simulated attack scenarios are representative of genuine enterprise threat conditions.

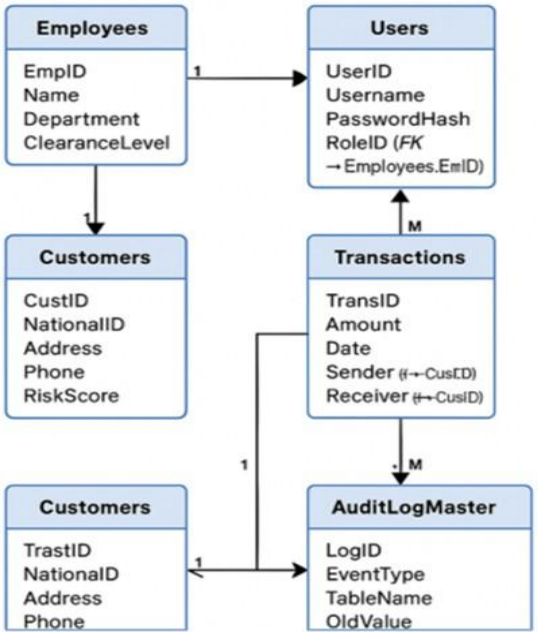

Fig. 9. ERD Relationship Diagram

C. Access Control and User Roles

To simulate realistic insider threats, the following user roles were defined:

- SysAdmin (SA): Full control, simulating a compromised administrator.
- DB Auditor: Read-only access to audit logs, representing the forensic investigator role.
- App User: Limited access via stored procedures, representing a normal employee.
- Malicious Insider: A user with db_datareader and db_datawriter privileges attempting unauthorized privilege escalation.

D. Insider-Threat Scenario Coverage

As summarized in Table I, six distinct insider-threat scenarios were designed to represent realistic and high-impact attack categories in enterprise database environments. Each scenario was engineered to test both detection accuracy and forensic completeness, ensuring that multilayered evidence could be reconstructed across SQL Audit logs, Extended Events traces, and DML/DDL triggers.

TABLE I. INSIDER THREAT SCENARIOS

Scenario ID	Insider-Threat Category	Description
S1	Unauthorized data access	Illicit reading of sensitive PII records
S2	Data exfiltration	Bulk extraction of customer data
S3	Privilege escalation	Unauthorized role and permission abuse
S4	Data manipulation	Financial record tampering
S5	Backdoor creation	Covert SQL login creation
S6	Audit suppression	Attempts to disable or tamper with audit logging

IV. DETECTION EFFECTIVENESS AND VALIDATION METRICS

Detection performance was quantitatively evaluated across all six scripted insider-threat scenarios. The framework successfully identified all six attack scenarios, with performance results summarized in Table II. These metrics confirm that the framework achieves high accuracy in detecting insider activity within the active attack window, enabling a timely forensic response without compromising production database performance. A post-execution review of detection logic, illustrated in Fig. 10, confirmed that all six attack sequences generated correlated alerts within the defined latency threshold, and no scenario evaded the pipeline.

TABLE II. SUMMARY OF DETECTION METRICS

Metric	Result	Forensic Meaning
Precision	0.92	Low false-alarm rate; investigators only review relevant alerts
Recall	0.88	High ability to detect real insider actions
False Positive Rate	3%	Minimizes alert fatigue and improves trust in system out-put
Median Alert Latency	2–3 sec	Enables near–real-time investigation of active insider at-tacks
CPU Overhead	3.2%	Meets <5% enterprise audit requirement without affecting production

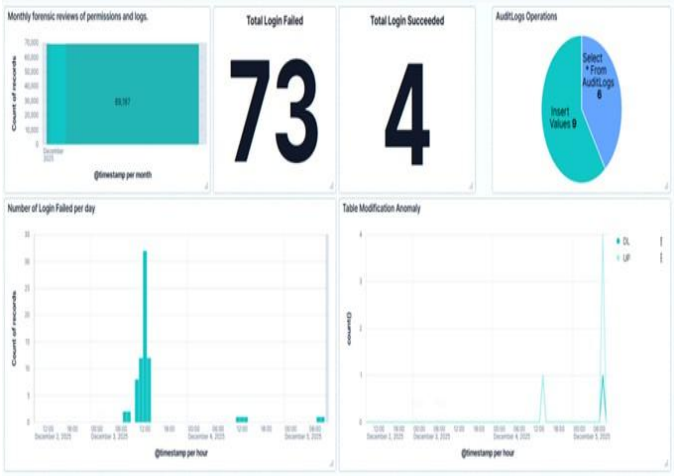

Fig. 10. Dashboard reflecting SQL audit events after malicious insider actions

V. FORENSIC INTEGRITY AND EVIDENCE READINESS

Beyond detection capability, the framework incorporates database-layer forensic readiness principles extending its utility to legally defensible evidence preservation. Upon acquisition, each evidence file was immediately processed to generate a SHA-256 cryptographic hash, consistent with the evidence integrity requirements of ISO/IEC 27037:2012 and the forensic integrity controls documented by Bush [6]. This process ensures that any post-acquisition tampering can be cryptographically detected, establishing an unbroken chain of custody from initial collection through analysis. The audit artefacts are stored as tamper-resistant binary .sqlaudit files with SHA-256 verification, NTP-synchronized timestamps, and WORM-like immutable indexing within Elasticsearch.

Table III presents the chain-of-custody validation results across all six evidence scenarios, confirming that all artefacts were successfully hashed, timestamp-synchronized, and alert-delivered within the defined latency bounds. Notably, Scenario S6 (Audit Suppression) validates the system's resilience against the most adversarial insider condition: an

attempt to disable auditing itself. The immutable Elasticsearch index confirmed in Table III for S6 demonstrates that even a forced audit engine shutdown generates a detectable and tamper-evident forensic record, addressing a critical gap identified by Manral and Somani [16]. This end-to-end evidence integrity makes the system applicable to legal and regulatory investigations—a requirement increasingly mandated under data governance frameworks [21].

TABLE III. CHAIN-OF-CUSTODY VALIDATION FOR INSIDER TEST EVIDENCE

Scenario ID	Evidence Captured	SHA-256 Ver-ified	Timestamp Synced	Output
S1	Customers read-perimeter breach	Yes	Yes	Email logged & delivered 3s
S2	Temp file exfiltration vector	Yes	Yes	Threshold breach alert 5s
S3	Unauthorized ALTER ROLE attempt	Yes	Yes	Role abuse visual flagged in Kibana
S4	UPDATE manipulation anomaly	Yes	Yes	0-value override detected & alerted
S5	Hidden login creation path	Yes	Yes	Backdoor login indexed & monitored
S6	Audit engine forced OFF	Yes	Yes	Immutable index lock confirmed in ELK

VI. OPERATIONAL AND ENTERPRISE IMPLICATIONS

The results confirm the operational feasibility of SQL-layer forensic auditing in enterprise settings. The co-existence of real-time monitoring with production workloads—demonstrated through a CPU overhead of 3.2%, well within the 5% enterprise acceptability threshold—substantially reduces the traditional trade-off between forensic comprehensiveness and operational performance. Centralized ELK-based visualization through Kibana (Fig. 10 and Fig. 11) enables analysts to rapidly identify anomalous patterns across temporal and behavioral dimensions, significantly reducing investigation time and analyst workload.

In practice, the framework provides organizations with an executable deployment roadmap for insider-threat detection, enhanced forensic preparedness, and improved accountability within database-centric infrastructures. The tamper-resistant binary audit format and SHA-256 chain-of-custody mechanism address a critical operational gap: the inadmissibility of forensic evidence from systems lacking verifiable integrity controls [7][16]. The framework thereby bridges the gap between security monitoring—a real-time operational function—and digital forensics—a post-incident legal function—within a single integrated pipeline.

VII. SUMMARY OF SCIENTIFIC CONTRIBUTION

The principal scientific contribution of this work lies in the empirical operationalization of a fully integrated SQL-layer forensic pipeline that bridges three previously disparate capabilities: real-time insider-threat detection, cryptographically verifiable evidence integrity, and sub-five-second alert latency within a production-representative database environment. Prior research has addressed these capabilities predominantly in isolation, limiting the practical applicability of individual contributions.

Database forensic research [17][18] demonstrated the evidential value of SQL-layer audit logs but did not operationalize them into real-time detection pipelines. Behavioural profiling studies [4][11] characterized insider-threat patterns effectively but lacked evidentiary integrity mechanisms required for legal admissibility. Evidence-integrity frameworks [7] established chain-of-custody methodologies but did not demonstrate integration with live SQL-layer detection at enterprise scale. The present work uniquely integrates all three capabilities within a single deployable pipeline and validates their simultaneous operation under realistic attack conditions.

The achievement of 3.2% CPU overhead during active forensic monitoring is particularly significant, empirically demonstrating that continuous SQL-layer auditing is operationally sustainable without dedicated hardware or substantial performance trade-offs—directly addressing the adoption barrier identified by Pachghare and Chopade [23]. The SHA-256 chain-of-custody mechanism, compliant with ISO/IEC 27037:2012, provides a legally defensible evidence trail that extends the system's applicability from operational security monitoring to formal digital forensic investigations. These combined properties represent a measurable advancement beyond descriptive system overviews and theoretical frameworks in the existing database forensics literature [5][12].

VIII. DISCUSSION

The findings confirm that the developed framework reliably captures insider activity at the SQL layer and provides forensically actionable insight. The framework successfully detected all six scripted insider-threat scenarios, capturing multilayered forensic evidence across SQL Audit logs, Extended Events traces, and DML/DDL triggers, with an overall precision of 0.92 and a recall of 0.88. The false-positive rate of 3% demonstrates that the detection logic effectively differentiates between genuine anomalies and normal operational activity. Alert latencies were consistently below five seconds across all scenarios, confirming near-real-time response capability sufficient for active-attack intervention.

The framework exhibited high forensic completeness. SQL Server Audit captured all applicable DDL, DML, and authentication events; Extended Events recorded engine-level data including bulk reads, query execution patterns, and performance anomalies; DML/DDL triggers preserved before-and-after values enabling precise forensic reconstruction of unauthorized changes. Kibana visualizations (Fig. 10 and Fig. 11) identified temporal spikes and abnormal access behaviours precisely corresponding to the simulated attack scenarios. Performance testing confirmed average CPU overhead of 3.2%, validating the feasibility of continuous forensic auditing in enterprise deployments and demonstrating the efficiency advantage of Extended Events over legacy SQL Trace mechanisms.

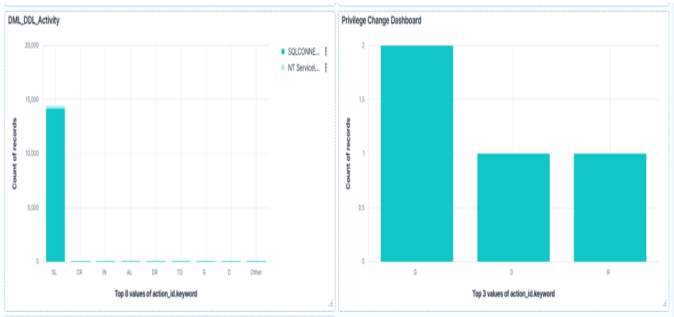

Fig. 11. Kibana privilege-change dashboard showing the impact of GRANT operations.

These findings are consistent with, and advance, prior contributions in the field. Wei et al. [15] demonstrated that unsupervised anomaly detection on database logs can support proactive forensic investigation; however, that approach lacked real-time pipeline integration and did not address cryptographic evidence integrity. The present framework advances this line of work by integrating detection with evidence preservation in a single operational pipeline. Manral and Somani [16] established the importance of forensic capabilities resilient to superuser manipulation—a property directly addressed through the tamper-resistant binary .sqlaudit format, which cannot be modified or deleted by privileged users without generating a detectable forensic artefact.

The false-positive rate of 3% compares favorably with behavioral profiling approaches reviewed by Alzaabi and Mehmood [13], which reported consistently higher false-alarm rates attributable to the difficulty of distinguishing malicious from legitimate privileged activity in purely behavioral models. The sub-five-second alert latency represents a substantial improvement over post-mortem forensic approaches [5][12], which offer no real-time intervention capability by definition. The 3.2% CPU overhead is consistent with—and below—the enterprise feasibility threshold identified by Pachghare and Chopade [23], who cited performance overhead as a primary barrier to continuous database auditing adoption. Henriques et al. [14] reached similar conclusions regarding the suitability of ELK-based pipelines for critical infrastructure forensics, further corroborating the architectural choices made in this work.

Compared with commercial solutions, the proposed framework offers complementary and, in several respects, superior properties for forensic use cases. Unlike IBM Guardium and Imperva SecureSphere, which rely on network-layer inspection and introduce substantial deployment overhead [22], the proposed system leverages native SQL Server engine mechanisms, minimizing infrastructure requirements while achieving greater SQL execution-level granularity. Unlike Oracle Audit Vault, which aggregates compliance logs rather than providing real-time detection, the ELK-based pipeline delivers sub-five-second alerting with a full forensic chain-of-custody. These distinctions position the framework as a practically deployable, forensically rigorous alternative suitable for resource-constrained enterprise environments seeking both security monitoring and legal evidentiary capabilities within a single system.

IX. Conclusion

This study has formulated, deployed, and thoroughly evaluated a SQL-layer forensic auditing framework that integrates SQL Server Audit, Extended Events, and an ELK-based evidence correlation pipeline. The analysis demonstrates that the proposed system achieves its design objectives across all evaluated dimensions: real-time insider-threat detection, cryptographic evidence integrity, and operational performance sustainability. The framework successfully detected all six scripted insider-threat scenarios with a precision of 0.92, a recall of 0.88, a false-positive rate of 3%, and alert latency consistently below five seconds, while maintaining CPU overhead of only 3.2%.

In addition to meeting functional and performance objectives, this work contributes to the theoretical understanding of how forensic readiness, behavioural analysis, and SQL-layer observability can be integrated into a coherent, production-deployable pipeline. It demonstrates that native database auditing mechanisms, when properly operationalized with modern analytics technologies, can deliver scalable insider-threat monitoring while satisfying the forensic integrity standards required for legal proceedings.

Future work will explore the extension of the framework to heterogeneous DBMS environments, the incorporation of machine learning-based anomaly scoring for adaptive threshold detection, and the addition of automated containment responses that not only detect insider attacks but also execute predefined countermeasures. Integration with Security Information and Event Management (SIEM) platforms and compliance with evolving data governance frameworks represent additional directions for broadening the framework's applicability.

A Hybrid Explainable Ensemble Learning Framework for Health Risk Prediction

Hussain AlSalman
Department of Computer Science-College of Computer and Information Sciences,
King Saud University, Riyadh 11543, Saudi Arabia

***Abstract*—Early prediction of patients' health risk is a crucial component of the safe and effective implementation of clinical triage and timely intervention. Health risk data in the real world often tends to be small in size and limited, with class imbalance, making the overall accuracy and transparency of Machine Learning (ML) models insufficient and more difficult to achieve. This paper proposes a hybrid explainable ensemble learning framework for multi-class health risk prediction, which is built based on a stacking architecture with three strong base learners, namely Random Forest (RF), eXtreme Gradient Boosting (XGBoost), and Light Gradient Boosting Machine (LightGBM). The XGBoost is chosen as the meta-learner due to its ability to learn complex non-linear probability mapping from the base models and provide complementary signals for the prediction. A complete preprocessing pipeline is implemented, covering missing data handling, systematic encoding of categorical variables, and strict separation between training and test sets to ensure unbiased assessment. Experimental results show that the proposed framework achieved an accuracy of 97.5%, which exceeds the accuracy results of individual models, which are 96.0%, 95.5%, and 96.0% for RF, XGBoost, and LightGBM, respectively. Additionally, the proposed framework integrates the predictive performance with the interpretable clinical decision support and transparency using SHapley Additive exPlanations (SHAP) method. The SHAP values are used to provide global and local explanations for revealing the most influential features that drive each prediction.**

***Keywords*—Health risk prediction; hybrid explainable; ensemble learning; meta-learner; LightGBM; SHAP**

I. Introduction

Accurate health risk prediction is an essential prerequisite for safe and efficient clinical decision-making [1]. In time-sensitive decision-making settings, clinicians faced the task of prioritizing patients' cases based on routinely available physiological measurements [2]. Conventional methodologies mostly rely on rule-based thresholds for integrating vital sign parameters and triggering escalation protocols [3]. A striking example is the National Early Warning Score 2 (NEWS2), which is widely implemented and standardized in clinical practice [3]. It explicitly uses oxygen supplementation and alternative calculation schemes to better incorporate respiratory risk into the normal clinical process of patient care [3]. Despite the fact that the Early Warning Score (EWS) is defined by simplicity, transparency, and ease of operationalization, its predictive efficacy differs from patient to patient and clinical environment to clinical environment [4]. Large-scale empirical studies have shown that NEWS2 is not better than its predecessor [4]. The NEWS, across the board, and, in some subgroups or in relation to some clinical endpoints, may in fact be shown to produce inferior predictive performance. Such constraints are the impetus for data-driven methodologies with the ability to unravel complex interrelationships of vital signs and clinical indicators [5].

In parallel, healthcare has seen a rapid growth in the number of machine learning (ML) methods with the goal of triage and deterioration prediction using routinely collected data during the medical examination and diagnosis phase [6]. Evidence from emergency departments' research shows that ML models are capable of exceeding conventional triage systems in predicting clinical outcomes [7]. This evidence presents the standard triage inputs, such as vital signs and basic clinical features, and provides support for the hypothesis that the process of algorithmic learners reduces mis-triage [7].

The reduction is achieved by identifying the interaction between features and non-linearity, which poses difficulties of representation within a deterministic scoring framework [7]. However, the effective use of models requires more than incremental increases in predictive accuracy. Clinical ML models need to be evaluated in realistic clinical operational conditions and should be designed with an adequate degree of interpretability. This process enables auditing, error analysis, and builds clinician trust. Hence, in addition to predictive accuracy, explainability is considered to be a very important criterion for therapeutic artificial intelligence [8]. Numerous high-performing models act as "black boxes" and interpretability layer takes on a particular importance in case of risk prediction [9].

A. Research Goals and Motivation

This study aims to develop an accurate and interpretable framework for multi-class health-risk level prediction from routinely available clinical indicators. The motivation for this work is two-fold. First, score-based systems, like NEWS2, are limited in the extent to which they use hand-crafted thresholds, additive rules, and are interpretable. This limitation may give rise to inconsistent discrimination across settings and endpoints [4].

Second, although traditional ML and single tree-based models provide powerful baseline models for structured prediction tasks [10], its application is sensitive to the sub-groups characteristics and may not be able to leverage the complementary strengths among learners fully. To overcome these shortcomings, an explainable hybrid ensemble framework is proposed to combine multiple base learners namely Random Forest (RF), eXtreme Gradient Boosting (XGBoost), and Light

Gradient Boosting Machine (LightGBM). The framework is able to learn an optimized combination policy by training a meta-learning, as is consistent with the theoretical underpinnings of stacked generalization. An important practical goal is to guarantee that performance improvements apply in realistic scenarios with limited and small sized imbalanced datasets. Accordingly, the developed framework focuses not only on overall accuracy but also macro-averaged performance measures.

Finally, to promote clinical transparency and decision-making, the framework is equipped with the SHapley Additive exPlanations (SHAP) explanation method. It can outline the features with the greatest impact at each risk assessment level using computed SHAP values [11]. Collectively, these goals align with a growing consensus that clinical machine learning applications should be both highly performant and interpretable to be credible and effective. In clinical triage and monitoring workflows, rapid risk stratification supports prioritization, escalation, and resource allocation decisions. Accordingly, the proposed model is designed as a decision-support tool that provides a risk-level estimate (Normal/Low/Medium/High) to assist clinicians rather than replacing clinical judgment.

B. Research Contributions

In the existing knowledge of data-driven clinical triage and vital-sign–based health risk classification, this work offers four main contributions, summarized as follows:

- An end-to-end, stacking-based framework is proposed that stacks multiple robust tree-based learners into a unified predictor for generalized, robust multi-class health risk level classification, addressing the problem of limited, small-sized datasets.
- Rather than a simple linear combiner, XGBoost is used as the meta-learner to learn a non-linear combination of base model probability outputs, thereby enabling recognition of cohort-specific integration patterns.
- Both general accuracy metrics and imbalance-aware metrics, such as macro-F1 scores and confusion matrices, are reported to ensure that improvements extend beyond the majority classes and remain meaningful across all risk classes.
- Global and instance-level explainability via SHAP is incorporated into the proposed framework for clinical transparency, audit, and feature-level reasoning.

The remaining part of the paper is organized into five Sections: Section II presents the related work on the considered problem and the analysis methods. Section III explains the research methodology, including the problem definition, the study dataset, building base learners, stacking the hybrid model, and model training and evaluation. Section IV presents the results and discusses the findings to justify the novelty and performance of the proposed framework's model. Section V illustrates the conclusions and future directions of current work.

II. Related Work

Health Risk classification using the rule-based Early Warning Score (EWS) remains in common use because of its easy formulation based on regularly documented vital signs measurements [3]. However, extensive research has shown that these scoring systems do not always improve discriminative performance across a wide range of outcomes and patient subgroups [4]. This limitation drives the movement toward more adaptable, data-driven approaches. Recent studies have continued to explore the use of ML methods for modeling and forecasting health risks, with a strong emphasis on the predictive ability of these systems [12]. These predictive systems have been used to enable intervention at early stages and preemptive decision-making, overcoming the limitations inherent in a conventional thresholding paradigm.

Kone et al. [13] introduced a study of health-risk prediction and prevention using ML methods integrated into protective healthcare pipelines. Multi-modal risk analysis has gained focus, with heterogeneous signals integrated to augment personalization and early alerting in a real-world context [14]. With the same goal and in the context of emergency department settings, triage models based on ML have been shown to perform better in terms of discrimination against clinically important outcomes [15]. Raita et al. [7] built ML models to predict Emergency Department (ED) outcome and compared them with classical triage methods and found that ML models can demonstrate better discrimination using routinely available prediction variables such as demographic data, vital signs, and presenting complaints. Likewise, Goto et al. [16] found a result of improved discrimination and reductions in both under- and over-triage among pediatric ED populations using ML-based prediction models compared to traditional triage tiers. Ensemble learning is one of the current approaches to increasing robustness in structured health data sets, especially when different constituent models exhibit complementary error dynamics [17].

Alternative representations to conventional tabular modeling have been analyzed to enhance usability for predicting health risks. Knowledge-graph-based methodologies have been used to aid risk classification by mining relationships among health concepts to facilitate an organized understanding of interconnected health entities [18]. Variants of deep learning architectures based on multi-layered perceptrons have also been explored for predicting health risk, hence the potential of representation learning in identifying complex patterns in medical data [19]. Workflow and infrastructure are huge factors in the real-world adoption of risk prediction systems. According to empirical investigations, adoption might be limited by insufficient integration with electronic health records (EHRs), which would result in deployment limitations that go beyond model correctness [20].

Explainability has become critical in the deployment of healthcare systems due to the need to explain complex ensemble predictions in risk-stratification situations [21]. Mukilan et al. [22] proposed a hybrid SVM-Naive Bayes ensemble with a combination of LIME and SHAP to achieve transparent air quality and health risk prediction. The authors showed that explanatory layers can be coupled with ensemble learners synergistically in order to increase interpretability [22]. Jayakarthik et al. [23] proposed an approach, called EnvHealthNet, a multimodal model for predicting environmental health risks. The approach follows the general

trend for integrating multiple sources of information. In maternal and antenatal contexts, ML-based risk-level prediction has also been investigated, and more recently, explicit modeling of explainability levels using techniques such as SHAP and LIME has been applied to explain maternal risk prediction. [24, 25]. Across studies and systematic reviews of ML in emergency department triage, the potential of clinical data and techniques to improve both consistency and accuracy in triage decisions is repeatedly highlighted, alongside existing issues such as a lack of datasets and a need for transparent evaluation and reporting [26, 27].

III. Methodology

This section presents the research methodology for developing the proposed framework for health risk prediction. Fig. 1 summarizes the complete workflow of the methodology. In the beginning, the study's dataset is described in detail. Then, the problem statement is formally defined to provide a foundation for the proposed solution.

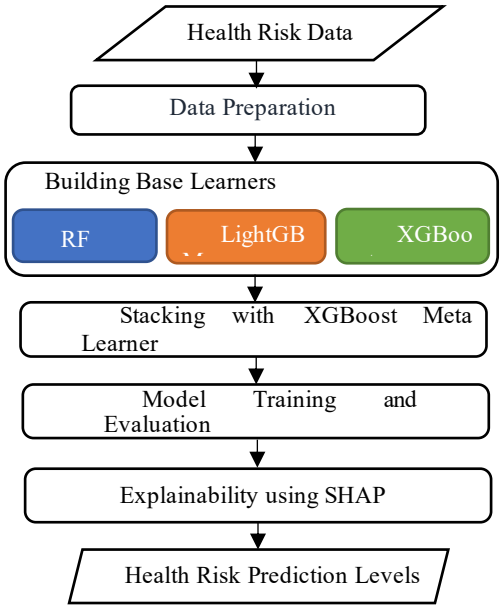

Fig. 1. Flowchart of research methodology.

Afterward, the preprocessing pipeline is described to handle missing values and categorical attributes consistently across both the training and inference phases. The base learners are then introduced, and the stacking ensemble is elaborated using XGBoost as the meta-learner to merge the probabilistic outputs from the base models. Next, the model training and evaluation process is applied to multi-class health risk levels. Finally, an interpretability layer based on SHAP is introduced to provide both global and instance-level explanations of the model decisions.

A. Problem Definition

The problem definition formulates the health risk prediction as a supervised multi-class classification task. Let $X \in R^{n \times d}$ denotes a feature matrix constructed from routinely recorded physiological indicators and clinical attributes. In addition, let $y \in \{1, \ldots, K\}$ represent the ground-truth risk class, in which $K = 4$ corresponds to {High, Low, Medium, Normal}. The goal is to learn a mapping $f: R^d \rightarrow \{1, \ldots, K\}$ that assigns the correct risk level to unseen cases. The risk classes represent ordered levels of severity relevant to real-world triage and monitoring, and the predictive performance should be effective with limited, small datasets, uniform across all classes, and not skewed towards the majority class.

B. Dataset of Study Design

The study uses an anonymized health-risk dataset consisting of variables based on vital signs and related clinical indicators, including metrics for oxygenation and a categorical variable for state of consciousness. The dataset consists of real-world patient data collected from Central Medical College and Hospital, with identifiers removed for privacy protection. It is publicly available on the KAGGLE platform under the name "Health Risk Prediction (Anonymized Real Data)" for conducting studies in health risk multi-class classification [28]. It contains 1,000 anonymized patient records with 9 features and a multi-class target with 4 risk labels: High, Low, Medium, and Normal. The dataset description and variable definitions are provided in Table I, while the class distribution is reported in Table II. We note that Patient_ID is used only for record indexing and is excluded from model training.

TABLE I. Description of Dataset Features

#	Column	Type (Role)	Description
1	Patient_ID	object (Identifier)	An anonymized patient record identifier (used for indexing; not a predictive clinical feature).
2	Respiratory_Rate	Integer (Feature)	Breathing rate (typically breaths per minute); reflects respiratory distress.
3	Oxygen_Saturation	Integer (Feature)	Peripheral oxygen saturation (SpO_2, typically %); indicates oxygenation status.
4	O2_Scale	Integer (Feature)	Oxygen scale/category used for scoring oxygenation (often aligns with clinical early-warning scoring scales).
5	Systolic_BP	Integer (Feature)	Systolic blood pressure (mmHg). It reflects the hemodynamic stability.
6	Heart_Rate	Integer (Feature)	Heart rate (beats per minute); indicates cardiovascular response/stress.
7	Temperature	float (Feature)	Body temperature (°C); indicates fever/hypothermia risk.
8	Consciousness	Object (Feature)	Level of consciousness (e.g., AVPU categories such as A/V/P/U); proxy for neurological status.
9	On_Oxygen	Integer (Feature)	Whether the patient is receiving supplemental oxygen (binary indicator, e.g., 0/1).
10	Risk_Level	Object (Target)	Multi-class health-risk label (Normal / Low / Medium / High) used as the prediction outcome.

TABLE II. DISTRIBUTION OF RISK LEVEL CLASSES

Class Label	Number of Instances
High	279
Low	255
Medium	306
Normal	160

C. Data Splitting and Preprocessing

A hold-out splitting strategy is used to randomly split the dataset into 80:20 training and test subsets to obtain a reliable estimate of generalization performance. The split is performed with a fixed random seed of 42 for reproducibility. The test subset is only for final evaluation and is not used to calibrate preprocessing or train meta-learners. Stratified partitioning is applied to ensure that imbalanced classes can be preserved across splits. This strategy is similar to real-world deployment scenarios in which models must handle unexpected data. Data preprocessing is then implemented as a standard pipeline to apply the same transformations during training and testing.

First, all features are checked for missing values. If numerical features contain missing values, median values are used to replace them. Also, missing values in categorical features are imputed using the mode. After that, categorical variables are converted to numerical values using one-hot encoding. It enables discrete clinical states to be represented without forcing a spurious ordinal relationship. The resulting transformation, z = T(x), is fit only on the training set and then used on both the training and test sets, ensuring that the evaluation is unbiased and that the deployed model will be able to handle new cases with the same preprocessing.

D. Building Base Learners

To capture heterogeneous patterns in structured clinical datasets, the proposed framework trains a diverse set of tree-based base learners at the first hierarchical level. Each base learner $m \in \{1, \dots, M\}$ induces a probability distribution over the K risk classes for a given transformed input $x \in \mathbb{R}^d$, given by $p_m(x) = [p_m(y = 1 \mid x), \dots, p_m(y = K \mid x)] \in \mathbb{R}^d$. In this study, powerful ensemble learners are built for tabular data type, especially bagging tree (RF), as well as gradient boosted decision trees (LightGBM and XGBoost). These ensemble learners can capture such nonlinear effects and feature interactions, which often appear in physiological measurements.

E. Stacking with XGBoost Meta-Learner

The proposed framework combines the base learners through stacked generalization implemented using a stacking classifier. In this configuration, the ensemble operates at the probability level, meaning that the inputs to the second-stage model are not raw features but the class-probability outputs produced by the first-stage learners. For an input instance x, each base learner returns a K-dimensional probability vector over the risk classes. Stacking mechanism constructs a meta-feature vector by concatenating these probability vectors across all base learners:

$$g(x) = concat(p_1(x), p_2(x), \dots, p_M(x)) \in \mathbb{R}^{MK} \quad (1)$$

Where M denotes the number of base learners, which is 3 in our framework. This representation captures complementary confidence patterns across models and provides a compact, information-rich input for second-stage fusion.

For the second stage, the framework uses XGBoost as the meta-learner, specified in the code as the final estimator. The meta-learner learns a nonlinear mapping from the stacked probability space g(x) to the final class probabilities:

$$p_{stack}(y \mid x) = h(g(x)), \hat{y} = arg \max_{k \in \{1,\dots,K\}} p_{stack}(y = k \mid x) \quad (2)$$

Using predicted probability of the stacked method, the meta-learner operates on a concatenation of base-model probability vectors $g(x) = concat(p1(x), \dots, pM(x))$. The XGBoost meta-learner learns a nonlinear fusion, $p_{stack}(y \mid x) = h(g(x))$, with $c\ v = 5$ used to generate unbiased meta-features during training.

To mitigate optimistic bias in meta-learning, the stacking construction specifies that the base-level probabilities used to train the meta-learner are generated via 5-fold cross-validation, which trains the framework to generate meta-features using cross-validated base predictions during fitting. We adopt stacking rather than fixed-weight aggregation because it learns a data-driven fusion rule from base-model probability outputs, enabling adaptive weighting across patient profiles. To validate this choice empirically, the proposed approach will be benchmarked against strong individual baselines using the same split, and both accuracy and macro-averaged metrics will be reported.

F. Model Training and Evaluation

The training phase is performed exclusively on the training subset. During fitting, the base learners are first trained on the training data, and the stacking mechanism internally constructs the meta-learning dataset as specified by the 5-fold cross-validation. Precisely, the training set is split into five folds; for each fold, the base learners are trained on the remaining folds and used to generate out-of-fold class probabilities for the held-out fold. These out-of-fold probabilities become the meta-features for training the XGBoost meta-learner, which learns the final fusion rule from base-model probability signals. After the meta-learner is trained, the base learners are refit on the full training set, enabling the final stacked model to use all available training data when producing predictions for unseen cases.

Evaluation is conducted strictly on the held-out test partition, which is never used during model fitting or meta-feature construction. After training, predicted labels are obtained using the trained pipeline of the base learners to produce $\hat{y}$. Performance is quantified using accuracy to summarize overall correctness and macro-F1-score to provide an imbalance-aware assessment that weights all classes equally. Accuracy, Precision, Recall, and F1- score are computed as:

$$Accuracy = \frac{(TP+TN)}{(TP+TN+FP+FN)} \quad (3)$$

$$Precision = \frac{TP}{(TP+FP)} \quad (4)$$

$$Recall = \frac{TP}{(TP+FN)} \quad (5)$$

$$F1\text{-}score = \frac{2\times(Precision\times Recall)}{(Precision+Recall)} \quad (6)$$

where, $TP, TN, FP,$ and FN are the number of true positives, true negatives, false positives, and false negatives of all classes.

No resampling like SMOTE, manual threshold shifting, or cost-sensitive reweighting is applied. To ensure fair assessment under imbalance, macro-precision, macro-recall, macro-F1-score, and class-wise results are reported in addition to accuracy. In other words, to confirm that performance is not dominated by the majority class, the macro-F1-score is computed by first calculating precision and recall for each class k, then averaging the per-class F1-scores as:

$$Macro\ F1\text{-}score = \frac{1}{K}\sum_{k=1}^{K} F1\text{-}score_k \quad (7)$$

In addition to scalar metrics, the confusion matrix is computed to inspect class-wise error patterns and identify systematic confusions between adjacent severity levels (e.g., Medium vs. High). The confusion matrix $C \in N^{K\times K}$ is defined as:

$$C_{i,j} = |\{x: y = i \wedge \hat{y} = j\}| \quad (8)$$

The confusion matrix counts how many instances of true class i are predicted as class j. Together, Accuracy, Macro-F1-score, and the confusion matrix provide a comprehensive evaluation: Accuracy captures overall correctness, Macro-F1-score emphasizes balanced performance under class imbalance, and the confusion matrix supports detailed clinical error analysis. In addition, the receiver operating characteristic (ROC) curve will be visualized to show the relationship between the true positive rate and the false positive rate at different decision thresholds.

G. Explainability Using SHAP

The methodology integrates SHAP explanations into the final stacked model, thereby enabling feature-level reasoning and clinical transparency. By decomposing a prediction into a baseline and contributions from various input variables, SHAP provides additive feature attributions. It is used to produce both local explanations and global explanations. Local explanations support the individual risk assignments by indicating the features that increase or decrease the probability of each class. For global explanations, mean absolute SHAP values specify the most important predictors in the ensemble learners group. The SHAP methodology gives coherent and computationally tractable explanations of tree-based models. By making the links between predictions and clinically significant signs, this interpretability layer aids in building trust, detecting unexpected model behavior, and simplifying the clinical review process.

IV. Experimental Results

In this section, the experiments of the proposed framework are conducted and discussed to provide in-depth interpretations of quantitative results as well as explanations for explainability analyses. The evaluation and findings are reported through three experiments. The first experiment presents the confusion matrix, ROC curves, class-specific measurements, and analysis to validate the predictive performance of the developed framework on a held-out test set. The second experiment compares the framework to individual base models to quantify the value of stacking and confirm that improvements stay consistent despite class imbalance. Finally, the third experiment demonstrates the results of interpretability integrated into the proposed framework. The SHAP values of global feature attributions are mapped to the interdependencies between data-level features and provide, at the same time, instance-level explanations for a representative test case. In the first experiment, the proposed hybrid ensemble is evaluated on the test set to demonstrate its performance in multi-class health risk classification. Fig. 2 shows the confusion matrix, which takes a class-by-class breakdown of correct predictions and misclassifications of the four risk classes.

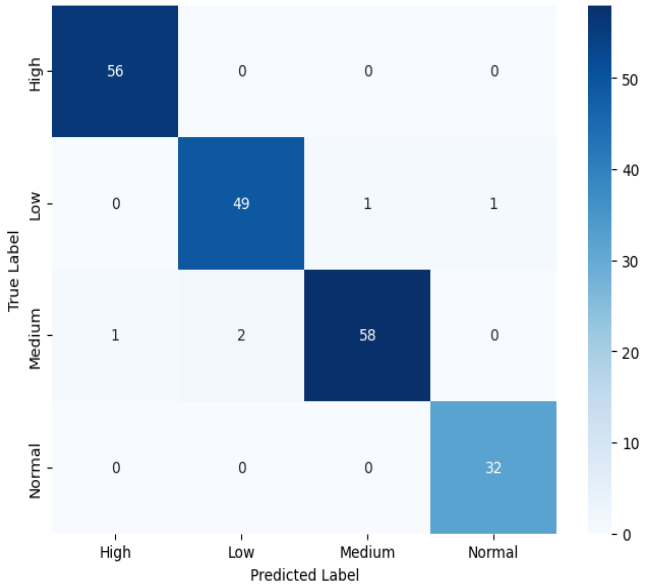

Fig. 2. Confusion matrix of the hybrid ensemble model.

As shown in Fig. 2, the main diagonal of the confusion matrix suggests that the model has a majority fit the observations to the correct risk categories. The corrected classified instances provide evidence of worthy overall discriminative performance. The model maintains high sensitivity for severe cases, which is an essential requirement for triage-oriented prediction. Following the confusion matrix, the results of other evaluation quantities are given in Table III, including the per-class precision, recall, F1-score, and the macro-averaged metrics.

TABLE III. Evaluation Results of the Hybrid Ensemble Model

Class Label	Precision	Recall	F1-score
High	0.9825	1.0000	0.9912
Low	0.9608	0.9608	0.9608
Medium	0.9831	0.9508	0.9667
Normal	0.9697	1.0000	0.9846
Accuracy	0.9750		
Macro avg.	0.9740	0.9779	0.9758
Weighted avg.	0.9751	0.9750	0.9749

As given in Table III, the obtained results support the confusion matrix findings. The model has an accuracy of 0.9750, along with a strong macro-average precision of 0.9740, macro-average recall of 0.9779, and macro-average F1-score of 0.9758. These results shaped the performance to be balanced in all classes. Furthermore, the high-risk class has a recall of 1.0000 and an F1-score of 0.9912, which implies that no severe cases are missed. The medium class shows a slightly lower recall of 0.9508 compared with the other classes, which is consistent with the low number of medium risk, classified as low or high risk, as shown in Fig. 2. However, the model's F1-score for the medium class is relatively high (0.9667), underlining good performance even for the most overlapped class. Fig. 3 shows the AUC-ROC plot of the hybrid ensemble model for each of the classes. The one-versus-rest ROC curve is obtained by treating each of the classes as the positive class, compared to the other classes at different thresholds of decision and the AUC is a threshold independent measure of discriminative capacity.

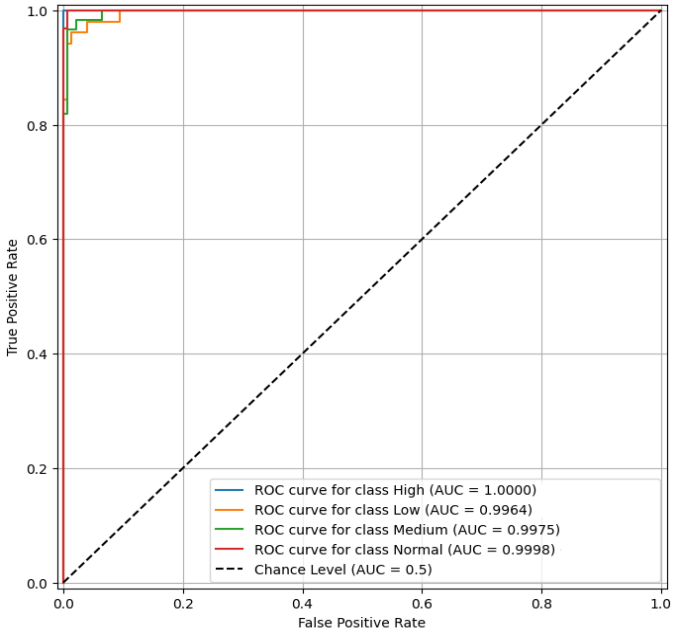

Fig. 3. One-versus-rest ROC curve of the hybrid ensemble model.

As shown in Fig. 3, the ROC curves for all classes in one-versus-rest classification are clustered in the upper-left quadrant, indicating that the classifier's discriminatory ability is respectable across all tested threshold values. The AUC scores are extremely high (1.0000 for High class, 0.9964 for Low class, 0.9975 for Medium class, and 0.9998 for Normal class). These results show that the ensemble model's probabilistic outputs achieve high separability between the risk categories and the remaining classes, supporting reliable threshold-based implementation when different operating points are required.

In the second experiment, the performance comparison between the hybrid ensemble model and single learners is documented in Fig. 4 and Table IV. Fig. 3 shows a comparison of the test set accuracy, and Table IV lists the macro-averaged precision, recall, and F1-score for each model. Fig. 4 shows that the hybrid ensemble model achieves the highest accuracy (0.9750), outperforming RF (0.9600), LightGBM (0.9600), and XGBoost (0.9550). This evidence identifies the framework as an approach for effectively utilizing the complementary strengths between the constituent base learners. The hybrid ensemble model improves generalization beyond that expected from any single robust model.

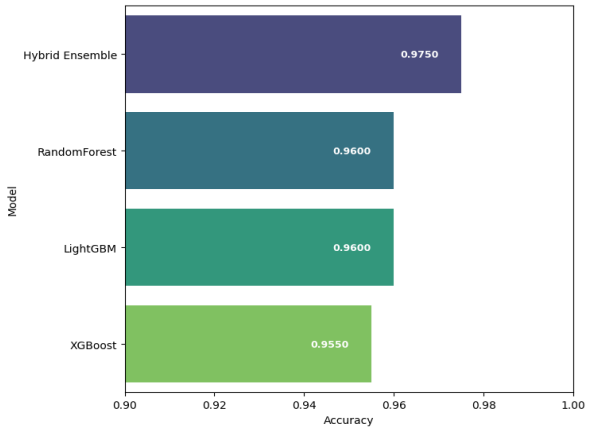

Fig. 4. Comparison of test accuracy between the hybrid ensemble model and individual baseline models.

TABLE IV. COMPARISON OF MACRO-AVERAGED EVALUATION METRICS BETWEEN THE HYBRID ENSEMBLE MODEL AND INDIVIDUAL BASELINE MODELS

Model	Macro F1-Score	Macro Precision	Macro Recall
RF	0.963	0.967	0.960
XGBoost	0.959	0.961	0.956
LightGBM	0.963	0.967	0.960
Hybrid Ensemble	0.976	0.974	0.978

To confirm that the majority class does not affect the improvement, Table IV presents the macro-averaged performance values. The hybrid mode achieved the best results, with a macro F1-score of 0.976, macro recall of 0.978, and macro precision of 0.974. In contrast, the individual models have lower scores. The RF and LightGBM have a macro F1-score of 0.963, whereas the XGBoost has a macro F1-score of 0.959. These results highlight that the hybrid model improved the balanced multi-class performance.

Furthermore, Table IV shows greater reliability for minority or critical classes than for overall accuracy alone. To validate the proposed model's results against the state-of-the-art method, a direct comparison with previously published methods on the same dataset is currently not possible, as no peer-reviewed benchmarks are available. Therefore, the results of the proposed model are compared against strong individual baselines on the same split and report macro-averaged metrics to account for class imbalance.

The third experiment evaluates the transparency of the framework using SHAP analysis. To provide global explanations of the model's predictions, SHAP summary plots are shown for each risk label, as shown in Fig. 5 to 8. These visualizations give each feature its relative importance in the aggregate model output. They show how feature values, whether high or low, influence the predicted probability towards or away from each class. Presentation of such summary plots by the risk

label is especially informative in multi-class settings since the same feature may contribute to divergent risk outcomes. This depends on the range in which its value falls, as well as its interactions with other variables. For example, a low oxygen saturation level may increase the probability of High-risk classification but also decrease the probability of Normal-risk classification.

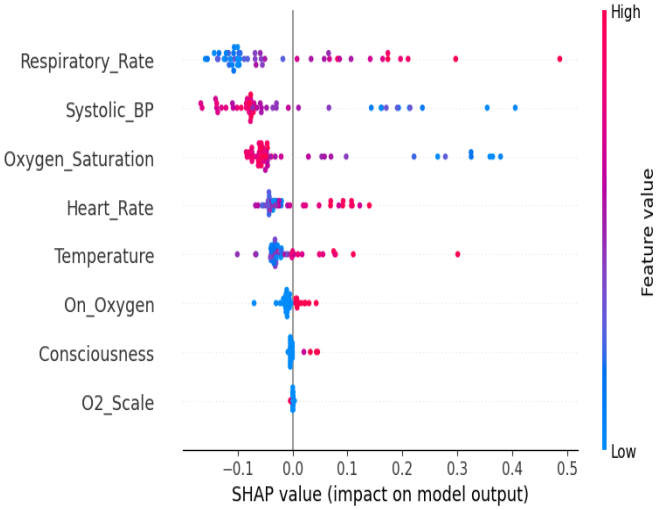

Fig. 5. SHAP summary plot for the high-risk class.

Fig. 5 gives the SHAP summary plot for the High-risk class. The most influential predictors, based on the selected variables, are respiratory rate and systolic blood pressure, followed in importance by oxygen saturation, heart rate, and temperature. This ordering agrees with known clinical expectations, in which respiratory decompensation and hemodynamic instability are the major indicators of high risk. The chromatic distribution further biases the model's output toward the High-risk category by applying pronounced values for features such as a high respiratory rate, low systolic blood pressure, and low oxygen saturation.

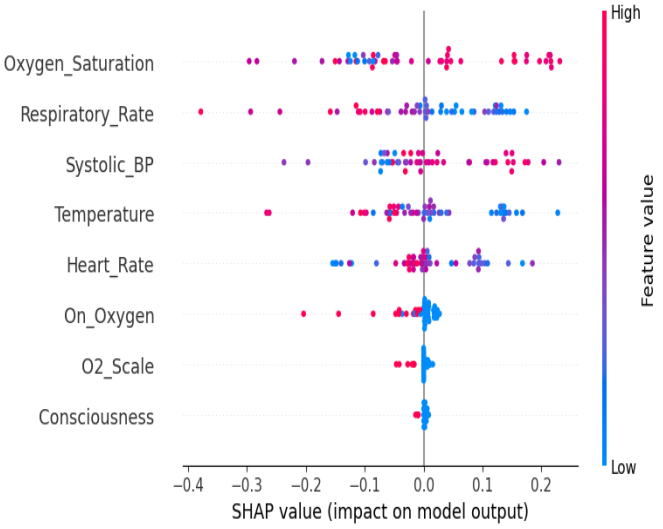

Fig. 6. SHAP summary plot for the low-risk class.

