Table of Contents

Paper 1: A Lifecycle-Oriented Taxonomy of Open-Source Tools for Machine Learning

Authors: Hamza Mallam Musa Mohammad, Isa Hussain Adam Mohammed, Abdullah Bajaber, Syed Abdur Rahman, Anas Sani, Atif Naseer

PAGES 1 – 12

Paper 2: Agentic Accountability: "The Buck Stops Where?" Ethical Frameworks for Human Oversight of Autonomous AI Systems

Authors: Ornella Bahidika

PAGES 13 – 22

Paper 3: ExtRA++: A Conceptual Architecture for a Deep Learning System for Aspect-Based Sentiment Analysis in User Reviews

Authors: G. Kanev, I. Valova

PAGES 23 – 29

Paper 4: Learning Analytics for Student Performance and Early Detection of At-Risk

Authors: Rhowel M. Dellosa

PAGES 30 – 38

Paper 5: An EWMA-Based Adaptive Thresholding Concept for Autoencoder-Based Concept Drift Detection in Data Streams

Authors: Siti Nurulain Mohd Rum, Qiao Song

PAGES 39 – 51

Paper 6: Hybrid CNN for Breast Cancer Detection in Multi-Modality Imaging

Authors: Emmanuel Ofotsu Kwesi Bannor, S. Sarah Maidin, Vinayakumar Ravi, Nguyen Thi Thu Thuy, Nghiem Thi-Lich

PAGES 52 – 60

Paper 7: A Strategic Cloud Adoption Readiness Index (SCARI) Framework: Empirical Development and Validation in the Ghanaian Context

Authors: Adade Sedom Percy, Emmanuel Ofotsu Kwesi Bannor, S. Sarah Maidin, Vinayakumar Ravi, Nguyen Thi Thu Thuy, Nghiem Thi-Lich

PAGES 61 – 68

Paper 8: Perceived Usefulness Without Ease of Use: A TAM-Based Evaluation of Enhanced Isabela State University Echague Online Resource App for a New Guild of Education (ISUE ORANGE) Functionalities

Authors: Ricardo Q. Camungao

PAGES 69 – 76

Paper 9: A Multilayer Secure Image Steganography Framework Using Edge-Adaptive Embedding and Pre-Encryption

Authors: A F M Zainul Abadin, Rossilawati Sulaiman

PAGES 77 – 87

Paper 10: Multimodal Machine Learning for Cybersecurity in Internet of Things Environments: A Literature Review

Authors: Abdelaaziz NASSIRI, Azeddine Khyat, Kama El Guemmat, Mohamed Aazi

PAGES 88 – 96

Paper 11: Optimizing the Multi-Omics Data Types and Variant Combinations for Accurate Breast Cancer Molecular Subtypes Classification

Authors: Sajid Shah, Azurah A Samah, Syed Hamid Hussain Madni, Sarina Sulaiman, Zuraini Ali Shah, Wong Yee Leng, Aryati Bakri

PAGES 97 – 107

Paper 12: An AI-Driven Framework for Software Effort Estimation Based on Developer Performance Metrics

Authors: Shaheer Ahmed, Nosheen Qamar, Faria Nazir, Nosheen Sabahat, Atif Ikram, Najla Abdulaziz Almousa, Hebah Abdullah Abubakr, Mohammed Abual-Rub, Abdulrahman Alojail, Marwan Abu-Zanona

PAGES 108 – 115

Paper 13: Cloud-Based Intelligent Surveillance for Digital Forensics: AI-Enhanced Criminal Investigations

Authors: Aseel Abdullah Aljuhani, Fatima Hamed Aljuhani

PAGES 116 – 123

Paper 14: A Fast and Efficient Residual Learning Framework Driven by Approximate Nearest Neighbor Search for Large-Scale Fingerprint-Based Visible Light Positioning

Authors: Huy Q. Tran, Huu Lam Phan, Tan Nguyen Van

PAGES 124 – 130

Paper 15: Insight Enhancement of Distortion Effects on the Quality in Imagery Environments

Authors: Hanan Hassan Ali Adlan, Mona Alanazi, Kolood Alenezi, Muneera Aldhabbah, Muneera Alsubai, Rafa Bahobail, Reem Alharbi

PAGES 131 – 145

Paper 16: A Hybrid Neuro-Fuzzy and Machine Learning Model for Student Performance Prediction in Online Mathematics Education

Authors: Beyza Esin Özseven, Turgut Özseven

PAGES 146 – 162

Paper 17: An Empirical Analysis of Google Play Data Safety Disclosures: A Consistency Study of Privacy Indicators in Mobile Gaming Apps

Authors: Bakheet Aljedaani

PAGES 163 – 175

Paper 18: Improving Emotion Recognition Accuracy Using a Multimodal Model (Face and Voice Video) Based on a Convolutional Neural Network (CNN)

Authors: Karnadi, Ermatita, Abdiansah

PAGES 176 – 185

Paper 19: Interlayer Coupling Strategy for Two-Layer Interdependent Command-and-Control Networks: Balancing Node Walk Betweenness and Operational Attributes

Authors: Bo Chen, Yangkun Wang, Yufeng Chen, Yuqi Yang

PAGES 186 – 197

Paper 20: Utilizing Structured Equation Modeling and Machine Learning in Investigating Digital Competency in Public School Teachers in Bukidnon, Philippines

Authors: Nathalie Joy G. Casildo

PAGES 198 – 207

Paper 21: DeepEdgeNet: An Edge-Cloud Deep Learning Framework for Efficient Environmental Monitoring in IoT Systems

Authors: Qamar H. Naith

PAGES 208 – 222

Paper 22: Machine Learning Evaluation of the HiTar-2024 Dataset for Intrusion Detection in Smart Manufacturing Environments

Authors: Adeeb Alhomoud

PAGES 223 – 232

Paper 23: ZK-FedMed: Privacy-Preserving Federated Learning for Cardiovascular and Renal Disease Prediction

Authors: Haewon Byeon

PAGES 233 – 244

Paper 24: An Interpretable Machine Learning Approach for Inflation Forecasting in Indonesia Using Domestic Macroeconomic Indicators

Authors: Ahmad Maimunif, Evaristus Didik Madyatmadja

PAGES 245 – 256

Paper 25: A Conceptual Model for Detecting Contactless Drug Distribution Based on Behavioural Analysis and Geospatial Visualisation

Authors: Medeu Kurmangali, Talgat Akimzhanov, Kanat Kazhibaev, Kulambayev Bakhytzhan, Moshkalov Altynbek

PAGES 257 – 269

Paper 26: Revisiting Support Vector Machines: A Distance-Based Alternative to Deep Learning for Efficient Text Classification

Authors: Siew Teng Koh, Anbuselvan Sangodiah, Norazira Binti A Jalil, Jafhate Edward, Nur Fatin Liyana Binti Mohd Rosely

PAGES 270 – 284

Paper 27: Pareto-Optimized Model Predictive Control for Dynamically Feasible Three-Dimensional Trajectory Generation in Robotic Manipulators