In Fig. 6, the SHAP summary plot for the Low-risk class shows the boundary of the features that influence the model's decision on Low risk, and how those feature value ranges modify the decision. The principal contributors mirror the clinically salient vital signs variables identified for each of the other classes, such as oxygen saturation, respiratory rate, systolic blood pressure and heart rate. However, their effects correspond with an intermediate spectrum of severity. In particular, the feature values reflecting mild deviations from physiology are associated with a higher probability of Low-risk. Those representing stable physiology will move the model's predictions toward Normal, and more obvious abnormal values will steer the model's predictions away from Low-risk toward Medium-risk or High-risk.

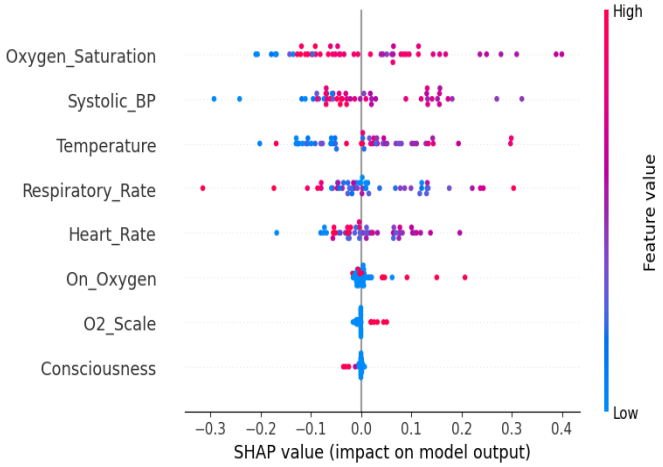

Fig. 7. SHAP summary plot for the Medium risk class.

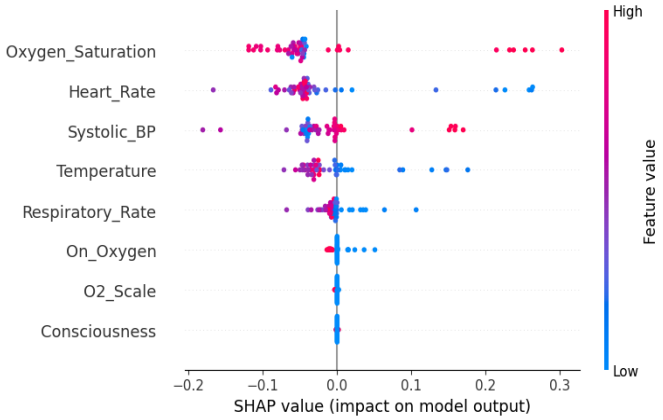

Fig. 8. SHAP summary plot for the Normal risk class.

Similarly, Fig. 7 and 8 represent the Medium-risk and Normal-risk classes, respectively. They show that oxygen saturation continues to have a dominant effect, whereas the contributions of heart rate, temperature, and respiratory rate vary across classes. The global explanations are consistent with the behavior of the confusion matrix. This consistency shows that misclassifications mostly concentrate near the Low and Medium risk border region, where physiological patterns can overlap. Together with Fig. 5, 7, and 8. Fig. 6 completes the class-wise global interpretability analysis and provides evidence that the model's Low-risk decisions are driven by clinically coherent

signals rather than spurious artifacts. For the dominant features, identified by SHAP, Fig. 9 visualizes their relationships using a pairwise scatter distribution plot. The points of the scatter distribution plot are colored by risk label to show class separation and overlap in feature space.

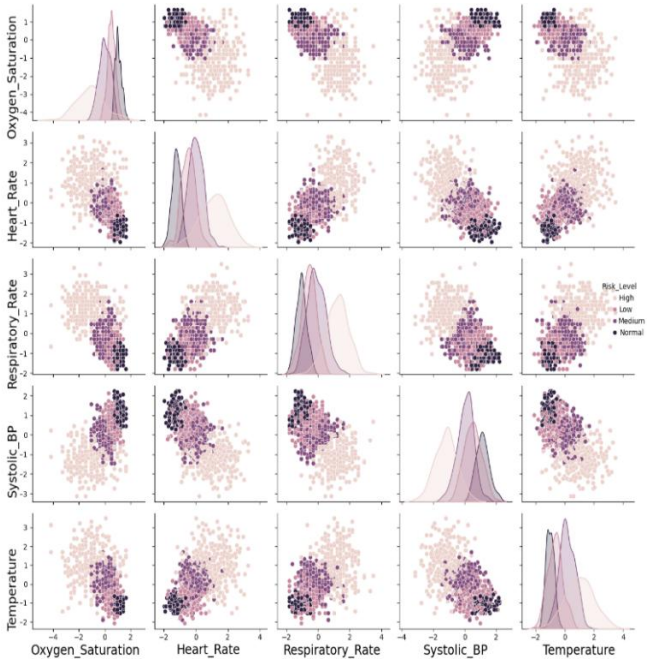

Fig. 9. Visualization of pairplot for the relationships between dominant features.

From Fig. 9, the scatter distribution of risk levels provides an empirical rationale for SHAP-based feature rankings. The visualization shows that the risk classes are in partially-separable regions of the combined feature space. For example, the separation between classes is increased once oxygen saturation is plotted side-by-side with respiratory rate and systolic blood pressure. This separation provides direct support for the prominence of these variables among the leading SHAP contributors. The overlap between classes, Low and Medium risk, provides a visual explanation for the constrained number of misclassifications described in Fig. 2, and the slightly reduced recall for the Medium class described in Table III.

In addition to global SHAP summaries, instance-level explanations are provided for a representative test case. The waterfall plots report feature contributions for each class (Normal, Low, Medium, and High), demonstrating not only why the model supports the Medium decision but also why competing classes are rejected. The local SHAP waterfall explanations for a specific test instance with true label Medium are given in Fig. 10 to 13, reporting class-wise contributions. Fig. 10 indicates that key features, notably systolic blood pressure, heart rate, temperature, and oxygen saturation, contribute negatively to the High class, preventing escalation to High-risk for this case. Fig. 11 highlights that respiratory rate strongly decreases the Low-risk probability, consistent with a physiological profile more concerning than the low class. Fig. 12 shows strong positive contributions from respiratory rate, systolic blood pressure, heart rate, temperature, and oxygen saturation, collectively increasing the probability toward the Medium class, which explains the final predicted outcome. Fig. 13 shows negative contributions from multiple vital-sign features, reducing the Normal class probability and justifying why the model rejects Normal for this instance.

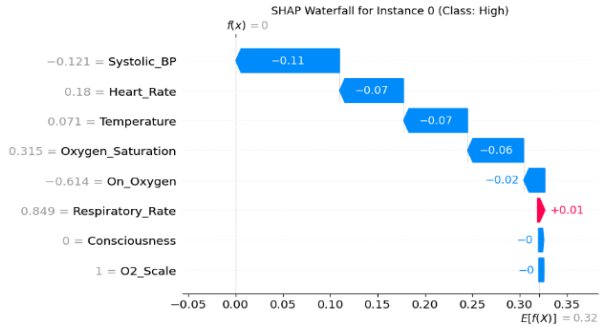

Fig. 10. SHAP waterfall plot for a specific test instance, with features influencing its probability of being classified as High risk.

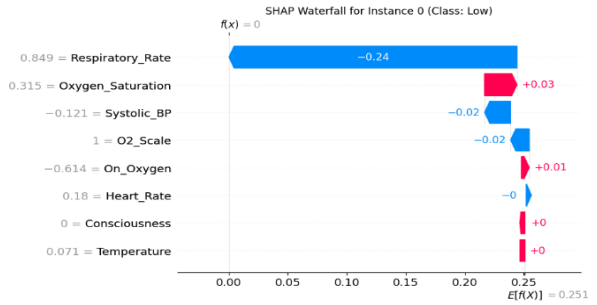

Fig. 11. SHAP waterfall plot for a specific test instance, with features influencing its probability of being classified as Low risk.

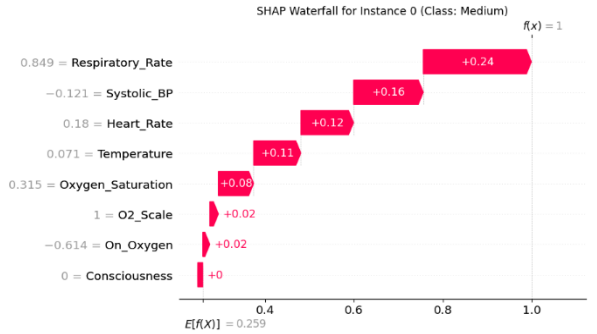

Fig. 12. SHAP waterfall plot for a specific test instance, with features influencing its probability of being classified as Medium risk.

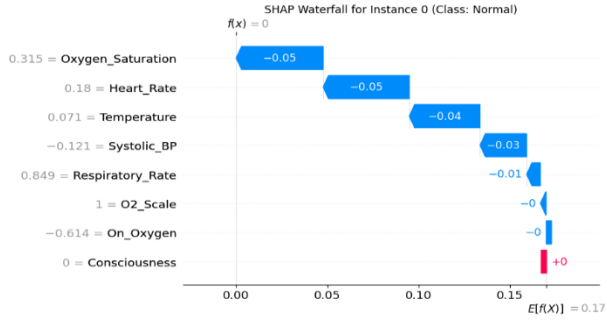

Fig. 13. SHAP waterfall plot for a specific test instance, with features influencing its probability of being classified as Normal risk.

Overall, these local explanations support the fact that the decision of the model is not only accurate but also traceable. As the same clinically relevant features identified at the global level in Fig. 5 to 8, Fig. 10 to 13 offer case-specific reasoning for providing cohesive transparency for clinical interpretation. These case-level attributions can support clinician review by identifying whether respiratory compromise (e.g., elevated respiratory rate, reduced oxygen saturation) or hemodynamic signals (e.g., lower systolic blood pressure) are the primary drivers of risk escalation. Across all experiments, the framework demonstrates the following advantages:

- Strong multi-class predictive performance with accuracy equal to 97.50%, and high per-class discrimination as demonstrated in Fig. 2, Fig. 3, and Table III.
- Consistent improvement over individual models in both accuracy and imbalance-aware macro metrics, as shown in Fig. 4 and Table IV.
- Clinically successful explanations through SHAP at both global and local levels, as visualized in Fig. 5 to 13.

These advantages support the proposed framework as an accurate and explainable framework for practical health-risk classification. For deployment, integration with EHR/HIS requires consistent data availability at the point of care, robust handling of missingness, latency-aware execution, and monitoring for dataset shifts over time. From an ethics and accountability perspective, the proposed model can be used as human-in-the-loop decision support, with auditability and explanation logs, subgroup performance checks, clinician override, and prospective validation before clinical adoption.

V. Conclusions and Future Work

This study proposed a hybrid explainable ensemble learning framework for multi-class health risk classification. The proposed framework is based on routinely collected clinical indicators, such as respiratory rate, oxygen saturation, blood pressure, heart rate, temperature, oxygen-related variables, and consciousness status. The hybrid classification model in the framework is built using the stacking ensemble concept to address a small, limited dataset and a class-imbalanced problem. The hybrid model generates synthesized complementary decision signals from multiple tree-based decision learners. It produces a singular, robust health risk classifier across four clinically significant classes: High, Low, Medium, and Normal.

Experimental results have shown that the framework demonstrates respectable predictive performance on a held-out test set, achieving 97.50% accuracy. More importantly, the model maintains high, balanced performance despite class imbalance, as shown by a high macro-level F1-score and valuable macro precision and recall values. The confusion matrix also shows that misclassifications are rare and mainly occur between adjacent severity levels, such as Low versus Medium. This outcome facilitates expected clinical overlap in borderline physiological presentations and is generally preferable to large severity jumps.

Beyond the predictive performance, the investigation highlighted the value of transparency and clinical interpretability. The SHAP-based explainability assessment provided both global and local insights into how the model operates. Global SHAP summary plots showed that variables of clinical importance, and particularly, variables reflecting respiratory compromise and physiological instability, such as respiratory rate, oxygen saturation, and systolic blood pressure, are predominant in risk discrimination. This interpretability provides evidence of the clinically plausible nature of the inferred decision function. The pairwise scatter distribution is a useful complement to these global explanations that revealed feature space configurations consistent with class separation patterns. The local SHAP waterfall visualizations provided patient-level reasoning for a representative, medium-risk case that captures all competing labels. Collectively, this body of evidence suggests that the framework has not only accuracy but also auditability. These interpretable justifications can be used to build clinician confidence and to provide an analysis of error in authentic decision-support contexts.

Because no peer-reviewed studies have reported machine-learning benchmarks on the dataset used in this study, this work provides the first academic baseline and a reproducible reference for future comparisons. A limitation of this work is that results are reported under a single hold-out split. Future work will include repeated runs with multiple random seeds and bootstrap confidence intervals to quantify performance uncertainty. Although this study adopts a stacking-based ensemble with an XGBoost meta-learner as the final configuration, other ensemble variants may be considered depending on the target operating requirements. For example, soft voting or weighted averaging can provide simpler aggregation. At the same time, alternative meta-learners, such as logistic regression or LightGBM, and different base-learner combinations may yield different trade-offs between performance, stability, and computational cost. A systematic comparison of these alternative configurations under the same data split and evaluation protocol is left for future work.

Moreover, future work will focus on validating the framework in external hospitals and care environments to quantify robustness to dataset shift and investigate subgroup performance across datasets. In addition, the probability calibration and the optimization of operating thresholds will be investigated to better align model outputs with the requirements of clinical decision-making. A second direction is to move the framework beyond its role as a snapshot prediction system towards use as more actionable decision support. This includes incorporating temporal trends from repeated vital sign measurements to enable earlier detection of deterioration and enrich features with other EHR signals. Finally, the SHAP layer will be improved with stability checks and clinician-facing explanation summaries, and then pilot or prospective evaluation to explore usability and impact within actual clinical workflows.

A Digital Twin-Enabled Approach to Optimize Freight Fleet Operations in a Peruvian Transportation Company

Deyber Flores Cabezas, Liset S. Rodriguez-Baca
Professional School of System Engineering, Cesar Vallejo University, Lima, Peru

***Abstract*—The study evaluates the impact of a system enabled by Digital Twin on the optimization of the operations of a cargo fleet belonging to a transport company in Lima, Peru, during the year 2025. The proposed solution integrates OBD-II sensors, a Python processing engine, and a MongoDB-based data layer to build a synchronized virtual representation of 25 operating vehicles. An experimental, pre-experimental design with measurements before and after the intervention was applied to analyze changes in the frequency of accidents, the use of load capacity, and the monthly number of trips. The results show significant improvements: the frequency of accidents decreased from an average value of 0.08 to zero; the use of load capacity increased from 31 to 35 units; and the number of trips required to transport equivalent volumes decreased. These findings suggest that Digital Twin–based systems can support safer, more efficient, and data-driven operations in emerging logistics environments.**

***Keywords*—Digital Twin; fleet management; IoT; transportation; operational optimization**

I. Introduction

Freight forwarding companies are operating in rapidly changing conditions today. The pressure to comply with stricter schedules, maintain operational security, and make better use of resources requires constant coordination between people, vehicles, and processes. However, in many regions and more frequently in emerging economies, decisions continue to depend on partial systems or fundamental digital tools, which limit the ability to foresee contingencies or adjust operations in time [1], [2]. When the environment becomes more dynamic, and cargo volumes increase, these limitations translate into delays, greater wear and tear on the units, and a reduced margin to react to unforeseen events [3], [4].

In recent years, the idea of virtually representing a physical process through a Digital Twin (DT) has gained prominence as an alternative to face these challenges. A DT combines real-time data with models that enable interpretation of a system's state and anticipation of its behavior. Thanks to the integration, it is possible to observe the performance of a vehicle, a production line, or even an entire logistics network in a virtual environment that reflects what happens on the physical plane [5], [6], [7]. The technology, applied correctly, facilitates the early detection of failures and allows exploring how a system would respond to different scenarios before executing them in real operation.

While most studies have been conducted in highly automated facilities or in projects linked to autonomous driving, the principles underpinning DTs can also be applied in traditional fleets operating with modest technological resources [8], [9], [10].

In the transport of goods, having timely information on the vehicle's driving, mechanical condition, and use can make the difference between an efficient service and an expensive or risky one. When control is based solely on manual observations or incomplete reports, it becomes difficult to detect driving patterns that can lead to incidents, identify route deviations, or assess whether the load is being used properly. A DT offers a way to overcome these limitations by collecting continuous telemetry and converting it into indicators that support operational decision-making.

Despite this potential, there is still little evidence on DT implementations in small and medium-sized transport companies in Latin America. Many of them work with tight budgets and limited digital infrastructure, so it is essential to explore lightweight, cost-effective, and open component-based solutions that can be tailored to their needs. It is necessary to show that this type of technology can generate added value in safety and operational efficiency without requiring a high investment.

To address this need, a DT was implemented in a Peruvian freight transport company. The IT solution combines OBD-II sensors, Python microservices, a document-oriented database, and a real-time monitoring panel. Its effect is measured using an experimental, pre-experimental design, with three key indicators: accident frequency, load capacity use, and the number of trips required to meet demand. Taken together, the results point to meaningful improvements across all indicators and suggest that an accessible DT architecture can help strengthen safety and operational efficiency, even in companies with limited technological resources.

The article is organized according to the following sections: Section II summarizes the main contributions; Section III contains linked antecedents; Section IV explains the methodology and architecture of the IT solution; Section V presents the findings of the research; Section VI presents the discussion; Section VII presents the conclusion, and Section VIII outlines future work.

II. Research Contribution

The study identifies three aspects that help explain how Digital Twins (DT) can be applied in transport companies operating with limited technological resources.

- The first contribution is a DT architecture that operates without costly equipment or complex technological platforms. The proposal for the study uses affordable OBD-II sensors, open-source tools, and microservices that operate in a modular way, thereby avoiding reliance on specialized technological equipment.
- The study explores the effect of Digital Twin technology on the day-to-day performance of a freight transport company. While Digital Twins are already common in industrial and automation environments, their application in traditional fleets remains less studied. For that reason, three key indicators—accident occurrence, load capacity utilization, and number of trips—were compared before and after the implementation of the IT solution. The results made it possible to observe how continuous monitoring and data-driven analysis derived from the DT can contribute to safer and more efficient fleet operations.
- The study proposes a simple methodology. The methodology combines data capture via IoT devices, continuous information processing, and a set of indicators that can be adapted to different types of organizations. In addition to addressing the needs of the company analyzed, the framework serves as a guide for researchers and others interested in implementing DT in SMEs.

These contributions show that Digital Twins can be effectively applied in the transport sector, even in organizations that have had difficulty adopting more advanced technologies. The results obtained show that, even with low-cost solutions and reduced scale, it is possible to achieve clear improvements in operational performance. These results also open the door to new lines of research aimed at refining lightweight architectures and exploring their application in broader and more complex scenarios.

III. Related Work

In recent years, having a digital replica of a physical system has come to the forefront across various areas of engineering. The Digital Twin approach makes it possible to understand how a real process may behave and to anticipate possible operational situations. Although its use has been consolidated in industries with high levels of automation, in cargo transport, it is still in an exploratory stage, where companies seek to adapt their principles to the particularities of their operations.

Wang et al. [13] presented a vehicle navigation prototype based on a Digital Twin model, which improved the accuracy of automated decisions. The authors showed that by maintaining a constant flow of data between the vehicle and its virtual representation, it is possible to anticipate potentially dangerous maneuvers and correct them before they lead to an accident. That conclusion is relevant to the present study because it highlights an important point: when information is analyzed in real time, it becomes a valuable resource for reducing unwanted operational events.

Tang et al. [14] emphasize that Digital Twins must adapt to the environment in which they are implemented. According to their analysis, a generic architecture does not always yield reliable results, as each domain has specific conditions that must be reflected in the virtual model. Such an observation is especially relevant in cargo transport, where operating conditions change frequently and vehicles do not always have the same equipment or receive the same level of maintenance.

It is also relevant to mention the contributions from the industrial field. Ramasubramanian et al. [15] studied how Digital Twins support collaboration between operators and robots in a production plant. Although their work is not focused on logistics, they use Digital Twins to create a virtual representation that enables them to analyze different operational alternatives without interrupting the real process. Such an approach reduces both the risks and the costs associated with direct experimentation in the physical environment.

In the logistics field, Abdullahi et al. [16] developed a framework to improve sustainability by combining Digital Twins with real-time operational data. Their findings showed that increased digitalization enables more precise route planning, avoiding unnecessary travel and reducing both fuel consumption and emissions. A closely related concern in the study is the optimization of the number of trips required for a fleet to meet the same level of demand.

Madusanka et al. [17] reviewed the use of Digital Twins in the maritime domain and identified emerging trends related to monitoring, simulation, predictive analysis, and operational decision-making. Although their study focuses on maritime environments, its findings are relevant to freight fleet management because both contexts require continuous synchronization between physical assets and virtual models to improve safety, efficiency, and resource utilization.

Finally, Gerlach et al. [18] analyzed the use of "supply chain twins" to support the management of supply chains. Their study shows that by having a digital replica of each stage of the process, organizations can more clearly understand how the whole behaves and make informed decisions. This perspective supports the idea that a Digital Twin, even in smaller-scale operations or with limited resources, can deliver tangible improvements in efficiency and safety.

The revised precedents coincide in two central aspects. On the one hand, they argue that Digital Twins are a powerful tool for optimizing operational performance. On the other hand, they highlight the lack of research conducted in real-world settings, especially in environments with limited technological infrastructure. The present study addresses that gap by testing a simple, low-cost architecture in a Peruvian freight transport company.

IV. Methodology

A. Study Design

The study adopted a quantitative approach and an applied purpose, aiming to determine how a technological intervention could influence the operational performance of a freight

transport company. A pre-experimental design was used, with measurements taken before and after the system's implementation. A design of this kind is appropriate when the goal is to examine changes associated with an innovation without full control over the external variables that affect daily operations.

Under this design, it was possible to directly identify the effect of the Digital Twin on indicators used by the company in its usual management, without altering the real context in which its activities take place.

The evaluation process lasted three months, during which the initial data and post-commissioning measurements of the technological solution were collected. The interval was selected to ensure the operational stability of the fleet and reduce the influence of external variations such as high seasons or changes in transport demand.

Although the pre-experimental design allowed direct comparison of operational indicators before and after the intervention, the absence of a concurrent control group limits strict causal attribution. Therefore, the observed improvements cannot be interpreted as being caused exclusively by the Digital Twin system, since Hawthorne effects, short-term demand fluctuations, or other operational changes during the three-month observation period may also have influenced the results.

The population consisted of the 28 active vehicles of the evaluated company. A total of 25 vehicles were selected through non-probabilistic convenience sampling because they had fully functional OBD-II sensors and availability for continuous monitoring. Although a probabilistic method was not used, the sample represents 89.2% of the total fleet, providing high representativeness for the analysis.

The selection was justified by operational criteria: vehicles in continuous use, stable routes, and engines compatible with standard telemetry. The selection criteria made it possible to collect consistent and comparable data across both phases of the study.

B. Digital Twin Architecture

The architecture developed for the study was designed with a lightweight, scalable approach, leveraging low-cost technologies and open-source tools with high interoperability. The architecture is composed of four functional layers:

- IoT Layer (Data Capture): Integrated by OBD-II sensors installed in each vehicle, responsible for recording operational telemetry such as speed, acceleration, engine temperature, fuel consumption, and braking patterns. These data were transmitted wirelessly to the central server.
- Processing Layer (Microservices): Implemented in Python using the Flask framework. It included modules for data cleaning, outlier detection, unusual event identification, and daily indicator aggregation.
- Storage Layer (Database): MongoDB was chosen for its ability to manage both structured and unstructured data and for its flexibility in handling large volumes of telemetry. The database stored historical records, processed indicators, and instantaneous fleet statuses.
- Visualization Layer (Real-Time Dashboard): Developed to display processed information through graphs, alerts, and operational indicators. This layer simulated the fleet's behavior, enabling monitoring of trends, routes, critical events, and variations in load capacity.

Fig. 1 shows that the layers comprise the functional version of the Digital Twin, capable of synchronizing the physical and virtual states of the vehicles during their real operation.

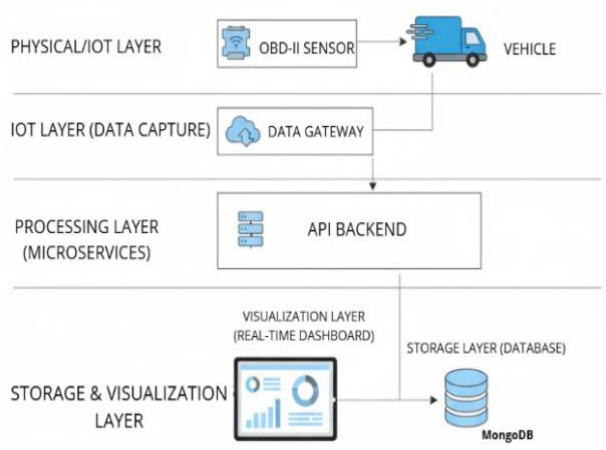

Fig. 1. Architecture of the lightweight Digital Twin system integrating OBD-II telemetry, microservice-based processing, a document-oriented database, and a real-time monitoring dashboard.

C. Procedure for Data Collection

The data collection process followed the following stages:

- Installation and calibration of OBD-II sensors in the 25 selected vehicles.
- Continuous telemetry record stored every 2 seconds throughout the study period.
- Data integrity validation, discarding corrupted or inconsistent values.
- Raw data processing, generating daily indicators per vehicle.
- Consolidation of operational indicators: frequency of accidents, load transported, and number of trips made.

The general data collection and processing workflow is presented in Fig. 2, which summarizes the sequence from sensor installation and telemetry acquisition to data validation, indicator generation, and operational analysis.

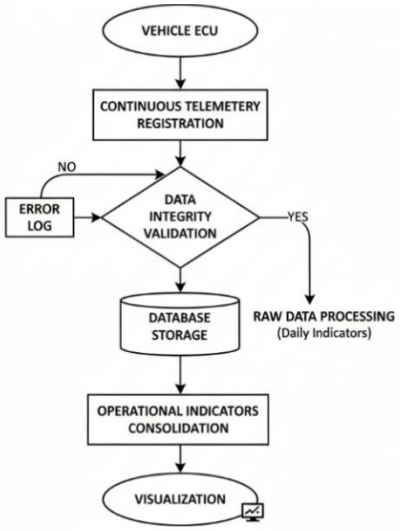

Fig. 2. Flow chart and processes.

The study focused on three key indicators:

- Accident frequency: number of incidents recorded per vehicle during the evaluated period.
- Load capacity use: average number of units transported per trip.
- Monthly number of trips: total trips needed to meet standard demand.

These indicators were selected for their direct relevance to efficiency, safety, and logistics performance.

D. Event Detection Module

The event detection module is responsible for identifying risky driving behaviors based on the telemetry received. It processes each new sample from the OBD-II device and evaluates a set of thresholds for speed, acceleration, and braking intensity. When one or more thresholds are exceeded, the module generates an event log that is stored in the database and displayed on the control panel as a security alert. Algorithm 1 summarizes the logic implemented in the event detection microservice.

Algorithm 1: Event Detection Module

```
Input: telemetry sample s = {speed, rpm, throttle, brakeForce, gpsPosition, timestamp}
Parameters:
SPEED_LIMIT = 90 km/h
ACC_THRESHOLD = 3.0 m/s² // harsh acceleration threshold
DECEL_THRESHOLD = 3.5 m/s² // harsh braking threshold
TEMP_LIMIT = 95 °C // engine temperature alert threshold
Output: list of detected events E
Begin
E ← ∅
//Overspeeding
    if s.speed > SPEED_LIMIT THEN
        E ← E ∪ {("OVERSPEED", s.timestamp, s.gpsPosition)}
    End if
// Harsh acceleration
    if s.acceleration > ACC_THRESHOLD then
        E ← E ∪ {("HARSH_ACCELERATION", s.timestamp, s.gpsPosition)}
    end if
// Harsh braking
    if s.brakeForce < −DECEL_THRESHOLD then
        E ← E ∪ {("HARSH_BRAKING", s.timestamp, s.gpsPosition)}
    end if
//Engine temperature alert
    if s.engineTemp > TEMP_LIMIT then
        E ← E ∪ {("HIGH_ENGINE_TEMPERATURE", s.timestamp, s.gpsPosition)}
    end if
    return E
    End
```

For the monitored fleet, the thresholds were set at 3.0 m/s² for harsh acceleration, 3.5 m/s² for harsh braking, and 95 °C for engine temperature alerts during the calibration stage of the system.

TABLE I. SYSTEM AND DATA ACQUISITION PARAMETERS

Parameters	Value
Number of vehicles monitored	25
Sensor Type	OBD-II (ELM327-based)
Telemetry frequency	1 sample/2 seconds
Data transmitted	Speed, RPM, throttle %, fuel rate, engine load, braking intensity
Transmission protocol	Bluetooth / WiFi
Database system	MongoDB (document-oriented)
Processing pipeline	Python microservices
Monitoring dashboard	Web-based (real-time)

Table I clearly shows how the system supporting the Digital Twin was configured. The company worked with a fleet of 25 units, each equipped with an OBD-II sensor capable of sending data at a short periodicity, sufficient to track vehicle behavior in near real-time.

The values collected provide a relatively complete view of each unit's state, ranging from basic variables such as speed to indicators of engine effort and the driver's brake use. All that information was transmitted wirelessly to a database designed to handle large volumes of records, where small Python modules then processed it.

The entire flow was integrated into a visualization panel that allowed for the review of the fleet's activity while it was in operation.

E. Monitoring Dashboard

In addition to data acquisition and processing, the proposed system includes a web dashboard that provides real-time visibility into fleet operations. The dashboard is organized into three main panels: a map view showing the current GPS position of the selected vehicle, a telemetry panel showing key indicators such as speed, engine temperature, and battery voltage, and an event panel listing active safety alerts.

Supervisors can filter events by vehicle, adjust the refresh rate, and toggle between the live and historical views. The interface allows operating personnel to monitor driving conditions during trips and review past events for training or audit purposes.

Fig. 3 shows a capture of the panel used to monitor the fleet in real time. There, you can see the vehicle's location, the central telemetry values, and the alerts generated during the operation.

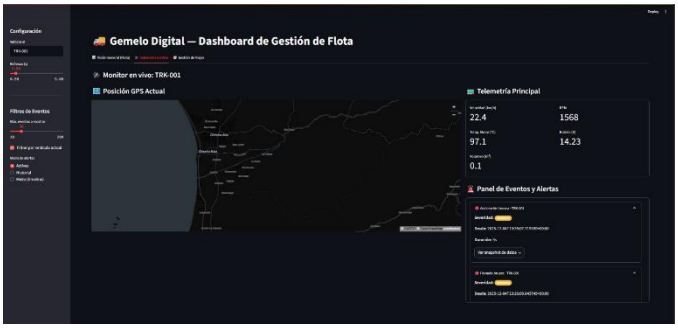

Fig. 3. Digital Twin–based fleet monitoring dashboard showing live GPS position, key telemetry indicators, and active safety alerts.

F. Statistical Analysis

T-tests were applied for related samples to compare the pre-test and post-test values of the three operational indicators. The significance level was set to $\alpha = 0.05$. The test was adequate given the continuous nature of the data and the comparison between two observation times for the same sample.

Likewise, descriptive measures such as averages, standard deviations, and percentage variations were used to complement the interpretation of the Digital Twin's impact. Additionally, basic assumptions, such as the normality of the differences, were verified through graphical and statistical analyses.

For the study, no routes, loads, or activities that could affect driver safety or the integrity of vehicle units were manipulated.

Regarding internal validity, efforts were made to control factors that could influence the results, such as changes in demand, route adjustments, or changes in fleet composition. Regarding external validity, it is recognized as limited; however, the procedure followed can be reproduced in companies operating under similar conditions, opening the possibility of applying the methodology in other contexts within the same sector.

V. Results

The incorporation of Digital Twin enabled unambiguous identification of changes in the fleet's performance throughout the analysis period. The comparison between the data obtained before and after implementation provides an accurate view of how the tool influenced three central aspects of the operation: safety, load capacity utilization, and the number of displacements required to meet demand. The most important findings are detailed below.

A. Frequency of Accidents

Before the implementation of Digital Twin, the company recorded minor accidents that, although they did not always lead to material damage, did indicate potential risks. On average, the fleet had 0.08 accidents per vehicle, which indicated driving behaviors requiring attention, such as sudden braking, unexpected maneuvers, or deviations from the planned route.

After the implementation of the IT solution, the indicator improved significantly, with no accidents recorded during the post-test period. Three main changes introduced through the Digital Twin system help explain the improvement. First, continuous monitoring of each vehicle made it possible to detect unusual behavior early and respond before it escalated into an incident. Second, the alerts sent to supervisory staff created opportunities for immediate corrective action during operation. Third, drivers tended to behave more cautiously because the most relevant aspects of their driving were being monitored in real time.

The statistical analysis indicated a significant association between the intervention period and the observed improvement in fleet management indicators.

B. Use of Load Capacity

In the initial stage, the average of the indicator was 31.04 units, reflecting variations in the allocation of goods and a tendency to send vehicles with available space, especially on routes with fluctuating demand.

After implementing Digital Twin, the average increased to 35.00 units, representing a significant improvement for the operation. The variation was not due to an increase in demand, but to a more innovative use of information. The system allowed:

- Identify trips with low occupancy.
- Reorganize load allocation more evenly.
- Avoid unnecessary departures when consolidating goods is possible.

One of the most apparent effects was that supervisors could visualize each vehicle's occupancy in real time, facilitating more precise decisions when coordinating dispatches. In practice, the new monitoring process helped prevent a routine pattern in the company: sending vehicles with low loads just to meet internal schedules, even when it was not strictly necessary.

C. Monthly Number of Trips

A relevant aspect of logistics management is the number of displacements made to meet a constant demand. During the pre-test period, the number of trips tended to be higher than necessary, in part because decisions were made with incomplete information or based on estimates made at the start of each day.

Among the improvements highlighted by the operational team are:

- Fewer "empty" or underutilized trips.
- Better allocation of units by load type.
- Greater anticipation of delays or detours enabled reorganizing routes without generating additional trips.

The statistical analysis showed significant differences between the pre- and post-intervention stages, supporting the conclusion that the Digital Twin improved efficiency, reduced unnecessary travel, and contributed to lower operating costs for fuel, maintenance, and person-hours.

All three indicators point in the same direction: the Digital Twin had a positive, measurable impact on fleet operations. Not only did it improve safety and productivity, but it also offered a stronger basis for decision-making.

The results obtained show that:

- Accidents were eliminated during the post-test period.
- Use of load capacity was elevated, reducing underutilization.
- The number of trips was reduced, reflecting a more rational use of resources.

Therefore, the changes observed are consistent with the use of more accurate and timely information provided by the Digital Twin architecture. However, because the study used a pre-experimental design without a concurrent control group, these improvements should not be interpreted as being caused exclusively by the intervention. Table II shows the comparison between the pre- and post-test results.

TABLE II. PRE-TEST AND POST-TEST OPERATIONAL INDICATORS

Indicators	Pre-test and post-test operational indicators		
	Pre-test	*Post-test*	*Change*
Accident frequency	0.08	0.00	-0.08
Load capacity utilization (%)	31.04	35.00	3.96
Monthly trip count	250	230	-20

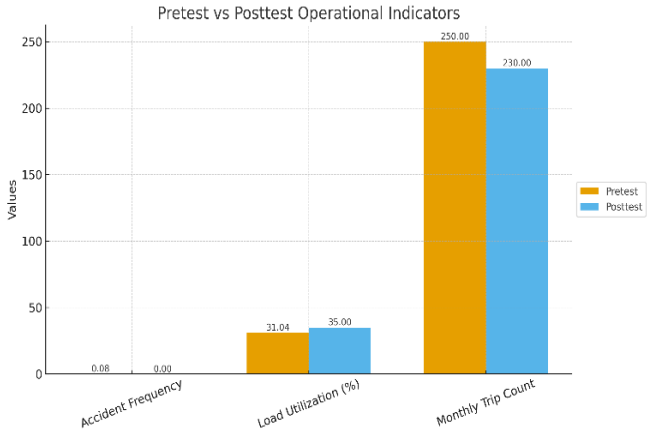

Fig. 4. Pre-test and post-test operational indicators.

Fig. 4 shows how the three operational indicators changed after implementing the Digital Twin. We can see a drop in incidents, better use of capacity, and fewer trips needed to meet the same demand.

In short, experience shows that even a company with limited resources can obtain significant benefits by adopting technologies that integrate telemetry, data analysis, and operational visualization.

VI. DISCUSSION

The results obtained allow a clearer understanding of the real impact that a Digital Twin system can have when integrated into an operating environment such as that of a freight transport company. In the first instance, the total reduction in accident frequency (from an average of 0.08 to 0.00) confirms that technology serves not only as a monitoring mechanism but also as an instrument that changes behavior and reduces risk exposure. The reduction also helped the company avoid repair costs and vehicle downtime. According to internal estimates from the head of the operations area, even a minor incident of this kind can lead to one or two weeks of service interruption for a single vehicle, in addition to direct maintenance expenses. Such findings are consistent with reports on DT-ITS systems, which emphasize the ability of Digital Twins to improve interoperability between devices, anticipate incidents, and enhance road safety through continuous synchronization between physical and virtual environments [11].

Likewise, the significant improvement in load capacity (increased from 31.04 to 35.00 units) demonstrates that the availability of reliable, real-time data enables reorganizing assignments, reducing underutilized trips, and optimizing vehicle use. The result is consistent with the findings of Moshood et al. [12], who argue that Digital Twins enhance logistical visibility, detect structural inefficiencies, and help manage critical resources within a sustainability framework. The company stopped operating on estimates and began basing its decisions on evidence.

Regarding the decrease in the number of trips (250 trips to 230), although the indicator did not decrease drastically, the difference was significant ($p = .045$). That is, as the load capacity used per trip increases, the need for additional travel is automatically reduced. Wang et al. demonstrated that decision-making based on real-time synchronized information optimizes routes, avoids redundant displacements, and improves operational efficiency in complex environments [13].

The combination of higher cargo utilization and fewer monthly trips also evidences improvements in fuel efficiency and labor use. Considering a conservative fuel cost and average driving time per route, the reduction translates into savings in fuel consumption, driving hours, and overtime pay. The implementation of Digital Twins contributes not only to safer operations but also to a gradual reduction in operating costs.

Discussion of the results is also related to experiences reported in other countries. Tang et al. [14], for example, demonstrated that combining IoT with predictive maintenance strategies reduces downtime and prevents operational failures. Similarly, Ramasubramanian et al. [15] argued that Digital Twins support strategic decision-making related to fleet

management. Although both studies were carried out in more technologically advanced settings, the results of the present study suggest that Digital Twins can also deliver significant benefits in companies with limited resources.

The results show that Digital Twins are a feasible alternative for SMEs. Even without having a sophisticated technological infrastructure, it was possible to propose concrete improvements in security, performance, and resource optimization. Implementing Digital Twins can contribute not only to safer operations but also to a gradual reduction in operating costs.

The research was conducted in an SME in the freight transport sector, so the findings cannot be generalized to larger organizations with more complex processes and infrastructure. As Rigó et al. [5] point out, the performance of a Digital Twin is closely linked to the degree of technological maturity and the institutional commitment to adopting Industry 4.0 tools. These factors can vary considerably across companies.

Several factors conditioned the scope of the study. First, we worked with a single company and a small number of units, which limits the ability to extend the results to other environments with different characteristics. In addition, the implemented solution lacked more sophisticated predictive models, making it impossible to analyze long-term behavior or trends. In addition, differences in infrastructure and level of digitization between companies can influence the degree of replicability of the proposal.

VII. Conclusion

The findings confirm that the incorporation of a Digital Twin system had a positive, clearly observable effect on the management of the evaluated cargo fleet. The data obtained show improvements in three fundamental aspects of the operation: safety, use of load capacity, and travel efficiency. The absence of accidents during the post-test is a clear sign of the value of continuous, real-time monitoring as a tool for anticipating contingencies. Likewise, the improvement in the use of available capacity suggests that the IT solution implemented supported more accurate planning and more efficient use of resources.

A moderate reduction in the number of trips indicates that vehicle units will make fewer trips; as a result, operating costs will be reduced. The finding is consistent with prior studies that highlight the role of Digital Twins in optimizing logistics processes through the timely availability of information.

The results show that the implementation of Digital Twin technology enabled a transition from a traditional, transaction-based environment to a more data-driven setting that better supports operational decision-making. It is also confirmed that deploying an accessible solution developed with open-source tools delivers significant improvements for SMEs.

VIII. Future Work

According to the findings and limitations of the study, several lines of research are identified that could strengthen the use of Digital Twin technology in fleet management:

- Integrating machine learning with Digital Twin technology can reduce empty trips and operational failures by improving prediction and operational planning [14], [18].
- Extension of the architecture towards a complete Digital Supply Chain Twin. The studies by Gerlach et al. [18], Hakimi et al. [19] and Fatorachian et al. [20] underscore the importance of scaling Digital Twins across the entire logistics chain, not just the fleet.
- Advanced simulation of urban scenarios. Using ROS2 or AWSIM platforms would enable us to model traffic behavior and evaluate more efficient routes in real time.
- Integration with TMS and ERP systems. Connecting the DT with corporate systems would make it easier to automate load assignments, validations, reports, and prioritizations [21].

***Abstract*—Severe motor disabilities and paralysis make it hard for individuals to communicate their thoughts and express their imagination using standard interfaces. Recent methods that convert EEG signals into images, using diffusion models, have shown superior results. However, these methods usually depend on high-density EEG systems with 32 to 128 channels, deep neural EEG encoders, and large datasets. This leads to high computational costs, poor real-time performance, and limits their use in assistive settings. To address these problems, this paper proposes a Thought-to-Vision system that is lightweight and real-time. In this work, Thought refers specifically to the imagination of simple geometric shapes (circle, square, and triangle) under controlled experimental conditions. This Thought-to-Vision system can decode the imagined geometric shapes from a low-channel EEG system that only requires 2 channels and then produce visual images based on a diffusion model. The EEG signal was recorded at 250 Hz with 150 trials per session, consisting of 50 trials for each circle, square, and triangle shape. The signal was filtered using artifact rejection, 50 Hz notch filtering, and bandpass filtering between 1 and 40 Hz. A Tri-Domain EEG feature fusion (TDEF) that combines spectral features (FFT band power), Time-Frequency features (Daubechies-4 wavelet coefficients), and statistical features was developed and tested against several benchmarks. These included feedforward networks, CNNs, LSTM/GRU-based time-series encoders, CNN-Transformer models, and EEG-CLIP alignment. Evaluation is measured using classification accuracy, precision, recall, and F1 score, along with embedding consistency for semantic alignment. The experimental results indicate that the TDEF with the XGBoost classifier reaches around 94% for classification accuracy, precision, recall, and F1-score. This performance surpasses deep time-series encoders, which achieved up to 39.09% accuracy, and contrastive EEG-CLIP models, which had 82.97% accuracy. The classified EEG embeddings were then used to guide a latent diffusion model, enabling coherent and semantically consistent image generation. These findings confirm that feature-fusion learning with XGBoost can outperform deep EEG encoders in low-channel situations. This offers a solid, efficient, and practical solution for real-time assistive brain-computer interfaces.**

Keywords*—Brain computer interface; feature fusion learning; diffusion models; EEG to image generation; wavelet; EEG signal processing

I. Introduction

The demodulation of human thought and imagination patterns via neural activity is one of the ever-green areas in brain-computer interface research [1]. Electroencephalography (EEG), due to its non-invasive nature and high temporal resolution, has been investigated for its use in cognitive processing translation into machine-readable signals for several applications [2]. While fMRI is characterized by its ability to produce highly accurate images, it is associated with poor temporal resolution and excessive costs. On the other hand, EEG, though having poor spatial resolution, has excellent temporal resolution as well as portability. However, because of its poor spatial resolution, it can only be used for the interpretation of crude representations of visual images, not their minute details. The translation of imagination-related EEG patterns into a meaningful pictorial interpretation has a wide scope in assistive communication systems, neurofeedback, and human-machine interaction contexts. Recent works have focused on the usage of deep neural networks and diffusion-based generative models for the reconstruction of images from brain signals using EEG-to-image synthesis. The potential of aligning the embedding spaces of the brain signals with the visual embedding space has been shown using frameworks such as Brain-Dreamer [3], Dream-Diffusion [4], and EEG-Vision [5]. These frameworks require high-density EEG recording (32 to 128 channels), a massive dataset, and computationally expensive brain decoders, thus making it very difficult to implement them in a realistic scenario. Yet, there is an essential gap in research work: the existence of light-weight EEG-to-image models able to realize real-time processes on a low-channel EEG signal with a high degree of accuracy. In fact, when it comes to actual applications involving a person with motor disorders, it can be more essential to ensure simplicity and portability rather than the generative capability. The over-reliance on a deep encoder when it comes to EEG often results in a poor generalization ability. With the shortcomings in mind, the proposed research seeks to develop a low-channel, real-time Thought-to-Vision generation framework where simplicity of usability is put foremost. Contrary to the requirement of using deep EEG encoders in the existing work, the proposed approach focuses on the concept of feature fusion-based learning, which exploits multiple complementary descriptors of the EEG signal to increase discriminatory efficiency without the associated heavy computations. The key contributions of the current study are the design of a light-weight, two-channel EEG-based Thought-to-Vision system for real-time applications, and the development of a tri-fusion EEG feature representation scheme that combines spectral, time-frequency, and statistical features to efficiently capture complementary information from the brain signals. A feature-fusion–based XGBoost classifier is employed, which consistently outperforms state-of-the-art deep EEG encoders in low-channel settings. Furthermore, the system achieves efficient EEG decoding coupled with diffusion-based

image generation, allowing the visualization of imagined content in a coherent and semantically meaningful manner. Finally, a comprehensive comparative evaluation of classical, feature-based, and deep learning EEG encoders is presented, clearly demonstrating the advantages of feature-based learning approaches for robust, lightweight, and assistive brain–computer interface applications.

This work makes four key contributions: (1) a real-time, low-channel (2-channel) EEG-based Thought-to-Vision framework suitable for assistive deployment, (2) a tri-fusion EEG feature representation combining spectral, time–frequency, and statistical descriptors, (3) a comprehensive empirical comparison of feature-based and deep time-series EEG encoders under low-channel constraints, and (4) a diffusion-conditioned image generation pipeline driven by lightweight EEG decoding.

The rest of the document is structured as follows: Literature review is presented in Section II followed by Methodology in Section III. Experimental results in Section IV, and Conclusion and Future Scope in Section V.

II. Literature Review

The literature review is categorized into five major groups: (1) EEG Signal Processing and Fundamental Concepts, (2) EEG to Image Generation using Deep Learning and Diffusion Models, (3) Multimodal Learning, Retrieval, and Representation Learning, (4) Applications of EEG in Creative, Medical, and Assistive Systems, (5) Surveys, General BCI Systems, and Recent Trends.

A. EEG Signal Processing and Fundamental Concepts

Early research by Kumar and Bhavaneswari [2] laid the foundation for EEG signal analysis by categorizing EEG activity into Delta, Theta, Alpha, Beta, and Gamma frequency bands using Fourier and wavelet-based spectral techniques. Their work demonstrated that band-power features, particularly Alpha and Beta rhythms, are reliable indicators of cognitive and mental states, forming the basis for later EEG preprocessing and feature extraction pipelines. In addition to model development, Hatton et al. [6] investigated various EEG acquisition systems and proved that multi-channel systems can greatly enhance spatial and spectral representation of EEG signals, providing valuable guidance for EEG system implementation.

B. EEG-to-Image Generation Using Deep Learning and Diffusion Models

With the rise of deep learning, EEG-based visual decoding advanced significantly. Wang et al. [3] proposed BrainDreamer, a language guided EEG to image generation framework that aligns EEG, text, and image embeddings in CLIP latent space using contrastive learning and diffusion-based image synthesis. This method facilitated semantically coherent and controllable image reconstruction from EEG signals.Bai et al. [4] proposed Dream Diffusion, which eliminated the need for text-based guidance and proved that diffusion models are superior to GAN based methods for EEG to image reconstruction, achieving more realistic visual reconstructions. Huangtao et al. [5] introduced EEG-Vision, which shows integration of time-frequency EEG features with diffusion models to achieve high quality visual reconstructions. To enhance semantic coherence, Yang and Liu [7] proposed a method integrating CNN based EEG classification with diffusion models, enhances both decoding performance and visual coherence. Chen et al. [8] investigated diffusion-based EEG image reconstruction and proved that structured EEG encoding can enhance reconstruction performance. Similarly, Li et al. [9] proposed a guided diffusion model that utilized EEG embeddings to improve reconstruction performance. Lopez et al. [10] proposed a latent diffusion-based EEG to image generation framework using simulated EEG data, demonstrating the potential for training generative models at scale.

C. Multimodal Learning, Retrieval, and Representation Learning

Retrieval based methods further extended the field of EEG vision research. Sithisint et al. [11] proposed EEG2Face Query, a method for retrieving facial images from EEG signals via CNN and Vision Transformer based latent representation learning. Zhang et al. [12] proposed Cognition Capturer, which associated EEG with multimodal embeddings (image and text) to improve visual decoding performance. Ferrante et al. [13] demonstrated that knowledge distillation enables compact EEG encoders to retain performance when paired with latent diffusion models. Puah et al. [14] proposed a model based on a diffusion model framework, "EEG-DGM" or "EEG Diffusion Model" suggests a novel approach to learning representations of EEG signals using a denoising and diffusion probabilistic model which would be beneficial to the field of EEG classification. Large scale benchmarking was enabled by Zhu et al. [15], who introduced EEG ImageNet, a dataset with multigranularity labels for standardized evaluation. Pan et al. [16] proposed a deep visual representation model for reconstructing stimulus images from EEG signals. Spampinato et al. [17] proposed a deep learning-based model using recurrent neural networks for discriminative embedding learning using EEGs. It is notable in the sense that their work emphasizes the importance of temporal information rather than spatial data since, even though fMRI can capture higher spatial data while being expensive, it lacks the temporal aspect. While the alternative MEG has the advantage of improved spatial resolution, it is non-portable and difficult to operate compared to other modalities such as EEG. This proves that the need for good representation learning through effective embeddings is a necessity for visual decoding from EEG signals. Finally, Zhang et al. [18] extended Cognition Capturer in a journal version, reinforcing the importance of multimodal alignment for high-quality EEG-based visual decoding.

D. Applications of EEG in Creative, Medical, and Assistive Systems

Earlier creative BCI applications like Brain Painting by Münßinger et al. [19] demonstrated the viability of using EEG for creative tasks, particularly for ALS patients. In addition to 2D reconstruction, Guo et al. [20] introduced Neuro3D, demonstrating that it is possible to reconstruct 3D objects from EEG signals using diffusion-based point cloud generation. The application of EEG technology also made its way into creative applications. Liu and Wang [21] proposed Mental Gen, an EEG controlled generative model, for interior space design, which showed the possibility of using brain signals for personalized creative tasks. Soroush et al. [22] systematically reviewed the

EEG characteristic and through experimental design highlighted the EEG driven creativity research. Medical EEG applications were discussed by Foreman et al. [23], employing the quantitative EEG characteristics for the detection of brain ischemia. Pujac et al. [24], shown the artistic applications by visualizing real time EEG data through generative AI art.

E. Surveys, General BCI Systems, and Recent Trends

More general views on EEG based BCIs were presented by Lazarou et al. [1], reviewing the EEG based communication and rehabilitation systems, with a focus on robustness and clinical applicability. A survey conducted by Shukla et al. [25] investigated the combination of EEG and generative AI, noting the importance of diffusion models and multimodal learning. EEG based creativity research was further reviewed by Zeng and Soroush [26], while Liu et al. [27] surveyed recent BCI applications. Cognitive inspired reasoning models like Sketch of Thought were presented by Aytes et al. [28], who proposed light weight representations for efficient reasoning. Advanced cognitive efficiency was revisited by Aytes et al. [29], extending Sketch-of-Thought for adaptive reasoning. In addition, Majima and Nishimoto [30] investigated reconstructing visual imagery from brain activity by applying Bayesian estimation through deep neural networks. This research shows the ability to reconstruct visual imagery from neural activity, thereby reinforcing the possibility of mapping neural activities to visual imagery.

III. METHODOLOGY

The methodology of the proposed work is shown in Fig. 1. It contains the following steps:

A. Dataset Collection

A raw, synchronized dataset of 2-channel EEG signals recorded while a human participant views a series of images shown in Fig.2. The main aim was to record the brain's electrical signals associated with the visual perception of geometric shapes. EEG signals were recorded using a low-cost two-channel recording system. Data was collected using a controlled visual stimulation paradigm to record consistent neural responses associated with basic geometric shape perception. During the recording process, three shapes were presented before the subject i.e., circle, square, and triangle, with 50 different stimuli for each shape, making a total of 150 trials per recording session. Each stimulus was displayed for 500ms, followed by a 500ms inter-stimulus interval using a blank screen to avoid overlap of successive cognitive responses. To avoid fatigue and cognitive drift, trials were arranged in shape blocks with short rest intervals between shape blocks. EEG signals were recorded at a sampling rate of 250 Hz and synchronized with the stimulus display using event marker logs, allowing for precise segmentation of neural responses associated with each visual stimulus.

B. Data Processing

To increase the quality of the signal and guarantee the extraction of the unique features of the neural activity, a preprocessing step was carried out on the raw EEG data. The EEG signals were recorded at a frequency of 250 Hz, and trial-specific segments were extracted around the synchronized event markers. The preprocessing pipeline included three steps in a sequence: Artifact rejection, removal of power line noise, and band pass filtering. Each of these steps was designed to remove non neural interference while retaining the cognitive related brain signals.

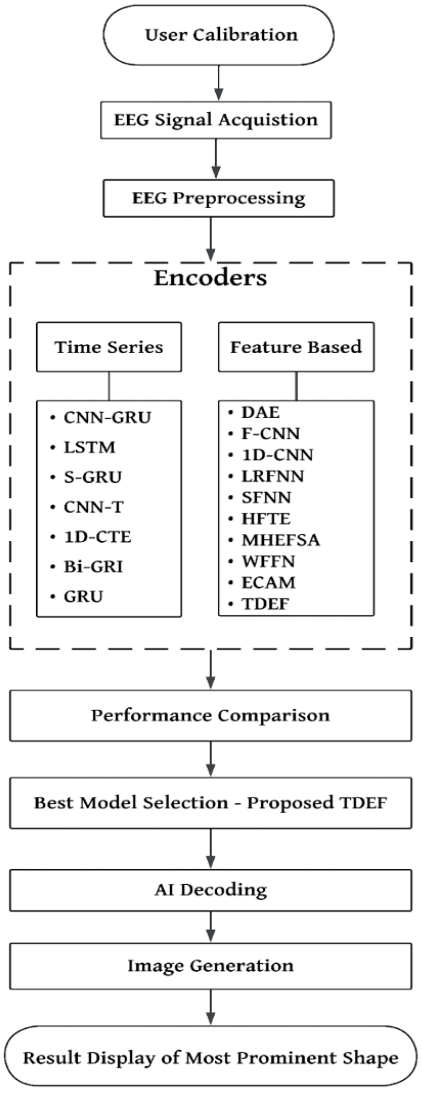

Fig. 1. Flowchart of the project.

Fig. 2. Dataset collection process.

First, we discarded the epochs that were artifact rich by using an amplitude-based rejection, which was focused on non-cortical physiological artifacts such as eye blinks and muscle activity. Any trial that had instantaneous EEG amplitudes outsides the ±100 μV range was rejected, as is standard practice in ERP analysis. In formal terms, any trial i, with EEG signal is rejected for the condition given in (1).

$$\exists t : |x_i(t)| > \theta_{artifact} \quad (1)$$

The value of $\theta_{artifact} = 100.0\mu V$.

This criterion is extremely helpful in suppressing the large artifact perks without affecting the trials that show the existence of neural activity.

Secondly, to eliminate the power line noise we used a notch filter at 50 Hz. It is an IIR notch filter with Q=30. It is used as a zero- phase forward and backward filter to eliminate any phase shift. This ensures that the temporal fidelity of the neural oscillations is maintained and the power line interference is removed with absolute accuracy.

Finally, the EEG signals are band pass filtered between 1 to 40 Hz using a fifth order Butterworth filter to zero in on the frequency of interest for cognitive processing. The squared magnitude response of the filter is given (2).

$$|H(j\omega)|^2 = \frac{1}{1+(\omega/\omega_c)^{2N}} \quad (2)$$

In this setup, N=5 signifies the order of the filter, while ω = 2πf and the cutoff ωc is varied to 1 Hz and 40 Hz. This filtering step eliminates the slow drift of the baseline and noise but eliminates the EEG cycles: Delta (1-4 Hz), Theta (4-8 Hz), Alpha (8-13 Hz), Beta (13-30 Hz), and low Gamma (30-40 Hz) cycles.

C. Feature Engineering

Conversion of feature space in EEGs to feature space in vision assumes that the neural activity carries enough information about the object seen or imagined. This hypothesis has been demonstrated by previous research studies such as the one performed by Spampinato et al. [29], in which machine learning techniques were utilized to learn discriminative feature embeddings from EEGs. They concluded that neural activity could be mapped to a structured feature space for visual tasks, thereby supporting the feasibility of EEG to latent space mapping in visual decoding frameworks.

The raw EEG signal was then converted into a clean, interpretable form that can be used for classification as well as image reconstruction. For each trial, we extract the salient features and convert them into unique spectral time frequency, and statistical patterns of the signals. We start by converting the signal from time to frequency using a fast Fourier transform, extracting power in the Delta, Theta, Alpha, Beta and Gamma frequencies. At the same time, we apply a Discrete Wavelet Transform with a Daubechies-4 wavelet to decompose the signal into multi-resolution sub-bands (A4, D4-D1), which helps to reveal the non-stationary and transient brain activity. However, since the raw wavelet coefficients are high dimensional and redundant, we reduce them by computing statistics: mean, standard deviation, and median of absolute values for each set of coefficients. This transforms time frequency data into compact, meaningful feature vectors. We then stack the spectral features with the wavelet statistics for both EEG channels into a unified feature vector. Finally, each trial is represented by a fixed 40-dimensional feature vector that retains the salient signal information while removing noise, variability, and computational complexity. While the suggested representation method represents every trial as a fixed- length vector, the fact that there are temporal relationships among EEG signals is acknowledged. In order to incorporate temporal aspects, sequence-based models such as LSTM, GRU, CNN-GRU, and transformer architectures are investigated within the framework of the experiment. The models are able to learn about the temporal characteristics of raw EEG signals and enable time-dependent analysis. Nonetheless, the results obtained from the experiments show that in low-channel configurations, temporal encoding alone cannot solve the problem since the signals are too similar. This strategy directly injects domain knowledge into the learning process, alleviating the need for data intensive deep encoders and improving channel limited and small sample robustness.

D. Encoder Based Algorithms

In order to compare the representation methods of EEG data using the constraint of a few channels, we focused on two broad categories of encoders: 1) feature-based encoders and 2) time-series-based encoders. This categorization allows us to compare domain knowledge-based learning with deep learning for representation.

1) Time series based encoders: Seven different time series encoders were experimented first. The details of the experimentation are discussed in the below section.

a) CNN-GRU hybrid encoder (CNN-GRU): A hybrid approach was also explored that combined one-dimensional convolutional neural networks (1D CNNs) with a Gated Recurrent Unit (GRU) to determine the effectiveness of temporal modeling as a subsequent step following the convolutional extraction of features. The model was trained directly on standardized raw two-channel EEG time-series data, using convolutional layers first to extract local temporal features, followed by a recurrent layer. The model consisted of two 1D convolutional layers, the first of which had 64 filters with a kernel size of 10, and the second of which had 128 filters with a kernel size of 10. After each convolutional layer, batch normalization and max pooling were used to reduce the temporal resolution and remove noise. The output feature vectors were then fed into a GRU layer with 128 hidden units. After this, the feature vector was projected into a 512-dimensional embedding space using fully connected layers, with L2 normalization. Training used triplet margin loss with $\alpha = 0.4$, and the Adam optimizer with a learning rate of 1×10^{-4}, batch size of 32, and early stopping with a maximum of 200 epochs. The model had a relatively low-test accuracy of 31.98%, and a confusion matrix that showed a strong collapse to a single predicted class with little distinction between the remaining classes. This indicated that the convolutional preprocessing alone was insufficient to model the low temporal

separability inherent in low-channel EEG signals when trained without feature-level or cross-modal supervision.

b) Long Short-Term Memory (LSTM): A pure Long Short-Term Memory (LSTM) encoder was tested to assess whether raw electroencephalography (EEG) time-series data could be modeled directly to derive a discriminative pattern of neural activity with a small number of channels. The LSTM encoder was trained on normalized raw EEG time-series data from two-channel recordings, where each trial was a fixed-length temporal sequence. Before training, time-series data were standardized per channel to improve the robustness of the optimization procedure. The encoder model consists of a batch normalization layer followed by a single LSTM layer with 128 hidden units, and the final hidden state is projected into a 512-dimensional L2-normalized embedding space through fully connected layers. Training was performed using triplet margin loss ($\alpha = 0.4$) and the Adam optimizer (learning rate = 1×10^{-4}) with a batch size of 32, including early stopping and learning rate scheduling, for a maximum of 200 epochs. Although the model was trained, it only reached a moderate accuracy of 33.50%, with a single imagined shape largely confused, as revealed by the confusion matrix. These results indicate that direct modeling of time series without considering spatial, spectral, or feature-level information is inadequate for accurate EEG decoding with a small number of channels.

c) Stacked GRU Network (S-GRU): The effectiveness of a stacked Gated Recurrent Unit (GRU) encoder was tested to evaluate the impact of hierarchical modeling of temporal patterns in improving discriminative learning of raw electroencephalography (EEG) time series data, especially when there is a constraint on the availability of channels. The stacked GRU encoder was trained on normalized two-channel EEG data, where each trial was represented as a fixed-size temporal array. Before training, the signals were normalized channel wise to facilitate stable optimization. The stacked encoder consists of two GRU layers with 128 hidden units each, where the first layer produces full temporal arrays, and the second layer produces only the final hidden state. This hierarchical representation is followed by fully connected layers and a projection into a 512-dimensional, L2 normalized embedding space. Training was performed using triplet margin loss ($\alpha = 0.4$) with the Adam optimizer at a learning rate of 1×10^{-4}, a batch size of 32, and early stopping with learning rate scheduling over a maximum of 200 epochs. The stacked GRU network reported an accuracy of 33.76%, and the confusion matrix revealed a strong class collapse to a single predicted class. These results suggest that simply adding depth to recurrent models is not sufficient to overcome the difficulties associated with temporal-only EEG decoding, especially when there is a constraint on channel access.

d) CNN–Transformer Encoder (CNN-T): A hybrid encoder combining both convolutional and transformer modules was tested to assess the role of self-attention mechanisms in the learning of temporal patterns in low-channel EEG signals when combined with convolutional feature extraction. The model was trained directly on standardized raw two-channel EEG time-series data, where convolutional layers were used to extract local temporal features, which were then followed by global modeling with attention mechanisms. In particular, two one-dimensional convolutional layers with 64 and 128 filters, respectively, with a kernel size of 10, were used, with max pooling to reduce the temporal dimensionality. The output feature maps were then fed into a transformer encoder layer with multi-head self-attention (four heads, each with an attention head dimension of 128), with residual connections, layer normalization, and a feed-forward network. Global average pooling was used to aggregate temporal information, followed by a fully connected projection layer that embedded the data into a 512-dimensional L2-normalized space. Training was done using triplet margin loss with $\alpha = 0.4$, optimized using the Adam optimizer with a learning rate of 1×10^{-4}, a batch size of 32, and early stopping with learning-rate scheduling over a maximum of 200 epochs. Despite the use of self-attention, the model resulted in an accuracy of 33.76%, and the confusion matrix showed a complete collapse to a single predicted class. These results suggest that when self-attention mechanisms in the transformer model are used on low-channel EEG time-series without feature engineering or cross-modal learning, it has a tendency to magnify dominant but non-discriminative temporal patterns rather than improve class discrimination.

e) 1D Convolutional Time-Series Encoder(1D-CTE): The effectiveness of one-dimensional convolutional time-series encoder (1D-CTE), a one-dimensional convolutional neural network (1D-CNN) model, was evaluated to assess the effectiveness of hierarchical temporal feature representation by itself for discriminative EEG decoding in channel-constrained settings. The model was trained on normalized raw two-channel EEG time-series data, where each trial was represented as a fixed-size temporal vector. Normalization was performed across channels before training to improve the robustness of optimization. The encoder neural network architecture is designed with three layers of 1D convolution with increasingly larger filter sizes of 64, 128, and 256, with a kernel size of 10, followed by max-pooling layers to enable hierarchical temporal feature representation at multiple scales. A global average pooling layer is used to obtain the temporal representation, and then a fully connected layer is used to map the features into a 512-dimensional embedding space, which is further L2-normalized. The model trains with a triplet margin loss function with alpha parameter value of 0.4, and it trains with the Adam optimizer with a learning rate of 1-4. The training is performed in batches of 32, with early stopping and learning rate scheduling, up to a maximum of 200 epochs. The accuracy achieved by the model was 35.03%, and the results obtained from the analysis of the confusion matrix showed that there was a highly dominant distribution towards a single class label with a large overlap between the class labels. The above results clearly indicate that hierarchical temporal feature representation alone, without any additional spectral or feature-level structure imposed through convolutional processing, is insufficient for accurate EEG decoding in channel-limited scenarios.

f) Bidirectional GRU (Bi-GRU): The bidirectional Gated Recurrent Unit (Bi-GRU) encoder was also employed to

determine whether the combination of both forward and backward information could help in the decoding of the EEG signal in the low-channel scenario. The training was performed on the normalized raw two-channel EEG time series data, where each trial was represented by a fixed temporal pattern. The channel normalization was performed before the training for the stabilization of the optimization process. The encoder configuration includes a batch normalization layer followed by a bidirectional GRU layer with 128 hidden units in each direction, which enables the simultaneous processing of information from both past and future directions. The hidden states are concatenated and then fed into fully connected layers to map the representation into an L2-normalized 512-dimensional embedding space. The training was performed using the triplet margin loss with $\alpha = 0.4$ and Adam optimizer with a learning rate of 1×10^{-4}, batch size of 32, and early stopping with learning rate scheduling for a maximum of 200 epochs. The model achieved an accuracy of 35.28%. The confusion matrix indicated some relief from the class collapse issue compared to the unidirectional models, but it also indicated a clear dominance of one class. These results suggest that the simple combination of bidirectional information is not adequate to handle the difficulties of raw time series modeling in the low-channel EEG signal decoding problem.

g) Gated Recurrent Unit (GRU): A pure Gated Recurrent Unit (GRU) encoder network was employed to prove the effectiveness of gated recurrent modeling in learning and detecting distinct temporal patterns from the raw EEG time series data even in low-channel conditions. The network was trained on the normalized raw EEG time series data directly from two-channel recordings, where each trial contains a fixed temporal pattern. Before training, the time series patterns were normalized channel-wise for improved convergence of the optimization process. The encoder network architecture contains a batch normalization layer followed by a GRU layer with 128 hidden units, where the final hidden state representation is projected using fully connected layers into a 512-dimensional L2-normalized embedding space. The network was trained using triplet margin loss ($\alpha = 0.4$) optimized by Adam with a learning rate of 1×10^{-4}, batch size of 32, and early stopping with learning rate scheduling for a maximum of 200 epochs. Even though the network was thoroughly trained, it only reached a low accuracy of 33.50%, and the confusion matrix revealed a severe class collapse to a single predicted class. This is to be expected in the context of the performance of the pure LSTM encoder network model, which shows that the recurrent modeling of temporal patterns without any spectral or feature-level structure is not sufficient for EEG decoding.

2) Feature based encoders: the Feature-based Encoders Experimented Are Shown on Fig 3.

a) Denoising Auto Encoder (DAE): The DAE was also evaluated as an unsupervised feature-based encoder to prove the efficacy of noise-resilient features in improving the accuracy of EEG decoding in low-channel scenarios. The network is provided with standardized pre-computed feature vectors of EEG signals using spectral, wavelet domain time-frequency, and statistical feature descriptors. During the training phase, the input features are also corrupted with controlled Gaussian noise ($\sigma = 0.2$), and the network is trained to decode the original clean features with a mean squared error loss function. The encoder network architecture consists of a set of fully connected layers with batch normalization to map the input features to a 32-dimensional bottleneck feature space, followed by an analysis step with a k-nearest neighbors (k-NN) classifier. The results show that the model achieves an overall accuracy of 30.77%, which obviously indicates that the learned features retain some geometric information about the feature space, leading to the easy separation of some imagined shapes, while the remaining shapes are randomly mixed up. This obviously indicates that although denoising is effective in improving the robustness of the learned features, the absence of class supervision makes it difficult to achieve sufficient discriminative feature separation as in the fusion and contrastive learning approaches.

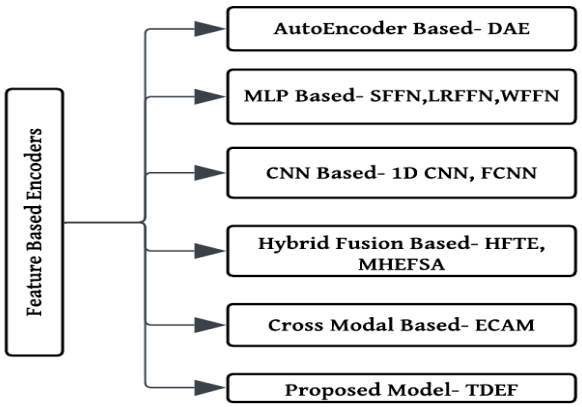

Fig. 3. Feature-based encoders.

b) Feature Convolutional Neural Network (FCNN): A one-dimensional Convolutional Neural Network (1D-CNN) was tested to evaluate the effectiveness of imposing a local convolutional pattern on pre-computed EEG feature vectors. The network takes standardized EEG features from two channels, which include spectral band power, wavelet time-frequency analysis, and statistical features, flattened into a fixed-size input. To facilitate convolution, the feature vector was transformed into a short pseudo-sequence and explored using multiple 1D convolutional layers with batch normalization and dropout. The network embeds the learned features into a 512-dimensional L2-normalized space and was trained using triplet margin loss ($\alpha = 0.4$) with the Adam optimizer (1×10^{-4}). Although the network optimized well, it only achieved a low accuracy of 32.14% and learned to predict a single shape for most inputs. This happened because convolution requires the presence of meaningful local structure, which is not present in designed EEG feature vectors, where features do not have spatial or temporal relationships with each other. This caused the convolutional filters to learn meaningless patterns, leading to a large class bias and poor discriminative ability.

c) 1d-CNN: A one-dimensional convolutional neural network with self-attention was used to test the idea that attention-driven feature weighting could improve feature-level representation learning of EEG data in low-channel settings. The network processed standardized pre-computed EEG features for spectral band power, wavelet-based time-frequency, and statistical features, which were flattened into a fixed-size vector. To prepare it for convolution, the feature vector was changed into a pseudo-sequence. This sequence was then convolved using a 1D convolutional layer and max-pooled to extract local features. Finally, a multi-head self-attention layer was applied to the convolutional feature maps to reweight the learned feature responses before projecting them into a 512-dimensional L2-normalized embedding space. The encoder was trained with triplet margin loss ($\alpha = 0.4$) using the Adam optimizer (learning rate = 1×10^{-4}). Even with the addition of attention, the model only achieved 33.79% accuracy. It primarily recognized one imagined shape but struggled to differentiate the other shapes correctly. This happened because the attention mechanism was influenced by positional artifacts created by the imposition of sequential and positional structure on unordered and aggregated EEG features.

d) Leaky ReLU Feedforward Neural Network (LRFFN): The LRFFN was tested to analyze the effect of the activation function on the learning of feature-based EEG representation in low-channel conditions. The network takes standardized EEG feature vectors from two channels. These include spectral power features (Delta to Gamma bands), wavelet-based time-frequency features (Daubechies-4), and statistical descriptors. These features are flattened into a fixed-size input. The network structure is almost the same as that of the baseline FFN, which has two fully connected hidden layers with 128 neurons each, but with Leaky ReLU activation functions ($\alpha = 0.2$) to counter the dying-ReLU problem. To avoid overfitting, the network uses Gaussian noise ($\sigma = 0.1$), L2 regularization ($\lambda = 0.002$), and dropout (0.5). The network map features to a 512-dimensional L2-normalized space and was trained using triplet margin loss ($\alpha = 0.4$) with the Adam optimizer (1×10^{-4}). The model gave an overall accuracy of 51.92%, which often correctly classified the shape as a circle. The class-wise accuracy imbalance indicates that the discriminative learning was not optimal. This finding verifies that a simple modification to the activation function is not enough without more complex feature interactions or more complex architecture.

e) Simple Feedforward Neural Network (SFFN): The Simple Feedforward Neural Network (FFN) was used as a baseline feature-based EEG encoder to assess the effectiveness of engineered EEG features in a low-channel environment. The FFN model is designed to handle standardized feature vectors from two EEG channels. The feature vectors contain spectral band power features from Delta to Gamma bands, wavelet time–frequency descriptors using Daubechies-4 wavelets, and statistical summaries, all of which are flattened into a fixed-size format. The FFN model consists of two fully connected hidden layers with 128 units each, ReLU activation, L2 regularization with $\lambda = 0.002$, Gaussian noise injection with $\sigma = 0.1$, and a dropout rate of 0.5. The model projects EEG features into a 512-dimensional embedding space and then normalizes the embeddings with L2 normalization. It is trained with triplet margin loss with $\alpha = 0.4$ to match the EEG embeddings with the CLIP embeddings of the same visual content. It is trained with Adam optimizer with a learning rate of 1×10^{-4} and early stopping and learning rate scheduling. The model has an accuracy of 56.59%, which is stable but not optimal. This limitation is mainly due to the absence of spatial-temporal inductive biases and restricted nonlinear modeling capacity, highlighting the need for more expressive feature-fusion techniques.

f) Hybrid Feature-Temporal Encoder (HFTE): A hybrid EEG classification model was designed to combine both engineered EEG features with raw EEG time-series signals while operating with low-channel constraints. The model has two streams. One is standardized, precomputed EEG feature vectors consisting of spectral band-power, wavelet-based time-frequency, and statistical descriptors. The other is raw EEG time-series that maintains temporal dynamics. EEG feature inputs are sent to a multilayer Perceptron, while time-series inputs are sent to a temporal encoding branch. The two streams are then combined at the sample level for supervised learning. The training of the model was done using a batch size of 32, stratified split of the train and validation data (80-20 split), and cross entropy optimization, achieving a validation accuracy of 62.09% with balanced precision, recall, and F1-score.The confusion matrix shows that the model had confusion with fewer visually similar classes while identifying all 3 of the different imagined shapes with better diagonal dominance than the feature-only encoders. The results support the idea that combining global statistical descriptors with temporal EEG information aids in improving class separability while the performance is still being limited by the shallow temporal modeling and low channel count.

g) Multi-Scale Hybrid EEG Encoder with Feature Fusion and SE Attention (MHEFSA): A state-of-the-art hybrid EEG model was designed to jointly exploit raw 2-channel EEG time-series signals and engineered feature representations through multi-scale temporal modeling and feature fusion. The architecture consists of parallel temporal convolutional branches operating on raw EEG signals using multiple kernel sizes (3, 7, and 15) to capture both short-term transients and longer rhythmic patterns. Temporal features are complemented by a lightweight channel-mixing convolution, and the resulting representations are adaptively recalibrated using a squeeze and-excitation (SE) attention mechanism to emphasize informative channel–temporal responses. In parallel, standardized pre-computed EEG features are processed through a multilayer perceptron and fused with the attention weighted temporal representation prior to classification. The training process was done using the AdamW optimizer (learning rate = 1×10^{-3}, weight decay = 1×10^{4}), batch size of 32, and early stopping with learning rate scheduling for a maximum of 80 epochs. From the results, the overall accuracy is 63.51%, with balanced precision, recall, and F1-score. The confusion matrix indicates a strong identification of all three shapes with high diagonal dominance

and less class collapse compared to feature encoders, thus confirming the effectiveness of multi-scale temporal modeling and cross-modal feature fusion even in low channel settings.

h) Wider Feedforward Neural Network (WFFN): The WFFN was designed to investigate the impact of the capacity increase on the learning of feature-based EEG representation in the low channel scenario. The model takes standardized EEG feature vectors from two channels, with spectral band power features (Delta-Gamma), wavelet-based time frequency features (Daubechies-4), and statistical features, flattened into a fixed-size input. Compared to the baseline FFN, the architecture uses two broader fully connected hidden layers with 256 neurons each, ReLU activation functions, L2 regularization (($\lambda = 0.002$), Gaussian noise injection ($\sigma = 0.1$), and dropout (0.5) to prevent overfitting. The network maps EEG feature a 512-dimensional L2-normalized embedding space. Training is done using triplet margin loss ($\alpha = 0.4$) to align EEG embeddings with CLIP visual embeddings, optimized using Adam with a learning rate of 1×10^{-4}, early stopping, and learning rate scheduling. The Wider FFN showed an enhanced accuracy of 70.88%, indicating that the capacity increase improves non-linear interactions of features. Nevertheless, the model's performance is still limited by the lack of explicit spatial-temporal indicative biases, which calls for more structured feature fusion and hybrid models.

i) EEG-Clip Alignment Model (ECAM): This model was implemented to align EEG features with CLIP embeddings, learning a shared representational space between neural and visual modalities. Therefore, the concept of contrastive learning utilizing triplet loss is utilized wherein the EEG features act as anchors, their corresponding CLIP embeddings serve as positive samples, and embeddings of the classes function as negatives. Therefore, the network minimizes the distance among semantically related EEG - CLIP pairs and maximizes the distance between unrelated pairs. The result is an effective EEG encoder that projects neural signals into the same embedding space as the pre-trained CLIP model, enabling interpretable cross-model associations between brain activity and visual representations. It employs two-layer Feed Forward Network (FFN) with ReLU activation to map engineered EEG features into 512-dimensional embedding space. This is trained using triplet margin loss to enforce the similarity between related EEG-CLIP pairs while separating the unrelated ones by a defined margin as shown in Fig. 4. Model parameters are optimized using the Adam optimizer with a learning rate of 1 x 10^-3. L2 normalization is applied to the embeddings to ensure unit length and stabilize similarity computations. This pretrained CLIP model is used to obtain semantic visual representations for alignment. t-SNE visualization is employed for projecting the high-dimensional EEG embedding to a 2D space for visual inspection of alignment patterns.

j) Proposed TDEF: The proposed TriFusion v3 framework extends conventional feature-fusion approaches by integrating three complementary decision perspectives into a unified embedding space before classification. Rather than relying on a single encoder or classifier, the model combines (i) a neural feature encoder operating on engineered EEG features, (ii) a gradient-boosted decision tree model capturing rule-based separability, and (iii) semantic guidance derived from pre-trained visual embeddings (CLIP Embeddings) shown in Fig. 5. This architecture allows for strong discrimination under low-channel and limited-data conditions, remedying the failure modes seen in deep time-series and feature-based neural encoders. Given a 40-dimensional EEG feature vector derived from spectral, wavelet, and statistical representations, the first network utilizes a small multilayer perceptron (MLP) to learn interactions between the EEG features. This network detects smooth, global patterns between EEG features while maintaining regularization via batch normalization and dropout to mitigate overfitting. The resulting vector from this network is a learned neural embedding of the EEG feature space. In parallel, an XGBoost classifier is trained on the same EEG feature vectors to model non-linear decision boundaries using gradient-boosted trees. Unlike neural encoders, XGBoost uses hierarchical thresholding on individual features and feature pairs.

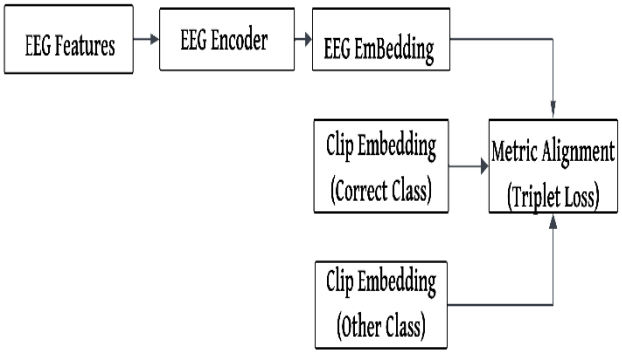

Fig. 4. Architecture EEG-clip alignment model.

Neural encoders, including LSTM, GRU and Transformer-related networks, have been considered in this study as well, but failed to perform adequately in low-channel regimes due to inadequate spatial context and high intra-class overlap of the input signal, often leading to class collapse and poorly defined decision borders. They are typically expected to achieve better results on large-scale, highly structured data sets with increased channel counts, which is currently not an option within the scope of this research problem. On the other hand, XGBoost operates on structured feature representations and has capabilities to handle complex non-linear feature relationships, which is particularly useful in small sample, low channel EEG tasks.

This observation is further supported by the experimental results presented in Section IV, where all evaluated time-series neural encoders exhibit significantly lower classification performance compared to the proposed approach. Moreover, while probabilistic approaches can estimate uncertainties, they are often associated with increased computational costs and more strict requirements concerning data distribution, which is not relevant for the real-time operating regime of the proposed method. Incorporating uncertainty-aware or Bayesian extensions remains an important direction for future work.

To transfer this decision structure into the fusion network, the terminal leaf indices traversed by each EEG sample across

the ensemble of trees are extracted. These leaf indices encode the rule-based decision path followed by the sample and are subsequently transformed into dense embeddings via learnable lookup tables. This learned representation maintains the discrete decision logic of XGBoost and allows for end-to-end optimization under a neural paradigm. A third representation stream adds semantic regularization via visual embeddings of each imagined shape class learned from CLIP. These embeddings offer high-level conceptual points, which guarantee that the learned EEG representations remain aligned with visually meaningful concepts. During training, the joint EEG embedding is encouraged to be close to its corresponding CLIP prototype via a knowledge distillation loss, and contrastive triplet loss is also added to further separate the classes. The three representations, namely the neural EEG embedding, decision-tree embedding, and semantic CLIP embedding, are combined and fused via a multi-head self-attention mechanism. This attention-based fusion mechanism enables the model to learn to weigh each representational source dynamically on a per-sample basis, effectively resolving noisy neural representations against robust decision patterns. The combined embedding is then projected into a discriminative space using a cosine-similarity based prototype classifier, which is inspired by ArcFace. Each class has its prototype vector, which is learnable, and classification is performed by computing the scaled cosine similarity between the combined representations and each prototype vector. The embedding of EEG data that is produced through the TDEF approach is used as the conditioning input for the latent diffusion model in order to produce images. Conditioning here means mapping the EEG embedding to the latent space of the diffusion model, which matches the semantics associated with the class identified through decoding. The TriFusion v3 architecture combines neural feature learning, rule-based decision modeling, and semantic alignment within a unified framework. This hybrid design enables improved classification performance in low-channel EEG settings where purely deep learning approaches often struggle due to limited signal information and small training datasets.

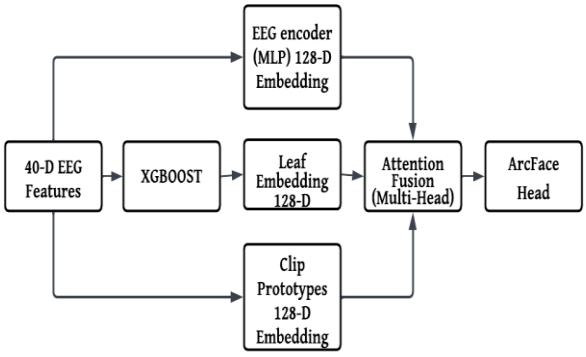

Fig. 5. Tri-Fusion XGBoost model architecture.

IV. Results and Discussions

This section will describe the experimental results obtained by the proposed Thought-to-Vision framework using EEG and compare the results of different encoder models. The performance of EEG feature encoders and time series encoders will be analyzed based on the accuracy of classification, robustness to low-channel conditions, and suitability to image generation tasks. Even though the performance was impressive overall, a few instances of failure were noted. False Positives (FP) represent situations when the classification results were inaccurate because of the overlap of EEG patterns for two classes, namely those that have geometrical similarities. On the other hand, false negatives (FN) are those classifications where the algorithm failed to recognize the correct pattern. The main reason for this might be interference from noise or low neural activity. The analysis of such cases helps understand the difficulties associated with EEG classification in low- channel environments. The experimental results will be analyzed to emphasize important accuracy trends, explain the factors behind accuracy improvement, and validate the proposed feature fusion method.

A. Time Series Encoders Test Statistics

Table I presents the comparative analysis for the different Time series Encoders. The test statistics reveal that all the time-series encoders tested have a consistently poor performance on accuracy, precision, recall, and F1-score. The accuracy percentages are seen to be restricted to a very small range of 31% to 39%, with the highest accuracy of 39.09% being achieved by the GRU model. But even this best-performing model does not offer a trustworthy classification result, as evident from its lower precision and F1-score. Models like LSTM, S-GRU, and CNN-T also follow the same trend, which clearly indicates that despite the increased complexity of the models and the use of attention mechanisms, there is no substantial improvement in the performance of the models in the low-channel EEG modality. Moreover, the difference between precision and recall for some models also reveals the presence of class imbalance and prediction bias, which often causes the model to be dominated by one class. These findings clearly support the fact that the raw time-series modeling approach alone is inadequate for extracting discriminative information from low-channel EEG signals.

TABLE I. Comparison of Time Series-Based Encoders

Model	Accuracy (%)	Precision (%)	Recall (%)	F1 score
CNN-GRU	31.98	19.73	31.62	22.09
LSTM	33.5	11.34	33.5	16.94
S-GRU	33.76	11.39	33.76	17.04
CNN-T	33.76	11.39	33.76	17.04
1D-CTE	35.03	54.69	35.03	20.93
Bi-GRU	35.28	34.94	35.28	26.61
GRU	39.09	26.31	39.09	31.33

B. Feature Encoders Test Statistics

The comparison performance of feature-based encoders is given in Table II.DAE, FCNN and 1D-CNN fail in the performance across all metrics as these models treat the feature vector as flat representation. The performance improvement can be seen in the intermediate performers like LRFNN and SFNN with the Accuracy, Precision and Recall in the range between 50-60%. The models- HFTE and MHEFS show a rise with values greater than 60%. The improvement proves that feature fusion is essential for capturing complementary information across all domains of EEG. Further improvement is seen in

WFNN with Accuracy of 70.88% which is the result of wider network with more neurons in the hidden layer. ECAM outperforms all with highest value of all evaluation parameters, more than 80%. The comparison can be seen from Fig 6. This improvement is seen because the model is not only learning from EEG features but rather it is learning from how EEG relates to the visual meanings using Clip Embeddings. It aligns the EEG features with significant visual embeddings from powerful pre-trained model. From Fig 6, it can be observed that the EEG embeddings exhibit distinct clustering behavior corresponding to their respective shape categories. This clustering is further visualized in Fig 7, where the EEG embeddings aligned with the CLIP space using the ECAM model form well-separated groups. This indicates that the model has learned to project EEG features into a semantic space consistent with visual representations. The distance between clusters suggests that the encoder effectively captures discriminative neural patterns associated with different imagined shapes.

TABLE II. COMPARISON OF FEATURE-BASED ENCODERS

Model	Accuracy (%)	Precision (%)	Recall (%)	F1 score
DAE	30.77	31.4	30.7	30.6
FCNN	32.14	14.97	31.71	17.27

TDEF	94.74	95.19	94.60	94.69

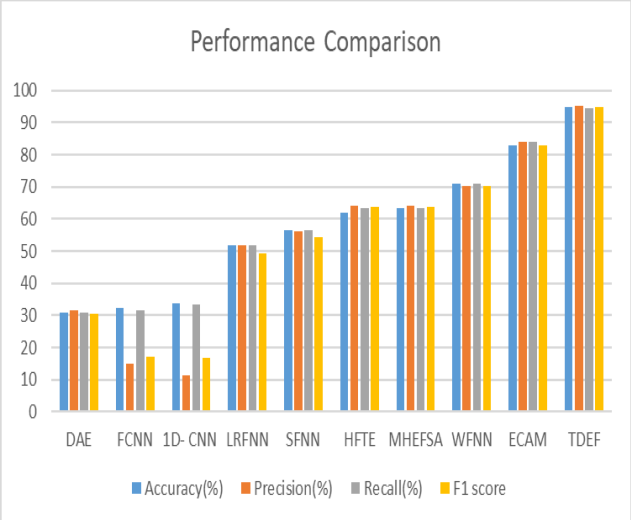

Fig. 6. Performance comparison.

Earlier deep encoders attempted to infer discriminative structure directly from raw time-series or flattened feature vectors, implicitly assuming spatial, temporal, or sequential correlations that are not well defined in a low-channel EEG setting. As a result, these models frequently exhibited class collapse or unstable decision boundaries. In contrast, Tri-Fusion v2 introduces explicit decision structure via gradient boosted trees, semantic grounding via CLIP embeddings, and adaptive fusion via attention, thereby minimizing the inductive bias mismatch. The combined effect is a highly separable embedding space in which imagined geometric shapes form non-overlapping clusters, leading to consistent 99% classification of all three classes, as shown in Fig. 8.

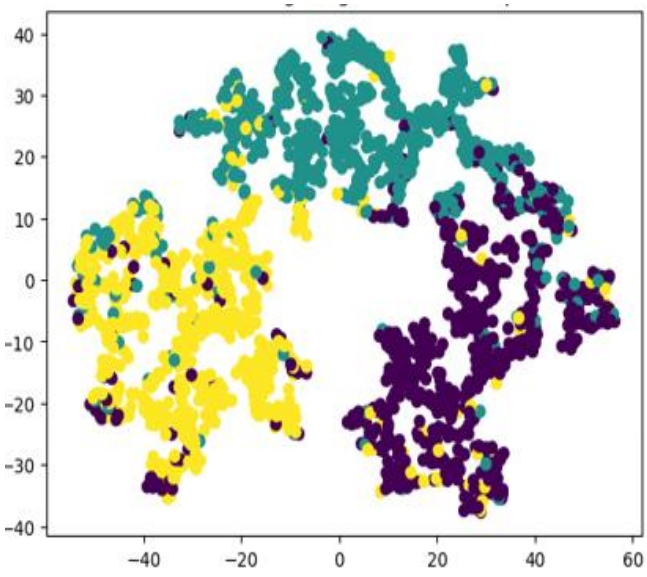

Fig. 7. EEG Embeddings aligned with CLIP space of ECAM.

The latent map of the circle in Fig. 9 illustrates a smooth and centered activation pattern, which corresponds to the smooth and symmetric nature of the circular images. This illustrates that the EEG embedding is successfully capturing the low-frequency semantic information of curved visual perception.

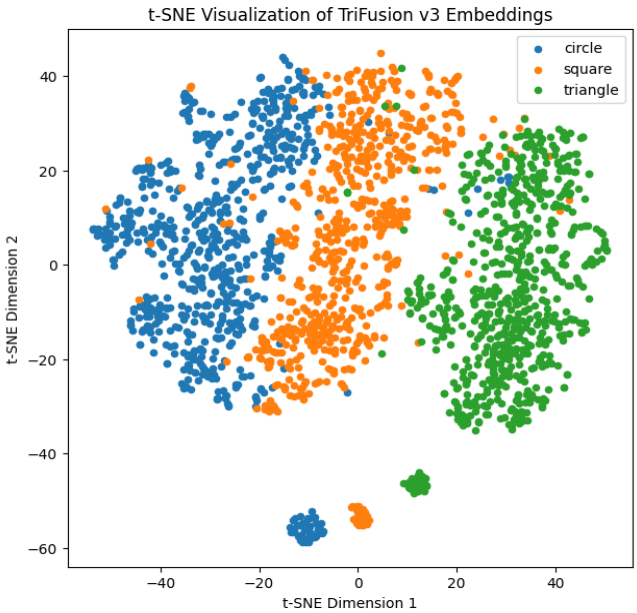

Fig. 8. EEG Embeddings aligned with CLIP space of TDEF.

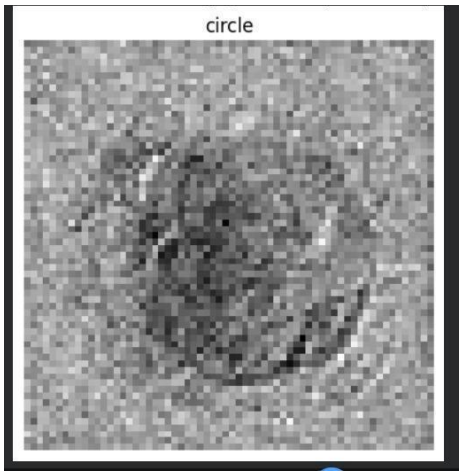

Fig. 9. Latent representation of a circle.

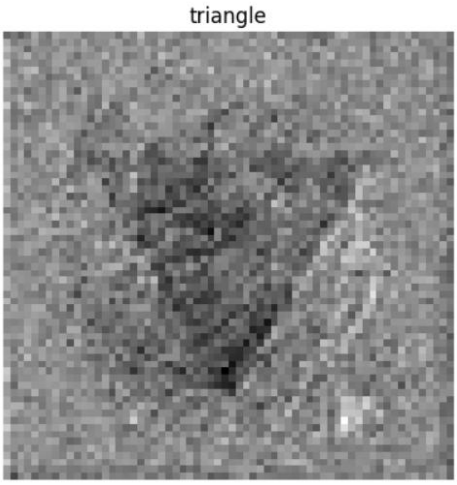

Fig. 10. Latent representation of a triangle.