Authors: Zeinel Momynkulov, Sayat Ibrayev, Azizah Suliman, Yegenberdi Tenizbayev, Batyrkhan Omarov

PAGES 285 – 299

Paper 28: Enhanced IoT-Driven Load Forecasting with Metaheuristic-Optimized Deep Learning for Logistics Planning

Authors: Ramadan Babers, Walid Atwa, Mohamed Meselhy Eltoukhy, A. M. M. Madbouly

PAGES 300 – 309

Paper 29: A Smart IoT-Based Communication and Optimization System for Hajj and Umrah Services

Authors: T. H. F. Harumy, M. Gahara, M. F. Sipahutar, A. Zakiyah, N. A. Hasna, E. Ikhsan, Yusuf N. Buwono, Haposan Delon Pasaribu

PAGES 310 – 316

Paper 30: Blockchain Consensus Mechanisms Contributing to Improved Trust in Knowledge Sharing: A Systematic Review

Authors: Mohammad Fairus Bin Zulkifli, Rabiah Abdul Kadir, Mohamad Nazir Ahmad

PAGES 317 – 334

Paper 31: Generative AI in Higher Education: A Systematic Review with Emphasis on Programming and Computer Science Education

Authors: Abdulaziz Saidu Yalwa, Mohd Shahizan Othman, Lizawati Mi Yusuf, Muteb Sinhat Almarshadi

PAGES 335 – 347

Paper 32: Translating Job Advertisements into Competency Taxonomy: An Interpretable Approach for Robotics Recruitment Analysis

Authors: Zhiyan Xue, Yang Zhou

PAGES 348 – 363

Paper 33: Enhancing User Experience in Virtual Reality for Children with Autism: A Significant Review

Authors: Nur Aleesya Mohd Asri, Normala Rahim, Norsuhaily Abu Bakar, Wan Rizhan, Ismahafezi Ismail, Nur Saadah Mohd Shapri, Sarah Farhana Juhari

PAGES 364 – 376

Paper 34: Credit Card Fraud Anomaly Detection in Mobile Cloud Service Security Using Extended Isolation Forest with Hyperparameter Optimization

Authors: Nur Izura Udzir, Nur Farihin Bidin, Aliyu Usman Shehu, Madihah Mohd Saudi, Azuan Ahmad, Muhammad Harith Noor Azam, Shazrin Azlin Ruslan, Nor Azlinda Abdul Halim

PAGES 377 – 384

Paper 35: Fine-Grained Image Classification Using Vision Transformer Model

Authors: Zunaira Saleem, Uzma Jamil, Saman Iftikhar

PAGES 385 – 393

Paper 36: MRAE: Multi-Resolution Attention Ensemble with Hybrid CNN–Transformer Fusion for Breast Ultrasound Classification

Authors: Hemin Kareem Azeez Alshateri, Ahmed Harbaoui

PAGES 394 – 403

Paper 37: COAT: A Cross-Omics Attention Transformer for PAM50 Breast Cancer Subtype Classification

Authors: Soufiane El Atfa, Abdelmajid Hajami, Hamid Machhour, Hakim Allali

PAGES 404 – 415

Paper 38: Efficient Vulnerability Classification in IoT Networks: An Approach Using Convolutional Neural Networks and Tabu Search Optimization

Authors: Feras Fares AL-Mashagba, Mohammad Othman Nassar, Essam Said Hanandeh

PAGES 416 – 434

Paper 39: Scoping Review on Global Digital Policies and Transformation Strategies for Ageing Societies: Implications for Malaysia

Authors: Ahmad Wiraputra Selamat, Shamsul Arrieya Ariffin

PAGES 435 – 444

Paper 40: A Mid-Level Feature Fusion Framework Integrating PHLF and VGG16 for Robust Batik Pattern Detection

Authors: Jani Kusanti, Edi Noersasongko, Purwanto, Moch Arief Soeleman

PAGES 445 – 450

Paper 41: YOLO-CBAM: A Lightweight Attention-Guided Deep Learning Framework for Real-Time Road Damage Detection

Authors: Olzhas Olzhayev, Bakhytzhan Kulambayev, Azizah Suliman, Assel Rustem, Almira Madiyarova, Batyrkhan Omarov

PAGES 451 – 459

Paper 42: Deep Learning-Based Recommender System for Arabic Content with Integrated Sentiment Analysis of User Reviews

Authors: Amani Al-Ajlan, Nada Alshareef

PAGES 460 – 466

Paper 43: A Knowledge-Enhanced Cross-Modal Transformer Network for Sentiment Analysis in Intelligent Interaction

Authors: Chunyan Huang, Xinlu Sun

PAGES 467 – 478

Paper 44: Enhancing Traffic Congestion Forecasting with Explainable Deep Learning: A Framework Using LIME for Transparent Intelligent Transportation Systems

Authors: Ouhmidou Hajar, Nabou Abdellah, Elikram Moulay Ahmed

PAGES 479 – 486

Paper 45: Mammographic Image Classification Based on KAN-CBAM

Authors: Yuanyuan Wang, Vladimir Mariano

PAGES 487 – 498

Paper 46: Enhancing Virtual Team Performance Through a Quantitative-Based Management Model (VTPM)

Authors: Sathya A/L Nantha Kumar, Zulkefli Mansor

PAGES 499 – 509

Paper 47: An Explainable XGBoost-Based Framework for Robust Multi-Cohort Prediction of Pancreatic Cancer

Authors: Nada Ahmed El-Gammal, Rania Ahmed Abdel Azeem Abul Seoud, Sayed T. Muhammad

PAGES 510 – 519

Paper 48: A Hybrid PCA–Random Forest Model for Predicting Employee Performance from Work Ethics and Work Values

Authors: Nova E. Arquillano

PAGES 520 – 529

Paper 49: A New Approach for 3D Shape Retrieval Based on an Explainable Boosting Classifier

Authors: Fatima Rafii Zakani, Mohcine Bouksim, Khadija Arhid, Taoufiq Gadi, Mohamed Aboulfatah

PAGES 530 – 538

Paper 50: HBC-Glicko: A Bloom-Constrained Adaptive Assessment Architecture with Uncertainty-Aware Progression

Authors: Wissal EL Fougour, Mohamed Erradi

PAGES 539 – 552

Paper 51: A Secure Chaotic DNA-Based Framework for Satellite Image Encryption

Authors: Asim Seedahmed Ali Osman, Ibrahim Rizqallah Alzahrani, Aeshah Khalil I Alotaibi, Adil Mahmoud Mohamed Mahmoud, Daifallah Zaid Alotaibe

PAGES 553 – 562

Paper 52: A Diffusion-Based Generative AI Framework: An Exterior House Design from Textual Descriptions

Authors: Muhammad Amirul Akmal bin Ajusin, Noor Hasimah Ibrahim Teo, Rosniza Roslan, Raseeda Hamzah, Anita Ahmad Kasim

PAGES 563 – 570

Paper 53: Integration of Random Forest and Hough Transform for Cancer Classification Using Microarray Gene Expression Data