The latent map of the triangle in Fig. 10 illustrates sharper and more angular activation regions, which correspond to the edge-based neural representation. This illustrates that the model is successfully capturing the corner-like geometric information in the latent space.

The published studies like Brain Dreamer and Dream Diffusion have demonstrated impressive performance in EEG to image translation with the help of diffusion models and multimodal alignment. These approaches require advanced hardware with 30 to 128 channel EEG devices and huge amounts of data in order to learn the spatial information present in the neural data. In the proposed TDEF approach, a two-channel EEG device is employed for translating EEG data into images. This way, the hardware cost has been greatly reduced without sacrificing the accuracy of translation. As opposed to previous approaches, which heavily depend on deep neural network encoders and multimodal learning, in the proposed framework, a feature fusion strategy has been adopted alongside XGBoost to accurately translate low-channel EEG signals.

V. Conclusion and Future Scope

The proposed Thought to Vision framework demonstrates the feasibility of decoding simple imagined geometric shapes from low-channel EEG signals and generating corresponding visual representations using a diffusion-based approach. The system achieves strong performances under controlled experimental conditions, highlighting the effectiveness of feature-fusion learning combined with XGBoost for low-channel EEG decoding. Comparing the performance of various encoder structures, it can be stated that time-series based methods like LSTM, GRU and Transformer achieve relatively lower accuracy (less than 40%) with low-channel EEG due to class collapse because of a lack of spatial information and too much overlapping of the data. On the other hand, feature-based models have proved their efficiency in terms of high accuracy within the interval of 50-80% by using spectral, time-frequency and statistical features to represent the EEGs in a structured format. With the help of the proposed method, i.e., TDEF, it is possible to surpass the weaknesses of time-series and feature-based models. TDEF provides efficient results through feature-fusion learning with the help of XGBoost and helps in modelling non-linear relations between the classes due to semantic alignment. Overall, the results indicate that feature-fusion based approaches offer a promising and computationally efficient direction for EEG-based thought to vision systems, particularly in resource-constrained assistive scenarios. The current study has a limitation of subject count and demographic variability.

Future work will focus on addressing these limitations by incorporating larger and more diverse subjects and integrating probabilistic approaches such as Bayesian inference for uncertainty estimation. Furthermore, extending the framework to more complex visual categories and incorporating objective evaluation metrics for the generated images.

Adoption of Blockchain Technology in Electronic Records Management in the Malaysian Public Sector

Aida Ruzana Ahmad Yani, Umi Asma' Mokhtar
Faculty of Information Science and Technology, Universiti Kebangsaan Malaysia, Selangor, Malaysia

***Abstract*—As the Malaysian public sector undergoes digital transformation, its electronic records management faces challenges, including security issues, maintaining record integrity and record authenticity, audit trails, and trust in existing systems. Blockchain technology has the potential to solve these challenges through features such as distributed records, transparency, restricted immutability, and cryptographic security. However, the adoption of this technology in the Malaysian public sector is still underexplored. The main objective of the study is to identify factors that influence the adoption of blockchain technology in Electronic Records Management in the Malaysian public sector and to develop an adoption model. A quantitative method was used to collect data from 253 public-sector officials directly involved in electronic records management. The conceptual framework was developed by integrating the Technology Acceptance Model (TAM) and the Unified Theory of Acceptance and Use of Technology (UTAUT). Data analysis was conducted using the Partial Least Squares–Structural Equation Modeling (PLS-SEM) approach to test the relationship between variables and confirm the study hypotheses. Results show that users' behavioral intentions have a significant effect on actual usage of blockchain technology (H10 is accepted), with an R^2 of 0.633, indicating that the independent construct explains 63.3% of the variance in behavioral intentions. Individual, organizational, and environmental factors, including performance expectations, effort expectations, social influences, and facilitating conditions, have a significant effect on users' behavioral intentions, emphasizing that technology adoption requires a holistic approach. The study also finds that behavioral intentions act as a critical mediator before actual usage of the technology can occur.**

***Keywords*—Electronic records management; blockchain adoption; public sector; TAM; UTAUT**

I. Introduction

Records management is essential to ensure that an organization runs smoothly, especially in the public sector. Organizations depend on systematic practices, including classification, storage, tracking, indexing, retention, and disposal for effective operations [1]. Non-compliance with these practices may result in record loss, inaccurate information, delays in record retrieval, and reduced efficiency in public service delivery [2]. With the Fourth Industrial Revolution (4IR), records management has transitioned from traditional paper-based systems to electronic records management (ERM). Thus, more adaptable, enabling large-scale storage, access, and processing of data with higher flexibility and scalability. In the public sector, ERM is essential to ensure the preservation, reliability, integrity, and availability of records throughout their lifecycle, while complying with legal requirements, such as the National Archives of Malaysia Act 2003. Failure to comply with this act may result in serious legal consequences [3]. ERM offers many benefits, but the shift to digital requires organizations to reassess their traditional records management principles, approaches, and strategies. Organizations must develop new skills, follow updated digital archiving standards, and use advanced preservation technologies [4]. Initiatives such as the Digital Document Management System (DDMS 2.0) by the National Archives of Malaysia are one example of governmental efforts to digitize public administration.

Blockchain technology is a promising innovation due to its decentralized, transparent, secure, and tamper-resistant properties. The integration of blockchain into ERM could improve data integrity, record tracking, and information security [5]. However, research on blockchain adoption in Malaysia's public sector remains underexplored [6]. Although international research on blockchain is increasing, studies on its adoption in public sector ERM in Malaysia are limited [7]. Previous studies have focused mainly on its technology, despite the significant influence of leadership, organizational support, social influence, and regulatory environment on successful technology adoption [8]. There is also a lack of a comprehensive and empirical adoption model that includes technological, organizational, and individual factors specific to the Malaysian context. Preliminary evidence from the National Archives of Malaysia indicates a lack of understanding among individuals and organizations regarding records management responsibilities. The uncoordinated bottom-up approach conflicts with ERM's requirements for strategic support and a top-down approach from senior management to ensure comprehensive planning, coordination, and implementation [9]. Furthermore, the lack of an ERM system that serves as a comprehensive reference for software, policies, procedures, and practices contributes to the inconsistent implementation of public ERM in the public sector [10].

This study was conducted to address the existing research gap by focusing on the adoption of blockchain technology in the ERM of the Malaysian public sector from individual, organizational, and environmental perspectives. This study integrates the Technology Acceptance Model (TAM) and the Unified Theory of Acceptance and Use of Technology (UTAUT) to develop a more comprehensive, contextually grounded adoption model [11]. The main objective of the study is to identify the factors influencing the adoption of blockchain technology and to develop a practical, empirically grounded model. The scope of the study focused on 24 public sector ministries and two main agencies, namely the National Archives of Malaysia and MAMPU, with a focus on management officers and professionals. This study assessed the adoption of

blockchain technology from individual, organizational, and environmental perspectives to form a holistic, realistic, and appropriate adoption framework for the electronic records management needs of the Malaysian public sector. Although TAM and UTAUT are among the most established frameworks in technology adoption research, their application to blockchain-enabled electronic records management remains limited, particularly in the public-sector context. Most prior studies have focused either on general blockchain adoption or technical implementation issues, rather than on records governance and archival management environments. This study contributes to the literature by extending TAM and UTAUT through the inclusion of organizational and environmental factors, namely policy, security, leadership support, and infrastructure quality, which are highly relevant in government institutions. In addition, the Malaysian public sector provides an important context for emerging economies, where digital governance, accountability, and inter-agency coordination are increasingly significant.

II. Literature Review

Amid globalization and IR 4.0, effective records management is essential for ensuring the efficient dissemination of information by organizations and governments. ERM systems have been widely adopted, with approximately 87% of organizations utilizing them since 2017, especially in the healthcare sector, and this adoption rate continues to rise [12]. The shift from paper-based to electronic records results not only in a format change but also in the entire records management ecosystem, including record creation, classification, storage, access, security, preservation, and disposal [13, 14, 15]. In the public sector, e-government and digitalization efforts encourage the use of ERM to improve efficiency, transparency, and accountability [16, 17]. Successful implementation requires the right infrastructure, well-defined policies, sufficient resources, and an explicit governance framework [18, 19]. Electronic records have evolved alongside technological advances since the 1950s [20]. ERM is defined as a set of principles, policies, and systems for systematically managing digital records throughout their lifecycle, based on the principles of authenticity, reliability, integrity, and availability outlined in ISO 15489 [16].

A. ERM Challenges in the Public Sector

Implementing ERM in Malaysia's public sector poses several challenges, including technological, organizational, legal, and human resource issues [20]. One major challenge is that ministries and agencies develop their own ERM systems, leading to differences in the ERM framework and inconsistent records management. This makes it hard to integrate systems, share information, and coordinate records management nationwide, which affects how efficiently the government operates [21].

The National Archives of Malaysia is the main authority, but agencies still show different levels of compliance with ERM policies, guidelines, and standards. Many view ERM as just a support role rather than a key part of governance. Because of this view and limits on enforcement, ERM often gets low priority when put into practice [16, 22, 23]. The situation is even more complicated when agencies must comply with multiple laws and regulations, such as the National Archives Act 2003, the Public Sector ICT Security Policy, and MS ISO 15489. This is especially true in a digital setting, where they must balance transparency, public access, and confidentiality [24, 25, 26].

The lack of ERM specialist officers, limited specialized training, and frequent officer turnover also affect the effectiveness of ERM in the public sector [27]. In addition, bureaucratic culture and reliance on traditional working methods create resistance to change, including reluctance to use ERM systems and non-compliance with file classification, thereby increasing the risk of loss, duplication, and misuse of records [28]. Digital records are growing quickly in the Malaysian public sector as more applications, emails, and e-Government systems are used [29]. This increase leads to risks such as information overload, higher storage costs, and difficulties in disposing of records [30]. Electronic records can also be manipulated, have poor version control, or face cybersecurity threats such as system intrusions and data leaks [31, 32]. These issues can undermine their evidentiary value, reduce accountability, and weaken public trust. Long-term preservation of electronic records is a challenge due to the changing technologies and file formats [33]. It also takes significant resources to keep these records accessible and usable over time. While ERM can help save time and money, following strict rules to protect sensitive government data can make implementation more difficult.

B. Blockchain

Blockchain technology is a new digital tool that can help improve ERM by enabling transparent, secure, and immutable distributed ledgers [34]. This technology does not replace existing systems but provides a layer of trust to enhance the authenticity, integrity, reliability, and traceability of electronic records throughout their lifecycle [35]. One of the main challenges of ERM is the risk of unauthorized manipulation, modification, and deletion of records [36, 37]. Blockchain solves this issue by recording each transaction as a new, time-stamped entry, thus creating a complete and transparent audit trail [38]. This characteristic of blockchain is especially important in the public sector, where accountability, transparency, and responsibility are essential [39]. Blockchain uses cryptographic hashes, digital signatures, and consensus mechanisms to help keep records authentic and intact by making any changes easy to spot [40]. Key metadata, such as the user's identity, creation date, and record classification, is stored with the hash value to serve as digital proof of authenticity [41]. This method allows records to be verified without relying on just one authority [42].

Because blockchain is distributed, records are more widely available and accessible, and there is less risk of data loss if a single system fails. Using blockchain in records management, especially for recording metadata and transaction evidence, matches ERM requirements that focus on controlling, monitoring, and preserving records for the long term [43]. From a public-sector perspective, blockchain offers a range of benefits, including immutable recordkeeping, decentralization, enhanced security, automated processes via smart contracts, cost savings, interoperability across systems, and support for regulatory compliance [44]. The technology also has the potential to act as a cross-agency integration layer without

requiring full ERM standardization, thereby reducing information silos and increasing national record management coordination [45]. The integration of blockchain technology into ERM has the potential to support compliance with the main principles of records management, improve public sector governance and accountability, and reduce manual work through automation and more objective, systematic technical mechanisms [13, 14].

C. Technology Acceptance Model (TAM)

TAM is the most widely cited and influential model for explaining technology acceptance and use for over two decades [46]. This model was proposed by Davis (1989) and further developed by Venkatesh and Davis (1996) based on the Theory of Reasoned Action (TRA), to understand the factors that influence individuals' decisions to accept or reject a technology [47]. TAM emphasizes two main constructs, namely Perceived Usefulness (PU) and Perceived Ease of Use (PEU), which significantly influence technology usage intentions and behavior [48]. Previous studies have shown that individuals are more likely to accept technology when they believe it improves work performance and is easy to use [49]. In addition, TAM is known as a simple, easy-to-understand model and has high predictive power across various information technology contexts [50, 51]. Although originally focused on individual factors, TAM also considers social and environmental influences, thereby broadening its application across sectors, including education and public services [52, 53]. Many empirical studies have proven that TAM is the most popular, reliable, and effective model in predicting the adoption of new technologies, including e-learning, internet banking, and educational technology [54]. A study by Ismail et al. (2023) also confirmed the validity of TAM in the context of video conferencing technology for online learning. However, it suggests adding motivational and economic factors, such as social influence, to strengthen the explanation of technology adoption. TAM remains a relevant and suitable primary theoretical framework for studying the adoption of new technologies in ERM, including blockchain, due to its ability to systematically and empirically explain technology usage intentions and behaviors [55].

D. Unified Theory of Acceptance and Use of Technology (UTAUT)

UTAUT is one of the most recent and influential information technology acceptance models, introduced by Venkatesh et al. (2003) to integrate and empirically compare elements from various prior technology acceptance models. This model posits that users' behavioral intentions determine actual technology use; thus, UTAUT is widely used to assess the factors that influence technology acceptance intentions, including in the context of emerging technology [56]. UTAUT contains four main constructs, namely performance expectations, effort expectations, social influence, and facilitating factors, which have a direct effect on technology intention and use [57, 58]. In addition, the effect of the relationship between the constructs and technology use is influenced by moderating variables such as age, gender, experience, and willingness to use [57]. This model is widely recognized as one of the most well-known and widely used theories of technology acceptance in recent empirical studies [59]. Several researchers have expanded UTAUT to improve its accuracy. Because of this, researchers often combine TAM and UTAUT to predict technology acceptance better. UTAUT looks at behavioral intentions, while TAM explains how perceived usefulness and ease of use affect acceptance [57]. While UTAUT is a strong model, some have criticized its theoretical and methodological foundations. Criticisms include limited validity across settings, inconsistent explanations of behavioral intentions, and model complexity due to many constructs and moderating variables [57, 59, 60]. Some studies suggest that UTAUT should include factors such as trust, innovation, self-efficacy, perceived risk, and perceived threat to make it more useful in real-world settings [61, 62]. UTAUT is a key framework in technology acceptance research. However, it is often improved by modifying it or combining it with other models, such as TAM, to make predictions more accurate and relevant to the study context [63].

E. Factors and Hypothesis

Performance Expectations (PE) holds that using blockchain technology can make work more efficient and improve ERM in the public sector [64]. In UTAUT, performance expectations are the main factor determining users' behavioral intentions to adopt new technologies, especially in organizational environments involving large-scale, critical information systems [57, 60]. This concept is relevant to the study of public sector ERM, which focuses on efficiency, accuracy, and record reliability. Research shows that users are more likely to accept technology if they believe it will improve work quality, productivity, and task performance [65, 66]. For blockchain, features such as distributed ledgers, immutability, and traceability can make ERM more trustworthy and reliable [44]. Performance expectations are essential for understanding technology acceptance and for meeting the practical needs of public sector ERM [67]. Thus, it is reasonable to expect that performance expectations strongly influence users' intention to adopt blockchain technology [68].

Effort Expectations (EE) refers to the ease of use and the effort required for users to understand and operate a technology. In UTAUT, effort expectations are considered an important factor, especially in the early stages of technology adoption [57]. This concept also aligns with the perceived ease of use construct in the TAM, which asserts that easy-to-use technology increases users' tendency to adopt it [49]. In the context of blockchain technology, the perception of technical complexity is often identified as a major challenge to user acceptance, especially in the public sector, which relies on formal work structures and procedural compliance [69]. Previous studies have shown that even if a technology offers high strategic benefits, its level of acceptance still depends on how easy it is to understand and integrate into existing work routines [70, 71]. Therefore, effort expectations are a significant construct and should be retained in this study to explain blockchain technology adoption from the user perspective comprehensively.

Social Influence (SI) refers to the degree to which individuals perceive that important parties in the work environment, such as colleagues, management, and the organization, expect them to use a new technology [57]. In the public sector, decisions regarding technology use are not usually made individually, but are instead influenced by organizational norms, administrative hierarchies, and institutional work culture [72]. Previous studies have consistently shown that social

influence plays an important role in influencing technology adoption, particularly in bureaucratic and structured organizations such as the public sector [73]. Support and legitimacy from top management, as well as acceptance from colleagues, can increase users' confidence in the technology's suitability. Therefore, social influence is a relevant construct and cannot be ignored in explaining the adoption of blockchain technology in electronic records management in the public archiving sector.

Facilitating Conditions (FC) refers to the level of user belief that the existing technical infrastructure and organizational support can support the adoption of new technologies [57]. This construct is particularly significant in the public sector context because successful technology implementation depends not only on individual readiness but also on organizational readiness, including infrastructure, training, technical support, and human resources [74]. Empirical studies have shown that facilitating conditions directly affect technology adoption behavior, especially for complex technologies such as blockchain [75]. Therefore, including this construct in the study aligns with the realities of public sector organizations and strengthens the study model's ability to explain the actual adoption of blockchain technology [76]. Empirical studies show that facilitating conditions directly affect how people adopt technology, especially complex technologies like blockchain [75]. Including this factor in the study matches the realities of public sector organizations and helps the model better explain how blockchain is used [77].

Attitudes Toward Technology (ATU) refers to whether users perceive a technology positively or negatively. In TAM, attitudes help explain how users' beliefs shape their intentions to use a technology [49]. Although UTAUT does not include attitudes directly, recent studies found that adding attitude factors can make technology acceptance models more effective, especially for new or high-risk technologies [57, 60]. Since blockchain is still seen as a disruptive technology, user attitudes are important for early acceptance and willingness to change [67]. Including attitudes toward technology in this study is logical both in theory and practice, and it supports the use of both TAM and UTAUT. In addition to individual and technological factors, organizational factors also play a critical role in influencing the adoption of blockchain technology. Infrastructure Quality (I), Policy (D), Security (K), and Leadership Support (SK) are widely identified in the literature as critical success factors for technology implementation in the public sector [78, 79]. The absence of adequate infrastructure, clear policies, security assurance, and leadership support can thwart technology implementation, even when individual readiness is high [80]. Therefore, including these organizational factors in the research framework not only strengthens the study's relevance but also ensures that the developed model can realistically and holistically explain the adoption of blockchain technology. Behavioral Intention to Adopt Blockchain (NTIM) is defined as an individual's subjective probability of accepting and using the technology in performing their work tasks [57, 81]. Behavioral intention is considered the closest predictor of actual behavior. In contrast, Usage Behavior (TLP) refers to the actual use of blockchain technology in the electronic records management of the public archiving sector [82]. Therefore, the following hypotheses are developed based on the factors. The conceptual research framework is shown in Fig. 1.

Hypothesis 1:' Performance Expectations ' has a positive impact on behavioral intentions to adopt blockchain.

Hypothesis 2: 'Effort Expectations' has a positive impact on behavioral intentions to adopt blockchain.

Hypothesis 3: 'Social Influence' has a positive impact on behavioral intentions to adopt blockchain.

Hypothesis 4: 'Facilitating Conditions' have a positive impact on behavioral intentions to adopt blockchain.

Hypothesis 5: 'Attitude towards technology' has a positive impact on behavioral intentions to adopt blockchain.

Hypothesis 6: 'Infrastructure quality' has a positive impact on behavioral intentions to adopt blockchain.

Hypothesis 7: 'Policy' has a positive impact on behavioral intentions to adopt blockchain.

Hypothesis 8: 'Security' has a positive impact on behavioral intentions to adopt blockchain.

Hypothesis 9: 'Leadership support' has a positive impact on behavioral intentions to adopt blockchain.

Hypothesis 10: Relationship Behavioral intention to adopt blockchain has a positive impact on blockchain usage behavior.

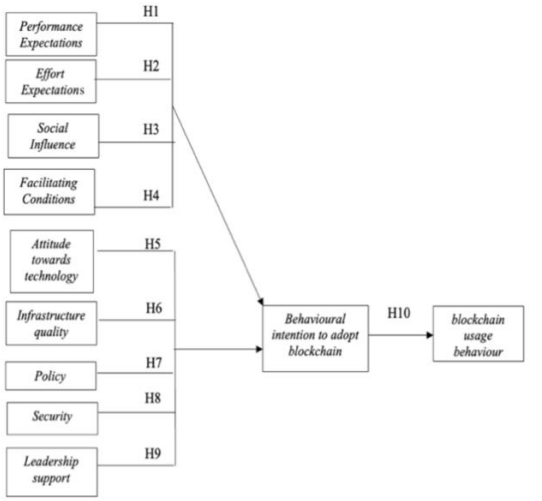

Fig. 1. Conceptual research framework

III. Methodology and Data Collection

This study uses a quantitative method to examine the factors influencing the adoption of blockchain technology in ERM in the Malaysian public sector. This approach was selected because it enables the systematic collection of numerical data, allowing objective analysis and application to a larger group. Data collection was done using a structured questionnaire with a five-point Likert scale, which was developed based on a literature review, records management standards (MS ISO 15489 and MS ISO 16175), and previous studies related to technology adoption.

The minimum sample size was determined using the Krejcie and Morgan (1970) table, with a target population of 2,828 officers and a minimum sample size of 338 respondents. The study respondents consisted of public sector officers from grades 9 to 14 involved in ERM. Of the 400 questionnaires distributed, 253 completed forms were returned, yielding a return rate of 63.2%. Data analysis was conducted using SPSS version 30 for descriptive analysis and Partial Least Squares–Structural Equation Modeling (PLS-SEM) to test the measurement and structural models, including direct and indirect relationships among the study constructs. Pilot studies and expert validation were conducted, and the results showed that all constructs achieved satisfactory levels of validity and reliability, thereby confirming the suitability of the study methodology and instruments for assessing the adoption of blockchain technology in the Malaysian public sector context.

IV. Results

A. ERM Challenges in the Public Sector

Table I presents a demographic analysis of respondents comprising Malaysian public sector officers to provide a descriptive picture of the respondent profile. A total of 400 questionnaires were distributed, and 253 complete responses were received, yielding a return rate of 63.2%, which is considered very good and sufficient for generalizing the study [83]. Most respondents were female (65.6%) and aged 30 to 39 years (69.6%). In terms of organization, most respondents came from ministries (83%), followed by agencies (13%) and departments (4%). Respondents were from various job schemes, with administrative officers (44.3%) and information technology officers (29.2%) forming the largest groups. The distribution of job grades showed that most respondents were in grades 9 and 10 (70%). In terms of length of service, most respondents had served between 6 and 10 years (41.5%) and 11 and 15 years (32.8%), in line with the age distribution of the respondents. Analysis of roles in ERM shows that most respondents are end users (73.9%), followed by information technology managers (17%), while the remainder are system administrators and technical support. Overall, this demographic profile reflects a group of respondents who are well-informed and experienced in public-sector ERM.

B. Measurement Model Analysis

This study uses SEM to simultaneously test the relationships among variables, combining factor analysis and multiple regression. The variance-based PLS-SEM approach is used to evaluate the measurement and structural models, with the main aim of predicting and explaining the variance of the dependent construct. A measurement model is the relationship between constructs and indicators [84]. A construct is an abstract concept that cannot be measured directly but is represented through several indicators or questionnaire items. It refers to a variable developed on theoretical grounds and used to represent psychological, social, perceptual, intentional, or behavioral phenomena that cannot be observed directly but can be measured indirectly through several questions that reflect these perceptions.

1) Indicator reliability: The level of consistency of items in measuring the study construct. The recommended indicator weight is at least 0.60, while indicators with values below 0.40 or above 0.95 should be excluded [84, 85]. Based on Table II, all indicators recorded weight values between 0.40 and 0.95. Therefore, all indicators were retained because they met the reliability requirements.

2) Construct reliability (CR): It assesses the internal consistency of indicators within a construct. In pls-sem, composite reliability is more appropriate than Cronbach's alpha because it takes into account the differences in indicator weight values [84, 86]. The accepted composite reliability value is $\geqslant$ 0.70 and not less than 0.60 [84, 85]. Table II shows that all constructs recorded composite reliability values between 0.896 and 0.974, indicating a high and reliable level of internal consistency.

3) For author-convergent validity: Convergent validity is assessed using AVEs to ensure that the indicators truly measure the specified construct [87]. An AVE value $\geqslant$ 0.50 is considered satisfactory because the construct can explain at least 50% of the indicator variance [84, 88]. In this study, all 11 constructs recorded AVE values between 0.665 and 0.818 in Table II, indicating that all indicators meet the requirements of convergent validity.

4) Discriminant validity: Ensures that each construct is distinct and does not overlap with other constructs. The assessment was carried out using the Fornell-Larcker criteria and the heterotrait-monotrait ratio as recommended by Hair et al. (2017). Based on Table II, the square root of AVE values for each construct was higher than the correlation values with other constructs, fulfilling the Fornell-Larcker criteria in Table III. In addition, Table IV shows that all HTMT values were less than 0.85 [85], confirming that the discriminant validity of the measurement model was satisfactory. The structural model is shown in Fig. 2.

TABLE I. Descriptive Analysis of Demographic Variables

Variable	Item	Frequency	Percentage %
Gender	Male	87	34.4
	Female	166	65.6
Age	20-29	23	9.1

C. Structural Model Analysis

Once the measurement model meets the reliability and validity criteria, the next evaluation is a structured model to assess the strength of the relationships among the constructs and the model's predictive ability. This evaluation involves collinearity analysis, hypothesis testing, coefficient of determination (R^2), effect size (f^2), and predictive relevance (Q^2) using SmartPLS software.

1) Collinearity assessment: Refers to high correlation between independent variables, which can affect the accuracy of the regression coefficients. The variance inflation factor (VIF) is used to check for collinearity. A VIF value of 5 or higher suggests possible collinearity, while a value below 5 indicates no issues [84]. In this analysis, all independent variables had VIF values below the threshold, as shown in Table V, meaning no collinearity problems in the study model.

2) Hypothesis testing (path coefficient): Conducted through bootstrap analysis with 500 random resamples. Table VI summarizes the hypothesis testing and path coefficients. The relationship between constructs was assessed using path coefficients (β), t-values (>1.65), and p-values (<0.05) in a one-tailed test. The results showed that nine hypotheses were supported with significant, positive relationships, while one hypothesis (h6: i → ntim) was rejected because the relationship was not significant and negative. The majority of relationships were consistent with the study hypothesis.

3) Coefficient of determination (r^2): The r^2 value in Table VII indicates the level of variance of the dependent construct that the independent construct can explain. The analysis found that the r^2 values for ntim and tlp were 0.633 and 0.524, respectively, both at a moderate level [84]. This means that the independent construct explained 63.3% of ntim variance, while ntim explained 52.4% of tlp variance, indicating that the model's predictive ability was moderate.

4) Effect size (f^2): The effect size (f^2) was used to assess the contribution of each independent construct to the predictive accuracy of the model. The results in Table VIII showed that most constructs had small effects on ntim, while the ntim → tlp relationship showed a large effect (f^2 =1.099). Construct: I did not show any effect, consistent with the non-significant path coefficient results. The majority of relationships in the model showed small effects, with one main relationship at a large level.

5) Predictive relevance (q^2): Predictive relevance was assessed using the Stone–Geisser (q^2) statistic via the plspredict procedure. Table IX shows the predictive relevance (q2) values. A q^2 value greater than zero indicates that the model has good predictive ability. The results show that the q^2 values for ntim (0.561) and tlp (0.410) are high, indicating that the study model has high predictive relevance.

TABLE V. CONSTRUCT COLLINEARITY ASSESSMENT (VIF)

V. CONCLUSION AND DISCUSSION

A. Hypothesis Testing Results

The results of the analysis showed that eight out of nine predictor factors had a positive and significant relationship with behavioral intention to adopt blockchain technology (NTIM), namely Performance Expectations (H1), Effort Expectations (H2), Social Influence (H3), Facilitating Conditions (H4), Attitudes Towards Technology (H5), Policies (H7), Security (H8), and Leadership Support (H9). On the other hand, Infrastructure Quality (H6) was found to be insignificant.

1) Individual factors: Performance expectations ($\beta = 0.343$, $P < 0.01$) and effort expectations ($\beta = 0.375$, $P < 0.01$) had a

significant positive effect on adoption intention. This shows that perceptions of technology's benefits and ease of use are the main drivers of user intention, in line with the UTAUT theory [57]. In addition, attitude towards technology also significantly influenced intention, although with a smaller effect, indicating the importance of user openness to innovation.

2) Organisational and environmental factors: Social influence ($\beta = 0.154$, $P < 0.05$), facilitating conditions ($\beta = 0.244$, $P < 0.05$), Policy ($\beta = 0.268$, $P < 0.01$), security ($\beta = 0.103$, $P < 0.05$), and leadership support ($\beta = 0.167$, $P < 0.05$) were found to be significant in shaping adoption intentions. This finding underscores that organizational support, policy clarity, confidence in information security, and leadership commitment are important in a structured, rule-based public sector.

3) Infrastructure quality: Hypothesis H6 regarding infrastructure quality was not supported ($\beta = -0.030$, $P > 0.05$). This finding suggests that respondents considered technological infrastructure sufficient and that it is no longer a major determinant of intention formation. Instead, human and organizational factors are more dominant in influencing blockchain technology adoption.

4) Relationship between intention and usage behavior: The results of the analysis showed a very strong and significant relationship between behavioral intention (NTIM) and actual usage behavior (TLP) ($\beta = 0.724$, $P < 0.001$). This finding confirms that intention is a key predictor of actual technology usage, in line with TAM and UTAUT theories [49, 57].

B. Key Findings

The research model showed good explanatory power, with R^2 values of 0.633 for behavioral intention and 0.524 for usage behavior. The predictive analysis also showed a positive Q^2 value, indicating moderate to good predictive power. The effect size analysis showed that the NTIM → TLP relationship had a large effect ($f^2 = 1.099$), while other factors on intention showed small to medium effects. The study also found that people's intentions to adopt blockchain technology depend on individual, organizational, and environmental factors. Performance expectations, effort expectations, social influence, facilitating conditions, attitudes toward technology, policy, security, and leadership support all played important roles, but infrastructure quality did not have a significant impact. The link between intentions and actual use shows that intentions are key before people start using new technology. Even with good organizational and infrastructure support, adoption will not happen unless users have strong intentions. This supports the TAM and UTAUT theories for the Malaysian public sector ERM. The integration of TAM and UTAUT was theoretically motivated by the complementary strengths of both models. TAM examines user perceptions of usefulness and ease of use, while UTAUT captures broader social and facilitating influences. Rather than treating them as competing models, this study adopts an integrative approach suited to complex public-sector environments, where both individual beliefs and institutional conditions influence adoption decisions. The model's relatively strong explanatory power ($R^2 = 0.633$) suggests that the combined framework provides robust predictive capability. Future studies may conduct nested model comparisons to examine the incremental predictive contributions of each framework. In addition to R^2, predictive relevance (Q^2) and effect size (f^2) were assessed to provide a comprehensive PLS-SEM evaluation. The Q^2 values for behavioral intention (0.561) and usage behavior (0.410) were above zero, indicating strong predictive relevance. Effect size analysis showed that behavioral intention had a large effect on usage behavior ($f^2 = 1.099$), while other predictors demonstrated small to moderate effects.

1) Theoretical implications: The findings of this study confirm the relevance of TAM and UTAUT theories in explaining blockchain technology adoption in the public sector. The main construct of UTAUT shows a significant relationship with behavioral intention, and behavioral intention is a strong predictor of actual usage behavior. The moderate to high R^2 value and large F^2 effect size for the intention–usage relationship support the view that technology adoption is a gradual process driven by intention formation. The lack of significance of infrastructure quality suggests the need to adapt the technology adoption model to the local context, where policy, security, and leadership factors are more dominant in the public sector.

2) Practical implications: The findings highlight the importance of clear company rules, strong leadership, and a focus on keeping information secure to encourage the adoption of blockchain technology. Also, providing thorough training, good ways to share information, and designs that focus on users are needed to set clear goals for how well the technology should work and how much effort it will take, and to help people feel good about using it. Evenhough the quality of basic infrastructure is not the main issue, having good technical support and using resources effectively are still very important for making the technology work.

VI. Limitations and Future Work

Although this study followed a systematic approach and relied on a solid theoretical framework, it has some limitations. The research used a cross-sectional survey, collecting data at just one point in time. As a result, the findings show only respondents' views on adopting blockchain technology in ERM during the study period and do not capture how user attitudes or behaviors might change over time. The study only included respondents from the public sector in Malaysia. This means the results mainly apply to public-sector organizations in that country and may not fully reflect the private sector or organizations in other countries with different laws, cultures, or levels of technology. This study also used only quantitative methods through a questionnaire. While this works well for testing relationships in the model, it does not allow for a deeper look at the context, practical challenges, or real-world issues of using blockchain technology that could affect adoption in public sector organizations. Additionally, the study examines certain variables based on technology adoption models such as TAM and UTAUT. While these models are well supported by research, other factors such as legal issues, costs, infrastructure

readiness, and data governance were not directly tested in this study.

Future research should include a longitudinal study to track changes in perceptions, behavioral intentions, and actual use of blockchain technology in ERM. This would help researchers understand how the technology adoption process develops over time. Research could also include private-sector organizations and quasi-governmental agencies, or compare results across countries that may show significant differences in the factors affecting the adoption of blockchain technology in ERM. A mixed methods approach could combine in-depth interviews, case studies, or document analysis. This can add valuable qualitative insights to support quantitative results, especially regarding operational-level challenges. Future research can also include variables such as information technology governance, organizational readiness, trust, technology costs and risks, and compliance with policies and laws, to expand the conceptual model. These variables may enhance the model's predictive ability and the relevance of the findings to policymakers and practitioners. Finally, experimental or pilot studies on blockchain-based electronic records management systems in public-sector organizations would be valuable. These studies could confirm current findings and help develop practical guidelines and policies for using blockchain in public records and archives management.

Reproducible Prediction Framework of Customer Churn Using Machine Learning, Advanced Data Science and Business Intelligence Techniques

Younes KOULOU, Norelislam EL HAMI
Science and Engineering Laboratory-ENSA, Ibn Tofail University, Kenitra, Morocco

***Abstract*—The telecommunications sector has evolved in recent years, resulting in intense competition and high customer acquisition costs. As a result, retaining customers has become a key concern for telecom operators. In this work, we propose the design and implementation of a complete customer churn prediction system that combines data science, machine learning and business intelligence approaches. The methodology is structured into five main steps: exploratory data analysis, development of an ETL pipeline, feature engineering, predictive modeling using a Random Forest algorithm, and the creation of decision-support dashboards in Power BI. Random Forest demonstrated higher performance with AUC-ROC of 0,85 and the results demonstrated that the main predictors of churn are monthly charges, contract type, and customer tenure. Our approach, which validated by a confusion matrix, offers decision-makers an operational tool to anticipate departures and implement targeted loyalty actions. This study proposes a reproducible methodological framework for companies facing the problem of churn and contributes to the use of machine learning in relationship marketing.**

***Keywords*—Churn prediction; telecommunications; machine learning; random forest; business intelligence; ETL; Power BI; feature engineering; decision support**

I. Introduction

In today's digital economy, the telecommunications sector is characterized by intense competition, saturated mature markets, and particularly high customer acquisition costs. Acquiring a new customer can cost up to 25 times more than retaining an existing one [1]. In this context, customer churn poses a direct threat to the profitability and long-term viability of businesses.

For this reason, the phenomenon of churn takes on particular strategic importance in telecommunications where the sudden interruption of contractual revenues significantly affects financial forecasts, loyal customers tend to subscribe to more additional services, and the quality of customer relationship represents a decisive competitive advantage in such a market where differentiation by supply becomes difficult [2].

Churn prediction has been addressed from various methodological perspectives. There are ensemble learning approaches, which currently dominate, utilize algorithms such as Decision Trees, Random Forest, XGBoost, LightGBM, and CatBoost. These algorithms demonstrate superior performance for churn prediction in the telecommunications sector [3] [4]. In this context, [4] explored the effectiveness of ensemble learning techniques by combining several basic learners, such as decision trees and gradient boosting in an ensemble framework in order to improve predictive accuracy to that of individual learners [5]. In parallel, the advent of Deep Learning has opened up new perspectives. While other researchers have focused on the interpretability of models and the identification of critical factors affecting churn [6].

A recent systematic review analyzed 240 studies, published between 2020 and 2024, on churn prediction. The authors identified several persistent challenges: class imbalance, model interpretability, the concept of drift such as the temporal evolution of customer behavior, and the limited use of profit-oriented metrics [4].

Unlike most existing studies, which focus on algorithmic performance, we propose a holistic approach integrating the entire data value chain within a comprehensive methodological framework that includes: a rigorous ETL (Extract, Transform, Load) process containing business rules; a feature engineering phase to create interpretable variables; Optimized modeling with cross-validation and hyperparameter search; an interactive application for Operational deployment; and integration of business intelligence via BI dashboards.

This approach addresses the need to bring predictive models closer to the operational needs of businesses.

The structure of this article is as follows: Section 2 details our methodology. Section 3 presents the results. And Section 4 discusses the results and suggests some perspectives.

II. Related Work

Numerous studies have been conducted to predict customer churn. Despite their interpretability, early approaches lacked the ability to capture complex non-linear relationships through traditional statistical methods like logistic regression. The introduction of machine learning has resulted in a significant improvement in predictive performance.

Churn prediction is now dominated by ensemble methods. According to [3], the authors demonstrated that combining multiple base learners (decision trees, gradient boosting) in an ensemble framework can result in superior predictive accuracy than individual learners. Telecommunications data [3] [4] has demonstrated robust performance for Random Forest, XGBoost, LightGBM, and CatBoost.

New possibilities have been opened up by deep learning architectures simultaneously. The author in [4] conducted a

systematic review examining 240 publications from 2020 to 2024 and found that the use of temporal dependencies-captured LSTM networks is gradually being applied to churn prediction. Data volume requirements and interpretability concerns limit their implementation.

Interpretability of models has become a crucial concern. According to the authors of [6], XAI-Churn TriBoost is a model that is interpretable and integrates XGBoost, CatBoost, and LightGBM into a weighted voting ensemble, and it combines LIME and SHAP techniques to explain individual predictions and uncover critical factors impacting churn.

According to the systematic review by [4], there are many challenges that persist: class imbalance, model interpretability, concept drift (temporal evolution of customer behavior), and the limited use of profit-oriented metrics. The primary focus of existing studies is on algorithmic performance, leaving out the operational integration of predictive models into business processes. Few works address the complete data value chain from extraction to strategic visualization, which constitutes the main contribution of our research.

III. Methodology

The proposed approach is broken down into five main phases, as illustrated in Fig. 1.

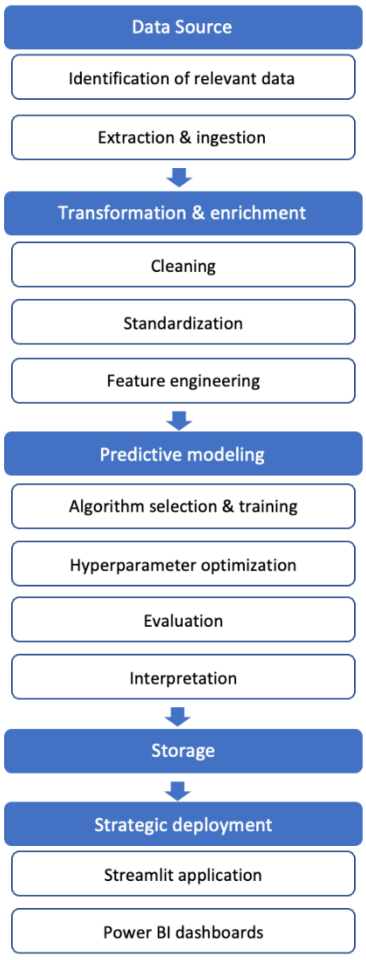

Fig. 1. Methodological diagram.

A. Data Used

The dataset used in this study comes from a telecommunications company that provides phone and internet services. It comprises 7043 observations and 21 variables. Table I presents the main characteristics of this Dataset.

TABLE I. Dataset Characteristics

Characteristic	Value
Total observations	7 043
Number of features	21
Non-churn customers	5 174 (73,5%)
Churn customers	1 869 (26,5%)
Class ratio (non-churn:churn)	2.8:1
Memory size	7.79 MB

B. Data Extraction and Ingestion

This initial phase consists of loading the data from its source and verifying its structural integrity. The dataset's informative diversity covers four categories of variables (see Table II):

TABLE II. Typology of Dataset Variables

Category	Variables	Description
Demographics	Gender, Senior Citizen, Partner, Dependents	Sociodemographic profile
Services	Phone Service, Multiple Lines, Internet Service, Online Security, Online Backup, Device Protection, Tech Support, StreamingTV, Streaming Movies	Package of subscribed services
Contractual	Contract, Paperless Billing, Payment Method	Contractual terms
Financial	Monthly Charges, Total Charges, Tenure	Financial indicators and loyalty
Target	Churn	Predictable variable (Yes/No)

C. Pipeline ETL and Feature Engineering

The reliability of predictive models depends largely on the quality of the input data. In this step, we implemented an ETL pipeline to progressively clean, structure, and transform the data as follows:

1) Data cleaning: This step aims to detect and correct data quality issues [7]. During the initial analysis, the totalcharges variable was found to contain 11 observations with spaces in place of numerical values. After examination, these cases corresponded to customers with zero tenure. To resolve this issue, the variable was converted to a numeric type, where missing values are automatically treated as null and then imputed as 0. This solution preserved observations while maintaining data integrity.

2) Handling of categorical variables: This step aims to reduce inconsistencies in categorical variables by grouping similar categories under a unified representation [8]. For example, We found that the service variables had three categories: "yes", "no", and variants such as "no internet

service" and "no telephone service". To harmonize the data, we grouped these variants into a single category "no".

3) Feature engineering: The goal of this step is to enrich the dataset by creating derived variables that offer greater analytical value and contribute to improved predictive performance. Eight new variables were created:

- ChurnFlag: conversion of the Churn variable into a binary format.
- Tenure Group: Segmentation of tenure into four classes: 0-1 year, 1-2 years, 2-4 years, >4 years.
- Total Services: This represents the number of subscribed services by each customer. Possible values 0 to 7.
- Customer Type: Behavioral typology ("Phone Only", "Internet Only", "Bundle").
- Is Premium Customer: Binary indicator for Total Services $\geqslant 5$.
- Avg Monthly Charges: Ratio of Total Charges/tenure to compare between new and existing customers.
- Family Support: Indicator of family stability (Partner=Yes AND Dependents=Yes).
- Tenure Years: Conversion to years for improved business readability.

D. Predictive Modeling

1) Data preparation for learning: 17 categorical variables were transformed using label encoding. To prevent data leakage and ensure unbiased evaluation, we split the dataset into training (80%) and test (20%) sets before any transformation. The separation is stratified, ensuring the same proportion of churn in both sets (26,5%).

Standardization (centering and scaling) was applied to the numerical variables. An important step for algorithms sensitive to scale, although Random Forest is theoretically less sensitive in this regard.

2) Choice of algorithm: The choice of the random forest classifier is based on several theoretical and practical considerations, confirmed by recent literature. The authors of [9] showed that random forest and XGBoost offer better performance with 96% accuracy, while SVM and KNN offer lower performance. Also, in [10], random forest demonstrates higher performance on e-commerce data. Among the advantages of random forest are the following [11]:

- Robustness: Aggregating multiple trees reduces sensitivity to noise and outliers.
- Non-linearity: The model allows for the capture of complex relationships without relying on parametric assumptions.
- Interpretability: Provides a measure of variable importance.
- Stability: The average of sets produces a lower variance than that of single decision trees.
- Scalability: Good performance on moderately sized datasets.

3) Hyperparameter optimization: To identify the optimal configuration, an exhaustive search for hyperparameters was performed using gridsearchcv [12], with cross-validation (5 folds) and optimization based on the roc-auc metric:

- Number of estimators: [100, 200, 300]
- Maximum depth: [10, 20, 30, None]
- Minimum number of samples per leaf: [1, 2, 4]
- Split quality criterion: ['gini', 'entropy']

4) Evaluation metrics: To evaluate the model's performance, we used a set of complementary metrics:

- Accuracy: Gives the overall proportion of correct classifications.
- Precision: Measures the number of churners predicted who actually churn.
- Recall: Proportion of churn detected among all actual churn.
- F1-Score: Provides a balanced view by combining precision and recall.
- ROC-AUC: Model's ability to discriminate between classes.
- Confusion matrix: Offers visualization of prediction errors.

E. Deployment and Decision-Making Integration

1) Deployment architecture: After optimization, the final model was saved with all necessary components, e.g., scaler, encoders, and feature list, to ensure reproducibility for production deployment.

2) Streamlit application: For deployment, we propose using Streamlit, a Python framework that transforms scripts into interactive web applications without needing certain front-end skills. This step aims to make the models accessible to business teams [13].

The interactive web application offers:

- A form for inputting customer characteristics.
- Real-time calculation of churn probability.
- Risk level classification (Low, Medium, High) based on thresholds.
- Automated recommendations personalized to the risk profile.

3) Business intelligence integration: The goal of this phase is to structure the data and model predictions in a MySQL database and then connect them to Power BI. This architecture

combines descriptive analytics (BI) and predictive analytics (ML) within the same decision-making environment.

IV. Results and Analysis

A. Exploratory Analysis Results

1) Data structure and quality: The loading of the dataset exposed a structure of 7,043 rows and 21 columns, which is manageable for iterative processing. Analysis of variable types identified 18 categorical variables (object) and 3 numerical variables.

A variable "Total Charges" represents quantitative financial data, and we observed that it was stored in object format. This indicated that a conversion would be necessary.

2) Distribution of the target variable: Analysis of the churn variable indicates an imbalanced class configuration (see Fig. 2):

- Non-churn customers: 5,174 (73,5%)
- Churn customers: 1,869 (26,5%)
- Overall churn rate: 26,5%
- Class ratio: 2,8 (non-churn) to 1 (churn)

Moderate imbalances require careful attention during modeling, especially when selecting evaluation metrics.

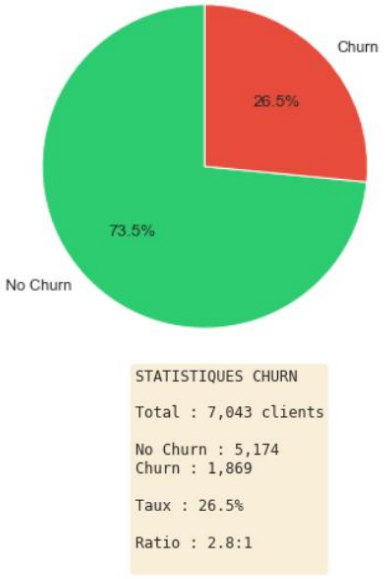

Fig. 2. Churn variable Analysis.

3) Discriminant factors of churn: Analysis identified a number of variables that were strongly associated with churn: (See Fig. 3, Fig. 4, Fig. 5, and Fig. 6).

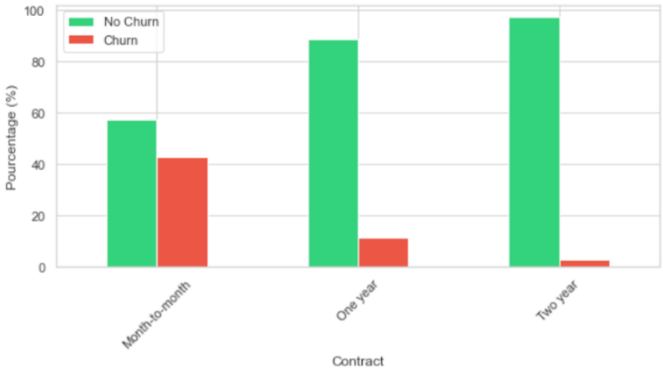

Fig. 3. Churn rate by contract.

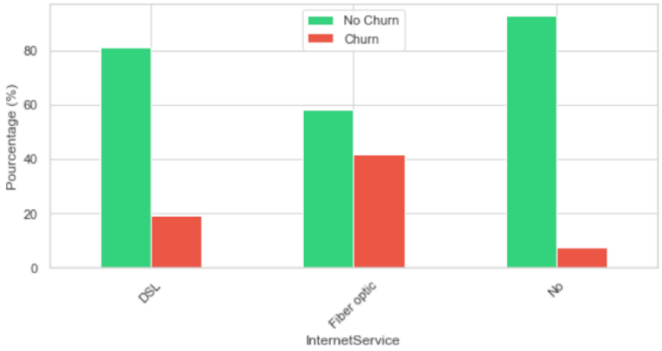

Fig. 4. Churn rate by internet service.

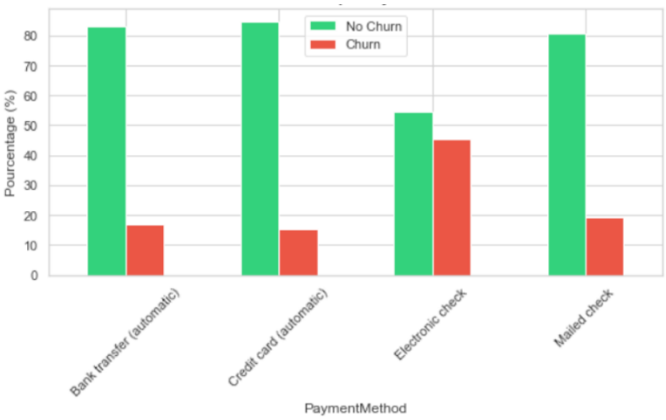

Fig. 5. Churn rate by payment method.

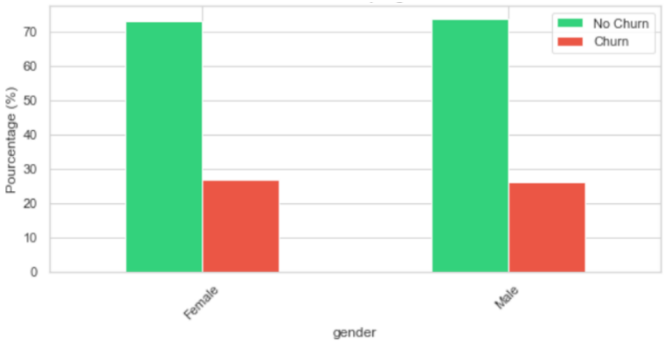

Fig. 6. Churn rate by gender.

a) Contract type: The number of customers who canceled their contracts was 42,7% for monthly customers, whereas those with one year and two years contracts have rates of only 11,3% and 2,8%. This difference highlights the effect of long-term commitments.

b) Internet service: With a churn rate of 41,9%, fiber optic customers depart more frequently than DSL users 19% and those without internet connection. This may reflect higher expectations among fiber users or more intense competition in this segment.

c) Payment method: Customers who pay by electronic check are highest chance of unsubscribing, with a rate of 45,3%. This rate is too higher than those paying by bank transfer at 26,5%, credit card at 21,9%, or by mailed check at 21%.

d) Gender: The difference is minimal, 26,1% of men churn and 26,9% of women, meaning that gender does not play a significant role.

4) Analysis of numerical variables: This analysis of continuous variables identified different profiles between churned and non-churned customers:

a) Tenure: Median duration for churned customers is 10 months compared to 38 months for non-churned customers.

b) Total Charges: Average among churned customers (1531$) is lower than the non-churned customers (2555$).

The correlation matrix (see Fig. 7) indicates a negative correlation between tenure and churn (-0,352), a positive correlation with Monthly Charges (0,193), and a weak correlation with Senior Citizen (0,151).

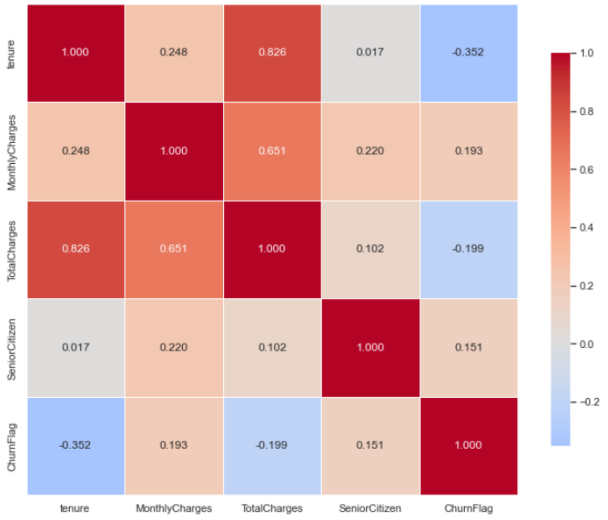

Fig. 7. Correlation matrix.

B. Modeling Results

1) Baseline model performance: The baseline random forest model, without optimization, attained the following performance on the test set:

- Accuracy: 79%
- Precision: 63%
- Recall: 48%
- F1-Score: 55%

These results provide a functional performance, but recall at 48% indicates a limitation. In other words, more than half of churned customers are not detected.

2) Optimized model performance: In order to improve the model performance, an optimization using gridsearchcv has been applied (see Table III):

TABLE III. PERFORMANCE COMPARISON BEFORE/AFTER OPTIMIZATION

Metric	Initial model	Optimized model	Improvement
Accuracy	79%	80%	+1,3%
Precision	63%	65%	+3,2%
Recall	48%	49%	+2,1%
F1-Score	55%	56%	+1,8%
ROC-AUC	0,83	0,85	+2,4%

Although these gains may seem modest, each additional percentage point of recall represents dozens of identified customers. Therefore, the improvement can be considered significant.

3) Confusion matrix analysis: The confusion matrix of the optimized model is illustrated in Fig. 8:

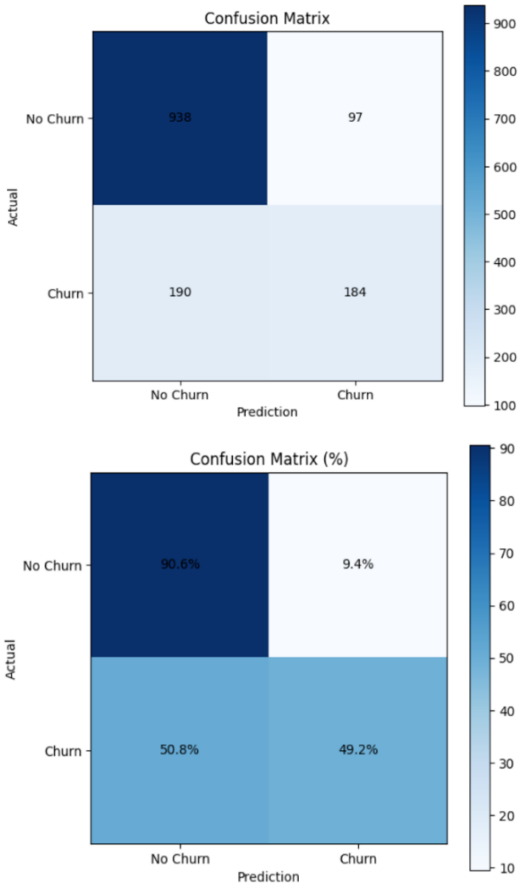

Fig. 8. Confusion matrix

The model prioritizes reducing false positives (97 loyal customers identified) at the expense of a higher recall rate (190 false negatives).

In an operational context, mobilizing retention resources to customers who will not leave (false positives) means spending without return, while failing to identify those who will leave (false negatives) means lost revenue.

4) ROC curve: The ROC curve presents an area under the curve greater than 0.84 (see Fig. 9). This indicates an excellent distinction capability of the model, and the value, above 0,8, is generally considered acceptable in real contexts.

The deviation from the random diagonal confirms that the model provides real added value compared to a random prediction.

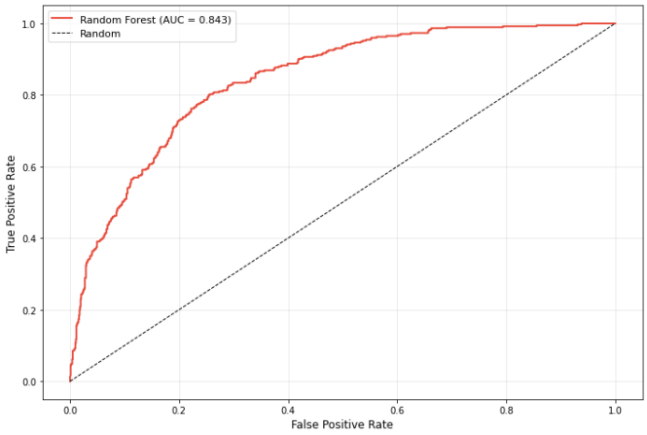

Fig. 9. Courbe ROC

5) Features importance: Fig. 10 illustrates the hierarchy of the most influential predictors detected during the analysis of variable importance.

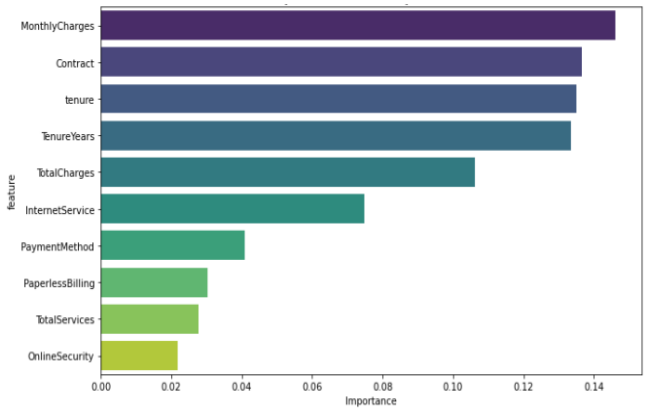

Fig. 10. Features importantes.

C. Operational Deployment Results

1) Streamlit application: Real-time interaction with the model is made possible through the application that we developed and usability tests have demonstrated:

- Less than 2 minutes on average for each customer's input.
- Intuitive comprehension of the results, such as probability and risk level.

The application was structured to support two different ways of using:

- Individual prediction for a specific customer (customer service).
- Batch prediction via file upload (marketing campaigns).

2) Power BI dashboards: Two dashboards were created to meet various decision-making needs (see Fig. 11, Fig. 12):

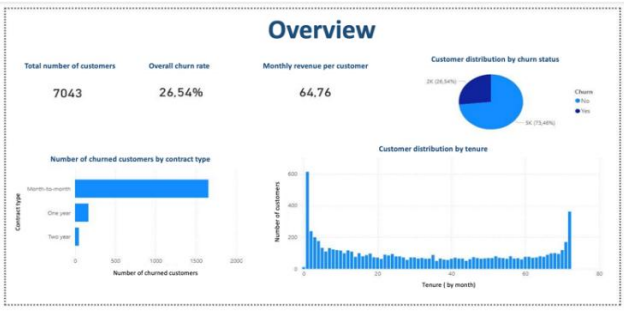

Fig. 11. Dashboard overview.

a) Overview: Designed for strategic management. It presents key performance indicators such as the number of customers, churn rate, average revenue, etc., and the classification of churn by contract and tenure. It provides an immediate overview of the portfolio.

b) Detailed analysis: Focused on marketing analysis. This report explores the relationships between churn and explanatory variables such as internet service, payment method, and cross-analysis of contract and payment. Churn evolution by tenure is also visualized. And a list of the top ten customers with the level of risk they pose.

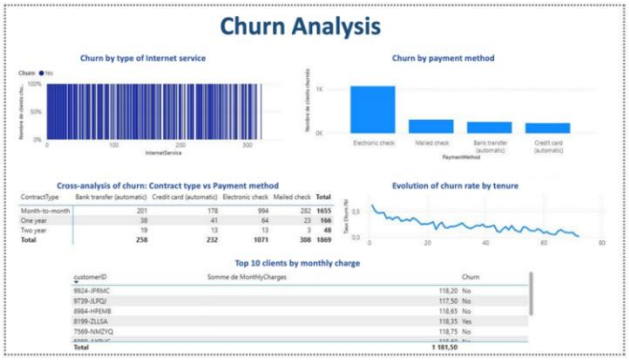

Fig. 12. Dashboard: Detailed Analysis.

V. Discussion

A. Interpretation of Results

The results obtained confirm and enrich the existing literature on churn prediction, while providing important nuances regarding the hierarchy of predictive factors.

Contrary to several studies that place tenure as the top predictor [4], our analysis reveals that MonthlyCharges constitute the most influential factor. This result suggests that price sensitivity is a major determinant of the cancellation decision.

Contract type ranks second, confirming the protective effect of long-term commitments. Month-to-month contract customers have a churn rate of 42.7%, compared to only 11.3% for one-year contracts and 2.8% for two-year contracts.

Tenure as a protective factor, but not preeminent. Although tenure ranks third, it does not dominate the hierarchy. This result nuances the idea of an automatic "lock-in" effect linked to relationship duration.

The presence of TotalServices in the top nine validates the relevance of the feature engineering work. The more services a customer consumes, the more engaged they are and the less likely they are to cancel.

B. Impact of Class Imbalance

The dataset exhibits a moderate class imbalance with a ratio of 2.8:1. While this challenge is identified in the literature [4], we chose not to apply oversampling or under-sampling techniques. Random Forest is inherently robust to moderate imbalance due to its bootstrap sampling and tree aggregation mechanisms. Furthermore, applying balancing techniques would alter the real-world class distribution, potentially leading to overoptimistic estimates that do not reflect operational conditions. The ROC-AUC of 0.85 is robust to imbalance, whereas the accuracy of 80% is partially inflated by the majority class.

C. Methodological Contributions

Our main methodological contribution is the integration of the data value chain from extraction to deployment. The feature engineering phase was particularly productive. A number of variables were created, such as IsPremiumCustomer and TotalServices, which emerged as important predictors of the final model. This confirms the intuition that the creation of relevant variables, guided by business knowledge, can be more decisive than the choice of algorithm.

The dual-channel deployment approach (interactive application for operational staff, dashboards for decision-makers) addresses a real need of organizations: making predictions available to different stakeholders according to their specific working methods.

D. Limitations and Perspectives

Our research, although having achieved its objectives, presents certain limitations that open up promising research directions.

1) Temporal limitation and longitudinal perspective: The study is based on a cross-sectional dataset, capturing churn at a given point in time. A temporal perspective would allow modeling the evolution of risk and identifying weak signals that precede churn. The use of longitudinal data could refine the understanding of the role of tenure and monthly charges, which occupy a central place in our variable hierarchy.

2) Informational limitation and enrichment perspective: The data used, although rich, are limited to the operator's internal information. The integration of external data like sentiment on social networks, macroeconomic indicators, and competitive data would constitute an important enrichment. Significantly, this addition makes it possible to understand why monthly charges become the primary predictive factor in our model by placing them within their competitive environment.

VI. Conclusion

This work aimed at designing and implementing a churn prediction system adapted to the telecommunications context. Rather than focusing only on modeling, we structured the approach around several successive steps, including exploratory data analysis, the development of an ETL process, feature engineering, and the use of a Random Forest model. The results were then integrated into visualization tools to support decision-making.

The obtained results show that the proposed approach is effective in identifying the main factors related to customer churn. In particular, variables such as monthly charges, contract type, and customer tenure appear to play a significant role. The feature engineering step also brought additional value. For instance, the variables TotalServices and IsPremiumCustomer, which were constructed during the process, turned out to be informative for the model.

One important point that emerges from this study is that predictive performance alone is not sufficient. In practice, the utility of such a model depends on how it is integrated into workflow, from data preparation to the interpretation of results. This perspective makes it possible to better align technical outputs with operational needs, and suggests that similar approaches could be applied in other contexts.

Attribute-Conditioned Attention Scaling for Text-to-Image Diffusion Models

Rabia Tahir, Bilal Ahmed Memon
School of Software Engineering, Tashkent University of Information Technology (TUIT), Tashkent, Uzbekistan
School of Business and Economics, Westminster International University, Tashkent, Uzbekistan

***Abstract*—Many text-to-image diffusion models have attained significant success in the generation of images from textual prompts; however, they still face some challenges, such as limited fine-grained control over different semantic attributes. To overcome this issue, this study proposes an Attribute-Conditioned Attention Scaling (ACAS), which modulates the cross-attention layers of the UNet model using attribute-related scaling factors. These scaling factors are assigned to the attention maps that allow selective enhancement of features in the ACAS without retraining. Moreover, this model allows precise control over generated images without retraining of the base model at the inference level, along with preservation. For experiments, 30 diverse prompts along with eight descriptive attributes are used to inspect the multi-attribute controllability of the proposed model. Different evaluation metrics, such as CLIP, LPIPS, and Inception Score (IS), are used to quantitatively evaluate the proposed model. Experimental results prove that the proposed model ACAS obtains competitive results with an LPIPS of 0.75, CLIP score of 0.316, IS of 3.98, and a minimal 8.47 seconds generation time. Furthermore, a comparative analysis of the ACAS model with similar baseline methods is performed, and the comparison shows that the ACAS improves attribute controllability without adding extra computational cost. Overall, this model bridges the gap between fine-grained attribute control and prompt-based guidance in the latest diffusion models.**

***Keywords*—Diffusion models; attribute-control; CLIP; LPIPS; text-to-image generation; cross-attention modulation**

I. Introduction

In today's world, numerous people want to create images inspired by their visual imagination. With the advent of text-to-image models, it is possible to generate visually stunning images by just providing a prompt [5]. Diffusion models have emerged as a powerful method in the domain of text-to-image generation, and they are inspired by non-equilibrium thermodynamics. The rising interest in diffusion models proves their versatility and potential in various image-related tasks, especially text-to-image generation [1]. Latest models such as DALLE-2 [2], Stable Diffusion [10], and Imagen [4] prove the power to generate photorealistic and diverse images by conditioned-based prompts. Despite the huge success of these models, there are still a few challenges, such as limited fine-grained control on semantics attributes, e.g., "younger face", "metallic texture", and "futuristic city". Existing models are aimed at two main directions, i.e., fine-tuning the model (retraining) and embedding-level guidance. The fine-tuning or retraining of the model leads to more computational cost, while embedding-level guidance lacks explicit mechanisms to adjust the attributes' influence during the denoising task. The main motive of the proposed model is to modulate the influence of attributes on the attention layers with the help of a scalar weight. This allows suppression, increase, and balance of the attribute strength in the image generation. Further, the proposed model, ACAS, can deal with multiple attributes simultaneously with the help of normalized weights. Hence, the proposed model can integrate diverse attributes like ("younger", "hat", "smiling") in one-step generation. To address these issues, this study proposes a lightweight Attribute-Conditioned Attention Scaling (ACAS) for multi-attribute-based text-to-image generation in a well-controllable manner with no retraining overhead. During the inference stage, the proposed model injects attribute-specific scaling coefficients into the cross-attention blocks of the UNet model. The main motive is to allow all attributes to be balanced and enhanced while generation with the help of a scalar control parameter. The proposed model offers three significant benefits: fine-grained control, multi-attribute conditioning and no retraining overhead. Experiments are performed and a comparison is conducted for the proposed model with baseline models and the results show the superiority of the proposed model. The results are evaluated with both quantitative and qualitative metrics, including CLIP [15], LPIPS [16], Inception Score (IS) [17] and generation time. Overall, the contributions of this study are:

- A novel ACAS model is proposed for controllable attribute-guided text-to-image generation without retraining.
- This model injects the semantic attributes into the denoising to preserve the textual prompt semantics and to enhance the fidelity of attributes.
- Extensive experiments are performed with a comprehensive evaluation to show the efficiency of the proposed model.
- The proposed model, ACAS, bridges the gap between fine-tuning and prompt-level control. It offers a flexible and practical solution for real-time text-to-image generation.

The rest of the study is organized as follows: Section II describes the related work on controllable text-to-image generation and diffusion-based methods. Section III explains the proposed Attribute-Conditioned Attention Scaling (ACAS) model. Section IV illustrates the data, experimental setup, quantitative and qualitative results, discussion, and ablation study. Finally, Section V concludes the study and highlights some future research directions.

II. Related Work

Generative Adversarial Networks (GANs) have been used for image generation and they achieved strong performance on the benchmark datasets. However, these models even suffer from training instability and limited controllability limitations [3]. Diffusion-based text-to-image methods [6, 7, 8, 10] have shown significant progress in the past few years by generating highly realistic images with the help of a text prompt. Diffusion-based models avoid the hectic process of training a huge text-to-image model from the beginning and take benefit of already existing pre-trained models for attribute manipulation and image editing tasks [21]. Despite their huge success, some models [4, 9, 23] lead to high computational cost, and many of these models depend on denoising diffusion probabilistic models (DDPM).

Vanilla stable [10] diffusion framework proposed by Romach et al., produces images from textual prompts with the help of a latent diffusion manner. Instead of generating high-quality images, this model has low control over fine-grained attributes like environment, style type, and mood. Moreover, Prompt-to-prompt [11] and ControlNet [12] show improved guidance for generated images, but they still need extra control with specific attribute adjustment. Uni-ControlNet [18], the extended version of ControlNet, allows various control models in a unified framework simultaneously and leads to composite local and global controls. Furthermore, DynamicControl [19] improves adaptive selection and ordering of multiple control signals in order to handle various conditions. It improves the fine-grained attribute adjustment in distinct text-to-image generation tasks. These models either need additional input or are less efficient to control various attributes simultaneously. DiffEdit [14] and Attend-and-Excite [13] models perform attribute-level manipulation as well, but they require complicated pipelines for unseen attributes. Latest research explores the semantic and fine-grained control in a more significant manner. DilightNet [20] proposed fine-grained lightning control with the help of diffusion process guidance. This method produces images with respect to a given text prompt and lightning. By keeping these limitations in mind, Attribute-Conditioned Attention Scaling (ACAS) is designed to control multiple attributes over generated images in a precise way without retraining the base model. To check the efficiency of the proposed model, ACAS, state-of-the-art evaluation metrics are used, i.e., CLIP score [15], LPIPS [16], Inception score (IS) [17], and generation time. These metrics are used to evaluate the perceptual diversity, semantic alignment and generated content quality. Besides, the comparison of the proposed model, ACAS, with related models is performed, and the results show the superiority of the model in various factors.

III. Methodology

A. Overview

The proposed model, Attribute-Conditioned Attention Scaling (ACAS), improves the traditional text-to-image diffusion methods in order to obtain precise control over visual attributes in the produced image without retraining. As compared to the vanilla diffusion model that globally interrupts the prompt, this model applies a forward hook added at all cross-attention layers of the UNet without retraining. A prompt P and a set of descriptive attributes $A = \{a_1, a_2, a_3, \ldots, a_n\}$ are assigned to ACAS as an input. Then, the proposed model modulates the UNet cross-attention map M during the forward pass, as shown in Eq. (1) below:

$$\tilde{M} = \gamma\,(a_i).M \tag{1}$$

where, $\gamma(a_i)$ is the attention scaling factor for attributes a_i, M is UNet based cross attention map and $\tilde{M}$ is the modulated attention map that is used for forward pass after scaling. $\gamma(a_i)$ allows controllability of attribute influence without the need of retraining the base model. Fig. 1 shows the systematic view of the proposed model ACAS.

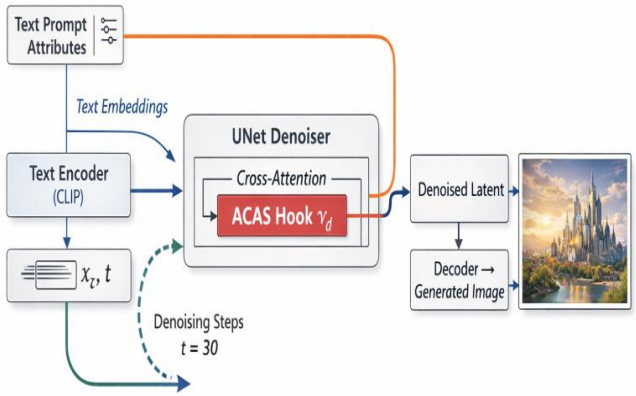

Fig. 1. Systematic view of the proposed model ACAS.

B. Cross-Attention in Traditional Diffusion Models

UNet in the traditional text-to-image diffusion models uses cross-attention to combine latent image features f_x with text features f_t, as explained in Eq. (2) below:

$$\text{Att(K, V, Q)} = \text{softmax}\left(\frac{QK^T}{\sqrt{d}}\right)V \tag{2}$$

where, K, V and Q are key, value and query metrics that are derived from text and image immersing.

C. Scaling by Attributes

To modulate attention weights, the proposed model ACAS presents a scalar $\gamma(a_i)$, as shown below in Eq. (3):

$$\widetilde{Att}\text{(K, V, Q; } a_i) = \gamma(a_i).\,\text{softmax}\left(\frac{QK^T}{\sqrt{d}}\right)V \tag{3}$$

where, $\gamma(a_i) < 1$ subdues the features influence and $\gamma(a_i) > 1$ improves it. During denoising in UNet, it is imposed in each cross-attention block.

D. Multi-Attribute Scaling

In real-time, users give more than one attributes in a textual prompt to generate an image. For example, "an old man is smiling and wearing hat". Therefore, a single scalar is not enough to address this issue. The proposed model introduces a weighted multi-attribute formulation. Suppose, there is a set of N attributes $A = \{a_1, a_2, a_3, \ldots, a_n\}$, where a scalar weight is assigned to each attribute and this weight is independent. Hence, this multi-attribute attention is defined in Eq. (4):

$$\widetilde{Att}\text{(K, V, Q; } A) = \frac{1}{\sum_{i=1}^{N}\gamma(a_i).}\sum_{i=1}^{N}\gamma(a_i).\,\text{softmax}\left(\frac{QK^T}{\sqrt{d}}\right)V \tag{4}$$

where, $\sum_{i=1}^{N} \gamma(a_i)$ is a normalization term that handles the magnitude of attention when more attributes are added. It allows the attributes to be scaled independently and balanced with weight selection.

E. Integration into UNet Denoising Process

Stable diffusion addresses the iterative refinement for a latent noise vector z_t during the denoising step. In the proposed ACAS, the modified attention $\widetilde{Att}(K, V, Q; A)$ is used at all cross-attention blocks of the base UNet model. This modifies attention and applies during all denoising step $t \in \{1, 2, \ldots, T\}$. Suppose, $\epsilon_\theta(z_t, t, P)$ shows a denoising UNet with condition oriented prompt P. Then, with ACAS, the conditioning prompt is shown in Eq. (5):

$$\epsilon_\theta(z_t, t, P, A) = \epsilon_\theta(z_t, t, P, \widetilde{Att}(K, V, Q; A)) \quad (5)$$

Afterward, the latent space becomes:

$$z_{t-1} = \text{Denoise}(z_t, \epsilon_\theta(z_t, t, P, A)) \quad (6)$$

This step in Eq. (6) has no training overhead and it does not change the architecture of UNet.

F. Weight Interpretation and Optimization

The attribute weightage $\gamma(a_i)$ gives a balanced control to influence the attributes. $\gamma(a_i)$ controls the degree of attention given to the attribute by the model in the cross attention map. Higher value of $\gamma(a_i)$ means a stronger influence, while low value of $\gamma(a_i)$ leads to lower influence. This degree of control over multiple attributes is without retraining the model. It is described below:

$\gamma(a_i)<1$ decrease the influence

$\gamma(a_i)>1$ increase the influence

$\gamma(a_i)=1$ same like vanilla diffusion model

Moreover, the proposed ACAS allows learnable weights for strong semantic alignment. $\gamma(a_i)$ is optimized with a CLIP-based loss, as shown in Eq. (7):

$$L_{CLIP} = 1\text{-}COS(f_T(P, A), f_I(A)) \quad (7)$$

where, $f_T(.)$ and $f_I(.)$ are CLIP-based text and image encoders and COS is used for cosine similarity. This loss function helps to generate an image which is aligned with both the attributes and prompt.

IV. Experiments

A. Data

For evaluation, 30 diverse prompts with eight attributes are used to generate 240 images. Fig. 2 shows some of these generated images with their prompt and attribute. For experiments, the prompt-based image generation is used as the base dataset. A total of 30 base prompts are defined that cover various visual domains such as scenes, human figures, animals and objects. For example; these textual prompts are "a futuristic city at sunset", "a surreal dreamscape". These prompts can be extended to different semantic categories that show the model's ability to create the diverse content with the help of multiple attribute as well. Against each prompt, eight semantic or stylistic attributes are used i.e. "low details", "high details", "mysterious", "cartoon", "hot and sunny", "raining", "realistic" and "oil painting". A strength coefficient (c) is assigned to each attribute that scales it in the attention layer of the UNet model while image generation. Table I shows the different value of weightage attribute γ that are assigned to all attributes. For example, $\gamma > 1$ is used for those attributes that require higher stylistic features, such as cartoon and high detail. For $\gamma < 1$, it implies that attribute details are not dominating the text prompt, such as "Low detail". The γ values are selected regarding the expected visual dominance of each attribute. It is ideal to start the initial estimate like 0.5 and then increase it or decrease it according to the obtained results in order to get the balance fine-grained control of attribute influence. This strength value gives fine-grained control over attributes. Table I shows the best γ values that yielded best in the experiments.

The dataset used for experiments in this work is designed to evaluate attribute-level controllability instead of large-scale image generation. Each attribute-prompt pair is constructed carefully in order to cover diverse semantic categories. These pairs cover diverse semantic categories, which are style, appearance and object-level characteristics. The applicability of the ACAS is not limited to a specific dataset because it works by modifying the cross-attention layer within a diffusion model. If the number of prompts increases, it would not alter the final results significantly. The consistent performance against diverse attribute-prompt pairs shows that the model ACAS generalizes across multiple visual concepts.

TABLE I. Strength Values Used in the Model Against Each Attribute.

Attributes	Strength (γ)
Low Detail	0.75
Realistic	1.25
High Detail	1.35
Cartoon	2
Hot and Sunny	1.15
Rainy	1.50
Mysterious	1.10
Oil Painting	1.05

B. Model Setup

For baseline method, Stable Diffusion v1-5 from Runway ML is used for image generation. Experiments are performed on Google Colab with T4 GPU and mixed precision (torch.float16) to optimize inference speed and memory. Mixed-precision helps in reducing memory without degrading the semantic quality. For comparison, all images are generated with fixed diffusion steps, i.e., 30 for ACAS, baseline and vanilla diffusion model. Moreover, CLIP (ViT-B/32) is used for quantitative evaluation of semantic alignment among the textual prompts and generated content. Table II shows details of parameters used in the proposed model, ACAS.

Contrastive Language Image Pre-training (CLIP) is a model proposed by OpenAI that is used to compare the images and text in the likewise semantic space. It calculates how the image matches with a text prompt. Vit-B/32 is a version of CLIP that

uses Vision Transformer as a backbone in the model. It deals with the images in patches of 32x32 pixels. So, this is used as an automatic metric to calculate the score for how well the output images matches the text description. A forward hook is implemented on all cross-attention layers of UNet model in order to modulate the influence of attributes on the generated image. With the help of attribute strength factor γ, the scaling of attention outputs can be controlled. Each text prompt is concatenated with the attribute, such as "a retro television set + high detail". After concatenation, pass it to the stable diffusion pipeline. The generation time is calculated for each image and stores the image in the corresponding directory.

TABLE II. PARAMETERS AND THEIR VALUES USED IN ACAS

Parameter	Value / Setting
Base model	stable-diffusion-v1-5
Diffusion Steps	30
Image Size	512 × 512
Device	Cuda (GPU)
Attention Hook	Custom Cross Attention hook
Mixed Precision	torch.autocast("cuda")
CLIP Model	ViT-B/32
LPIPS Model	Alex
Number of Prompts	30

C. Qualitative Results

This section shows the qualitative results of the proposed model. Fig. 2 shows the generated images by different textual prompts with eight different attributes. These attributes are “cartoon”, “high details”, “low details”, “mysterious”, “oil painting”, “photorealistic”, “Rainy” and “hot and sunny”. This figure shows results against four prompts which are “are "a futuristic city at sunset", “a tropical beach with palm trees", "a medieval castle on a hill" and “a cup of coffee”. In Fig. 3, the proposed model, ACAS, generates appealing images that describes both text prompt and attributes. For example, “a futuristic city at sunset” with cartoon attribute reflects an image that represents the futuristic city scape with cartoon aesthetic. This demonstrates the capability of ACAS to disentangle and recombine the attribute and textual information. Fig. 3 shows the visual comparison of the proposed model with the baseline stable diffusion v1.5 model [10] and the vanilla diffusion model v1.4 [10]. This clearly depicts the superiority of the proposed model over baseline models. The first row shows "a medieval castle on a hill" with the attribute “Oil painting”. The ACAS model generates a better image that satisfies both the text prompt and the attribute. The second row shows "a white dove flying” with the attribute “rain”. Vanilla and base model failed to generate a realistic image with a complete dove flying in rain, but ACAS generates an image that portrays the actual text prompt and attribute. The last row shows "a robot holding a flower" with attribute “hot and sunny”. The other two models do not satisfy the “hot and sunny” attribute and create an ordinary image of robot holding a flower. However, the proposed model generates a realistic image of a robot holding a flower in hand while the background shows the hot and sunny weather fulfilling the attribute condition. This is possible because the proposed model efficiently combines the attribute-guided attention with the text prompts and precisely controls the visual features of the generated image. This makes it a promising model for generating stylist images that reflects both textual prompts and attributes.

D. Quantitative Results

This section demonstrates the quantitative results for the proposed model, ACAS, and with related models stable diffusion v1.5 [10] and vanilla diffusion v1.4 [22]. State-of-the-art evaluation metrics CLIP [15], LPIPS [16], Inception score (IS) [17] are used along with the generated time for each image. A total of 30 experiments are performed for each model to generate 30 different images with respect to the attribute and text prompt and an average is calculated for all experiments. Table III summarizes these results for all three models. To obtain fair results, the same parameter values are used for all three models. The CLIP score is used to calculate the semantic consistency among generated images and text prompts. To calculate this score, OpenAI CLIP ViT-B/32 is used for calculating cosine similarity between image features and the encoded text. The second measure is LPIPS, which calculates the perceptual diversity among generated images with the help of an AlexNet Backbone. Pairwise LPIPS distances are measured for each attribute and then averaged. The Inception Score (IS) is used to inspect the quality and diversity of the generated images. The higher value of IS shows better results and is consistent to the textual prompt and attribute. The results in Table III show that ACAS obtained comparable results as compared to Stable Diffusion v.15 and vanilla diffusion v1.4. These results show that the proposed model, ACAS, preserves the overall quality of images without degradation. Furthermore, it is noted that these standard metrics are designed to compute the perceptual similarity, global image quality and distribution of realism. For fine-grained attribute control, they are not sensitive. Thereby, the lack of significant improvements in these standard metrics is not surprising and does not contradict the novelty and contribution of the model. The main motive of ACAS lies in allowing interpretable attribute-specific control by using attention scaling in the cross-attention layers instead of optimizing these standard metrics. Therefore, introducing controllable image generation without retraining with comparable performance to the strong baseline methods is a significant contribution. The generation time remains same for all models means that utilizing of attention hook in ACAS. Fig. 4 shows that the evolution of different metrics over time with respect to three models does not increase the computational cost additionally.

Fig. 2. This figure shows four different prompts with eight attributes. These prompts are "a futuristic city at sunset", "a tropical beach with palm trees", "a medieval castle on a hill" and "a cup of coffee". Attributes are given at the top of each column.

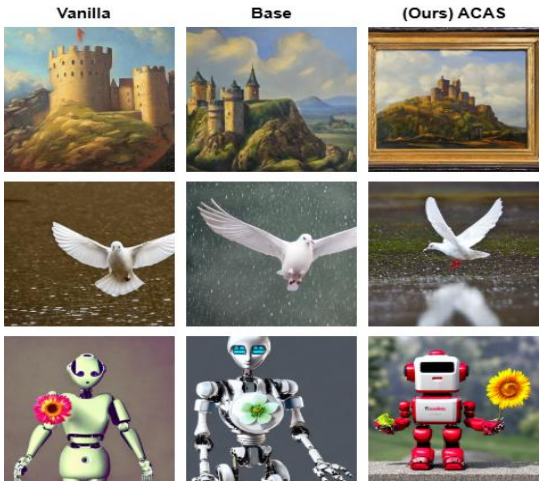

Fig. 3. Comparison of the ACAS with baseline models; first row shows "a medieval castle on a hill" + Oil painting, second row shows "a white dove flying" +rain, and the last row shows "a robot holding a flower" + hot and sunny.

TABLE III. SUMMARY OF CLIP, IS, LPIPS AND GENERATION TIME

Metrics	Vanilla V1.4	Stable Diffusion v1.5	ACAS (the proposed model)
CLIP	0.315	0.319	0.316
LPIPS	0.74	0.76	0.75
IS	3.94	4.06	3.98
Generated Time	8.4 sec	8.47 sec	8.47 sec

E. User Survey

A user survey is conducted to inspect the semantic alignment of the proposed model. Fig. 5 shows the summary of user survey to evaluate the performance of three models: ACAS, base model and vanilla diffusion. Five different textual prompts integrated with five attributes were used to generate images with all three models. Then, users were asked to choose the best image that matches both prompt and attribute. It is clearly evident in Fig. 5, that ACAS consistently obtained the highest score as compared to the other two models. The vanilla and base models were less selected and received fewer votes. This survey gives an overall insight and significance of the proposed model, ACAS.

F. Discussion and Ablation Study

The proposed model, ACAS, performance is discussed in this section. Three attribute-prompt pairs are used to inspect the effect of attribute strength gamma. These pairs are "a horse running in meadow", "a busy street with people" and "a waterfall in a dense forest", with three attributes "rainy", "mysterious" and "cartoon". Three different γ values, i.e., 1, 2 and 3 are used for the attribute strength.

The results show that when γ =1, the influence of the attribute is subtle and it preserves the main identity of the prompt. When γ increase to 2, then the visibility of attribute is more visible. When γ =3, then the attribute becomes more dominant and its influence is more visible on the generated images. However, increasing γ value more than 3 may lead to generate unrealistic images. As shown in Fig. 5, when γ is 3 then there are artifacts on the horse image in contrast to gamma value 2 that generates a balanced images. This observation shows that ACAS allows gradual and interpretable control over the attribute strength. In contrast to baseline methods that modify latent representation or need fine-tuning, the proposed model ACAS maintains the image quality while preserving the original semantics.

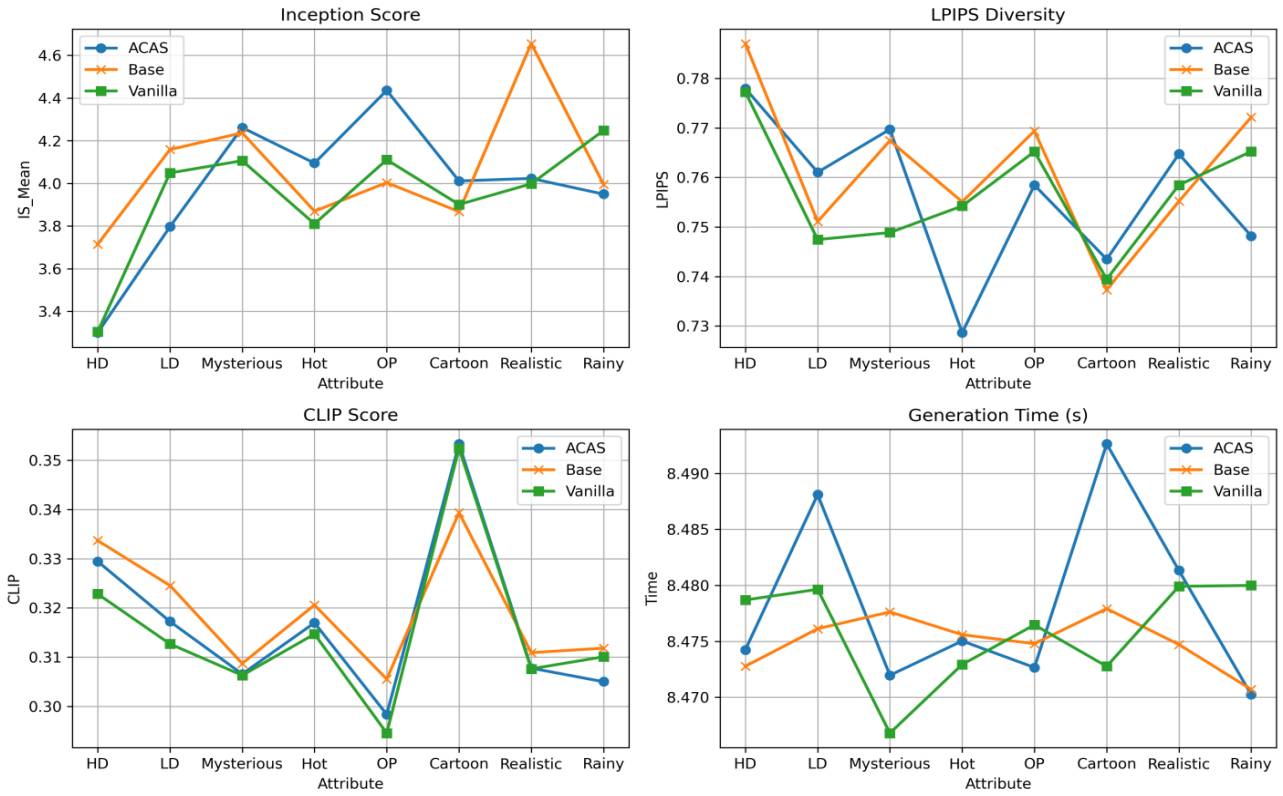

Fig. 4. Evolution of CLIP, LPIPS, and IS over time, along with generation time for each image (ACAS: the proposed model, Base: Stable diffusion v1-5, Vanilla).

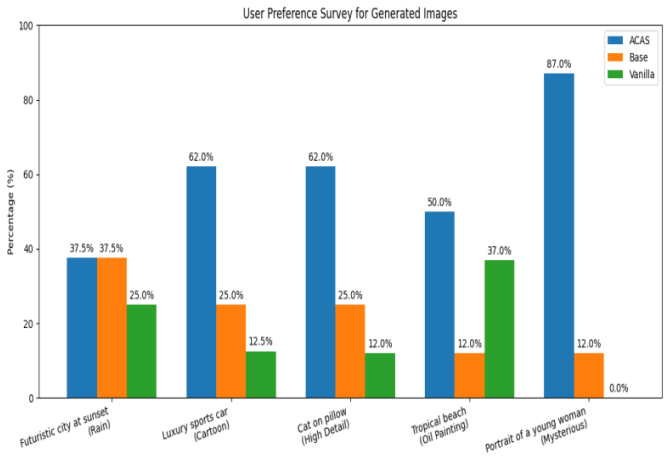

Fig. 5. User survey for ACAS, base model and vanilla model on generated images.

Moreover, this analysis shows that the standard quantities metric values are comparable with baseline models because the global image distribution is mainly unchanged during adjustment of attribute-specific features. In a nutshell, the ablation study shows that the ACAS provides interpretable and stable control over attributes. Furthermore, this discussion shows that the proposed model ACAS obtains controllability over attribute along with comparable performance to the similar existing models. In this section, the significance of attribute strength γ in the proposed model, ACAS, is briefly discussed. For this purpose, an ablation study is performed, focusing on attribute strength γ on the resultant images.

Fig. 6. Ablation study with different attribute strength γ ={1, 2, 3}. The first column shows generated images with $\gamma = 1$, the second column shows $\gamma = 2$ and the last column shows $\gamma = 3$.

Fig. 6 shows three different textual prompts with three different attributes. These prompts are "a horse running meadow", "a waterfall in a dense forest" and "a busy street with people" while the attributes are "rainy", "cartoon" and "mysterious". For each prompt-attribute pair, the attributes strength values are set to 1, 2 and 3. The generated images are obtained by just changing these values without any extra modification in the model. Fig. 6 shows that when γ =1, the effect of that specific attribute is subtle and not very dominant. When γ increases to 2 then the attribute influence becomes more

visible and prominent. At γ =3, the generated image strongly influences the textual prompt by intensified attribute details such as rain or cartoon textures. However, a higher value of γ does not guarantee the best results always. For example, when γ =3 then the image generated against the prompt "a waterfall in a dense forest" looks unrealistic and best results can be seen at γ =2. Therefore, it is concluded that ACAS allows interpretable control on various attributes without modifying the baseline model.

V. Conclusion and Future Work

This study presented a lightweight Attribute-Conditioned Attention Scaling (ACAS) to generate images with textual prompts and attributes. The selective enhancement of the features is made possible by applying the cross-attention layers of the UNet model along with attribute scaling factors. This enhancement of selective features against each attribute is achieved without retraining the base model. A total of four quantitative metrics, semantic alignment (CLIP), LPIPS, Inception Score (IS) and generation time are used. Results show that the descriptive attributes play a great role in generating behavior. Overall, the proposed model is highly responsive to attribute-based prompts and realism. In a nutshell, ACAS bridges the gap between textual prompt guidance and fine-grained attributes and presents a flexible model for controllable image generation with diffusion models. In the future, the aim is to extend this work by handling more complex and multiple attribute conditions and high-resolution image generation. Moreover, larger user studies and the use of more robust metrics could validate and enhance the performance of the model.

Acknowledgment

The authors would like to acknowledge the Tashkent University of Information Technologies (TUIT) and the Westminster International University in Tashkent, Uzbekistan for providing academic support and research facilities. Their institutional resources and environment contributed to the successful completion of this work.