Authors: Hibah Alatawi, Hechmi Shili

PAGES 571 – 586

Paper 54: Detection of Unauthorized Use in SIEM Through Behavioral Analysis and Adaptive Rules

Authors: Julio Armando Landázuri Castro, Renato M. Toasa, Maryory Urdaneta Herrera

PAGES 587 – 594

Paper 55: Semantic Modeling of Medical Specialty Relationships Using Large Language Models

Authors: Ismail Bouajaja, Omar Elfahim, Omar Bouattane, Oussama Barakat, Abdelaziz Daaif

PAGES 595 – 602

Paper 56: An Intelligent Semantic-Aware Academic Library System Using Natural Language Processing and Knowledge Graphs

Authors: Mohamad Shady Alrahhal, Bandar Abdulwahed Fallatah, Omar F. Aloufi, Abdullah M. Barakeh

PAGES 603 – 612

Paper 57: Rice Pest Detection Using Enhanced YOLOv8n with Multilayer Contextual Attention and Deformable Snake Convolution

Authors: Shuangyuan Li, Jianglong Lin, Jiaming Liang, Tianyu Li

PAGES 613 – 623

Paper 58: Data-Driven Excimer LiDAR Framework for Joint Surface Reflectivity Mapping and Atmospheric Pollutant Profiling

Authors: Sandugash Dospanbetova, Gulzat Ziyatbekova, Murat Baktybayev, Botakoz Smagul, Yermakhan Zhabayev, Zhanar Bidakhmet

PAGES 624 – 635

Paper 59: Cervical Cytology Classification Using Multiple CNN Architectures with Transformer-Based Feature Enhancement

Authors: Mehreen Sirshar, Omama Shakeel, Nayyab Asim, Fakeeha Jafari, Hani Almoamari, Adnan Nadeem, Mohammad Zubair Khan, Ibrahim Aljubayri

PAGES 636 – 646

Paper 60: Methodology for Identifying Soiling on PV Panels Using RGB Images and Deep Learning

Authors: Katerina Gabrovska-Evstatieva, Tsvetelina Kaneva, Irena Valova, Dimitar Trifonov, Nikolay Valov, Ventsislav Keseev, Nicolay Mihailov, Boris Evstatiev

PAGES 647 – 655

Paper 61: Gas-Efficient Smart Contract Design: Quantifying Refactoring Impact on EVM Execution Costs

Authors: Nur Haliza Abdul Wahab, Juniardi Nur Fadila, Nur Faszha Razali, Keng Yinn Wong

PAGES 656 – 668

Paper 62: Agent-Oriented Fuzzy Decision Support System for Multi-Criteria Evaluation of Sustainable Investments in the Agro-Industrial Sector

Authors: Aigerim Omurtayeva, Ulzhan Makhazhanova, Akmaral Kulamanova, Dinara Kargabaeva, Bolat Tassuov, Adilbek Tanirbergenov

PAGES 669 – 679

Paper 63: Phonetic Completeness Over Prosodic Diversity: Syllable-Level Synthetic Corpus Construction for Low-Resource Penang Hokkien Speech Synthesis

Authors: Yu Liang Lai, Yen Min Jasmina Khaw, Seng Poh Lim, Tien Ping Tan

PAGES 680 – 690

Paper 64: Exploring New Possibilities: Virtual Reality in Supporting Children with Autism

Authors: Brayan J. Lozano-Martel, Eduardo F. Araujo-Vasquez, Segundo E. Cieza-Mostacero

PAGES 691 – 698

Paper 65: Augmented Reality in Automotive Technical Training: Technological Innovation Through Mobile Applications in Trujillo

Authors: Julissa B. Polo-Holguin, Eduardo F. Araujo-Vasquez, Segundo E. Cieza-Mostacero

PAGES 699 – 708

Paper 66: CFD-Based Aerothermal Design Verification of Coffee Cabinet Dryer

Authors: Gerry M. Castillo, Aeron R. Mojica, Jhon Heron P. Carsocho, Ray Rojan C. Romeroso, Sheryl Dinglasan-Fenol, Al Eugene L. Torres, Gee Jay C. Bartolome

PAGES 709 – 718

Paper 67: Unveiling Temporal Dynamics of Consumer Emotions in Online Reviews: An Emotion Mining Approach Using Ekman's Emotion Model

Authors: Azra Shamim, Abdulwahab Ali Almazroi

PAGES 719 – 730

Paper 68: Privacy Preserving Federated Graph Learning with Data Envelopment Analysis Driven Interpretable Customer Segmentation Framework

Authors: Pentareddy Ashalatha, G. Krishna Mohan

PAGES 731 – 743

Paper 69: Explainable Cognitive Graph Intelligence Framework for Multi-Task Graduate Employability and Salary Prediction

Authors: Hameeda Khatoon, Chandra Prakash Vudatha

PAGES 744 – 758

Paper 70: Large Language Models for Arabic Automated Essay Scoring

Authors: Leena Najjar, Liyakathunisa Syed

PAGES 759 – 769

Paper 71: Revolutionizing Urban Waste Systems: A Comprehensive Review of IoT, AI, and Optimization Techniques for Smart Waste Management

Authors: Lahcen GOUSKIR, Abdelmoula ABOUHILAL, Mohamed GOUSKIR, Mohamed BASLAM, Soufiane BELHOUIDEG, Hanaa Hachimi

PAGES 770 – 777

Paper 72: Deep Learning-Enhanced Excimer Laser LiDAR System for High-Resolution Earth Surface Monitoring and Multi-Platform Validation

Authors: Sandugash Dospanbetova, Gulzat Ziyatbekova, Murat Baktybayev, Botakoz Smagul, Yermakhan Zhabayev, Zhanar Bidakhmet

PAGES 778 – 788

Paper 73: Federated and Cross-Domain Student Performance Prediction

Authors: Sam Zhe Xuan, P. Ganesh Kumar, C. Rani, Kanagalakshmi, R. RajiniGanth, Atif Mahmood

PAGES 789 – 798

Paper 74: Intelligent Traffic Surveillance: Machine Learning-Based Detection of Vehicle Speed Violations

Authors: Niloy Kanti Paul, Dipanwita Saha, Kaushik Biswas, Sultanul Arifeen Hamim, Tanvir Ahmed, Rifath Mahmud

PAGES 799 – 810

Paper 75: Malak: A Python Toolkit for Edge AI Model Optimization

Authors: Mohammed Hassan Alnemari

PAGES 811 – 818

Paper 76: RGB-D Bin-Picking System for Ergonomic Automotive Clip Assembly: 3D Annotation, Deep Learning, and 6-DOF Pose

Authors: Brahim Bergor Beguiel, Ibrahim Hadj Baraka, Yassir Zardoua

PAGES 819 – 833

Paper 77: Urdu-ClimateGPT: Adapting LLM for Climate Data in Urdu Language

Authors: Muhammad Farooq, Muhammad Asif Habib, Jabeen Sultana, Muhammad Umar Aftab

PAGES 834 – 843

Paper 78: Leveraging MCESTA and Large Language Models for Next-Generation Similarity Learning