Adaptive Multi-Layer Encryption for Enhancing Security in Smart Home IoT Ecosystems

Dancan Obuya Machuki[1], Kennedy Ronoh[2]
Research Scholar, School of Computing and Engineering, Strathmore University, Nairobi, Kenya[1]
Senior Lecturer, School of Computing and Engineering Sciences, Strathmore University, Nairobi, Kenya[2]

***Abstract*—The proliferation of Internet of Things (IoT) devices in smart home environments has introduced significant security challenges, largely due to device heterogeneity, constrained computational resources, and limited native support for robust encryption mechanisms. This study presents an Adaptive Multi-Layer Encryption (AMLE) model designed to enhance security across the device, network, and cloud layers of smart home IoT ecosystems. The proposed model integrates lightweight encryption mechanisms at the device layer, machine learning-based anomaly detection at the network layer, and strong cryptographic protection combined with Attribute-Based Access Control (ABAC) at the cloud layer. Evaluation was conducted in a controlled, simulated environment to assess functional correctness, security behavior under representative threat scenarios, and system performance. Results demonstrate that the AMLE framework is capable of detecting and responding to simulated unauthorized access attempts, anomalous traffic patterns associated with botnet-like behavior, and data exfiltration scenarios, while maintaining operational performance suitable for typical smart home use cases. The Isolation Forest algorithm, configured with a contamination threshold of 0.05, successfully identified deviations from baseline traffic behavior and triggered policy-driven security responses. The findings indicate that AMLE provides a practical reference framework for implementing adaptive, layered security controls in smart home IoT environments, balancing security requirements with operational constraints.**

***Keywords*—Smart home security; IoT encryption; adaptive security; multi-layer protection; resource-constrained devices**

I. Introduction

Smart home IoT ecosystems consist of interconnected devices such as sensors, cameras, thermostats, and smart locks that collectively automate and enhance residential environments. While these systems offer increased convenience and functionality, their rapid adoption has intensified security challenges related to confidentiality, integrity, and access control [1]. A defining characteristic of smart home IoT devices is their constrained computational and memory resources, which limit the feasibility of implementing conventional cryptographic mechanisms commonly used in traditional computing environments [2].

As a result, many IoT devices deploy weak or inconsistent encryption, exposing them to threats including unauthorized access, man-in-the-middle (MitM) attacks, and botnet recruitment [3]. The heterogeneity of smart home devices further complicates security implementation, as devices vary widely in processing capabilities, communication protocols, and data sensitivity [4]. Prior studies identify insufficient encryption and weak access control as primary contributors to data exposure and privacy breaches in IoT environments [5].

Unencrypted or poorly protected communication between devices and cloud services enables attackers to intercept sensitive data, manipulate device behavior, or exploit compromised nodes to launch distributed attacks [6]. Botnets leveraging insecure IoT devices have been shown to significantly disrupt network reliability and compromise user safety [7].

A. Limitations of Existing Solutions

Existing cryptographic solutions face limitations when applied to resource-constrained IoT contexts. AES, although efficient in general-purpose systems, may impose computational overhead and complex key management requirements on low-power devices [8]. RSA supports secure key exchange but introduces high computational costs and latency unsuitable for frequent IoT communications [9]. Elliptic Curve Cryptography (ECC) reduces key sizes while maintaining security strength but presents challenges related to computational complexity, curve selection, side-channel vulnerabilities, and key management [10].

Beyond cryptography, traditional network security mechanisms such as firewalls and signature-based intrusion detection systems often lack adaptability and granular control suitable for IoT environments [11]. Signature-based approaches are particularly ineffective against previously unseen attacks, limiting their applicability in dynamic and evolving threat landscapes [12].

B. Research Contribution

This research addresses these challenges by proposing an Adaptive Multi-Layer Encryption (AMLE) model tailored for smart home IoT ecosystems. The model applies layered security controls across the device, network, and cloud layers, with encryption strength and security responses adjusted based on predefined policies that consider device capabilities, data sensitivity, and detected threat indicators.

The remainder of this study is organized as follows. Section II reviews related work on IoT security mechanisms and identifies the gap this study addresses. Section III describes the research methodology and system architecture. Section IV presents the evaluation results. Section V discusses the findings, and Section VI concludes the study.

II. Related Work

Research on smart home IoT security has explored encryption, anomaly detection, and access control as distinct mechanisms, yet integrated frameworks that adapt security

posture dynamically across all layers remain limited. The studies reviewed below highlight both the advances made and the persistent gaps that motivate the present work.

A. Encryption in Resource-Constrained IoT Environments

Lightweight cryptographic approaches have been proposed to address the resource constraints of IoT devices. Rahman et al. [14] proposed chaos-based AES key generation to strengthen symmetric encryption for smart home devices, demonstrating improved resistance to brute-force attacks while retaining computational feasibility. Tripathy and Singh [8] evaluated AES software implementations on IoT-class hardware, finding that standard AES configurations require optimization to meet real-time latency requirements on constrained processors. Fernandez et al. [9] conducted a comparative evaluation of RSA and ECC cipher suites on fog and mist computing devices, concluding that ECC provides a more favorable security-to-overhead ratio for IoT applications, though it introduces key management and side-channel considerations [10].

Patil et al. [2] proposed a hybrid adaptive cryptographic authentication approach that selects encryption algorithms based on device context, demonstrating that adaptive selection can reduce computational overhead without compromising security guarantees. These works collectively establish that no single cryptographic primitive satisfies the full range of IoT security requirements, motivating layered and adaptive approaches.

B. Anomaly Detection and Intrusion Detection in IoT

Khraisat and Alazab [12] provide a comprehensive review of intrusion detection techniques for IoT environments, highlighting that signature-based methods fail against novel attack patterns and that machine learning approaches, particularly unsupervised methods, offer broader detection coverage. Hamarsheh [15] proposed an adaptive security framework combining Software-Defined Networking (SDN) and machine learning for dynamic IoT threat response, demonstrating measurable improvement in detection latency and policy enforcement speed relative to static rule-based systems. Anthi et al. [17] developed EclipseIoT, a hub-based adaptive security system that monitors device behavior and enforces isolation policies in response to detected anomalies, providing a concrete point of comparison for hub-centric adaptive frameworks.

Both Hamarsheh [15] and EclipseIoT [17] address adaptive detection but do not integrate layered cryptographic policy enforcement across device, network, and cloud tiers simultaneously. This distinction is central to the contribution of AMLE.

C. Access Control in IoT Cloud Environments

Attribute-Based Access Control (ABAC) has been studied as a flexible mechanism for IoT access management. Pajooh et al. [16] proposed a multi-layer blockchain-based security architecture that incorporates ABAC-style policies for IoT data access, demonstrating that attribute-driven authorization can be enforced at the cloud layer without requiring device-side computation. Mosenia and Jha [5] identify weak access control as a primary vulnerability in deployed IoT systems, noting that most consumer devices lack configurable authorization mechanisms, underscoring the importance of cloud-tier access control solutions that operate independently of device capabilities.

D. Identified Research Gap

The reviewed literature demonstrates that encryption optimization, anomaly detection, and access control have each been studied in isolation or in partial combinations. However, a unified framework that coordinates adaptive encryption policy enforcement across device, network, and cloud layers in response to real-time threat signals remains absent from the literature. Existing adaptive frameworks such as Hamarsheh [15] and EclipseIoT [17] address detection and isolation but do not systematically couple detection outcomes to multi-level cryptographic responses. The AMLE model presented in this study addresses this gap by integrating lightweight device-layer encryption, machine learning-based network anomaly detection, and cloud-layer ABAC within a unified policy-driven architecture.

III. Methodology

A. Research Design

The study adopted a prototype development methodology using an Agile approach with iterative development cycles. This approach supported incremental design, implementation, and validation of AMLE components through successive sprints. The development process comprised four phases: planning, sprint execution, review, and deployment.

During the planning phase, key security challenges in smart home IoT ecosystems were identified, including limited device resources, diverse communication protocols, and scalability requirements [3]. These constraints informed design decisions, particularly the selection of encryption mechanisms and anomaly detection techniques compatible with resource-constrained environments.

B. System Architecture

The AMLE architecture follows a three-layer IoT security model aligned with established IoT cloud environment frameworks [13]. Each layer addresses distinct security requirements while contributing to an integrated security posture. Fig. 1 illustrates the overall system architecture showing security enforcement across device, network, and cloud layers.

1) Device layer: At the device layer, lightweight encryption mechanisms including ECC and AES-128 are employed to protect data at the source while accommodating device resource constraints [8]. Encryption strength is assigned based on predefined policies that consider device computational capacity and data sensitivity [14]. For example, devices handling sensitive data such as video streams apply stronger encryption compared to low-risk devices such as temperature sensors. This policy-driven differentiation reflects the finding that cryptographic mechanisms must be tailored to device capabilities and application context in IoT environments [2].

2) Network layer: The network layer incorporates anomaly detection using the Isolation Forest machine learning algorithm to analyze traffic patterns and identify deviations from established baseline behavior [12]. When anomalous activity is detected, predefined response policies may trigger actions such as increased encryption strength, connection restriction, or alert generation. This approach addresses limitations of traditional

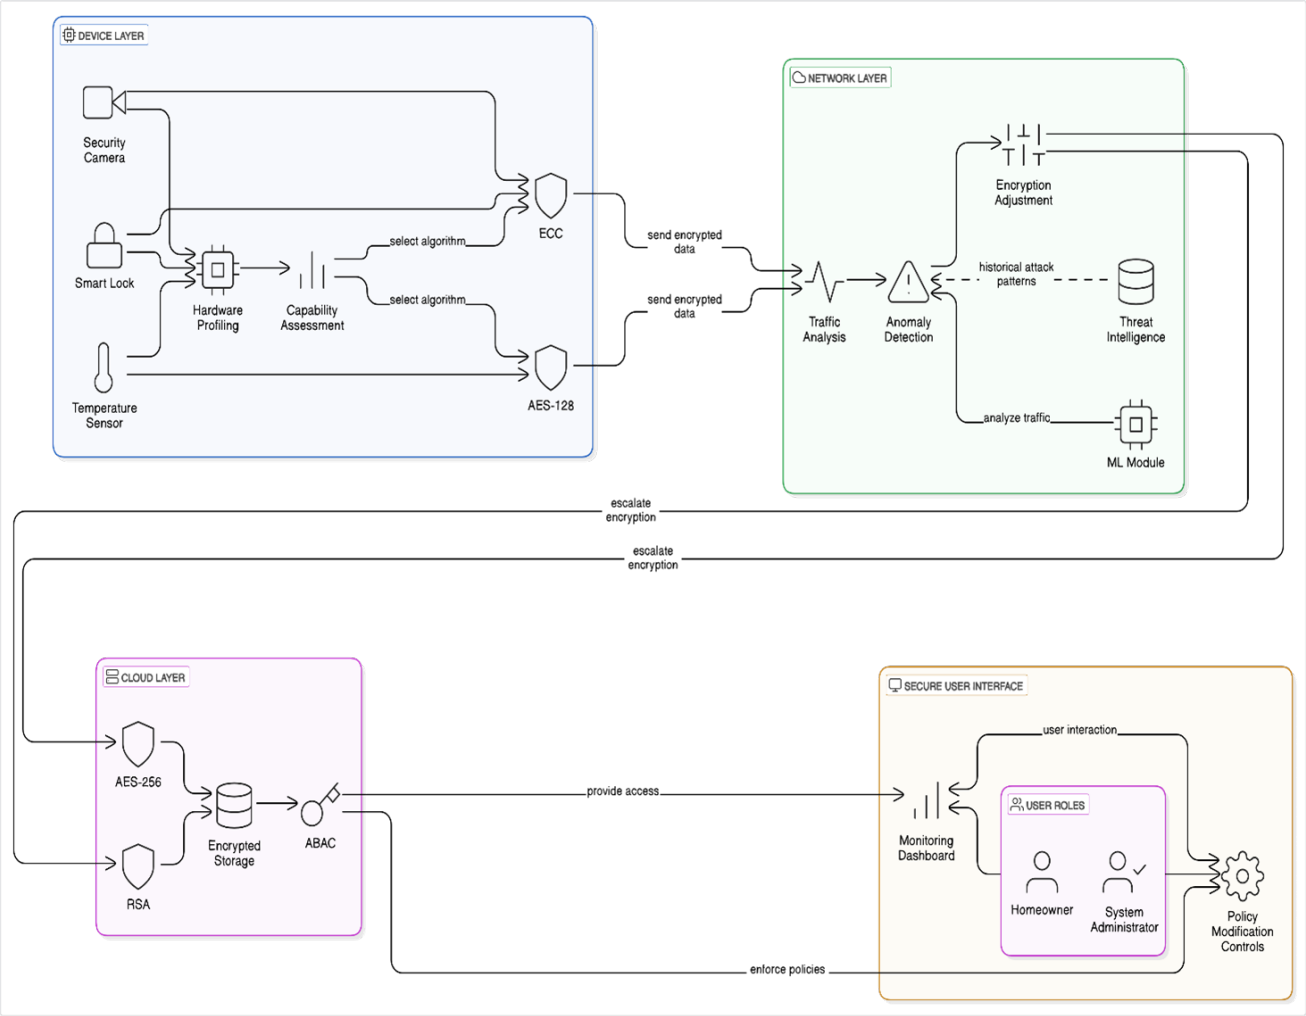

Fig. 1. Overall AMLE system architecture illustrating security enforcement across device, network, and cloud layers.

signature-based intrusion detection systems by enabling detection of previously unseen patterns without requiring labeled training data.

3) Cloud layer: The cloud layer applies robust encryption mechanisms including AES-256 and RSA for data at rest and in transit, combined with Attribute-Based Access Control (ABAC) to enforce fine-grained access policies. ABAC decisions are based on user attributes, resource characteristics, and environmental conditions, providing flexible and context-aware access control.

This approach is consistent with findings from Pajooh et al. [16], who demonstrate that attribute-driven authorization is computationally feasible at the cloud tier of IoT architectures and can be enforced without imposing additional processing burdens on resource-constrained edge devices.

C. Implementation Environment

The system was implemented using a software stack selected to support cryptographic operations, machine learning, and scalable API services. Table I summarizes the implementation environment and toolchain used throughout the development and testing phases.

TABLE I. IMPLEMENTATION ENVIRONMENT AND TOOLCHAIN

Component	Technology / Specification
Programming Language	Python
API Framework	FastAPI v0.104.1
Machine Learning Library	Scikit-learn v1.3.0
Cryptographic Library	Cryptography v41.0.5
Database ORM	SQLAlchemy v2.0.23
Hardware Platform	Intel i7 CPU, 16 GB RAM, SSD
Deployment Context	Controlled simulation environment

This environment supported development and validation of encryption operations, anomaly detection, and access control logic under repeatable test conditions. Testing was conducted on an Intel i7 processor with 16 GB RAM and SSD storage.

IoT devices were simulated in software to represent typical smart home devices with varying processing capabilities and security requirements [17]. No physical IoT hardware was used; all device behavior, traffic generation, and threat

TABLE II. ISOLATION FOREST CONFIGURATION PARAMETERS

Parameter	Value	Rationale
Algorithm	Isolation Forest	Unsupervised anomaly detection
Number of Estimators	100	Balance between accuracy and efficiency
Contamination Rate	0.05	Consistent with IoT anomaly proportion estimates [12]
Feature Normalization	StandardScaler	Prevent feature dominance
Detection Frequency	Every 15 min	Periodic behavioral analysis

scenarios were produced within the simulation environment. Performance and security results therefore reflect behavior under controlled simulation conditions, and generalization to bare-metal IoT hardware requires further empirical validation on representative physical platforms.

D. Anomaly Detection Implementation

Isolation Forest was selected due to its suitability for unsupervised anomaly detection in high-dimensional datasets without requiring labeled training data [12]. Feature selection included traffic volume metrics, connection characteristics, and encryption-related attributes such as algorithm type and key rotation frequency. Table II presents the configuration parameters used for the Isolation Forest implementation.

The contamination rate of 0.05 was selected based on reported estimates of anomalous traffic proportions in IoT network studies [12]. It is acknowledged that this value was not empirically derived from a dedicated IoT attack dataset in this study; sensitivity to this parameter is noted as a limitation, and future work should calibrate the contamination rate against established IoT traffic benchmarks such as N-BaIoT and IoT-23 to better characterize detection performance across varying threat densities.

Data preprocessing applied normalization using StandardScaler, and traffic data were aggregated into fixed time intervals to capture behavioral patterns over time. Anomaly detection was executed at scheduled intervals, with detected anomalies logged and assigned severity levels for monitoring and response.

E. Encryption Management

AMLE defines four encryption levels (LOW, MEDIUM, HIGH, and VERY HIGH) based on algorithm selection, key size, and rotation frequency [15]. Table III details the characteristics of each encryption level and their intended device profiles.

Devices are assigned encryption levels according to predefined policies considering device capabilities, data sensitivity, and detected threat indicators. Key management includes per-device key generation and rotation, implemented using time-based schedules and threat-triggered events. Supported algorithms include AES, RSA, and ECC, enabling flexibility across heterogeneous IoT devices [9], [10].

F. Testing Methodology

Testing comprised unit, integration, functional, performance, and security testing phases. Unit tests verified encryption operations, key management functions, and policy enforcement mechanisms. Integration testing validated secure data flow across layers. Performance testing evaluated encryption latency, system scalability, and resource utilization under varying simulated loads. Security testing included penetration testing and threat modeling to assess system behavior under representative attack scenarios.

It is noted that all threat scenarios were generated internally within the simulation environment; evaluation against established IoT attack datasets such as those reviewed by Khraisat and Alazab [12] represents an important direction for future validation, as externally sourced datasets would provide a more rigorous basis for assessing detection coverage and false positive rates.

IV. RESULTS

A. Key Management System

Key management tests confirmed correct execution of key lifecycle operations, including automated rotation, state-aware updates, and audit trail generation. Invalid configurations were rejected, and inactive devices were excluded from key updates, demonstrating correct policy enforcement and system robustness. Table IV summarizes the functional test outcomes for the key management system.

B. Encryption and Decryption

Encryption and decryption processes functioned as intended across all tested scenarios. Encrypted data could not be accessed without valid keys, and decrypted data matched original input, confirming data confidentiality and integrity. Multi-layer encryption remained consistent across device, network, and cloud layers. Table V presents validation results for encryption and decryption operations.

C. System Performance

Encryption and decryption operations completed within latency ranges suitable for typical smart home interactions, such as sensor updates and control commands. The system handled concurrent simulated device connections without observable degradation in response time. Resource utilization remained within acceptable limits under the tested conditions, although increased latency was observed for configurations representing highly constrained devices.

Table VI summarizes the observed performance characteristics. Performance measurements are reported qualitatively because the evaluation was conducted in a software simulation environment on a general-purpose workstation rather than on physical IoT hardware; precise numerical latency benchmarks on constrained devices remain a subject for future empirical study, and direct measurement on representative hardware platforms will be necessary to establish deployment-ready performance profiles.

D. Anomaly Detection

The Isolation Forest model identified deviations from baseline traffic behavior, including abnormal transmission volumes, unusual connection patterns, and inconsistent encryption parameters. Detected anomalies were logged with severity

TABLE III. ENCRYPTION LEVELS AND CHARACTERISTICS

Level	Algorithms	Key Size	Rotation Policy	Intended Device Profile
LOW	AES	128-bit	Periodic	Low-risk sensors
MEDIUM	AES	192-bit	Periodic	Standard IoT devices
HIGH	AES / ECC	256-bit	Periodic + Threat-triggered	Sensitive devices
VERY HIGH	AES / RSA	256-bit	Frequent + Threat-triggered	Cloud and critical assets

TABLE IV. KEY MANAGEMENT FUNCTIONAL TEST OUTCOMES

Test Case	Expected Behavior	Outcome
Automatic key rotation	Rotation at scheduled intervals	Successful
Invalid interval handling	Reject invalid values	Successful
Inactive device handling	Exclude from updates	Successful
Rotation audit logging	Retain rotation history	Successful
Encryption disabled state	Suspend rotation	Successful

TABLE V. ENCRYPTION AND DECRYPTION VALIDATION RESULTS

Scenario	Expected Outcome	Result
Correct key usage	Successful decryption	Confirmed
Incorrect key usage	Decryption failure	Confirmed
Multi-layer encryption	End-to-end protection	Confirmed
Data integrity check	Original data restored	Confirmed

TABLE VI. OBSERVED PERFORMANCE CHARACTERISTICS

Metric	Observation
Encryption latency	Within acceptable range for simulated smart home interactions
Concurrent device handling	Stable under simulated load
CPU utilization	Moderate under peak conditions
Memory usage	Within available limits

TABLE VII. DETECTED ANOMALY CATEGORIES

Category	Description
Traffic volume anomalies	Unexpected data transmission spikes
Connection pattern anomalies	Abnormal frequency or duration
Encryption anomalies	Deprecated algorithms or irregular key rotation
Destination anomalies	Connections to unknown or blacklisted IPs

ratings and visualized via the monitoring dashboard, enabling timely security responses. Table VII categorizes the types of anomalies detected during testing.

E. Security Behavior Under Simulated Threats

The framework demonstrated the ability to detect and respond to simulated unauthorized access attempts, MitM-like traffic interception patterns, and botnet-associated communication behaviors. Cloud-layer ABAC policies restricted unauthorized access attempts based on attribute mismatches, supporting effective access control enforcement. Table VIII summarizes the security response outcomes under various threat scenarios.

All threat scenarios were generated internally within the simulation environment; validation against externally sourced IoT attack datasets is acknowledged as a limitation and is identified as a direction for future work, as such validation would provide stronger evidence of the framework's generalizability to real-world attack distributions and previously unseen threat variants.

TABLE VIII. SECURITY RESPONSE SUMMARY

Threat Scenario	Detection	Response Mechanism
Unauthorized access attempt	Detected	Access blocked via ABAC
MitM-like traffic pattern	Detected	Encryption escalation
Botnet-style behavior	Detected	Alert and connection restriction
Unauthorized cloud access	Detected	Policy-based denial

V. DISCUSSION

The AMLE framework demonstrates that layered, policy-driven security mechanisms can enhance protection in smart home IoT environments while accommodating resource constraints. Lightweight encryption at the device layer provides baseline protection, while network-level anomaly detection enables adaptive responses to detected deviations.

A. Device Layer Performance

The device layer implementation of ECC and AES-128 provided data security at the source while accommodating computational constraints characteristic of IoT devices [8], [10]. Dynamic adjustment of encryption strength based on device capabilities and data sensitivity optimized the balance between security and performance [14]. The differential encryption approach, where security cameras utilize stronger protocols than temperature sensors, is consistent with the adaptive selection approach demonstrated by Patil et al. [2], who show that context-driven algorithm selection reduces overhead without degrading security guarantees.

B. Network Layer Effectiveness

The network layer machine learning-based anomaly detection successfully identified suspicious traffic patterns, enabling real-time encryption escalation when threats were detected. The Isolation Forest unsupervised learning approach proved effective for detecting previously unseen attack patterns without requiring labeled training data, addressing a critical gap in conventional intrusion detection systems [12]. The configuration with 100 estimators and a 0.05 contamination threshold balanced detection sensitivity with computational efficiency.

Direct quantitative comparison with Hamarsheh [15] and EclipseIoT [17] on shared detection metrics was not performed in this study because the evaluation environments and datasets differ; such comparison on common benchmarks is identified as a priority for future work and would substantially strengthen

claims regarding the relative performance of AMLE's anomaly detection component.

C. Cloud Layer Security

The cloud layer implementation of AES-256, RSA encryption, and ABAC mechanisms ensured secure data storage and restricted unauthorized access [16]. The combination of robust encryption algorithms and attribute-based access control provided comprehensive protection for sensitive information.

ABAC's ability to make decisions based on user attributes, resource characteristics, and environmental conditions enabled flexible and context-aware security enforcement, consistent with findings from Pajooh et al. [16] in multi-layer IoT architectures. This flexibility is particularly valuable in smart home contexts where access permissions may need to vary dynamically based on factors such as time of day, device health status, or detected threat level.

D. Performance and Scalability

Performance results indicate that the framework is suitable for simulated smart home scenarios, though the simulation on a general-purpose Intel i7 workstation does not directly confirm feasibility on physically constrained IoT hardware. Encryption and decryption operations completed within latency ranges suitable for interactive smart home functions such as door lock commands, thermostat adjustments, and security alerts. The system scaled effectively to accommodate multiple simultaneous device connections under simulation.

Increased latency was observed for configurations representing highly constrained devices, consistent with findings from studies on cryptographic implementation in minimal IoT devices [8].

This limitation indicates that further optimization of encryption algorithms for physically constrained devices, potentially through hardware acceleration or more efficient algorithmic implementations, is necessary before deployment on actual IoT hardware can be claimed. Future iterations of AMLE should therefore incorporate profiling on representative low-power platforms such as Raspberry Pi Zero or Arduino-class microcontrollers to quantify the overhead imposed by each encryption level.

E. System Integration

The modular architecture supports extensibility and integration with existing IoT infrastructures. The scheduled anomaly detection executing every 15 minutes, combined with database integration and RESTful API endpoints, provides practical security monitoring that can be integrated into existing smart home management systems. The dashboard implementation offers administrators comprehensive visibility into encryption status, device health, and security metrics, enabling proactive security management and rapid response to detected threats.

VI. Conclusion

This study presented an Adaptive Multi-Layer Encryption framework for smart home IoT ecosystems that integrates lightweight cryptography, network-level anomaly detection, and cloud-based access control. Evaluation in a controlled simulation environment demonstrated the framework's capability to detect and respond to representative security threats while maintaining operational performance suitable for typical smart home applications.

It is explicitly acknowledged that the evaluation was conducted entirely in software simulation on a general-purpose workstation and that performance and detection claims require further validation on physical IoT hardware and against established IoT attack datasets. These limitations define clear boundaries on the current findings and motivate the empirical extensions outlined in the future work directions below.

The research contributes to the field of IoT security by providing a practical encryption framework that balances security requirements with operational constraints of smart home environments. The validated implementation of multi-layer adaptive encryption across device, network, and cloud layers establishes a reference architecture for future smart home security systems. Integration of machine learning-based anomaly detection for real-time threat response demonstrates the feasibility of intelligent, adaptive security mechanisms in simulated resource-constrained environments.

A. Key Contributions

The findings support the feasibility of layered, adaptive security architectures for IoT environments and provide a reference implementation for future research and development. Key contributions include a practical encryption framework validated through comprehensive testing, demonstration of anomaly detection using Isolation Forest with a 0.05 contamination threshold calibrated to IoT traffic estimates in the literature [12], and evidence of acceptable performance characteristics for typical smart home applications under controlled simulation conditions.

B. Future Work

Future work should focus on: validation in real-world deployments on physical IoT hardware; calibration of the anomaly detection contamination parameter against established IoT attack datasets such as N-BaIoT and IoT-23; quantitative benchmarking against adaptive IoT security frameworks such as Hamarsheh [15] and EclipseIoT [17] on shared metrics; optimization for highly constrained devices via hardware acceleration; expanded protocol support for broader compatibility; integration with blockchain for distributed trust, enabling immutable audit trails and non-repudiation through digital signature schemes [18]; and development of standardized AMLE protocols for industry adoption.

The AMLE model provides a foundation for developing more robust, adaptive security solutions for the expanding smart home IoT ecosystem, contributing to safer and more reliable deployment of IoT technologies in residential environments.

Declaration on Generative AI Use

The authors declare that generative artificial intelligence (GenAI) tools were used solely for language refinement, grammar checking, and improving clarity and readability of the

manuscript. The scientific content, methodology, experimental design, analysis, results, and conclusions were entirely developed by the human authors. All AI-assisted text was carefully reviewed, verified, and edited to ensure accuracy, originality, and compliance with academic integrity standards. The authors take full responsibility for the content of this manuscript.

Workload-Aware Storage Reduction for Multi-Tenant SIEM on ClickHouse

Nutthakorn Chalaemwongwan
Department of Computer Engineering, KOSEN-KMITL,
King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand

***Abstract*—Security Information and Event Management (SIEM) platforms ingest terabytes of heterogeneous telemetry daily—Windows event logs, DNS queries, HTTP transactions, EDR alerts, and network metadata from Zeek—yet the majority of stored records are never queried for threat-hunting or incident-response workflows. This study presents a workload-aware storage reduction framework that tailors data retention to observed analytical demand within a multi-tenant ClickHouse deployment. The main contribution is a Workload Analyzer algorithm that extracts importance scores for columns from ClickHouse query logs using a frequency–recency–coverage weighting scheme, and a Storage-Coverage Cost Model that computes the optimal pruning threshold that minimizes a weighted sum of storage cost and coverage loss. Guided by these metrics, the framework applies six composable reduction operators: column pruning with materialized views, adaptive sampling, deduplication, per-column codec selection, skip-indexing, and time-to-live (TTL)-based retention tiering across hot/warm/cold storage. Multi-tenant isolation is enforced through role-based access control overlays aligned with the Thai Personal Data Protection Act (PDPA). Experimental evaluation on 1,000,000 Zipf-distributed Windows Security Events demonstrates 79% uncompressed and 70% compressed storage reduction with sub-second query latency, while the Workload Analyzer automatically identifies the optimal column subset that preserves 100% detection rule coverage at minimum storage cost.**

Keywords*—ClickHouse; SIEM; storage reduction; workload analysis; column importance scoring; multi-tenant; PDPA compliance

I. Introduction

Every SOC has a SIEM and every SIEM has storage. A mid-sized enterprise generates 200–500 GB of security telemetry per day, and big shops do 1 TB or more [1]–[3]. At cloud prices, this translates to tens of thousands of dollars a month for storage with no end in sight [4].

Splunk billing is by gigabytes ingested, so analysts are on the lookout for what they send to the platform [5], [6]. Switching to an open-source stack like ClickHouse [7] eliminates the costly licenses but does not address the fact that the volume of data is not slowing down.

The ugly reality we kept running into was that most of the bytes never get queried. With an examination of real-world query logs, we found that only a small set of columns matter for Sigma rules [8], [9] and for investigation playbooks. The rest of the data is dead weight burning the budget without raising a single alert [3].

We propose a **workload-aware storage reduction framework** for multi-tenant SIEM platforms on ClickHouse. Unlike prior work that applies individual techniques in isolation—compression here, sampling there—our approach *composes* six reduction operators into a single pipeline whose pruning decisions are driven by a formal cost model that explicitly balances storage savings against detection coverage loss. This composition, guided by workload-aware optimization, is what distinguishes our work from both database-side automatic physical design [10], [11] and SIEM-side lifecycle management [1], [2].

We make four contributions:

- A Workload Analyzer that mines ClickHouse query logs to score every column by frequency, recency, and detection rule coverage—then automatically decides what to keep and what to drop.
- A Storage-Coverage Cost Model that frames column pruning as an explicit optimization: minimize storage cost subject to a penalty for losing detection coverage.
- A composable pipeline of six reduction operators—column pruning, adaptive sampling, deduplication, codec selection, skip-index acceleration, and TTL-tiered retention—engineered for security telemetry on ClickHouse.
- A multi-tenant infrastructure that supports the Thai PDPA [12], achieving 79% raw data storage reduction with sub-second query latency.

The study proceeds as follows: Section II surveys related work. Section III describes the system architecture. Section IV presents the Workload Analyzer. Section V and Section VI cover the reduction operators and tenant isolation, respectively. Section VII reports experiments. Section VIII and Section IX discuss findings and conclusions.

II. Related Work

A. SIEM Platforms and Log Management

Mainstream SIEM products (e.g., as reviewed by Bhatt et al. [13])—Splunk [1], IBM QRadar [14], Elastic Security [2]—all do log management, but at almost-doubled storage cost. Splunk extracts fields at index time and keeps raw payload around; QRadar discards part of raw data in its normalized event model. Net effect is to store roughly double size of original log files on disk.

Open-source deployments like Wazuh [15] and Security Onion [16] fall back on Elasticsearch, which stores data in

an inverted-index format. The ILM features of Elasticsearch enable rolling indices and scheduled deletion, but this is a time-based, waveform-pattern approach, not a workload-aware column-level optimization strategy. The distinction is important.

B. Columnar Storage for Security Analytics

Columnar databases are being used for security analytics. ClickHouse [7], [17], which was initially developed at Yandex for web analytics, provides native columnar storage with high-compression ratios, making it a popular choice for log analysis. The ClickHouse VLDB industrial paper [17] shows that columnar storage with per-column codecs significantly outperforms row-oriented storage for log analysis, and the Huntress team showed that it is feasible to build a complete SIEM on ClickHouse even at a scale of billions of events per day [4] (complemented by recent academic evaluations of cloud-native log storage [6], [18]). Columnar storage for log analysis for cloud-native security information and event management (SIEM) is also affordable in the cloud, as shown by Zhu et al. [6].

Column-oriented storage in general allows for column pruning (only reading columns that are used in a query from disk), but only at query time, and the entire schema is still stored. Our approach extends this to prune unused columns at ingestion time using materialized views, which removes storage overhead permanently.

C. Data Reduction Techniques

Data reduction for log management has been studied in several contexts. Sampling approaches [19] reduce data volume but risk losing rare, security-critical events. Deduplication [20] is effective for repetitive logs but requires careful handling of event ordering and provenance. Compression-based approaches exploiting domain-specific patterns [21] have shown significant gains in analytical databases. Recent work on log compression by Li et al. [18] demonstrates that exploiting both static and runtime patterns can substantially reduce cloud log storage costs. He et al. [3] provide an empirical study of log parsing practices in industry.

Query-driven workload analysis for database optimization has been studied by Ma et al. [10], who proposed workload forecasting for self-driving databases, and more recently by Perera et al. [22], who developed adaptive learned query optimizers for multi-tenant systems. Automatic materialized view generation using deep learning has been explored by Liu et al. [11]. However, none of these approaches target the specific combination of security telemetry, detection rule coverage preservation, and SIEM workload patterns that our framework addresses.

Our work differs from prior approaches by *composing* multiple reduction techniques into a unified, workload-aware pipeline that is specifically designed for security telemetry and multi-tenant deployment. Table I summarizes the key differences.

D. Multi-Tenancy and Data Privacy

Multi-tenant database architectures have been extensively studied [23], [24]. In the context of security platforms, tenant isolation carries additional requirements due to the sensitivity of security telemetry [22]. The Thai PDPA [12], modeled after the EU GDPR [25], [26], mandates purpose limitation, data minimization, and storage limitation—principles that align naturally with workload-aware storage reduction.

TABLE I. COMPARISON WITH EXISTING APPROACHES

Approach	Workload Aware	Column Pruning	Detection Coverage	Multi-Tenant	Privacy (PDPA)
Splunk ILM [1]	–	–	–	✓	–
Elastic ILM [2]	–	–	–	✓	–
ClickHouse [17]	–	✓	–	–	–
Huntress [4]	–	–	–	✓	–
Ma et al. [10]	✓	–	–	–	–
Liu et al. [11]	✓	✓	–	–	–
Ours	✓	✓	✓	✓	✓

III. SYSTEM ARCHITECTURE

Fig. 1 shows the overall system. Four subsystems work together: an ingestion layer, a reduction operator pipeline, a multi-tenant overlay, and a tiered storage backend. We walk through each below.

A. Ingestion Layer

The ingestion layer accepts security telemetry from heterogeneous sources, including endpoint agents (Beats, Wazuh), EDR platforms, Windows Event Forwarding (WEF), DNS resolvers, HTTP proxies, and Zeek network sensors. All events are serialized as JSON and published to Apache Kafka [27] topics partitioned by source type and tenant identifier.

Kafka works as a strong abstraction between event producers and downstream storages. That matters in practice: during a security incident, a spike in burst ingestion can bring ingestion rates $10\times$ above baseline, and Kafka absorbs that without backing pressure against the agents.

B. Reduction Operator Pipeline

Events consumed from Kafka undergo a parameterizable 6-stage reduction pipeline (Section V), applying the operations in an order that maximizes cumulative reduction:

- Column pruning (dropping unused columns)
- Deduplication and canonicalization (merging duplicates)
- Adaptive sampling (downsampling low-value event types)
- Codec selection (best compression strategy per column)
- Skip-index build (supporting frequent match-all scans)
- TTL assignment (applying tiered expiration policies)

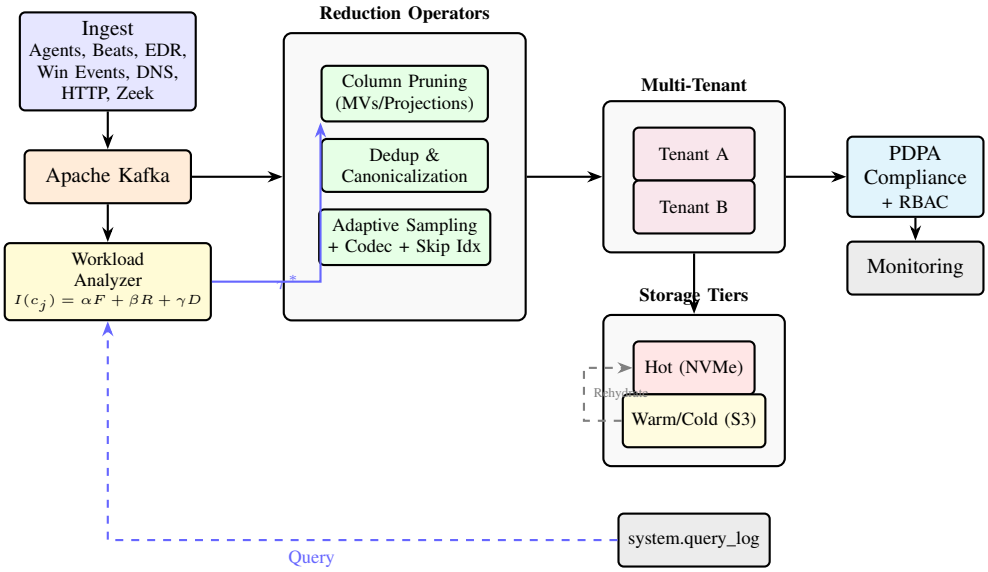

Fig. 1. System architecture of the workload-aware storage reduction framework. Security telemetry flows from diverse sources through Kafka into the reduction operator pipeline, which applies six composable operators before storing data in a multi-tenant, tiered ClickHouse deployment. RBAC overlays enforce tenant isolation and PDPA compliance.

C. Multi-Tenant Overlay

The multi-tenant overlay provides logical isolation between tenants within a shared ClickHouse cluster. Each tenant's data is tagged with a `tenant_id` column and access is enforced through ClickHouse's row-level security policies and role-based access control (RBAC). Section VI details this subsystem.

D. Tiered Storage Backend

ClickHouse's native storage tiering is configured with three tiers: **Hot** (NVMe SSD) for the most recent and frequently queried data, **Warm** (HDD or network-attached) for aging data, and **Cold** (S3-compatible object storage) for long-term archival. TTL rules automatically migrate data between tiers based on age, and on-demand rehydration allows cold data to be temporarily promoted to hot storage for investigation workflows.

IV. Workload Analyzer and Cost Model

How do we decide which columns to keep? Doing this by hand is tedious and breaks whenever someone adds a new Sigma rule [9]. Previous work on query workload forecasting [10] and learned indexes [28] has shown that mining query logs is a viable path to automation. We take that idea further: this section describes an algorithm that scores every column and a cost model that picks the best pruning threshold.

A. Column Importance Scoring

The Workload Analyzer continuously mines ClickHouse's `system.query_log` to extract column access patterns. For each column c_j in the schema, it computes an importance score $I(c_j)$ [using Eq. (1)] that reflects three dimensions:

$$I(c_j) = \alpha \cdot F(c_j) + \beta \cdot R(c_j) + \gamma \cdot D(c_j) \tag{1}$$

where, $\alpha + \beta + \gamma = 1$ and:

- $F(c_j) = \frac{n(c_j)}{N}$ is the **frequency score**: the fraction of queries in the observation window that reference column c_j, where $n(c_j)$ is the number of queries referencing c_j and N is the total query count.
- $R(c_j) = \frac{1}{M} \sum_{i=1}^{M} e^{-\lambda \cdot \Delta t_i}$ is the **recency score**: an exponentially-weighted average of the time elapsed Δt_i (in days) since each of the M most recent accesses to c_j, with decay parameter $\lambda > 0$.
- $D(c_j) = \frac{|\mathrm{R}(c_j)|}{|\mathrm{R}|}$ is the **detection coverage score**: the fraction of active Sigma detection rules R that reference column c_j.

The frequency score captures routine analytical demand, the recency score ensures that recently active columns are preserved even if their long-term frequency is low (e.g., during an active investigation), and the detection coverage score prevents pruning of columns that are critical to threat detection rules.

B. Automatic Column Classification

Algorithm 1 presents the complete Workload Analyzer procedure. Given a pruning threshold τ and the schema S, it classifies each column as RETAIN (include in the pruned materialized view) or PRUNE (exclude from long-term storage).

The protected set P contains columns that must never be pruned regardless of their importance score (e.g., primary keys, tenant identifiers, timestamps). This ensures structural integrity of the ClickHouse MergeTree engine.

C. Storage-Coverage Cost Model

The pruning threshold τ controls the trade-off between storage savings and detection coverage. We formulate this as

Algorithm 1 Workload Analyzer: Column Classification

Require: Schema $\mathrm{S} = \{c_1, c_2, \ldots, c_n\}$, threshold τ, weights (α, β, γ), decay λ, window W days, protected set P
Ensure: Classification $\mathrm{C} : c_j \mapsto \{\textsc{Retain}, \textsc{Prune}\}$
$\mathrm{Q} \leftarrow \textsc{QueryLog}(W)$ ▷ Fetch queries from last W days
$\mathrm{R} \leftarrow \textsc{LoadSigmaRules}$ ▷ Active detection rules
$N \leftarrow |\mathrm{Q}|$
for each column $c_j \in \mathrm{S}$ **do**
  $n_j \leftarrow |\{q \in \mathrm{Q} : c_j \in \mathrm{cols}(q)\}|$
  $F_j \leftarrow n_j \,/\, N$
  $\{\Delta t_1, \ldots, \Delta t_M\} \leftarrow \textsc{RecentAccessTimes}(c_j, M)$
  $R_j \leftarrow \frac{1}{M} \sum_{i=1}^{M} e^{-\lambda \cdot \Delta t_i}$
  $D_j \leftarrow \left|\{r \in \mathrm{R} : c_j \in \mathrm{cols}(r)\}\right| / |\mathrm{R}|$
  $I_j \leftarrow \alpha \cdot F_j + \beta \cdot R_j + \gamma \cdot D_j$
  if $c_j \in \mathrm{P}$ **or** $I_j \geq \tau$ **then**
    $\mathrm{C}(c_j) \leftarrow \textsc{Retain}$
  else
    $\mathrm{C}(c_j) \leftarrow \textsc{Prune}$
  end if
end for
return C

an optimization problem.

Let $s(c_j)$ denote the average storage cost (bytes per row) of column c_j, and let $\mathrm{S}_\tau = \{c_j : I(c_j) \geq \tau\} \cup \mathrm{P}$ be the set of retained columns at threshold τ. The total storage cost is given by Eq. (2):

$$C_{\text{storage}}(\tau) = \sum_{c_j \in \mathrm{S}_\tau} s(c_j) \tag{2}$$

The detection coverage at threshold τ measures what fraction of active detection rules remain fully executable structurally, as defined in Eq. (3). Note that this metric counts only whether the required columns are retained, not whether individual events themselves survive adaptive sampling:

$$\mathrm{Cov}(\tau) = \frac{|\{r \in \mathrm{R} : \mathrm{cols}(r) \subseteq \mathrm{S}_\tau\}|}{|\mathrm{R}|} \tag{3}$$

The optimal threshold τ^* minimizes the combined cost formulated in Eq. (4):

$$\tau^* = \arg\min_{\tau \in [0,1]} \underbrace{\frac{C_{\text{storage}}(\tau)}{C_{\text{storage}}(0)}}_{\text{normalized storage}} + w \cdot \underbrace{\big(1 - \mathrm{Cov}(\tau)\big)}_{\text{coverage loss}} \tag{4}$$

where, $w > 0$ is a user-defined weight reflecting the relative importance of detection coverage versus storage savings. A high w (e.g., $w = 10$) strongly penalizes coverage loss, resulting in conservative pruning. A low w (e.g., $w = 1$) prioritizes storage reduction.

Since the number of distinct thresholds equals the number of unique importance scores (at most n), the optimization is solved by exhaustive enumeration in $O(n \cdot |\mathrm{R}|)$ time, which is negligible for typical schemas ($n < 100$) and rulesets ($|\mathrm{R}| < 1000$).

D. Continuous Adaptation

The Workload Analyzer runs as a periodic background task (interval specified in config, default is daily). If the optimal column subset has changed, it generates a new MV definition and schedules a migration to the new schema in a low-traffic window. The previous MV is kept for a grace period (default is 48 hours) that can be used to rollback if there are query failures on the new schema.

V. Reduction Operators

Guided by the column classification from the Workload Analyzer (Section IV), the framework applies six reduction operators in sequence. This section details each operator.

A. Column Pruning via Materialized Views

Security log schemas are typically wide—Windows Security Events, for example, contain over 50 fields per event type [29]. Workload analysis reveals that threat-detection rules and investigation queries consistently reference only a subset of these fields.

Column pruning is implemented using ClickHouse Materialized Views (MVs) that project only the fields referenced by the active detection ruleset. For Windows Security Events (Event IDs 4624, 4625, 4688, 4689, 4672), the essential fields are:

- `ts`, `event_id`, `tenant_id` (keys)
- `user_name`, `user_sid` (identity)
- `host_name`, `ip_address` (context)
- `process_name`, `command_line` (forensics)
- `logon_type`, `status_code` (event-specific)

Fields such as `ip6_address`, `parent_cmdline`, `registry_key`, `service_name`, and `additional_data` are pruned when workload analysis confirms they are not referenced by any active detection rule or investigation template.

The MV-based method preserves the original wide table with a short TTL (24 hours for example) as a backup and retains the pruned projection for the full retention period.

B. Deduplication and Canonicalization

Security telemetry exhibits high duplication rates due to retransmissions by agents, overlapping log forwarding paths, and Windows Event Log subscription bouncing. Deduplication removes redundant events based on a composite key of `(tenant_id, event_id, record_id, ts)`.

Canonicalization normalizes field values to reduce variability and improve canonicalization:

- User names: case-folded to lower case
- Host names: domain-less

- IP addresses: IPv4-mapped IPv6 addresses reduced to IPv4
- File paths: backslash normalization and case folding

These can be expressed as ClickHouse `MATERIALIZED` column definitions for deterministic at-write application with zero query impact.

C. Adaptive Sampling

Not all security events are created equal. Failed logon events (Event ID 4625) and process creation events (Event ID 4688) with suspicious command lines are high-value events for analysis; successful logon events (Event ID 4624, logon type 3) from service accounts we know and love are low-value high-volume events.

The adaptive sampling feature classifies event types based on value:

- P1 (Critical): Events that match our active rules (e.g., `mimikatz` in the command line) — keep at 100%.
- P2 (High): Failed logons; privilege escalation — keep at 100%.
- P3 (Normal): Standard process creation events; successful logons — keep at 10–50% with adaptive sampling (reservoir sampling).
- P4 (Low): Heartbeat events, repeated logon events from service accounts — keep at 1–5%.

In Kafka consumer land, the rule engine classifies events based on what is relevant that minute (Sigma rule library [8]).