Authors: Mohamedou Cheikh Tourad, Abdelmounaim Abdali, Mohamed Dhleima, Naoual Mouhni, Sana Chakri, Ibtissam Amalou, Saadbouh Cheikh El Mehdy

PAGES 844 – 853

Paper 79: Enhanced Pied Kingfisher Optimization Algorithm with Hovering Scouts and Foraging Flocks Mechanisms

Authors: Aarhus Dela Cruz

PAGES 854 – 869

Paper 80: A Lightweight Explainable Hybrid Deep Learning Approach for Early Skin Disease Detection

Authors: Mohammad Barr

PAGES 870 – 879

Paper 81: Intrusion Detection System for Ransomware in Network Traffic Using Supervised Machine Learning

Authors: Ziad Almulla, Moath Alamri, Mounir Frikha

PAGES 880 – 897

Paper 82: Domain Knowledge-Enhanced Welding Robot Path Planning Algorithm

Authors: Ming Liu, Peng Shao

PAGES 898 – 908

Paper 83: Optimizing Whiteboard Digitization with Clarix: An Automated Vision-Based System for Real-Time Text Extraction and Surface Cleaning

Authors: Abdellah NABOU, Ameksa Mohammed, Ezzahoud Hajar, Bazgour Yassine, Abouhane Zahra

PAGES 909 – 916

Paper 84: Adaptive Temporal Windowing for Streaming Outlier Detection Under Dynamic Arrival Rates

Authors: Hend Maher, Mohamed Khafagy, Heba Nagaty

PAGES 917 – 925

Paper 85: Deep Learning-Based Road Damage Detection Using Improved YOLOv8: Model Performance and Implementation

Authors: Aulia Rahman, Hwa Jen Yap, Rusdha Muharar

PAGES 926 – 934

Paper 86: Smarter Bridges: Leveraging Artificial Intelligence to Reshape University-Industry Technology Transfer

Authors: Khaouja Mohammed, Sanaa DFOUF, Kaoutar ERRAKHA, Hanan ELHARISSI, Fekkak HAMDI

PAGES 935 – 949

Paper 87: Development of an Arabic Pet Adoption System with Hybrid Recommendations

Authors: Hailah Alballaa

PAGES 950 – 959

Paper 88: State-AttentNet: A Dynamic Volatility-Adaptive Hybrid Framework for Market State Classification in Frontier Economies

Authors: Md. Abul Kalam Azad, Abdul Kadar Muhammad Masum, Najmus Saadat, Esrat Jahan, Ramona Birău, Virgil Popescu, Iuliana Carmen Bărbăcioru, Ștefan Mărgăritescu

PAGES 960 – 970

Paper 89: Cognitively Aligned Assessment Item Generation with Open-Source LLMs: A Comprehensive Evaluation on LearningQ

Authors: Mahmoud Badry, Walaa Medhat, Shereen A. Taie, Asmaa Hashem Sweidan

PAGES 971 – 979

Paper 90: A Machine Learning Approach for Targeting Lucrative Customer Segments

Authors: Leen Almajed, Haifa Almakhdhoub, Jana Alzeydan, Alaa Bin Sleem, Ouiem Bchir

PAGES 980 – 990

Paper 91: A Human-Centered Evaluation of AI-Generated Guidance: Integrated Statistical and Machine Learning Analysis with a Risk Framework for High-Stakes Domains

Authors: Omar Al-Turki, Felwah Alqahtani, Eman Alqahtani, Sarah Alswedani, Sami Alshmrany, Rashid Mehmood

PAGES 991 – 1006

Paper 92: D-HAN-Net: A Hybrid Dual-Stream Architecture for Corporate Bankruptcy Prediction via Multimodal Fusion

Authors: Md. Abul Kalam Azad, Abdul Kadar Muhammad Masum, Najmus Saadat, Esrat Jahan, Ramona Birău, Virgil Popescu, Iuliana Carmen Bărbăcioru, Ștefan Mărgăritescu

PAGES 1007 – 1019

Paper 93: A Reliability-Aware Visual-Inertial Odometry for Dynamic and Low-Texture Environments

Authors: Yelu Liu, Ruokun Qu, Mengcheng Xu, Chenglong Li, Hui Jiang

PAGES 1020 – 1030

Paper 94: Trustworthy App Detection in Saudi Mobile Finance: Bridging Deep Learning and Interpretability

Authors: Raed Alharbi, Maryam Alghamdi

PAGES 1031 – 1041

Paper 95: Benchmarking Deep Learning for PM2.5 Forecasting in IoT-Based Smart Cities: GCN Spatial Encoding and Transformer Temporal Modeling

Authors: Abdessamad BADOUCH, Kaoutar BELHOUCINE

PAGES 1042 – 1049

Paper 96: A Controlled Benchmark of Open-Source and Proprietary LLMs for Few-Shot Microbiome IBD Classification

Authors: Nouhaila En Najih, Soufiane Hamida, Ahmed Moussa

PAGES 1050 – 1058

Paper 97: A Lightweight and Robust APBT–LBP Deep Feature Zero-Watermarking Framework with DNA Encryption for Medical Images

Authors: Ranjan Kumar Senapati, Prasanth Mankar, B Padmaja, Chilamakuru Nagesh, Pradeep Kumar, Gandikota Ramu, Gandharba Swain

PAGES 1059 – 1074

Paper 98: A Privacy-Aware Federated Hybrid Model for Multimodal Mental Health Analysis

Authors: Yusra, Riaz UlAmin

PAGES 1075 – 1084

Paper 99: Design and Evaluation of a Ubiquitous Learning Game for Adolescent E-Cigarette Addiction Prevention

Authors: Lamyae Bennis, Khalid Kandali, Hamid Bennis

PAGES 1085 – 1094

Paper 100: MILP for Multimodal Urban Transport: Formal and Informal Sectors

Authors: Oumar KONE, Yapi Fiacre Aristide EDI, Kouassi Hilaire EDI, Pawoumodom Matthias TAKOUDA

PAGES 1095 – 1107

Paper 101: Artificial Intelligence in Motorsport: A Scoping Review of Applications, Challenges, and Research Gaps

Authors: Radu C. Lucaciu, Cornelia Aurora Győrödi

PAGES 1108 – 1119

Paper 102: Benchmarking Deep Vision Architectures: From Controlled Datasets to Real-World Clinical Validation

Authors: Raghda Essam Ali, Noha Ahmed Saad El-Dien, Magi Hossam Eldin Mahfouz

PAGES 1120 – 1129

Paper 103: Smart IoT Framework for Sustainable Cities: Integrating Information Systems and Artificial Intelligence

Authors: Amarildo Rista, Alma Stana

PAGES 1130 – 1145

A Lifecycle-Oriented Taxonomy of Open-Source Tools for Machine Learning

***Abstract*—Machine learning (ML) offers various tools, frameworks and platforms for resolving complex problems in computational science and engineering. Machine learning frameworks have emerged as the cornerstone of modern research and innovation. It redefines how knowledge is produced, validated, and disseminated. Open-source machine learning frameworks are emerging as a promising way to solve the challenges of large datasets, real-time constraints and heterogeneous system components. This study provides an extensive overview of open source tools based on the ML lifecycle. These tools are evaluated based on their purpose and key features for each stage of lifecycle, assisting researchers and practitioners in making informed decisions according to their requirements. The key challenges are identified and future research directions are also outlined.**

***Keywords*—Open-source; lifecycle; taxonomy; machine learning; challenges**

I. Introduction

Recent developments in AI and ML, especially in their capabilities to automate complex operations, uncover hidden patterns from large amounts of data and help in predictive analysis. This insight is valuable in making decisions and have a significant impact on several sectors like the healthcare, finance, manufacturing and entertainment [1], [2], [3]. The core factors for these advances include open source solutions that ease the creation, development, testing and deployment of AI applications and ML models [4], [5], [6], [7], [8].

Open-source tools help to improve development, as well as make advanced analytics more accessible for users with different experience levels [9], [11], [10]. Nowadays, there is a variety of AI/ML tools available in the market to fulfill diverse needs and preferences of their potential customers [13], [12]. The available resources include fundamental ML libraries such as TensorFlow, PyTorch and high-level frameworks like Keras or Scikit-learn. In addition, complementary components enable structured knowledge representation, rule-based reasoning, uncertainty modeling, sequential decision-making, and integration with real-world systems such as robotics platforms. Furthermore, these tools offer essential functionalities that cover such areas as data pre-processing, features selection, algorithm choice, optimization, inference, model evaluation, deployment and help in achieving high performance in AI models [14], [15]. Despite the variety of available options, choosing an adequate tool is still difficult. It should be noted that the choice of the right tool depends on the type of problems, complexity of data, licensing issues and skills of the practitioner [7], [16], [17], [18].

The adoption of open-source artificial intelligence (AI) and machine learning (ML) frameworks has become fundamental to current computational research and innovation endeavors. In addition to economic benefits that open source technology offers, openness, collaboration and availability are among its most important features. These qualities align well with sound scientific research. Since licensing restrictions are not applicable to open source software frameworks, researchers, entrepreneurs, and other public institutions can use them for collecting data, processing, computations and model development. The open access to source code, model designs and training steps also improves reproducibility, which is the foundation of scientific research integrity.

Collective intelligence of global open-source communities works as an ongoing peer-review system. It is helpful for improvement of tools via prompt updates, bug fixes and new features. It is worth noting that such processes usually occur much faster compared to similar operations in closed proprietary projects. These community efforts promote best practices via providing quality documents, benchmarks and educational resources. The common formats and APIs help integrate various solutions within different organizations. Version history help in detecting early stages problems and facilitates track changes. Researchers and developers can reuse code, pipelines and shared libraries to match specific needs.Public availability of code enables a broad community of experts to identify bugs, detect vulnerabilities, and improve overall software reliability. Open-source tools are also useful in resource-constrained environments for developing local AI expertise. This approach facilitates global participation and provides more diverse ideas. Open-source solutions are very beneficial in improving governance and cyber-security. This aspect is particularly relevant in healthcare, transport, and climate science for continuous research growth in AI and machine learning.

This study presents a detailed review of the open-source ML tools by considering entire lifecycle based on SLR methodology [19], [20]. We focus on the features, advantages,

and limitations of these tools. This study aims to provide useful insights regarding the analysis of such tools and helping individuals in decision-making based on individual needs. The contributions of this research work are as follows:

- A detailed analysis of different stages of the machine learning lifecycle is provided.
- A lifecycle-based taxonomy is introduced for open source machine learning tools, which provide insight to different open source ML tools based on their functionalities. We explore their key features, use cases, and other distinguishing characteristics.
- A detailed discussion and comparative analysis is established on widely used ML tools, emphasizing their unique features and suitability for different types of machine learning applications.
- The key challenges, risks, and future directions are identified, providing insights into potential areas for improvement and innovation.

The remainder of this study is organized as follows: Section II present research methodology and initial analysis. Section III presents an end-to-end view of the machine learning lifecycle establishing the foundation for our analysis. Section IV introduces a lifecycle-oriented taxonomy to organize open-source tools by functionality, summarizes their capabilities, and use cases. Section V provides a comparative analysis and discusses trade-offs and selection guidance for different application contexts. Section VI outlines key challenges, risks, and future research direction. Section VII concludes with a synthesis of key findings and practical implications.

II. Research Methodology and Initial Analysis

This study systematically reviews recent publications in the field of open-source machine learning (ML) tools. We investigate open-source ML tools across different stages of the ML lifecycle, including problem framing, data collection and pre-processing, feature engineering, model development and training, deployment, monitoring, and governance. The investigation draws on sources from prominent academic research platforms and technical repositories, including ACM Digital Library, Elsevier, Google Scholar, IEEE Xplore, SpringerLink, and GitHub. All relevant publications and documentation available up to June 2025 were reviewed, with a primary focus on studies published from 2021 onward.

To ensure comprehensive coverage of the domain, two categories of keywords were used. The first set, including "ML lifecycle", "machine learning lifecycle", "ML lifecycle taxonomy", and "ML system engineering" was used to establish the scope of the overall investigation. The second set, comprising "open source ML tools", "data lifecycle open source tools", "deep learning open source tools", "development open source tools", "model deployment open source tools", "MLOps and workflow open source tools", "model serving and integration open source tools", "monitoring and governance open source tools" was used to refine the search toward specific lifecycle stages and functional tool classes. In the context of production deployment and trustworthiness, additional qualifiers were incorporated, including "privacy in machine learning", "supply-chain security", "fairness assessment", and "regulatory compliance".

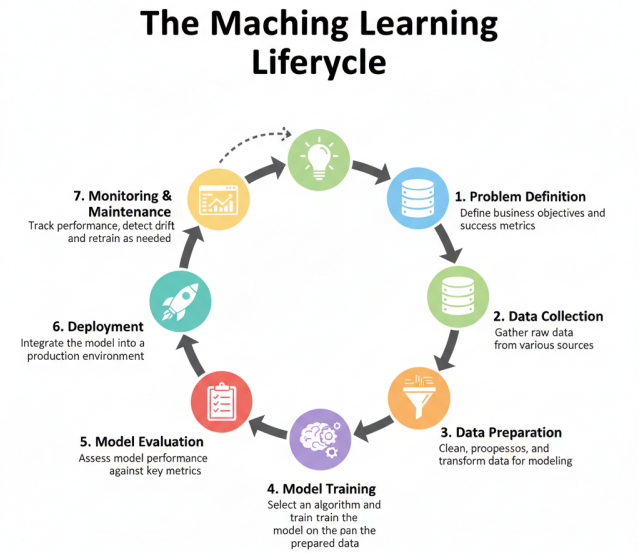

Fig. 1. Machine learning lifecycle.

At the beginning of the review process, an initial pool of research articles was identified based on relevance to the broad domain of open-source ML tools and frameworks. Following a rigorous screening process involving duplicate removal, abstract filtering, and full-text assessment, few publications were identified as directly aligned with the scope of this study.