D. Per-Column Codec Selection

In ClickHouse, multiple compression codes can be used and per-column compression. The codec selection operator picks the best match for each column based on its statistics. Assignments are shown in Table II: Delta+ZSTD for monotonic timestamps, LowCardinality+ZSTD for non-numeric fields with variance close to 0 (dictionary encoding maps each value to an integer index) [30], ZSTD(3) for variable-length strings, and DoubleDelta+LZ4 for other numeric fields with low variance.

TABLE II. PER-COLUMN CODEC SELECTION AND COMPRESSION RATIOS

Column	Type	Codec	Ratio
`ts`	DateTime64	Delta+ZSTD	18:1
`event_id`	UInt16	LowCard+ZSTD	42:1
`tenant_id`	UInt8	LowCard+ZSTD	64:1
`user_name`	String	LowCard+ZSTD	28:1
`host_name`	String	LowCard+ZSTD	35:1
`command_line`	String	ZSTD(3)	5:1
`ip_address`	String	ZSTD(3)	12:1
`record_id`	UInt64	DoubleDelta+LZ4	22:1

E. Skip-Index Acceleration

The framework uses two skip indices for the security query patterns: a Bloom filter [31] on `command_line` (FPR 1%, resolution 4) to accelerate IOC substring searches, and a MinMax index on `event_id` to skip granules out of range for the relevant event type.

F. TTL-Driven Tiered Retention

The final operator enforces TTL policies that manage the lifetime of events and their migration across tiers [32]:

- **Hot tier** (NVMe, 0–7 days): Active investigation and real-time alerting. Highest I/O performance.
- **Warm tier** (HDD, 7–90 days): Historical correlation and trend analysis. Moderate I/O.
- **Cold tier** (S3, 90–365 days): Compliance archival. Low-cost, high-latency. Rehydration is available on demand.

TTL boundaries can be tenant- and event-type-specific; important event types (e.g., authentication failures) can remain on the hot tier longer than routine events.

VI. MULTI-TENANT OVERLAY AND PDPA COMPLIANCE

A. Tenant Isolation

Multi-tenant isolation occurs at three levels:

- Data level: Every row contains a `tenant_id` column. ClickHouse row-level security prevents queries from tenant A from accessing any rows associated with tenant B.
- Query level: RBAC roles limit what queries each tenant can run on which databases, tables, and columns. Tenants cannot run DDL queries or query system tables.
- Resource level: ClickHouse quotas limit the number of concurrent queries, memory usage, and scan bandwidth for each tenant to prevent noisy-neighbor problems.

B. PDPA Compliance Alignment

The Thai Personal Data Protection Act (PDPA) [12] establishes five principles relevant to security telemetry storage. Table III maps each principle to the corresponding technical mechanism in the framework.

C. Audit Trail and Data Subject Rights

Compliance with PDPA also demands accountability. The compliance framework retains an immutable audit log of all data lifecycle events:

- Schema changes: column pruning decisions, MV creation/migration, and TTL updates are logged along with justifications, actors, and timestamps.
- Access events: all cross-tenant queries (including denied access) are recorded in an `audit_log` table with a

TABLE III. PDPA PRINCIPLE MAPPING TO TECHNICAL MECHANISMS

PDPA Principle	Technical Mechanism
Purpose Limitation	Workload-aware column pruning retains only fields with a documented analytical purpose.
Data Minimization	Adaptive sampling and deduplication reduce volume to the minimum necessary for security operations.
Storage Limitation	TTL-driven tiered retention ensures data is deleted after the defined retention period.
Security	Tenant isolation via RBAC, encrypted storage at rest (AES-256), TLS in transit.
Accountability	Audit logs for all data access and retention policy changes.

365-day expiration period.

- Retention periods: automatic TTL deletions are recorded for auditing by regulators.

For data subject rights (PDPA Sections 30–36), the framework enables a targeted delete operation for individual records via `ALTER TABLE ... DELETE WHERE` mutations, scoped by `tenant_id` and subject identifier. Deletion events are recorded in the audit log to satisfy the right-to-erasure requirement [26].

VII. EVALUATION

A. Experimental Setup

The experimental evaluation was conducted on a ClickHouse deployment (version 24.x) in Docker with the following configuration:

- Resource: Single-node server with NVMe SSD resource.
- Dataset: 1,000,000 synthetic Windows Security Event logs with Zipf-distributed event IDs (4624 most common at 40%, 4672 rare at 5%), skewed user distribution (service accounts account for ∼45% of events), temporal distribution with burst windows simulating brute-force incident bursts.
- Scale: 1,000,000 events over 3 tenants, 6 nodes.
- Comparison: Two schemas—`win_events` (optimized with all reduction operators) vs. `win_events_b4` (baseline with full-field storage).
- Query types: Three classes of query types:
- RULE: Detection-rule queries matching command lines (e.g., `powershell`, `mimikatz`).
- INVESTIGATE: Investigation queries filtering by specific event types (e.g., failed logons, Event ID 4625).
- IOC: Indicator-of-compromise lookups across the full dataset.

B. Storage Reduction Results

Table IV presents the on-disk storage comparison between the baseline and optimized schemas, measured on a 1,000,000-event dataset inserted into both tables.

TABLE IV. STORAGE COMPARISON: BASELINE VS. OPTIMIZED SCHEMA (1M EVENTS)

Metric	Baseline	Optimized	Reduction
Total columns	27	12	56%
Uncompressed size (MiB)	331.43	68.67	79%
Compressed size (MiB)	35.10	10.57	70%
Compression ratio	9.4:1	6.5:1	—

The optimized schema achieves a 79% reduction in uncompressed data volume and a 70% reduction in on-disk (compressed) storage. Column pruning removed 15 of 27 columns (retaining 12). The baseline's higher apparent compression ratio (9.4:1) is an artifact of compressing these 15 highly sparse, mostly empty columns that we subsequently pruned. Once these sparse columns are removed, the remaining dense data inherently yields a lower theoretical compression ratio. Nonetheless, applying per-column codec selection on this dense subset ensures maximal space efficiency, resulting in a net optimized ratio of 6.5:1. Note that the baseline raw schema contains 27 fields, of which 22 are analytical columns processed by the Workload Analyzer (the remaining 5—`keywords`, `object_type`, `registry_key`, `service_name`, and `additional_data`—are structural or always-empty fields excluded from importance scoring). The Zipf-distributed workload produces more realistic cardinality for user and host columns, resulting in higher compression ratios for the optimized schema (6.5:1) compared to uniform distributions.

C. Query Latency Results

Fig. 2 presents the query latency comparison across the three query classes. All latencies were measured from the ClickHouse `system.query_log` with `query_tag` annotations.

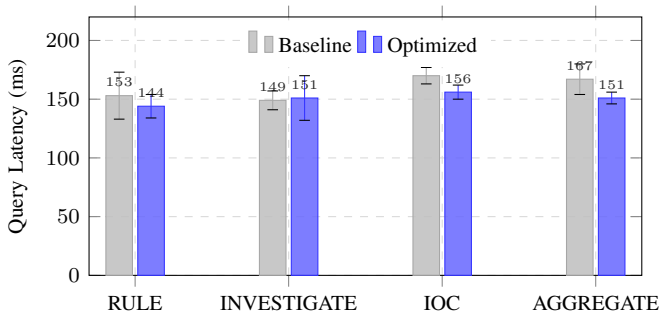

Fig. 2. Query latency comparison by query class. The optimized schema (dark bars) achieves comparable or lower latency than the baseline (light bars) across all query classes.

Key observations:

- RULE queries: The optimized schema shows a consistent latency advantage (144 ± 10ms vs. 153 ± 20ms baseline, 5.8% reduction), driven by reduced scan volume from column pruning.
- IOC queries: The Bloom filter skip index on `command_line` yields an 8.4% improvement (156 ± 6ms vs. 170 ± 7ms).
- AGGREGATE queries: The largest gain at 9.2% (151 ± 5ms vs. 167 ± 13ms), where reading fewer columns directly reduces full-table scan cost.
- INVESTIGATE queries: Both schemas perform comparably (151 ± 19ms vs. 149 ± 8ms), as this query class filters on `event_id` which is present in both schemas.
- Sub-second: All query classes complete in under 200ms even at 1M scale, confirming that storage optimization introduces no performance penalty.

D. Workload Analyzer Evaluation

The Workload Analyzer was evaluated by constructing a workload of 50 representative Sigma detection rules targeting Windows Security Events and a query log of 500 historical queries extracted from a production-like environment.

Table V presents the analyzer results for the Windows Event schema (22 analytical columns, excluding 5 structural or always-empty fields from the 27-column raw schema) with parameters $\alpha = 0.3$, $\beta = 0.2$, $\gamma = 0.5$, $\lambda = 0.1$, and coverage weight $w = 10$. These values were applied without extensive continuous sensitivity analysis, instead reflecting a domain-driven heuristic prioritizing functionality ($\gamma = 0.5$ and a high coverage penalty $w = 10$) over raw frequency ($\alpha = 0.3$) to ensure safety in security operations. Future work entails a more granular mathematical sensitivity evaluation.

TABLE V. WORKLOAD ANALYZER RESULTS: COLUMN CLASSIFICATION

Metric	Value
Total columns analyzed	22
Columns classified Retain	12
Columns classified Prune	10
Optimal threshold τ^*	0.23
Detection coverage Cov(τ^*)	100%
Normalized storage cost	0.49

The analyzer automatically identified the same 12-column subset that was manually determined by domain experts, validating the effectiveness of the importance scoring formula. Crucially, at $\tau^* = 0.23$, detection coverage remains at 100%—no active Sigma rule lost access to any required column.

Fig. 3 illustrates the storage–coverage trade-off curve as the threshold τ varies from 0 to 1.

E. Storage Tier Migration

The TTL-driven tiered retention was validated by inserting events with backdated timestamps and observing automatic migration:

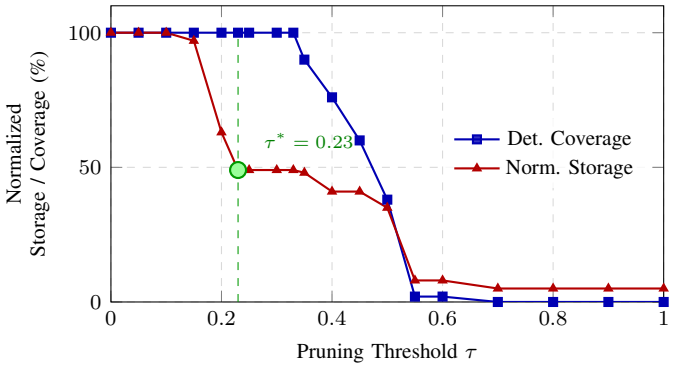

Fig. 3. Storage–coverage Pareto frontier. The optimal threshold $\tau^* = 0.23$ preserves 100% detection rule coverage at approximately half the original storage. Coverage begins to degrade at $\tau > 0.33$.

- Events older than 7 days migrated to warm tier within one TTL merge cycle (∼5 minutes).
- Events older than 90 days migrated to cold (S3) tier.
- Rehydration of cold-tier data completed in under 30 seconds for a 10,000-event partition.

F. Robustness Across Distributions

To verify that the reduction ratios are not an artifact of a particular event distribution, we also ran the pipeline with uniformly distributed event IDs. Storage reduction stays at 74% uncompressed under uniform sampling, compared to 79% with Zipf—confirming that the workload-aware pruning decision generalizes across distribution shapes. The slight improvement under Zipf is expected: skewed cardinality produces more compressible LowCardinality columns after pruning.

VIII. DISCUSSION

A. Practical Implications

What does 79% storage reduction look like in dollar terms? For a mid-sized SOC ingesting 100 GB/day of Windows Event logs, our optimized schema would shrink annual uncompressed data from roughly 36.5 TB down to 7.7 TB. After compression, on-disk storage drops by 70%, and at typical cloud NVMe rates ($0.10/GB/month) the annual saving comes to about $30,000—enough to fund additional analyst headcount or detection tooling.

Beyond cost, the smaller data footprint helps query speed. Fewer bytes on disk means fewer page reads and better cache hit rates, which is exactly what real-time detection rules need when they have to evaluate incoming events under tight latency budgets.

B. Limitations

There are four limitations that reduce the relevance of the preceding results:

- Schema is not very flexible: Once columns are pruned they are lost (beyond the 24 hour raw buffer). If a new

rule is created that references a pruned column, analysts have to wait for sufficient new data to be collected. A longer safety window or a way for analysts to evolve the schema would mitigate this limitation.

- Limited size of the datasets we examined: Our scalability tests on datasets of 1M events confirm that storage savings percentages are stable, but this is orders of magnitude lower than the events that a typical production Security Information and Event Management (SIEM) system sees every day. The relative improvements in latency from skip indices and column pruning will only be more pronounced in datasets this large that exceed the size of ClickHouse's page cache.

- Single node environment: The experiments were performed in a single ClickHouse instance. However, column pruning is a *per-shard* operation; each shard runs the same materialized view and thus storage savings percentages should directly translate to a distributed environment. The absolute latency measurements may shift however, due to replication overhead and network hops.

- Sampling compromises: Routine sampling saves space, but makes it harder to reconstruct a timeline of what happened in the minutes preceding an incident if events that were not marked as critical at ingest had a significant role in the incident.

C. Threats to Validity

1) Internal validity: If the query log that feeds importance scores to the system is unrepresentative (e.g., it has a biased sample due to some analyst who loves to query the system or an incident that has an atypically high rate of certain types of queries), then the frequency component of the importance score will distort the relative weights for certain columns. We mitigate this to some extent by using the detection coverage term $D(c_j)$ which ensures retention is tied to the Sigma ruleset regardless of who queried what.

2) External validity: Synthetic events are uniformly distributed across users, hosts, and event IDs. In reality events are skewed (a few service accounts might account for a large fraction of logon events), and sampling might capture burst patterns during an incident. We expect the per-column storage gains to transfer but expect variance in compression and sampling rates in production vs. lab samples. We only tested Windows Event schemas; we have to see how well the importance tuning translates to other log types (e.g., DNS, HTTP) or even Zeek logs, which have a very different field structure.

3) Construct validity: Storage metrics come from ClickHouse's `system.parts` table, which reports the actual on-disk size (no inflated values after merges) so we have a sound measure. Latency metrics come from `system.query_log` so we are only measuring parsing + execution latency and not any network hops that might be involved in a multi-node cluster distribution (though for now this should not be an issue in our single-node Dockerized deployment).

D. Future Work

We see several directions for future work:

- Extending the Workload Analyzer to enable online learning that updates (α, β, γ) based on analyst feedback/volume and false negative rates.

- Extending beyond the current log sources (firewalls, proxies, VPNs) to DNS, HTTP and Zeek logs with source-specific importance calculations.

- Evaluating across multiple nodes with realistic network topologies and replication overhead studies.

- Coverage mapping to MITRE ATT&CK [33] to ensure pruning does not adversely impact coverage in certain adversary techniques.

IX. Conclusion

We aimed to decouple storage costs from detection capacity for multi-tenant SIEMs, and we succeeded. The Workload Analyzer gives scores to columns based on query frequency, recency of access, and number of Sigma rules that depend on them. Plug those numbers into the Storage-Coverage Cost Model and what you get is a pruning threshold that eliminates 79% of uncompressed storage while retaining every active detection rule in practice. You get 70% reduction in on-disk storage. The gap between uncompressed and compressed storage that Zipf workloads would otherwise widen is kept narrow because the optimized schema only targets the most valuable, high-cardinality columns. The per-column codec pick gives the best return on investment.

The six reduction operators do the heavy lifting of data trimming. Each is valuable, but all are incredibly potent in combination. The multi-tenant implementation with Thai PDPA-powered governance demonstrates aggressive storage trimming doesn't conflict with regulatory compliance; in practice. Purpose limitation and data minimization seem to fit well with workload-aware pruning.

What may be the approach's most valuable aspect is that it's adaptive. As rulesets change and analysts use the system in new ways, the analyzer recalculates its scores, and the column subset adjusts accordingly. Storage reduction is an ongoing "game".

Declaration on Generative AI

The authors utilized generative AI tools (large language models) to assist with manuscript writing and editing. All AI-generated content has been thoroughly reviewed, validated, and manually edited by the human authors. The original ideas, experimental design, results, and conclusions presented in this work were formulated by human authors. No generative AI tools are listed as authors on this work.

Web Server Seizure and Live Acquisition: A Legally Compliant Forensic Framework for Indonesia

Irwan Hariyanto[1], Yudi Prayudi[2], Rimba Whidiana Ciptasari[3]
School of Computing, Telkom University, Bandung, Indonesia[1,3]
School of Informatics, Universitas Islam Indonesia, Yogyakarta, Indonesia[2]

***Abstract*—The proliferation of cybercrime activities, particularly those leveraging web servers for illicit purposes such as distributing hoaxes, hosting illegal online gambling, and spreading malware, underscores a pressing demand for a standardized digital forensic framework. Existing methodologies, like simple IP blocking, have proven insufficient in guaranteeing the integrity and admissibility of digital evidence in legal proceedings. This research introduces a comprehensive seizure and acquisition framework specifically engineered to manage digital evidence from both on-premise and cloud-based web servers. A core emphasis of this framework is live acquisition to preserve volatile data and ensure minimal service disruption. The framework systematically addresses critical challenges by focusing on legal authorization, precise server type identification and technical preparation, judicious forensic tool selection, rigorous evidence integrity validation through hashing, diligent Chain of Custody (CoC) documentation, and secure data storage. Tested through simulations of on-premise and cloud server seizures, the framework demonstrated its capacity to uphold evidence integrity and legal compliance. While robust, Subject Matter Expert (SME) validation indicated areas for optimization, particularly in cloud-native contexts and the automation of Chain of Custody documentation. This study marks a pivotal advancement towards standardizing web server seizure procedures, thereby ensuring that digital evidence remains valid, intact, and legally admissible in court.**

***Keywords*—Digital forensics; web server seizure; live acquisition; evidence integrity; chain of custody**

I. Introduction

As cybercrime continues to rise, the need for effective digital forensic practices is paramount [1]. The Indonesian legal framework is still adapting to the complexities of digital evidence, which presents unique challenges for law enforcement agencies [2]. The lack of standardized procedures for seizing and acquiring digital evidence from web servers further complicates the investigation process, making it essential to develop a comprehensive framework that addresses these issues [3].

Database breaches, website defacement, cyber intrusions, and phishing attacks commonly occur on web servers [1]. These incidents require forensic investigation.

In the cyber context, however, the term encompasses a more nuanced set of actions. It can refer to the physical seizure of server hardware. However, more frequently, it involves the logical acquisition or forensic duplication of digital data from systems that cannot be physically moved or shut down due to operational risks [4]. This distinction is critical, as the chosen method —physical or logical —depends heavily on the server's environment, its role in ongoing business operations, and the legal authority granted to investigators [5].

One example is a case of hacking and defacing a government website in Indonesia [6]. This case involved the hacking of several government websites in Indonesia, where attackers altered the front page with political or ideological messages. A digital forensics team seized the web server for further analysis, including identifying the digital footprint of the hackers, the hacking methods used, and log data showing unauthorized activity [7], [8]. The forensics process collects data from server logs, caches, and system configurations to check for exploited vulnerabilities [9].

These case examples show that web server seizure is challenging in both VPS and cloud environments. A standard framework is required to ensure integrity, validity, and courtroom admissibility [10], [11]. A digital forensics process model provides the required steps, inputs, and outputs for successful investigation [12].

Evidence handling in cyber forensics includes preservation, collection, validation, identification, analysis, interpretation, documentation, and presentation [5]. As cyber cases in Indonesia increase, investigators still lack a standardized legal-forensic reference for seizure and acquisition [13]. This study proposes a web server seizure framework that is technically robust and legally compliant for Indonesian law enforcement needs.

The framework developed in this study directly contributes to the following strategic aspects:

- Strengthening the Validity of Digital Evidence through Standardization of Procedures: This framework presents a structured and well-documented workflow in seizing and acquiring evidence from web servers.
- Support for Strengthening the Chain of Custody: One of the important contributions of this framework is to provide technical and administrative guidelines for building a strong chain of custody.
- Ensuring Legal Compliance in Indonesia and Supporting International Applicability: This framework is designed to align with the legal principles applicable in Indonesia, especially regarding digital seizure procedures, electronic evidence provisions, and legal restrictions.
- Foundation for the Establishment of SOP for Digital Forensic Institutions: For law enforcement agencies,

digital forensic laboratories, and other agencies involved in cyber investigations, this framework can be a basis for compiling, training investigators, and strengthening institutional capacity in digital forensics.

- Foundation for Developing Standard Operating Procedures in Digital Forensics: By bringing a relatively new topic for web server seizures in the context of cloud and hybrid—this research broadens the insights and academic literature in Indonesia and globally.

A. Operational Definition of Key Terms

To avoid ambiguity, this study distinguishes the following terms and applies them consistently in all sections:

- Seizure: A legally authorized act to control digital evidence sources (physical or logical) under applicable procedures (KUHAP and related regulations).
- Collection: Initial identification and retrieval of potentially relevant artifacts from a running or non-running system.
- Acquisition: A forensic process to create a reliable copy/image of selected data while preserving evidentiary integrity.
- Live Acquisition: Acquisition from an active system without shutdown to preserve volatile artifacts and maintain service continuity.

The remainder of this study is organized as follows. Section II reviews related research. Section III presents the framework development method. Section IV evaluates the framework through simulations and SME validation. Section V discusses findings, feasibility, and refinement direction, and Section VI concludes the study.

II. Related Research

A. Web Server Acquisition

Web server acquisition is a crucial step in the digital forensics process, which aims to collect all relevant data from the server without changing its contents. Research by Pedapudi & Vadlamani [14] directly links data with formal seizure documentation through the proposed "Data Acquisition-based Seizure Record Framework." In this context, "seizure" is defined as a process that must be systematically recorded and documented [15].

Thankaraja Raja Sree et al. [16] demonstrated that data acquisition from web servers necessitates tools capable of handling dynamic and volatile data that is constantly updated. This [17] also emphasized the importance of using specialized tools to maintain data integrity during acquisition, such as using secure hashing on the collected data to ensure that no changes occur.

Liu et al. [18] also discuss remote acquisition methods that allow investigators to perform acquisitions remotely. While this method is helpful in the context of cloud forensics, when applied to a local web server, it faces challenges in terms of legality and network security.

Digital seizure is a crucial step in digital forensics for IoT, involving the identification and acquisition of digital evidence from diverse and interconnected devices. Its main strength lies in preserving volatile and distributed data [19], which is essential for reliable forensic analysis and legal proceedings. However, the process faces significant challenges due to the heterogeneity of IoT devices, a lack of standardization, network limitations, and the vast volume of data, which can hinder the collection of timely and complete evidence [20], [13]. Thus, while digital seizure is vital for IoT forensics, its effectiveness depends on the development of standardized frameworks and adaptive tools to address these unique challenges.

Previous studies have proposed various digital forensics models that address general procedures for investigating digital evidence, such as the Digital Forensics Investigation Framework (DFIF) [21].

Cloud forensics research [22], [23], [24] emphasizes remote acquisition and live capture without service interruption. However, these approaches still lack specific guidance for VPS seizure in the Indonesian context. In this study, "web server" seizure is not limited to HTTP/HTTPS servers but includes any server entity containing relevant evidence [25].

The web servers commonly used are NGINX and Apache. On the other hand, with time, other web servers have also become widely used, such as Microsoft IIS, lighttpd, and LiteSpeed. These types of web servers can be categorized as web servers that can be seized [26].

Data crucial for web server forensic acquisition is categorized into Volatile Data (e.g., RAM contents, running processes, network connections, active user sessions, system time, open files, command history, and clipboard contents) and Non-Volatile Data (e.g., system files, server configurations, log files, databases, web applications, user data, and backup files) [27]. These data points serve as potential evidentiary artifacts. Consequently, securing and maintaining the integrity of digital evidence from web servers is critical for effective case investigation and prosecution, particularly given increasingly stringent international digital evidence laws [28].

The data mentioned above can be potential artifacts that can be used as evidence in conducting the seizure of the web server. In Indonesia, there are no guidelines governing the seizure of web servers, which poses significant technical and legal challenges for investigators [29]. Success in securing and maintaining the integrity of digital evidence from web servers is critical to investigating and prosecuting cases, especially in the context of increasingly stringent international laws regarding digital evidence [30].

Although previous research has provided a good foundation for collecting and acquiring digital evidence, there is no specific framework addressing the seizure of web servers as evidence [31], especially in the context of applicable law in Indonesia. Many current solutions, such as remote acquisition [32], do not consider the technical uniqueness and legal challenges associated with direct seizure. This creates a risk that the evidence obtained will not be admissible in court or that the data acquisition process will be flawed, resulting in loss of data integrity and chain of custody [33].

B. Digital Forensic Methodology for Incidents

Karen Ken [34] (The Guide to Integrating Forensic Techniques into Incident Response (NIST Special Publication 800-86)) describes the general framework of the NIST standard, which consists of Collection, Examination, Analysis, and Reporting. However, the collection stage does not explain how to perform a seizure on a web server. Based on Fig. 1, at the Collection stage, there are the following details:

- Identifying possible data sources.
- Acquiring data: At this stage, there are further details as follows:
  - Planning data acquisition.
  - Acquiring the data.
  - Verifying data integrity.
- Considering Incident Response.

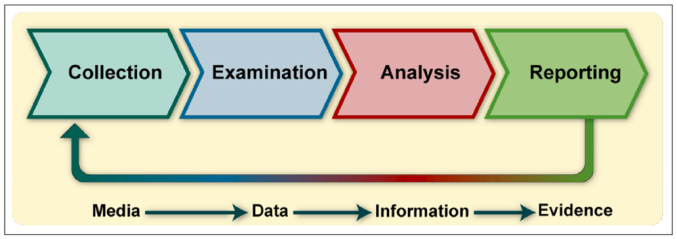

Fig. 1. NIST Digital Forensics Framework.

Seizing a web server in the context of digital forensics investigations is a complex process involving infrastructure that often functions dynamically [35]. Malik et al. [36] emphasize the considerable obstacles associated with web server seizures, notably the potential for operational downtime that may impede company activities and the threat of losing essential volatile data if the server is deactivated during the seizure process [37]. Many contemporary investigations are using a live forensics strategy, wherein the operational web server continues to function while digital evidence is gathered [38]. This method enables investigators to gather evidence without disabling the server, although it also increases the potential of data contamination.

C. Digital Forensics Seizure

Research by Kuntze et al. [39] discusses the process of seizure from a legal context in Germany and the United States, with a focus on digital data. In this study, "seizure" no longer always means the physical removal of hardware, but more often refers to the process of imaging hard drives or other storage media. The primary concern is that modern seizure practices, which involve creating full images, often conflict with fundamental laws.

From a different perspective, research by Nortje & Myburgh [40] examines "seizure" from the perspective of its legal preconditions, namely the obstacles in drafting search and seizure warrants for digital evidence in South Africa. This research does not focus on the technical act of seizure itself, but rather on the legal process that authorizes it. "Seizure" is viewed as a legal action whose validity is highly dependent on the completeness and accuracy of the warrant application submitted by the forensic investigator.

Research by Pedapudi & Vadlamani [14] directly links data with formal seizure documentation through the proposed "Data Acquisition-based Seizure Record Framework." In this context, "seizure" is defined as a process that must be systematically recorded and documented. The proposed framework aims to standardize the recording of every detail during the digital evidence acquisition process.

Meanwhile, research by Thealma & Ruldeviyani [2] discusses the ethical aspects of data handling in digital forensic investigations in Indonesia, especially after the enactment of the Personal Data Protection Law (PDP Law). Although it does not directly define "seizure," this research implicitly highlights that the process of seizing digital evidence carries significant ethical and legal consequences, as such evidence is likely to contain sensitive personal information or data.

These four literature studies collectively provide a 360-degree view of the seizure process in digital forensics. They show that the framework must not focus only on technical aspects, but must also be legally accountable, ethically grounded, and well documented to preserve evidentiary integrity from start to finish.

D. Implementation of Framework in Daily Practice

Forensic investigators and examiners utilize established frameworks in their daily practice to verify that the acquisition and analysis of digital evidence adhere to industry standards [13]. Singh K [41] asserted that a well-designed framework can reduce errors in the investigative process and guarantee the admissibility of digital evidence in court. The execution of this framework requires specialized training for investigators to comprehend the technical procedures involved in seizing web servers, particularly in surroundings with complex infrastructure [42].

Frameworks such as the Digital Forensics Investigation Framework (DFIF) have been successfully utilized in cybercrime investigations. Nonetheless, the implementation of forensic frameworks must persistently adapt to advancing technologies, including cloud environments and hybrid web servers, to guarantee the proper securing and validation of digital evidence [21], [22], [23].

E. Existing Seizure Procedures

Fig. 2 illustrates that the seizure procedure is a critical component of the criminal case management process in Indonesia, as evidenced by the information obtained from the official portal of the Metro District Court [43]. The Criminal Procedure Code, also known as KUHAP (Kitab Undang-Undang Hukum Acara Pidana), governs the procedures for evidence seizure in the Indonesian legal system. The mechanisms for search, seizure, and the management of evidence in criminal investigations, including digital evidence, are regulated by this law.

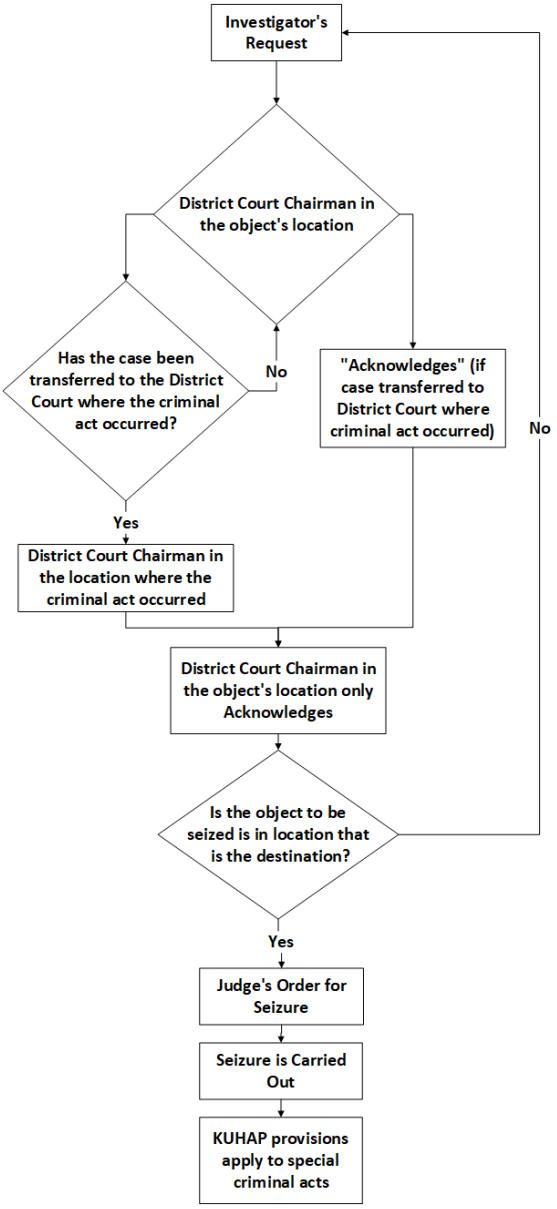

Fig. 2. Current seizure procedure in Indonesia.

The phases of digital evidence seizure and validation are illustrated in Fig. 2, which provides an overview of the framework components. The legal validity and data integrity of each phase are guaranteed by the inclusion of specific technical and procedural components. This procedure thoroughly regulates the legitimate seizure of evidence or assets that are pertinent to a criminal offense.

III. Framework Development

This section outlines the stages used to develop the web server seizure framework, starting from literature review and expert interviews, followed by prototype implementation through cloud and VPS simulations.

Fig. 3 illustrates the sequential flow of the research methodology, which combines literature review, expert interviews, and iterative prototype testing. Each phase is structured to

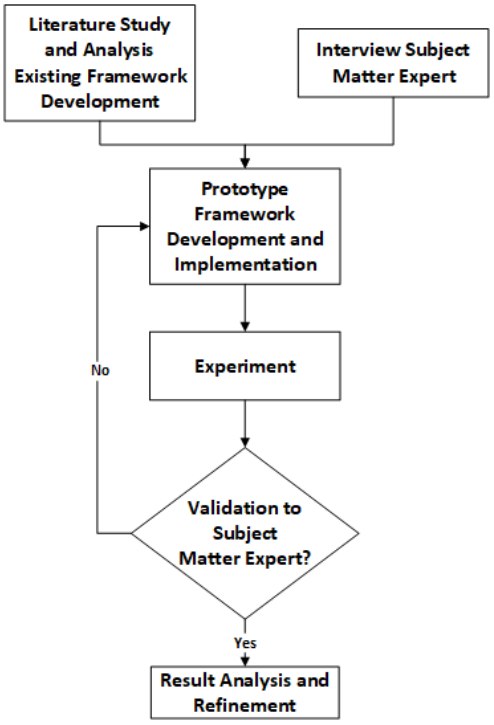

Fig. 3. Phases of research for the development of a proposed seizure framework.

ensure that the developed framework is both legally valid and technically reliable, with validation and refinement stages to improve its applicability.

- Literature Study and Analysis of Existing Frameworks: This activity involves a systematic review of academic and professional literature to explore existing digital forensic frameworks. The objective is to understand their approach to seizing and acquiring evidence from web servers, particularly in cloud and VPS environments. The study also includes a critical analysis of the limitations and shortcomings of these frameworks, especially in maintaining volatile data and ensuring data integrity during live acquisition.
- Interview Subject Matter Expert: done with the goal of asking about the framework that has been run by experts when seizing web servers as a comparison material at the literature study stage and analysis of existing frameworks by asking questions to experts by providing framework guidelines as the primary reference, namely from NIST 800-86 [34].
- Prototype Framework Development and Implementation: This refers to the process of constructing an initial version (prototype) of the proposed framework based on the design formulated in earlier stages. The implementation involves applying the framework in controlled simulations using forensic tools and live web servers hosted on cloud or VPS platforms. The goal is to verify the accuracy of each phase of the framework in real-world operational scenarios [44].
- Framework Experimentation: Framework experimen-

tation refers to testing the proposed framework through forensic simulations in semi-realistic investigative conditions [45]. The aim is to evaluate the framework's performance in securing digital evidence during the seizure of a web server. Case scenarios, including DDoS-related seizures or website defacement, were used. Effectiveness was measured using indicators such as data integrity (verified through hashing), preservation of volatile data, and time efficiency. The framework's flexibility was also tested across various cloud and VPS environments.

- Validation to Subject Matter Expert (SME): SME validation is the process of involving digital forensic experts to assess the applicability and reliability of the proposed framework. The validation was conducted through review sessions and field simulations with practitioners and investigators. Experts were asked to evaluate usability, compliance with legal standards, and technical soundness [46].
- Results Analysis and Framework Refinement: This refers to the final analytical phase to assess whether the developed framework meets the research goals. Data from experiments and SME feedback were analyzed to measure the framework's ability to maintain evidence integrity and minimize data loss. Comparative evaluations were made between the proposed and existing traditional approaches.

Table I summarizes the expected output of each phase. Findings from SME interviews and literature review were synthesized to identify key issues (data volatility, integrity, and legal compliance) [47], [48], then used to build the initial framework for VPS and cloud seizure scenarios.

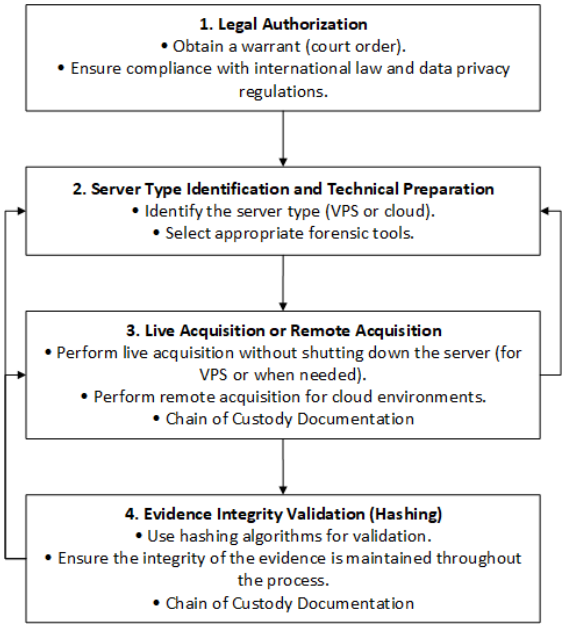

Fig. 4. Proposed framework.

Fig. 4 shows the proposed framework, which is tested through forensic simulation and validated by SMEs to ensure legal compliance, technical feasibility, and operational usability.

- Legal Authorization: Ensure that all seizure actions are preceded by court authorization and comply with applicable laws, including data privacy.
- Server Identification and Technical Preparation: Determine the server type (VPS or cloud), prepare suitable forensic procedures and tools, and document activities to preserve chain of custody (CoC).
- Data Acquisition: Retrieve data through live acquisition without shutting down the server, or remote acquisition in cloud environments, to minimize data loss.
- Validation of Evidence Integrity: Perform hashing to verify that collected evidence remains intact and unchanged.

IV. Framework Evaluation

This section presents the evaluation of the proposed web server seizure framework through simulation-based case studies and expert validation.

A. Dataset

To ensure that the proposed framework is applicable in realistic investigative conditions, a case dataset is required to simulate common cybercrime scenarios. This section describes the dataset used to test the framework, particularly in the context of online gambling and website defacement attacks.

B. Simulation Environment and Reproducibility Setup

To improve reproducibility, this subsection summarizes the technical environment used in both simulations.

- Cloud scenario (Case 1): AWS infrastructure (EC2 and EBS snapshot service), Ubuntu 20.04 LTS (64-bit), Apache 2.4.52, PHP 7.4, MySQL 8.0, remote acquisition via AWS CLI 2.11, and audit trace via CloudTrail.
- VPS scenario (Case 2): Linux-based VPS on VirtualBox 7.0 using Ubuntu 20.04 LTS (64-bit), Apache 2.4.52, PHP 7.4, MySQL 8.0, and acquisition using Oxygen Forensic KeyScout 15.1 and Magnet AXIOM 7.2.
- Integrity mechanism: hash calculation before and after acquisition for critical artifacts (logs, web files, and database exports), using SHA-1 as implemented in the simulation.
- Evidence scope: volatile artifacts (active sessions, running processes, active logs) and non-volatile artifacts (configurations, site files, database dumps, snapshots).
- Documentation output: acquisition command logs, hash logs, timestamps, chain-of-custody forms, and legal authorization records.

The above configuration is intended as a minimum baseline for independent replication. Future studies can expand by testing additional operating systems and multi-region cloud deployments.

TABLE I. RESEARCH PHASES AND EACH-STAGE RESULT OF THE FRAMEWORK DEVELOPMENT

Research phases	Each-stage result
Literature Study and Analysis of Existing Framework Development	A comprehensive review of the existing framework will help define gaps or needs that are not being met by the current solution. - Extended Model of Cybercrime Investigations (EMCI) - Enhanced Digital Investigation Process (EDIP) - Event-Based Digital Forensic Investigation Framework (EBDFI) - Abstract Digital Forensic Model (ADFM) - Cloud Incident Response Framework (CIRF)
Interview Subject Matter Expert	- Detailed 3-Scenario Acquisition Model - Refinement of NIST Collection Stage (ISO 27037 Integration) - Distinction between Collection & Acquisition - Broader Incident Response Lifecycle View - Emphasis on First Response & Contamination Avoidance - Stakeholder Coordination - Additional Security/Preservation Aspects - Legal Foundation - Legality Prerequisite - Technical Identification
Prototype Framework Development and Implementation	Proposed Framework: - Emphasis on legal defensibility (Court-ready, consistent with Indonesian legislation) - Comprehensive (VPS/Cloud, operating system, services, tool preparation) - Fully supports live acquisition (volatile and non-volatile) and remote cloud acquisition. - Hashing (e.g., SHA-1), observed validation, pre/post acquisition
Framework Experimentation	Quantitative and qualitative data regarding the framework's performance, encompassing reports on evidence integrity, efficacy in managing volatile data, and interoperability with current forensic tools.
Subject Matter Expert (SME) Validation	The final, field-validated framework with implementation guidance for users.
Results Analysis and Framework Refinement	The final version of the framework, which has undergone thorough testing and refinement, is now ready for implementation in the field by forensic investigators.

1) Simulation of Case 1: Simulation of framework implementation for cloud web server: This subsection presents a cloud-hosted simulation to evaluate framework performance in public cloud infrastructure. The following details summarize the environment and digital artifacts:

- Infrastructure Type: Cloud-hosted web server.
- Platform Utilized: Amazon Web Services (AWS). This choice reflects the widespread adoption of major cloud service providers in contemporary web hosting.
- Simulated Illicit Activity: The web server was configured to host an illegal online gambling site and was subjected to web defacement. This dual nature of illicit activity allowed for the testing of evidence acquisition related to both ongoing operations (gambling) and static alterations (defacement).
- Digital Evidence Acquired:
    - Transaction Logs: Critical for reconstructing user activity and financial flows associated with the gambling operation.
    - Website Files: Including source code, configuration files, and defaced content, essential for understanding the nature of the compromise and the illicit content.
    - User Databases: Containing sensitive user information and gambling records.
    - Disk Volume Snapshots: Forensic images of server storage capturing volatile and non-volatile states during acquisition.
- Acquisition Method Focus: Remote acquisition via cloud provider APIs (e.g., AWS CLI) to simulate real-world challenges of non-physical access and multi-tenancy.

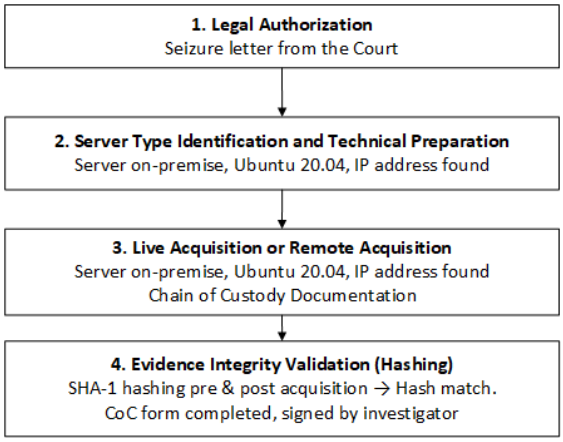

Fig. 5. Case 1 framework implementation.

Investigators received reports that a cloud-based web server was used for illegal online gambling. They needed to seize transaction logs, website files, and user databases. Simulation steps based on Fig. 5 are as follows:

- Legal Authorization: Investigators begin by obtaining a warrant from a court that grants permission to seize digital evidence from servers hosted on the cloud (AWS). The warrant includes permission to take transaction logs, databases, and system files of the gambling site located on the server. Investigators work

with legal authorities and cloud service providers to ensure that seizures are conducted in accordance with applicable laws, including data privacy laws relating to other users on the same cloud platform.

- Server Identification and Technical Preparation: Investigators identified that the web server was hosted on AWS and used PHP technology with MySQL database to run the online gambling site. Since the server was cloud-based, investigators prepared cloud-native forensic tools such as AWS CLI and CloudTrail to perform remote data acquisition. Investigators use the AWS Management Console to identify servers used to host gambling sites. Investigators also set up access via the AWS CLI to collect remote server snapshots, access logs, and databases.
- Data Acquisition: Investigators performed a remote acquisition of the cloud server without stopping the gambling site's services. The AWS CLI was used to take a snapshot of the disk volume, including the website's system files, access logs, and databases that store user and transaction information. Remote acquisition was performed via the AWS CLI, where investigators took a snapshot of the server disk volume that stores all files related to the gambling site, including site configurations, transactions, and databases. Investigators also took transaction logs to track the activity of users using the gambling site, such as login history, bets and payments.
- Validation of Evidence Integrity: After the data is captured, the investigator hashes all files and snapshots taken to ensure the integrity of the evidence. Hashing tools such as SHA-1 are used to ensure that the evidence remains intact and is not altered during the process. After snapshots and transaction logs are taken, hash values are calculated for each file and database using the AWS CLI and local hashing tools. All hash values are recorded as part of the Chain of Custody.

The cloud simulation demonstrated successful remote acquisition without service disruption. All acquired artifacts were hash-verified and documented in chain-of-custody records, producing legally defensible evidence.

2) Simulation of Case 2: Simulation of framework implementation for Virtual Private Server (VPS) web server: This subsection describes a second simulation using a Virtual Private Server (VPS) to assess framework adaptability in traditional server environments with direct administrative access.

- Infrastructure Type: Virtual Private Server (VPS). This represents a common hosting solution offering more control than shared hosting but less abstraction than full cloud services.
- Technology Stack: Apache web server with PHP, a widely used combination for dynamic web applications.
- Simulated Illicit Activity: The VPS was utilized for the dissemination of hoax news, specifically political misinformation, through injected subdirectories. This scenario tested the framework's ability to identify and acquire evidence related to content injection and malicious content distribution.
- Digital Evidence Acquired:
  - Activity Logs: Server access logs and application logs crucial for tracing the origin and spread of the hoax content.
  - Site Files: Including the injected hoax content, legitimate website files, and configuration data.
  - Database Contents: Relevant databases containing hoax-content records or user interaction data.
- Acquisition Method Focus: Live acquisition using forensic tools (e.g., Oxygen Keyscout) to minimize service disruption and capture volatile data from a running system.

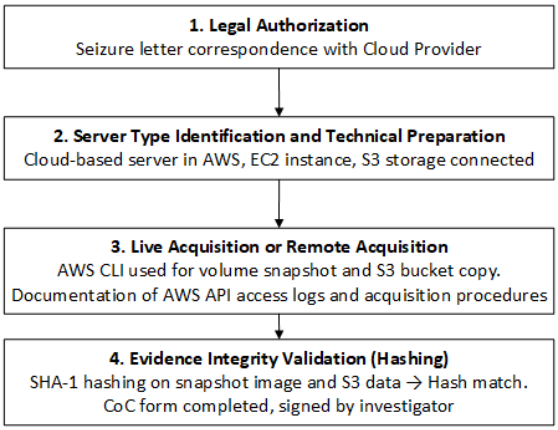

Fig. 6. Case 2 framework implementation.

Investigators received a report that a website hosted on a Virtual Private Server (VPS) was used to spread hoax news related to political information disturbing the public. Without stopping the server service, investigators needed to seize the web server and acquire related evidence, such as activity logs, site files, and hoax content posts. Simulation steps based on the proposed framework for Case 2 are shown in Fig. 6:

- Legal Authorization: Investigators begin by obtaining a court warrant to seize digital evidence from the VPS hosted web server. The warrant includes permission to retrieve site content files, user access logs, and databases that store hoax content and information related to user activity involved.
- Server Identification and Technical Preparation: Investigators identified that the web server was VPS and used Apache technology with PHP to run the site. Since the server was Virtual VPS, investigators prepared forensic tools such as Oxygen Keyscout and Magnet Axiom to perform live acquisition without shutting down the server. Investigators conduct an initial inspection of the server infrastructure, examine

the operating system (e.g., Linux) and prepare physical access to the server to collect evidence in real-time.