III. Machine Learning Lifecycle

To provide a comprehensive framework for analyzing open-source tools, this section will explain how the machine learning lifecycle works in various stages. The machine learning lifecycle involves several stages which are part of the systematic process in the development of the models [21]. A brief analysis of the machine learning lifecycle along with the evaluation of current applications of machine learning algorithms are described [22]. Fig. 1 presents the machine learning lifecycle.

A. Problem Framing

At the core level, the machine learning lifecycle starts with identifying a problem. In this phase, a problem is identified and its structure is defined [23]. It formulates objectives and performance metrics that ensure consistency between model goal and the company's objectives based on availability of data and resources. This is a joint effort between business experts and data scientists to determine the expected outcomes [24]. Ethical factors such as fairness, harms, and threats are very important and need to be taken into consideration at early stages because they greatly affect data collection, model creation and implementation subsequently [21]. The criteria for success should be more than accuracy and extend to robustness and reliability as well.

B. Data Collection

This stage focuses on acquiring raw data that are used for model training [24]. It involves collecting data samples

through observation and measurement of the real-world system, process, or phenomenon for which an ML model needs to be built [25], [26]. It is critical in the lifecycle of machine learning models, as the quality and relevance of the gathered information directly influence the model performance.

Data can be collected from a range of internal sources, such as organizational databases, logs, and historical records, as well as external sources such as open-source platforms like Kaggle or the UCI Machine Learning Repository, social media streams for sentiment analysis, and market research studies. It is important to ensure that the selected data are relevant to the defined problem. Data may take various forms, including structured formats stored in relational databases, unstructured content such as text, images, or audio, and semi-structured formats such as JSON or XML. It is also important to determine the appropriate amount of data, balancing volume and quality to avoid issues like under- or overfitting while considering computational constraints [21]. The quality and relevance of collected data is equally critical, as these factors directly impact model performance and validity of the predictions.

C. Data Preparation

Data preparation is an important stage in the machine learning lifecycle. At this stage, the raw data is transformed into a clean, organized and suitable format for model training and evaluation [27], [28], [29]. The data cleaning involves handling missing values through deletion or imputation, identifying and managing outliers using statistical techniques and removing duplicates to maintain data integrity. Once the dataset is clean, data transformation techniques are applied. The data transformation techniques may include normalization, standardization to scale numerical features appropriately and encoding methods (one-hot or label encoding) to convert categorical data into machine-readable formats. In data splitting, dataset is partitioned into training, validation and testing sets. It helps in model evaluation and prevents overfitting. The advanced data engineering practices, such as pre-processing have streamlined the exploratory data analysis (EDA) and data preparation stages [30].

D. Feature Engineering

Feature engineering plays a significant role in improving model performance by creating new meaningful features. It may involve mathematical operations and the selection of only the most relevant features using methods such as recursive feature elimination, statistical tests, or feature importance measures [31], [32]. Proper data splitting is also essential, dividing the dataset into training, validation and test sets to support model training, hyperparameter tuning, and unbiased performance evaluation. In cases involving image, text, or other unstructured data, data augmentation techniques can be applied to expand the training data set artificially through modifications such as rotations, noise addition, or text perturbations or to further add data samples to the dataset [34], [33].

Data normalization and feature scaling techniques may also be applied to ensure that data adhere to a uniform scale and facilitate the learning process [24].

E. Model Selection, Training and Optimization

The selection of an appropriate ML model depends on various factors, including the nature of the problem (classification, regression, etc.), the characteristics of the data (structured, unstructured), and the available computational resources. Popular choices include decision trees, support vector machines, neural networks, and ensemble methods [24].

Model training plays a pivotal role in the machine learning lifecycle. In this phase, the selected algorithm learns patterns from the prepared data set by adjusting its parameters to reduce prediction errors. Performance metrics such as loss and accuracy are monitored throughout to ensure proper convergence and detect issues such as overfitting. Hyper-parameters are high-level configuration settings of the ML algorithm that can significantly impact its learning capacity. In addition to this, key hyper-parameters such as the learning rate, the number of training epochs, and the batch size are configured to control the model's learning process. Optimization algorithms such as grid search, random search, bayesian optimization, stochastic gradient descent, or Adam iteratively update the model parameters to minimize loss [24].

F. Model Evaluation and Validation

After training, the model is validated on a separate validation set to evaluate its generalization capability and tune hyper-parameters if required [35], [36]. It ensures that the model generalizes well beyond the training dataset and meets the intended objectives. The process begins with the selection of appropriate evaluation metrics based on the type of problem [24]. Once metrics are defined, the model is assessed using a validation set.

Model evaluation involves checking for overfitting or underfitting by comparing training and validation performance. Overfitting occurs when the model performs well in training data but poorly in validation data, while underfitting indicates that the model is too simple to capture underlying patterns. Sensitivity analysis can be conducted to study how variations in input features influence predictions, revealing the model robustness and identifying critical features. By systematically evaluating the model, practitioners ensure that its performance is reliable, generalizes effectively and is suitable for real-world deployment.

G. Model Deployment

The deployment of the model is the decisive stage of the machine learning lifecycle, where the trained model is integrated into a production environment to generate predictions on new real-world data [24]. This phase ensures that the model operates efficiently, reliably and securely. The process begins with selecting an appropriate deployment method, such as batch processing for scheduled or real-time inference for applications that require immediate responses through APIs. The deployment environment may involve cloud platforms like AWS, Azure, or Google Cloud, chosen for their scalability, services and global reach. The model is then serialized into a suitable format, such as Pickle or TensorFlow, so that it can be easily loaded and executed in production pipeline. If the model needs to be accessed by external applications, an API is developed using frameworks like FastAPI or Flask. Once deployed,

continuous monitoring becomes critical to track performance metrics such as prediction accuracy, latency and resource usage. A structured plan for model updates helps maintain long-term performance by incorporating retraining schedules, version control and user feedback. The post-deployment performance evaluation ensures that the model continues to meet business goals.

H. Monitoring and Maintenance

Monitoring and maintenance are critical stages of the machine learning lifecycle, ensuring that the models remain reliable, accurate and aligned with real-world requirements. Once a model is operational, continuous performance monitoring becomes essential to detect degradation timely. This includes tracking key metrics (accuracy and precision) and system-level indicators (latency and throughput). The detection of data drifts is equally important, as it can significantly impact predictions. Logging and auditing play an important role in maintaining transparency and accountability by recording inputs, outputs, errors and model updates. User feedback also contributes to continuous improvement, offering practical insights into the behavior of the real-world model. In addition, regular reviews help address technical debt by refactoring code, updating dependencies and improving infrastructure reliability. The documentation must be kept up-to-date to reflect model updates, deployment changes and operational guidelines. The techniques such as model explainability, bias mitigation and transparency provide insight into model behavior, allowing stakeholders to assess model performance and compliance with regulatory and ethical standards [30]. Finally, a well-defined incident response plan enables teams to quickly mitigate issues related to performance or security breaches. Together, these monitoring and maintenance practices create a proactive framework that keeps machine learning models reliable and effective throughout their lifecycle.

IV. Lifecycle-Oriented Taxonomy of Open-Source Machine Learning Tools

The existence of a variety of open source machine learning tools enables a reliable, scalable, and reproducible data workflow throughout the machine learning pipeline. A structured taxonomy for machine learning experiment tracking is introduced and applied to widely used tools [37]. A comprehensive taxonomy of open source machine learning tools is presented in Fig. 2. It includes open source machine learning tools for data engineering, deep learning, model deployment and optimization, workflow orchestration, model serving and system integration, monitoring and governance, development, visualization and knowledge management.

A. Data Lifecycle

Data operations in machine learning pipelines include ingestion, distributed computing, quality and validation, lineage and governance, labeling and annotation, feature engineering, data augmentation, and privacy and compliance. Table I provides a summary of these operations.

Open source tools for data ingestion include Pandas, Dask, and Apache Spark. Pandas, for instance, is highly effective for in-memory processing of small to medium-sized datasets, while Dask and Apache Spark are designed for larger distributed datasets. These tools help to perform data preprocessing, loading, and transforming in large datasets. For computationally intensive ML operations, data are needed. can be computed in distributed or parallel fashion using tools e.g. Ray, Spark, and Dask. To ensure data quality by automating data profiling, validation and anomaly detection tools such as Great Expectations and Deepchecks can be helpful. For metadata management and lineage tracking tools, such as DVC, lakeFS, Pachyderm, OpenLineage/Marquez, and DataHub, enhance reproducibility and data control. Some supervised learning tasks require data labeling and annotation. For this purpose, the Label Studio and CVAT tools streamline the dataset labeling process. To automate feature extraction and centralized feature management, Featuretools and Feast can help in feature operationalization. In some scenarios, the data set available is insufficient for model training, data augmentation is used to create synthetic datasets to improve model robustness. For this purpose, tools such as SDV and Albumentations can be helpful. For data privacy and compliance libraries including Diffprivlib, Opacus, and TensorFlow Privacy, the library supports modern security and compliance standards. Together, these tools form a comprehensive foundation for handling data in machine learning pipelines.

B. Deep Learning

In the machine learning pipeline, a wide range of open-source libraries and frameworks are available to support deep learning development. The general purpose deep learning pipelines include scikit-learn, XGBoost, LightGBM, and CatBoost are helpful in ensemble methods, gradient boosting and supervised or unsupervised learning. These libraries are reliable for an efficient and scalable implementation of various applications. Neural networks are the primary foundation for deep learning. There are open source frameworks to facilitate their design, training, and deployment by supporting flexible model architectures, GPU acceleration, and automatic differentiation. It includes PyTorch, TensorFlow, JAX, and Keras. Similarly, for probabilistic models, libraries like Pyro, NumPyro, Stan, and TensorFlow Probability help in advanced statistical modeling and inference. There are many toolkits available for specialized domain specific tasks. The libraries such as PyTorch Geometric and DGL supports graph based frameworks. For time series libraries, darts, GluonTS, and Kats are helpful for sequential data analysis. To automate feature selection and optimize hyper-parameters(HPO) tools such as Auto-sklearn, AutoGluon, H2O-3 AutoML, TPOT, Optuna, and Ray Tune are helpful in feature engineering and parameter tuning. Collectively, using these resources, efficient models can be implemented across diverse ML workflows. Table II provides a summary of these tools.

C. Development and Visualization

The development and communication in machine learning workflows rely on versatile tools for coding, visualization, and documentation. Open source tools such as interactive notebooks and integrated development environments provide flexible platforms for experimentation, debugging, and iterative model development. Open source visualization libraries provide clear and insightful representation of data and model

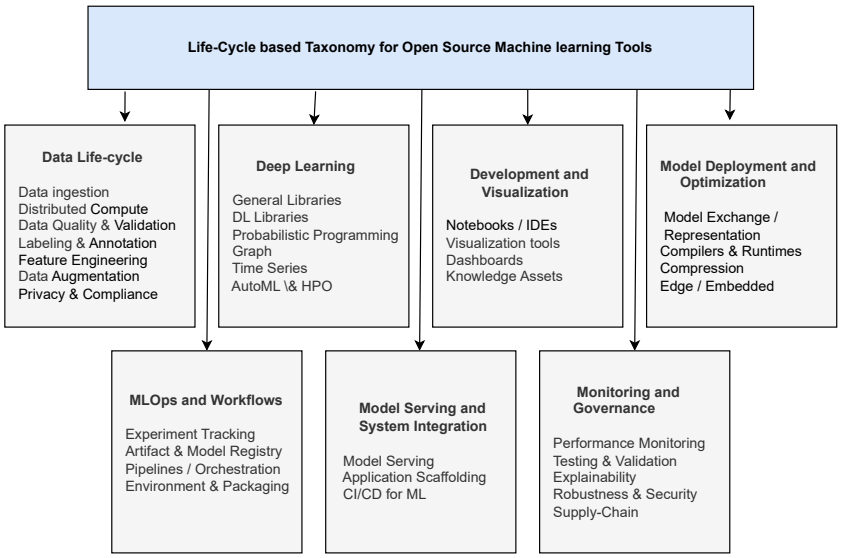

Fig. 2. Machine learning lifecycle-based taxonomy for open source ML tools.

TABLE I. OPEN-SOURCE ML TOOLS FOR DATA LIFECYCLE

Category	Tools	Languages	Purpose	Key Features
Data ingestion	Pandas [38], Dask [39], Apache Spark [40]	Python; Python; Python/Scala/Java	Data loading, preprocessing, transformation	Scalable ETL, distributed dataframes
Distributed Compute	Ray [41], Spark, Dask	Python; Python/Scala/Java; Python	Parallel and distributed execution for ML pipelines	Task scheduling, cluster management, scalable computation
Data Quality & Validation	Great Expectations [42], Deepchecks [43]	Python	Data profiling, validation, integrity checks	Automated tests, pipeline integration, anomaly detection
Data Lineage & Governance	DVC [44], lakeFS [45], Pachyderm [46], Marquez [47], DataHub [48]	Python; Python/Go; Go/Python; Python/Java; Java/Python	Dataset versioning, lineage tracking, metadata management	Git-like data control, governance
Labeling & Annotation	Label Studio [49], CVAT [50]	Python/JS	Creating and managing labeled datasets	Multi-format annotation, collaborative tools, automation support
Feature Engineering	Featuretools [51], Feast [52]	Python; Python/Go	Feature creation, storage, and serving	Automated feature engineering, centralized feature repository
Data Augmentation	SDV [53], Albumentations [54]	Python	Generating synthetic datasets	Advanced image augmentation
Privacy & Compliance	Diffprivlib [55], Opacus [56], TensorFlow Privacy [57]	Python	Differential privacy and secure ML training	Privacy-preserving training, noise mechanisms

outputs. JupyterLab and the open-source VS Code are examples of such platforms, whose visualization libraries include Matplotlib, Seaborn, Altair, and the open-source core of Plotly.