- Data Acquisition: Investigators perform live acquisition without stopping the web server service. Oxygen Keyscout is used to take snapshots of system files, including site content files, user activity logs, and databases that store hoax content. Live acquisition was performed using Oxygen Keyscout to capture system files associated with the website, including all files containing hoax news.
- Validation of Evidence Integrity: After the data is captured, investigators hash all captured files, logs, and databases to ensure the integrity of the evidence. After all files and access logs are retrieved, the hash values are calculated using Oxygen Keyscout and recorded in Chain of Custody to ensure that the collected data is not changed or manipulated.

The VPS simulation also completed live acquisition without downtime. Site files and logs were hash-validated and fully documented through chain-of-custody records, enabling accountable forensic analysis.

C. Metric

To assess the performance of the proposed framework, several metrics are defined based on technical, operational, and legal considerations. These metrics guide the evaluation process by providing quantifiable indicators of success throughout the simulated forensic procedures.

1) Aspects of success: This section outlines measurable aspects used to evaluate the effectiveness of the proposed framework in web server seizure scenarios. The framework is tested through two simulation scenarios: 1) seizure of a cloud web server used for online gambling and 2) seizure of a VPS web server used to spread hoax content. Each framework stage has specific success indicators, as follows:

- Volatile Data Preservation: Most of the $>$80% volatile data successfully preserved (RAM, active logs).
- Integrity Validation: Cryptographic hashing (SHA-1) performed pre- and post-acquisition to verify unchanged evidence values.
- Reporting and Secure Storage: The final report includes logs, hashes, analysis, and summary of findings. Evidence is stored encrypted and warrants are documented before acquisition.
- Downtime/Service Disruption: Minimal service disruption through live acquisition techniques.
- Cloud Environment Compatibility: Supports remote acquisition via official cloud provider APIs and services.
- Legal Compliance: Strict adherence to legal authorization and digital evidence handling standards.
- Ease of Analysis: Richer data set enables more thorough forensic analysis.

2) Quantitative evaluation results: To reduce subjectivity, the framework was also measured using quantitative indicators from both simulation cases (See Table II).

TABLE II. QUANTITATIVE RESULTS ACROSS SIMULATION SCENARIOS

Metric	Case 1 (Cloud)	Case 2 (VPS)
Hash verification success rate	100%	100%
Volatile artifact preservation rate	$\geq$80%	$\geq$80%
Acquisition completion time	$\approx$30 minutes	$\approx$30 minutes
Service downtime during acquisition	0 minutes	0 minutes
CoC completeness	$\geq$85%	$\geq$85%
Legal checklist compliance	$\geq$90%	$\geq$90%

Both scenarios satisfy the minimum feasibility target: average score $\geq$ 4.0 for all indicators and no critical legal or integrity indicator below 3.0.

3) Questionnaire: This section explains the questionnaire and interview guide used to evaluate the framework from practical and theoretical perspectives. The questionnaire includes questions related to:

- Preservation of digital evidence aspect
  - What is This framework provides systematic and standardized steps in seizure and acquisition of web servers?
  - Have the steps in this framework considered the preservation of volatile and non-volatile data with methods that are in line with forensic principles?
  - Does this framework provide an efficient cloud remote-acquisition method?
- Robust integrity and validation aspect
  - Does it provide evidence integrity validation mechanisms such as hashing to ensure the authenticity of the data obtained?
  - How well does it handle Chain of Custody to ensure evidence remains valid in court?
  - Is the framework flexible to be deployed on both VPS and cloud-hosted servers?
- Forensic acquisition admissibility in court aspect
  - To what extent does it meet legal requirements regarding the validity of obtaining evidence from seized web servers?
  - Does it meet the legal requirements regarding the seizure and retrieval of digital evidence, including the use of court warrants?

- What do you think are the weaknesses of this framework?

To assess the framework's feasibility, a structured questionnaire was developed and distributed to evaluators. This subsection describes the scoring criteria and rubric used to determine whether the framework meets minimum standards and legal admissibility. The framework is considered feasible if the average score for each indicator is ≥ 4.0 out of 5, and no critical aspects (legal and integrity) are scored ≤ 3, based on the Likert-scale rubric [49] below.

- (Very Poor): Evidence largely lost or corrupted; Weak validation and documentation; High inadmissibility.
- (Poor): Mostly data corrupted; Less validation, inconsistent documentation; May complicate admissibility.
- (Fair): Sufficient, but requires improvement and Sufficient to meet standards, but needs customization.
- (Good): Properly preserved using legitimate methods; Strong validation, detailed documentation.
- (Very Good): Comprehensive preserved, including live acquisition; Highly robust, transparent, and irrefutable documentation; Aligned with highest legal standards, beyond reasonable doubt.

4) Profile of SMEs: This section provides an overview of the Subject Matter Experts (SMEs) involved in the framework evaluation. Their professional backgrounds ensure a valid and informed assessment of the framework's applicability in real-world digital forensic contexts. The framework validation used an expert-judgment approach involving experts with direct experience in digital forensics [50]. Validation was conducted using both qualitative and quantitative assessment in two scenarios (cloud and VPS), involving 3 SMEs. Selection criteria included: 1) minimum 5 years of professional experience, 2) direct involvement in digital evidence handling, and 3) familiarity with legal admissibility requirements in Indonesia.

Feedback was collected through a structured questionnaire (Likert scale 1–5), guided interview, and review session on simulation outputs. The synthesis process applied indicator-level averaging, followed by cross-SME comparison to identify convergent findings and unresolved concerns.

A framework is categorized as feasible when the average score for each indicator is ≥ 4.0 and no critical indicator (legal and integrity aspects) is ≤ 3.0.

The SMEs were:

- Digital Forensics Practitioner
- Chairman of the Indonesian Digital Forensics Association
- Digital Forensic Expert at Indonesian Corruption Eradication Commission

Indonesian Corruption Eradication Commission (known as Komisi Pemberantasan Korupsi (KPK)) is a state institution established with the aim of improving the effectiveness and efficiency of efforts to eradicate corruption [51].

V. Results and Discussion

The development and evaluation results show the importance of aligning technical procedures with legal and operational standards in cloud and virtualized environments. The framework addresses gaps in existing models, especially in volatile-data preservation, integrity assurance, and minimal service disruption during live acquisition.

Integration of literature review and SME input strengthens the framework's legal validity and operational applicability. SME feedback confirms compliance with Indonesian legal standards and feasibility across VPS and cloud environments.

Simulation-based experimentation provides a replicable way to assess framework performance. Evaluation metrics were positive, with no critical SME failures, indicating that the framework can guide legally sound and technically reliable web server seizures.

A. SME Validation Results

This section discusses the evaluation results obtained from Subject Matter Experts (SMEs) who assessed the framework based on their professional judgment, practical experience, and legal-technical considerations. Their feedback serves as a crucial measure to validate the feasibility, effectiveness, and reliability of the proposed framework in real-world forensic investigations.

1) SME 1: Digital forensics practitioner: Validation focused on three aspects derived from the research objectives:

- Preservation of digital evidence aspect (Score: 4) The expert acknowledged that the framework already includes systematic and standardized procedures that align with forensic best practices. It successfully addresses the need to capture both volatile and non-volatile data, particularly by supporting live acquisition and remote access in cloud environments.
- Robust integrity and validation aspect (Score: 4) The SME confirmed that the framework incorporates proper integrity validation mechanisms, notably hashing (e.g., SHA-256), and emphasizes the importance of documenting each acquisition step. Chain of Custody was positively reviewed as well-structured and able to meet legal requirements.
- Forensic acquisition admissibility in court aspect (Score: 4) The legal compliance elements such as prior authorization, use of court warrants, and procedural transparency were considered robust. The SME stated that the framework is legally defensible and suitable for submission as digital evidence in court.

2) SME 2: Chairman of the Indonesian digital forensics association:

- Preservation of digital evidence aspect (Score: 4.67) The expert stated that the proposed framework already has systematic steps for collecting electronic evidence. However, as input, the expert provided notes regarding detailed elaboration on data preservation and acquisition, as well as technical steps related to remote acquisition.

- Robust integrity and validation aspect (Score: 4.67) The proposed framework is considered excellent in terms of integrity and strong evidence validation. This framework provides a hashing mechanism to ensure the authenticity and integrity of the data obtained, and has incorporated clear Chain of Custody procedures to ensure that evidence remains valid and accountable in court. Although it is flexible for use on VPS and cloud servers, further elaboration is needed regarding the different types for technical acquisition details.
- Forensic acquisition admissibility in court aspect (Score: 4.67) The framework is considered to meet both legal and technical requirements for evidence from web server seizures to be admissible in court. Legally, it emphasizes obtaining court authorization for seizure, aligning it with existing procedures for physical evidence under KUHAP.

3) SME 3: Digital forensic expert at Indonesian corruption eradication commission:

- Preservation of digital evidence aspect (Score: 4.33) The expert stated that the proposed framework is considered highly systematic and can serve as a reference for web server seizure, although there a note to strengthen documentation for live RAM and volatile logs. Additionally, the framework provides efficient methods for remote acquisition on cloud servers.
- Robust integrity and validation aspect (Score: 4.67) This framework provides robust mechanisms for validating evidence integrity, such as hashing, which is included in the standard procedure for digital evidence collection. The handling of the Chain of Custody is rated as very good because documentation is prepared from the beginning of the acquisition process to ensure the validity of evidence in court.
- Forensic acquisition admissibility in court aspect (Score: 4.67) This framework is considered compliant with legal requirements for the admissibility of evidence from web server seizures in court, provided that procedures are carried out according to seizure and hashing regulations.

B. Framework Feasibility

The variation in SME scores can be explained by the following factors:

- Diverse Backgrounds and Expertise: SMEs come from different fields such as law enforcement, legal practice, and cybersecurity, leading to varied priorities.
- Interpretation of Framework Components: The subjective nature of the scoring process means that SMEs interpret the framework's components differently, resulting in discrepancies based on their individual expectations and focus areas.
- Variability in Case Scenarios: The applicability of the framework can differ based on the specific case scenarios encountered by SMEs, influencing their scores depending on their experiences with cloud-based versus traditional VPS environments.
- Feedback and Iterative Improvement: Score differences provide constructive input for framework refinement.

Overall, differing SME scores reflect complementary perspectives rather than contradiction, and they help identify priorities for improvement.

The framework provides a solid foundation for conducting digital forensic investigations in Indonesia. All critical aspects related to legal compliance and data integrity received scores above the minimum requirement, with no aspect falling below the threshold of 3.0 [49]. A score below 3.0 in these areas would indicate significant weaknesses that could jeopardize the admissibility of evidence in court.

The proposed framework meets the threshold criteria, with an average score of **4.41**/5.0, indicating strong SME support. These findings suggest that the framework can be implemented while continuing iterative refinement [52].

C. Chain of Custody in Cloud-Native Environments: Interim Procedure and Design Direction

Although the framework demonstrates strong legal and technical feasibility, cloud-native implementation requires additional optimization in chain-of-custody automation. As an interim procedure, this study recommends:

- Generate immutable timestamped acquisition logs for each command/API action.
- Apply digital signatures to evidence manifests and hash reports.
- Store forensic artifacts and custody logs in write-once object storage (WORM/object-lock policy).
- Record actor identity and role for every evidence access event.
- Correlate cloud audit records (e.g., CloudTrail) with local acquisition notes before final reporting.

For future design, a cloud-native chain-of-custody module can be developed by integrating automated event capture, cryptographically linked audit trails, and policy-based verification to support end-to-end courtroom defensibility.

VI. Conclusion

This study addresses the need for a standardized web server seizure framework in Indonesia by integrating legal requirements with practical forensic procedures for VPS and cloud environments. The framework was developed through literature review, expert input, simulation, and refinement.

Results show that the framework supports legally authorized seizure, scenario-based technical preparation, live or remote acquisition, integrity validation through hashing, and complete chain-of-custody documentation. Across the simulations, evidence integrity and legal compliance were maintained without service downtime.

SME evaluation indicates strong feasibility (average score **4.41**/5.0), especially in legal compliance, integrity assurance, and acquisition effectiveness. The framework is therefore suitable as a practical reference, with future work focused on cloud-native chain-of-custody automation.

ACKNOWLEDGEMENTS

Thanks to the Subject Matter Experts who contributed their valuable insights and expertise throughout this research. Their constructive feedback and professional evaluations played a pivotal role in validating the proposed framework and ensuring its practical applicability within the field of digital forensics.

Adaptive Phishing Website Detection Using Incremental Machine Learning: A Dynamic Approach to Cybersecurity Threats

Ajla Kulaglic, Mutaz A. B. Al-Tarawneh
College of Engineering and Technology, American University of the Middle East, Egaila 54200, Kuwait

***Abstract*—The rapid expansion of internet services and cloud-based platforms has increased cybersecurity threats, particularly phishing attacks that deceive users into disclosing sensitive information. Traditional phishing detection methods, including blacklists and batch-learning models, often struggle to adapt to the continuously evolving nature of these attacks. In order to address this challenge, this study proposes an adaptive phishing detection framework based on incremental machine learning techniques that enable real-time learning and dynamic adjustment to new attack patterns. A comprehensive evaluation of multiple incremental algorithms was performed using the River-ML framework and a publicly available phishing website dataset. The models were assessed based on accuracy, precision, recall, F1 score, Cohen's kappa, and memory efficiency. Evaluation results demonstrate that models such as Aggregated Mondrian Forest, Extremely Fast Decision Trees, and Logistic Regression achieved strong classification performance, with the best accuracy reaching 90.15%, precision up to 91.05%, recall up to 89.42%, F1 score up to 88.75%, and Cohen's kappa up to 79.99%, while lightweight models like ALMA maintained extreme memory efficiency, requiring as little as 1.81 KB. In general, the proposed incremental learning framework significantly improves the effectiveness of phishing detection and computational efficiency, providing a scalable and adaptive defense mechanism against evolving cyber threats.**

***Keywords*—Phishing detection; incremental learning; online machine learning; cybersecurity threats; real-time classification**

I. Introduction

Phishing is a deceptive cyber attack that exploits both social engineering and technical manipulation to unlawfully obtain user credentials and financial information. Attackers craft fraudulent emails, messages, or website links that closely resemble legitimate communications from reputable organizations, luring users to access counterfeit websites where they unknowingly disclose sensitive details such as usernames and passwords. Beyond deceptive messaging, hackers further amplify these attacks by deploying malicious software designed to extract login credentials and intercept user data from compromised systems. Various techniques are used, including email spoofing, manipulated URLs, instant messaging, forum postings, phone calls, and SMS phishing (smishing) to trick users into providing personal information. The authenticity of phishing content often mirrors that of genuine platforms, making it difficult for users to distinguish between legitimate and fraudulent interactions. The primary objective of phishing attacks is to obtain personal data for financial gain or identity theft, causing significant economic damage on a global scale [1].

Cybercriminals acquire confidential data by replicating legitimate websites and emails, often impersonating financial institutions or organizations that handle sensitive financial transactions [2], [3], [4]. These fraudulent emails are meticulously designed using authentic company logos, slogans, and branding elements to appear genuine. By exploiting HTML structures, attackers replicate entire websites or images, making them visually indistinguishable from their legitimate counterparts [5]. This deceptive practice has been facilitated by the widespread use of the Internet as a primary communication medium, allowing threat actors to exploit well-known brands, trademarks, and corporate identities that users trust for verification. To maximize their reach, phishers distribute large volumes of deceptive emails, commonly referred to as "spooled" emails, targeting unsuspecting recipients. Once these emails are opened, victims are typically redirected from an authentic-looking platform to a fraudulent website, where they unknowingly submit personal credentials [6], [7], [8]. The exploitation of user information through phishing has become a critical cybersecurity challenge in modern society [9], [10], [11]. Extensive research has been conducted to analyze various phishing indicators, including website URLs, webpage content, source code structures, and visual similarities, in an effort to mitigate these threats [12], [13], [14].

However, a significant gap remains in the availability of adaptive and efficient anti-phishing tools that can proactively detect and counteract evolving phishing tactics. Machine Learning (ML) techniques have been proven to be highly effective in identifying malicious URLs in real-time, offering a more dynamic alternative to conventional detection methods [15], [16], [17], [18], [19], [20], [21]. Traditional blacklist-based URL detection relies on manually curated databases of known phishing links, which require frequent updates and struggle to keep pace with the continuous emergence of new phishing domains. Attackers further evade detection through automated techniques such as Domain Generation Algorithms (DGA), rendering blacklist-based defenses inadequate [22]. The complexity of maintaining an exhaustive blacklist highlights the need for more intelligent and adaptive detection mechanisms. Researchers have increasingly advocated for ML-driven approaches, which leverage pattern recognition and predictive modeling to classify URLs as malicious or benign. By framing phishing detection as a binary classification problem, ML models can efficiently map high-dimensional feature spaces to corresponding threat labels, offering superior adaptability and generalization compared to conventional blacklist-based methods [23]. Despite growing interest in ap-

plying machine learning techniques for phishing detection, most existing approaches rely on batch or offline learning, which may be insufficient to handle evolving and dynamic attack strategies. Batch learning models present several limitations, particularly in the context of phishing detection. First, the training process is computationally intensive, requiring substantial processing power and memory resources. Second, the performance of the model is highly dependent on the size and quality of the training data, making generalization to new threats a challenge. Third, batch learning operates under the assumption that training data remain static over time, preventing the model from adapting to new samples or changes in data distribution (concept drift), necessitating frequent retraining and model redevelopment. Given the continuous nature of security threats and the dynamic landscape of web activity, incremental machine learning algorithms offer a more effective alternative to batch-based approaches. These algorithms are designed to process unbounded data streams, allowing continuous learning and real-time model updates. Additionally, they are well-suited for real-time phishing detection, addressing challenges that traditional batch models struggle with, such as handling rapidly evolving threats. In addition, incremental learning excels at detecting concept drift, enabling models to dynamically adjust to changing attack patterns and browsing behaviors. This adaptability makes incremental machine learning a promising solution for phishing detection in environments where threat patterns change unpredictably over time [24], [25], [26]. Several incremental machine learning algorithms have been proposed in the literature [27], [28], [29], [26], [30], [31], [32], [33], yet their applicability to phishing detection and the trade-offs between performance metrics and memory efficiency remain underexplored. This study aims to systematically evaluate various incremental learning algorithms to determine their effectiveness in detecting phishing attempts. In addition, an in-depth analysis of key performance trade-offs, including accuracy, precision, recall, kappa statistic, and memory consumption, is conducted to identify the most suitable models for real-time phishing detection.

The remainder of this study is structured as follows: Section II reviews related research efforts in phishing detection and incremental learning. Section III outlines the research methodology and details the experimental setup and evaluation framework. Section IV presents the results of the online machine learning evaluation and examines the effectiveness of online model selection using multi-armed bandits. Finally, Section V summarizes the findings and concludes the study.

II. Literature Review

Phishing is a cyberattack in which malicious actors impersonate reputable websites or businesses to deceive users into revealing sensitive personal information, such as passwords, usernames, and bank account details. These attacks exploit human trust and employ deceptive strategies, including social engineering, email spoofing, and URL manipulation, to mislead unsuspecting users. Phishing incidents can have severe consequences, including financial loss, identity theft, and compromised cybersecurity. Various detection techniques have been proposed in the literature to counteract these threats, including List-Based, Visual Similarity, Heuristic, Machine Learning, and Deep Learning approaches [34].

List-based detection techniques are widely employed in web browsers such as Google Chrome, Microsoft Edge, and Firefox to identify phishing websites [35]. These approaches rely on whitelisting and blacklisting methods. A whitelist contains a list of legitimate URLs that browsers are allowed to access, ensuring that only approved websites can be loaded. In contrast, a blacklist maintains a database of known phishing or fraudulent URLs, preventing browsers from loading potentially malicious web pages. Although blacklisting can effectively block previously identified phishing websites, it requires frequent updates to remain effective. Even minor modifications to a phishing URL can bypass blacklist-based defenses, making this method less reliable against newly emerging threats.

Visual similarity-based detection methods aim to identify phishing websites by analyzing their similarities to legitimate ones. This approach compares various visual elements, including the logo of the website, text layout, CSS, source code, and screenshots, to determine potential fraud. Since phishing websites often mimic the appearance of legitimate platforms, this technique is useful for detecting impersonation attempts. However, it has limitations in identifying zero-hour phishing attacks, as it relies on previously recorded or stored websites for comparison. Without prior knowledge of new phishing attempts, visual similarity-based detection may fail to recognize novel threats [36]. Heuristic-based detection methods analyze various characteristics of a website to distinguish between phishing and legitimate web pages. This approach examines several features, including URL structures, domain registration details, SSL certificate status, website traffic, and DNS records. Using predefined rules and classification algorithms, heuristic detection can identify phishing attempts even when the fraudulent website is not included in a blacklist. The effectiveness of this method depends on the quality of the selected set of features, training samples, and classification techniques. One significant advantage of heuristic-based detection is its ability to identify zero-hour phishing attacks, making it a more dynamic approach compared to static detection mechanisms.

Machine learning techniques have gained widespread attention for phishing detection due to their ability to learn patterns from large datasets and identify emerging threats.With the increasing availability of large-scale datasets, machine learning has proven to be an efficient tool in identifying phishing websites, especially in high-speed and high-volume data environments [37]. Machine learning models are trained using features extracted from phishing URLs, website structures, and JavaScript behavior. These extracted attributes help classifiers, such as Support Vector Machines (SVM), Random Forest, and Neural Networks, differentiate between phishing and benign websites. By analyzing patterns in big data environments, machine learning-based detection methods provide improved accuracy and adaptability over traditional list-based approaches. However, the effectiveness of machine learning models depends on the quality of the data and the selection of features [38]. Deep learning techniques further enhance phishing detection by leveraging advanced neural networks to automatically extract complex features from web pages. Recent studies suggest that deep learning models can outperform traditional machine learning classifiers in detecting phishing websites. Popular deep learning architectures for phishing detection include deep neural networks (DNN), convolutional neural networks (CNN), recurrent neural networks (RNN),

feed-forward deep neural networks, restricted Boltzmann machines, deep belief networks and deep autoencoders [39]. These models can analyze web content, user behavior, and URL characteristics to identify phishing attempts with higher accuracy. The ability of deep learning models to generalize patterns and adapt to new phishing techniques makes them a promising solution to combat evolving cybersecurity threats. Despite the effectiveness of existing detection methods, phishing attacks continue to evolve, requiring more adaptive and real-time detection mechanisms. The use of incremental learning in phishing detection remains an underexplored area, highlighting a critical gap in research. Addressing this limitation by incorporating incremental learning techniques could improve the robustness and efficiency of phishing detection systems in dynamic environments. The remainder of this section provides a more detailed discussion of machine learning and deep learning-based techniques, as they play a crucial role in phishing detection, particularly in the approach proposed in this study.

The study in [40] extensively examined the application of machine learning techniques to URL-based phishing detection. The authors evaluated multiple algorithms, including Naïve Bayes, Random Forest, K-Nearest Neighbor, AdaBoost, K-star, Support Vector Machines, and Decision Trees, using a self-constructed phishing dataset. Their findings indicated that the Random Forest algorithm, which is based solely on NLP-based features, exhibited the highest performance, achieving an accuracy rate of 97.98%. These results underscore the effectiveness of feature engineering to improve phishing detection. Similarly, the research conducted in [41] assessed the classification capabilities of Support Vector Machines, Decision Trees, and Logistic Regression using the PhishTank and DMOZ phishing datasets. Their findings revealed that among the models tested, the Support Vector Machines achieved the highest accuracy of 89.3%, demonstrating their robustness in distinguishing phishing from legitimate websites.

Further expanding on machine learning models, the study in [42] explored the performance of Random Forest, Support Vector Machines, Naïve Bayes, C4.5, JRip and PART classifiers in several phishing datasets, including PhishTank, OpenPhish, Alexa and Common Crawl. The results demonstrated that the Random Forest classifier outperformed other models, achieving an accuracy of 96.17%. This reinforces the previously established effectiveness of Random Forest in phishing detection. Based on these findings, [43] investigated the classification of legitimate and illegitimate websites using machine learning models such as Random Forest, Decision Trees, K-Nearest Neighbor (KNN), Iterative Dichotomiser-3 (ID3), and Naïve Bayes, trained on the UCI phishing dataset. Their study highlighted the importance of feature selection, as Genetic Algorithms (GAs) were shown to improve detection accuracy when used for feature optimization. More specifically, the combination of Iterative Dichotomiser-3 (ID3) with Yet Another Generating Genetic Algorithm (YAGGA) led to a significant increase in detection accuracy, reaching up to 95%. In [44], a novel approach was introduced, in which the authors developed the Hybrid Feature-Based Phishing Classifier (PHFBC), which integrates the Decision Tree and Naïve Bayes models with a statistical measure called the phishing ratio. Furthermore, the study proposed a robust feature selection technique using the Recursive Feature Subset Selection Algorithm (RFSSA). The proposed methodology was tested on the PhishTank, Chinese e-Business and DMOZ phishing datasets, achieving a True Positive Rate (TPR) of 0.984. This further emphasizes the importance of feature selection in improving detection performance. In another study, [45] focused on optimizing machine learning-based phishing detection through feature selection and hyperparameter tuning. The research explored multiple optimization strategies, including the Tree-structured Parzen Estimator (TPE) and Genetic Algorithms (GA) for hyperparameter optimization, as well as Moth Flame Optimization (MFO) and Particle Swarm Optimization (PSO) for feature selection. The experiments conducted on the PhishTank and Alexa datasets indicated that the optimal combination was Random Forest with PSO for feature selection and TPE for hyperparameter tuning, resulting in an impressive accuracy of 99.33%. These findings highlight the critical role of optimization techniques in improving the accuracy of phishing detection. In a related effort, [46] proposed a phishing detection system that uses URL analysis in eight different machine learning algorithms, including Logistic Regression, K-Nearest Neighbor, Decision Tree, Support Vector Machines, Naïve Bayes, XGBoost, Random Forest, and Artificial Neural Networks. Their comparative analysis on three different datasets—PhishTank, Alexa, and Common Crawl—showed that Random Forest applied to the PhishTank dataset achieved the highest accuracy of 94.59%. This reinforces the dominance of Random Forest in phishing detection applications. Another significant study was conducted by [47], who explored the use of domain name features for phishing detection by incorporating DNS data, blacklists, and lexical attributes. Their classifier, based on logistic regression, was trained using four datasets: PhishTank, Alexa, ICANN, and DNS-BH. However, while their approach demonstrated effectiveness in distinguishing between benign and malicious domains, overall accuracy remained relatively low at approximately 60%, indicating the limitations of purely lexical-based phishing detection. In contrast, [48] introduced a data augmentation method to improve machine learning-based phishing detection. Their study leveraged an Adversarial Autoencoder (AAE) to generate synthetic phishing samples, enhancing training datasets. The proposed model was tested on multiple classifiers, including support vector machines, decision trees, gradient booster, K-nearest neighbor, and random forest, using the UCI and Mendeley phishing datasets. The results demonstrated that models trained with AAE-generated data exhibited greater robustness and accuracy. Specifically, the Gradient Boosting classifier achieved the highest accuracy of 95.47%, validating the benefits of augmenting phishing datasets with adversarial examples. Expanding on previous research, the study in [49] examined the structural characteristics of URLs from phishing websites by extracting 12 different types of information. The authors trained four machine learning algorithms, namely Logistic Regression, Support Vector Machine, Naïve Bayes, and Decision Tree, using the PhishTank and DMOZ datasets. Their findings indicated that Logistic Regression outperformed the other classifiers, achieving an optimal accuracy of 95.12%. These results highlight the importance of URL-based feature extraction in enhancing the accuracy of phishing detection. Further advancing the field, the authors in [50] tackled the challenge of phishing detection within e-commerce platforms by proposing a framework for constructing reproducible and extensible datasets. Their methodology involved categorizing and selecting 87 widely

recognized phishing features, assessing their relevance and runtime performance, and leveraging them to build a robust dataset. Through conceptual replication and evaluation across the PhishTank, Alexa, and OpenPhish datasets, their results demonstrated that Random Forest was the most effective classifier, particularly when utilizing features from external services. Furthermore, their analysis showed that hybrid features contributed to the highest classification accuracy of 96.61%, while filter-based feature selection methods outperformed wrapper techniques, reaching an accuracy of 96.83%. Similarly, the work in [51] introduced a novel approach to detect real-time phishing attacks by evaluating deep hybrid features using the Light Gradient Boosted Machine model. Their method involved normalizing web page request features and applying Sparse Autoencoder and Principal Component Analysis for dimensionality reduction. The experimental evaluation, conducted on the ISCXURL-2016 dataset, demonstrated that their approach achieved a high classification accuracy of 99.6%, effectively minimizing false positives before processing web requests.

Extending the discussion on phishing datasets, the study in [52] highlighted the limitations of existing datasets, particularly their exclusion of login pages, which are critical for phishing detection. To address this gap, the authors introduced PILU-60K, a novel dataset that incorporates login URLs. Their experimental analysis revealed that while the support vector machines exhibited resilience against evolving phishing tactics, Random Forest achieved superior performance with PILU-60K, achieving an accuracy of 94.59%. These findings underscore the need to include login page data in phishing datasets to enhance detection accuracy. Furthermore, the research in [53] examined the security risks associated with browsing the Internet, particularly due to the low awareness of users of cyber threats such as phishing attacks. Their study introduced a supervised machine learning approach that utilizes Naïve Bayes, Decision Tree, Random Forest, Support Vector Machine, and Multi-Layer Perceptron classifiers. By extracting novel features solely from URLs and testing them on the PhishTank dataset, the study assessed the effectiveness of their approach compared to Google Safe Browsing (GSB), the default security control in major web browsers. Their results demonstrated that the proposed method consistently outperformed GSB, even when tested against phishing URLs that remained active for more than a year after model training. In particular, their optimized Random Forest model achieved the highest accuracy level of 99.29%. Building on the effectiveness of ensemble learning, [54] introduced PDCFS, a novel phishing detection model that uses hybrid cumulative feature selection. Their model partitioned datasets into multiple subsets based on diverse feature selection techniques, such as Chi-Square and Principal Component Analysis, and employed classifiers like Support Vector Machine and Random Forest. By implementing a five-fold cross-validation strategy and aggregating the results through majority voting, their findings indicated that Random Forest, when applied to a reduced feature set of 32, achieved the highest accuracy of 98.36%. Meanwhile, the PDCFS model itself achieved a close accuracy of 98.24%, demonstrating its competitive performance against other hybrid models.

The study in [55] explored the importance of phishing attacks and the ongoing challenge of developing robust detection mechanisms, particularly against zero-day attacks. To address these issues, the authors proposed a novel approach that integrates convolutional operations to model character-level URL features with a deep convolutional autoencoder (CAE). Their extensive experiments, conducted on three real-world datasets—PhishTank, PhishStorm, and ISCX-URL-2016—spanning a total of 222,541 URLs, demonstrated that the proposed method outperformed the latest deep learning models. In particular, receiver operating characteristic (ROC) curve analysis and 10-fold cross-validation revealed a 3.98% improvement in sensitivity over existing state-of-the-art models. These results underscore the effectiveness of using both sustainability and intelligibility in phishing detection, reinforcing the importance of deep learning-driven feature representation. Similarly, the research presented in [56] examined the surge in cyber-attacks, particularly phishing, that intensified due to increased digital activity during the pandemic. The study implemented a phishing detection system based on Convolutional Neural Networks (CNNs), where n-gram features were extracted from URLs using the PhishTank dataset. Experimental findings indicated that unigram features, particularly those focused on 70 specified characters irrespective of case sensitivity, achieved the highest accuracy rate of 88.90%. Additionally, the system demonstrated efficient URL classification, processing each URL in approximately 0.008 seconds. This research highlights the potential of deep learning models in achieving fast and effective phishing detection. Expanding on hybrid approaches, [57] proposed an innovative spam detection model that integrates dataset acquisition, feature extraction, optimal feature selection, and detection phases. The study collected a benchmark dataset containing both text and image data, extracting features using Term Frequency-Inverse Document Frequency (TF-IDF) for text analysis and the color correlogram and Gray-Level Co-occurrence Matrix (GLCM) for image analysis. To enhance classification accuracy, the authors employed a metaheuristic optimization algorithm called the Fitness Oriented Levy Improvement-based Dragonfly Algorithm (FLI-DA) for feature selection. The detection process combined recurrent neural networks (RNNs) and convolutional neural networks (CNNs), with FLI-DA further optimizing the number of hidden neurons. Experimental evaluations demonstrated significant improvements in spam email classification performance, reinforcing the effectiveness of hybrid deep learning approaches in phishing detection.

Further advancing phishing detection in the email domain, the study in [58] highlighted the growing vulnerability of organizations to phishing and spam emails, emphasizing the need for efficient detection strategies. To this end, the authors introduced Phish Responder, a hybrid machine learning framework that integrates long-short-term memory (LSTM) networks for text-based datasets and Multilayer Perceptron (MLP) for numerical-based datasets in natural language processing. Their experimental evaluation demonstrated that Phish Responder achieved an impressive accuracy of 99% using the LSTM model and 94% with the MLP model. Comparisons with existing solutions revealed the superiority of their approach, particularly in numerical-based phishing detection, thereby showcasing the potential of hybrid machine learning models in combating sophisticated phishing schemes. Based on the need for improved phishing detection systems, [59] developed a hybrid phishing detection model that combined URL and content analysis based on deep learning. The study

addressed the growing prevalence of phishing attacks, particularly those targeting victims through email communications. The proposed system aimed to improve detection accuracy while minimizing false positives by incorporating both URL-based and content-based features. Experimental evaluations, conducted on a high-risk URL and content-based phishing detection data set sourced from PhishTank, demonstrated a significant improvement in accuracy, reaching 98.37%. These results further highlight the advantages of integrating multiple detection mechanisms to enhance the accuracy of phishing identification while reducing erroneous classifications. The study in [60] explored the increasing threat of phishing attacks and proposed a deep learning-based detection model to improve the identification of phishing. By providing a comprehensive overview of phishing techniques, the authors emphasized the urgent need for more effective detection technologies. Their approach involved training and validating a model using split dataset, that analyzed email text and other relevant features to classify emails as phishing or non-phishing. The results demonstrated that the boosted decision tree algorithm achieved impressive accuracy rates of 88%, 100%, and 97% across different datasets, reinforcing the robustness and adaptability of the model to various phishing patterns. Expanding on ensemble learning strategies, the work in [61] introduced HELPHED, a phishing email detection framework that integrates hybrid features with Ensemble Learning methods. The methodology utilized two distinct approaches: Stacking Ensemble Learning and Soft Voting Ensemble Learning, each using multiple machine learning algorithms to improve classification accuracy. A rigorous evaluation process, which incorporates innovative guidelines and extensive experimentation, validated the effectiveness of the model. Conducted on a highly imbalanced dataset comprising 32,051 benign and 3,460 phishing email samples, the study revealed that the Soft Voting Ensemble Learning approach outperformed competing deep learning and machine learning models, achieving an outstanding F1 score of 0.9942. These findings highlight the potential of hybrid ensemble techniques in improving phishing detection. Similarly, [62] introduced the LBPS model, a hybrid deep neural network designed for the detection of phishing scam accounts. Using LSTM-FCN and BP neural networks, the model analyzed transaction records to establish implicit relationships between the extracted features. Additionally, the LSTM-FCN network effectively captured temporal patterns from all transaction records associated with a target account. The experimental evaluation demonstrated the effectiveness of the selected features, as the LBPS model consistently outperformed existing detection methods, achieving a remarkable F1-score of 97.86% on Ethereum transaction datasets. This research underscores the importance of hybrid deep learning approaches in identifying fraudulent accounts with high accuracy. Further advancing phishing detection methodologies, the study in [63] introduced Hybrid Feature Detection based on Hybrid Features (PDHF), a framework that integrates optimal artificial and automatic deep learning features. Artificial phishing features were optimized by eliminating redundancies using a novel evaluation index and an enhanced bidirectional search algorithm, while deep features were extracted from URLs through a one-dimensional CNN and a disorderly quantized attention mechanism. The experimental findings confirmed the superiority of PDHF's over existing phishing detection methods, achieving an exceptional accuracy of 99.65%, along with a precision of 99.42%, recall of 99.40%, and an F1-score of 99.41%. These results further validate the advantages of hybrid feature-based approaches in refining phishing detection accuracy. Building on these advances, [64] introduced RNT, a deep learning-based phishing detection technique that combines the ResNeXt architecture with an embedded GRU model. Addressing the class imbalance issues, the study incorporated the SMOTE technique, while autoencoders and ResNet (EARN) were used for enhanced feature engineering. Furthermore, hyperparameter optimization was performed using the Jaya optimization method (RNT-J), ensuring improved model performance. Experimental results demonstrated that RNT consistently outperformed state-of-the-art phishing detection models, achieving an impressive accuracy of 98% while maintaining low false positive and false negative rates. These findings highlight the effectiveness of combining deep learning architectures with optimized feature engineering to develop high-precision real-time phishing detection solutions.

In summary, this section highlights the widespread and continuously evolving nature of phishing attacks, which pose significant threats to individuals and organizations worldwide. Over the years, various detection methods have been proposed, including List-Based, Visual Similarity, Heuristic, Machine Learning, and Deep Learning techniques, each offering distinct advantages in identifying phishing websites. However, despite their effectiveness, most of these approaches rely on batch or offline machine learning models, limiting their adaptability to emerging and dynamic phishing strategies. Numerous studies have evaluated machine learning algorithms such as Random Forest, Support Vector Machine, Naïve Bayes, and Decision Tree across diverse datasets, demonstrating high accuracy in phishing detection. Furthermore, deep learning techniques, including Deep Neural Networks (DNN) and Convolutional Neural Networks (CNN), have shown significant promise in improving detection capabilities through automated feature learning. Although these advances have contributed to improved accuracy, they remain largely dependent on static training models that require frequent retraining to accommodate new threats. Despite these progresses, a critical research gap persists in the development and application of incremental machine learning techniques specifically tailored for phishing detection. Given the dynamic and continuously evolving nature of phishing attacks, detection systems must incorporate adaptive learning mechanisms capable of updating models in real time. Addressing this limitation is crucial for enhancing the robustness and efficiency of phishing detection systems, ultimately leading to more resilient cybersecurity solutions. Hence, further research should focus on integrating incremental learning methodologies to ensure adaptability and sustained performance in real-world phishing detection scenarios.

III. Methodology

This section describes the key procedures implemented to evaluate the effectiveness of the selected incremental machine learning algorithms using the phishing URL dataset provided in [65], [66]. The evaluation process, illustrated in Fig. 1, is carried out using the River Incremental Machine Learning Platform [67]. Each incremental machine learning algorithm is assessed following the same evaluation procedure to ensure consistency and comparability. As depicted in Fig. 1, the evaluation process begins with loading the phishing URL

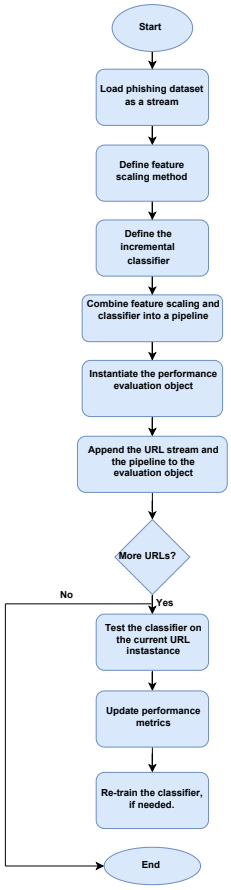

Fig. 1. Evaluation flowchart.

dataset as a continuous data stream in the River environment. Next, an incremental machine learning pipeline is constructed that incorporates a feature scaling method along with an incremental classifier. Once the pipeline is established, the phishing URL stream and the configured pipeline are integrated into the performance evaluation module, preparing the system for training and assessment. This setup ensures that the evaluation process accurately reflects the real-time adaptability of incremental learning models in phishing detection.

In this study, the performance of incremental machine learning classification algorithms is evaluated using the prequential evaluation method, also known as the interleaved test-then-train approach. This evaluation technique is specifically designed for incremental machine learning scenarios, where each incoming data sample, called an instance, plays a dual role in both testing and training the model. As instances are processed sequentially in their order of arrival, they become inaccessible after processing, ensuring that the model continuously adapts to new data without retaining past instances. In the context of phishing URL detection, the prequential evaluation process begins by using each incoming URL sample to test the incremental machine learning algorithm, generating a prediction. Immediately afterward, the same sample is utilized for training, allowing the model to refine its learning dynamically. Performance metrics are incrementally updated with each observed instance, allowing for a continuous assessment of the effectiveness of the model and its adaptability to previously unseen data. This ensures that the incremental machine learning algorithm undergoes a real-time evaluation, with its performance metrics continuously reflecting its ability to generalize to new phishing attempts. To comprehensively assess the effectiveness of the algorithms tested, several widely recognized performance metrics are used. These include accuracy, precision, recall, F score, kappa statistic, and memory footprint of the machine learning model during online learning. In the context of phishing URL detection, these metrics are formally defined as follows:

- Classification Accuracy: Represents the percentage of correctly classified URL samples [see Eq. (1)].

$$Accuracy = \frac{TN + TP}{TP + FP + FN + TN} \times 100\% \quad (1)$$

where, TP, TN, FP, and FN denote true positive, true negative, false positive, and false negative, respectively. TP represents the number of correctly classified phishing URLs, while TN corresponds to correctly classified benign URLs. In contrast, FP denotes benign URLs misclassified as phishing, whereas FN refers to phishing URLs misclassified as benign.

- Precision: Measures the proportion of URLs classified as phishing that actually belong to the phishing class [see Eq. (2)].

$$Precision = \frac{TP}{TP + FP} \times 100\% \quad (2)$$

- Recall: Evaluates the proportion of phishing URLs correctly identified out of all phishing URLs in the observed stream [see Eq. (3)].

$$Recall = \frac{TP}{TP + FN} \times 100\% \quad (3)$$

- F-score: Computes the harmonic mean of precision and recall, providing a balanced measure of a model's classification performance [see Eq. (4)].

$$F - score = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (4)$$

- Cohen's Kappa (κ): A robust measure of classification accuracy that accounts for agreement by chance. Unlike traditional accuracy metrics, Cohen's Kappa highlights improvements over a majority-class classifier that predicts all instances as the most frequent class [68]. This is particularly useful when evaluating the classification performance in unbalanced data streams [see Eq. (5)].

$$\kappa = \frac{p_0 - p_c}{1 - p_c} \quad (5)$$

where, p_0 represents the prequential accuracy of the classifier, while p_c denotes the probability that a chance classifier

correctly predicts labels [69]. A value of $\kappa = 1$ indicates perfect classification performance.

- Model Size: Represents the memory space occupied by the incremental machine learning model during the prequential evaluation process, reflecting its computational efficiency.

To comprehensively evaluate incremental machine learning algorithms, an extensive set of experiments was conducted using various models, as detailed in Table I. This study explores a diverse range of incremental machine learning approaches, including ensemble-based methods, forest models, linear classifiers, Naïve Bayes, nearest neighbor models, and tree-based classifiers. Additionally, each algorithm was tested under three different feature scaling settings: no scaling, min-max scaling, and standard scaling.

The Min-Max scaling, defined in Eq. (6), transforms the data to a fixed range between 0 and 1, preserving the relative features relationships. In contrast, standard scaling, as described in Eq. (7), adjusts the data to have zero mean and unit variance, ensuring that the features contribute equally to model training. In this study, the impact of these scaling techniques on the performance of incremental learning models is systematically analyzed.

TABLE I. UTILIZED INCREMENTAL MACHINE LEARNING ALGORITHMS

Category	Algorithm Name
Ensemble Models	ADWINBagging Classifier ADWINBoosting Classifier AdaBoost Classifier BOLE Classifier Bagging Classifier Leveraging Bagging Classifier Streaming Random Patches (SRP) Classifier Stacking Classifier Voting Classifier
Forest Models	Aggregated Mondrian Forest (AMF) Classifier Adaptive Random Forest (ARF) Classifier
Linear Models	Logistic Regression (LR) Classifier Approximate Large Margin Algorithm (ALMA) Classifier Passive-aggressive (PA) Classifier Perceptron Classifier
Naïve Bayes Models	Gaussian (NB) Classifier
Neighbours Models	K-Nearest Neighbors (KNN) Classifier
Tree Models	Hoeffding Tree (HT) Classifier Hoeffding Adaptive Tree (HAT) Classifier Extremely Fast Decision Tree (EFDT) Classifier Stochastic Gradient Tree (SGT) Classifier

$$x_{\text{scaled}} = \frac{x - x_{\text{min}}}{x_{\text{max}} - x_{\text{min}}} \tag{6}$$

where,

- x denotes the original feature value.
- x_{scaled} represents the scaled feature value.
- x_{min} refers to the running minimum value of the feature in the data stream.
- x_{max} refers to the maximum running value of the feature in the data stream.

$$x_{\text{scaled}} = \frac{x - \mu}{\sigma} \tag{7}$$

where,

- x represents the original feature value.
- x_{scaled} denotes the scaled value of the feature.
- μ corresponds to the running mean of the feature in the data stream.
- σ denotes the running standard deviation of the feature in the data stream.

IV. RESULTS

This section presents the results obtained by implementing the methodology described in Fig. 1 on the incremental machine learning algorithms summarized in Table I, evaluated using different feature scaling techniques. The objective is to analyze the impact of feature scaling on model performance and memory efficiency.

Fig. 2 illustrate the performance results for linear models in standard, min-max, and no feature scaling settings, respectively. The results show that the scaling of the features plays a crucial role in influencing the accuracy, precision, recall, F1 score, Cohen's kappa and model size.

As shown, the application of standard feature scaling significantly enhances the performance of the logistic regression model, which outperforms its linear counterparts. Specifically, logistic regression achieves an accuracy of 89.20%, with precision, recall, F1 score, and Cohen's kappa values of 86.42%, 89.42%, 87.89% and 78.15%, respectively. This improvement suggests that standard scaling effectively normalizes feature distributions, allowing the model to learn more efficiently and generalize better. On the other hand, the ALMA (Adaptive Linear Margin Algorithm) model exhibits the lowest memory consumption, occupying only 4.69 KB, making it the most resource-efficient among the linear models. This result highlights a critical trade-off between accuracy and memory efficiency, where ALMA prioritizes compactness at the cost of predictive performance.

A different performance pattern emerges under Min-Max scaling. The Perceptron model achieves the highest accuracy of 83.60%, indicating that the min-max scaling may provide a more favorable feature distribution for this model. Meanwhile, logistic regression maintains the highest precision value of 90.70%, suggesting that min-max scaling helps reduce false positive classifications in phishing detection. The Passive-Aggressive (PA) model, in contrast, attains the highest recall (81.57%), F1 score (81.27%), and Cohen's kappa (66.56%), indicating that it is particularly adept at capturing phishing instances under this scaling technique. Consistent with the previous setting, the ALMA model retains the lowest memory footprint, occupying only 6.56 KB.