To share results with stakeholders, frameworks like Streamlit, Panel, and Dash help in the deployment of user-friendly interfaces, and rapid prototyping. Additionally, knowledge asset frameworks facilitate systematic documentation of models and datasets, promoting reproducibility and informed decision-making throughout the machine learning lifecycle. Such frameworks include Model Cards Toolkit and Datasheet tooling. Table III provides a summary of these tools.

D. Model Deployment and Optimization

The deployment and optimization of machine learning models have been facilitated especially in model representation, compilation, run-time , compression, and deployment. Models trained in PyTorch, TensorFlow, or other platforms can be seamlessly executed in other environments. For this purpose, ONNX, enable interoperability across different frameworks. Machine learning models can be compiled and optimized using hardware acceleration. For this purpose, open source tools include TVM, IREE, XLA, OpenVINO, and ONNX Runtime. For model compression, Intel Neural compression, NNI, and SparseML help reduce model size and latency using pruning, quantization, and other techniques. The embedded applications require low latency execution on smart devices and microcontrollers. Lightweight inference engines such as TensorFlow Lite, TFLite Micro, and ONNX Runtime Mobile are a big support for this purpose. These tools help to secure, portable, and scalable model deployment in the ML pipeline. Table IV provides a summary of these tools.

TABLE II. OPEN-SOURCE ML TOOLS FOR DEEP LEARNING

Category	Tools	Languages	Purpose	Key Features
General Libraries	scikit-learn [58], XGBoost[59], LightGBM [60], CatBoost [61]	Python	Supervised/unsupervised ML, boosting gradient, ensemble methods	Easy-to-use APIs, high performance, scalable
DL Libraries	PyTorch [62], TensorFlow [57], JAX [63], Keras [64]	Python	Neural network design and training	GPU acceleration, automatic differentiation, flexible model building
Probabilistic Programming	Pyro [65], NumPyro [66], Stan [67], TensorFlow Probability [68]	Python; Python; Stan; Python	Bayesian modeling, probabilistic inference	Efficient sampling, variational inference, uncertainty quantification
Graph	PyTorch Geometric [69], DGL [70]	Python	Graph neural networks and structured data modeling	Message passing, graph convolutions, scalable GNN
Time Series	darts [71], GluonTS [72], Kats [73]	Python	Forecasting, time-series analysis	Forecasting, anomaly detection
AutoML & HPO	Auto-sklearn [74], AutoGluon [75], H2O-3 AutoML [76], TPOT [77], Optuna [78], Ray Tune [79]	Python; Python; Java/Python; Python; Python; Python	Model selection, hyperparameter optimization	Feature selection, ensemble building, distributed optimization

TABLE III. OPEN-SOURCE ML TOOLS FOR DEVELOPMENT AND VISUALIZATION

Category	Tools	Languages	Purpose	Key Features
Notebooks / IDEs	JupyterLab [80], VS Code (OSS) [81]	Python; Multiple	Interactive development and code editing	Rich IDE, debugging, plugins, notebook
Visualization	Matplotlib [82], Seaborn [83], Altair [84], Plotly (OSS core) [85]	Python	Create static and interactive data visualizations	Plotting, interactive charts, statistical visualization, figures
Dashboards	Streamlit [86], Panel [87], Dash [88]	Python	Build interactive dashboards and data-driven applications	Rapid prototyping, Visualization, low-code development
Knowledge Assets	Model Cards Toolkit [89], Datasheets tooling [89]	Python	Document model details and dataset characteristics	Standardized metadata capture, transparency, governance support

TABLE IV. OPEN-SOURCE MODEL DEPLOYMENT AND OPTIMIZATION TOOLS

Category	Tools	Languages	Purpose	Key Features
Model Exchange / Representation	ONNX [90]	Python, C++	Cross-platform deployment	Interoperability, model format standardization, framework-agnostic conversion
Compilers & Runtimes	TVM [91], IREE [92], XLA [93], OpenVINO [94], ONNX Runtime [90]	Python, C++, MLIR	Optimized compilation and runtime execution	Graph-level optimizations, target-specific compilation, hardware acceleration
Compression	Intel Neural Compressor [90], NNI [95], SparseML [96]	Python	Quantization, pruning, and compression	Reduced model size and latency, hardware-aware optimization
Edge / Embedded	TensorFlow Lite [97], TFLite Micro [98], ONNX Runtime Mobile [90]	Python, C++	Deployment on resource-constrained devices	Low-latency execution, mobile and microcontroller support

E. MLOps and Workflows

In the deployment of machine learning models, the use of robust tools and frameworks is of primary importance to ensure efficient management of data, models, and computational workflows. The open source experiment tracking platforms include MLflow, Aim, Sacred, and Guild AI. These platforms enable systematic comparison and iterative improvements. It also provides comprehensive mechanisms to log hyperparameters, metrics, and results. To facilitate collaboration, artifact and model registries can store different versions of trained models, datasets, and other resources. Open source tools include MLflow Model Registry, ModelDB, and DVC in this domain. Efficient environment management and packaging are very helpful in enabling reproducible computational environments and dependency management across different systems. For this purpose, tools such as Conda, Mamba, Poetry, pip-tools, Docker, and Nix can be a game changer. Automated execution of sequential and parallel tasks can be streamlined with orchestration. Such frameworks include Apache Airflow, Argo Workflows, Kubeflow Pipelines, Dagster, and Metaflow. These tools enhance the scalability and reproducibility of machine learning production pipelines. Table V provides a summary of these tools.

F. Model Serving and Integration

The reliable model serving and integration frameworks are important for translating models into commercial applications. There are many open source tools to support high performance solutions to expose trained models as APIs to support real-time and batch inference. Such platforms include KServe, Seldon

TABLE V. OPEN-SOURCE MLOPS AND WORKFLOW MANAGEMENT TOOLS

Category	Tools	Languages	Purpose	Key Features
Experiment Tracking	MLflow [99], Aim [100], Sacred [101], Guild AI [102]	Python	Track experiments, log metrics and parameters	Versioned results, reproducibility, visualization
Artifact & Model Registry	MLflow Model Registry [99], ModelDB [103], DVC artifacts [104]	Python	Store and manage models	Model versioning, metadata management, pipeline integration
Environment & Packaging	Conda/Mamba [105], Poetry/pip-tools [106], Docker [107], Nix [108]	Python, Shell	Manage dependencies and reproducible environments	Dependency resolution, environment isolation
Pipelines / Orchestration	Apache Airflow [109], Argo Workflows [110], Kubeflow Pipelines [111], Dagster [112], Metaflow [113]	Python, YAML, Shell	Design, schedule, and orchestrate ML pipelines	Workflow management, task scheduling, scalable execution

TABLE VI. OPEN-SOURCE MODEL SERVING AND SYSTEM INTEGRATION TOOLS

Category	Tools	Languages	Purpose	Key Features
Model Serving	KServe [114], Seldon Core [115], TorchServe [116], BentoML [117], NVIDIA Triton Inference Server [118]	Python, C++	Deploy trained ML models for production inference	Scalable serving, standardized APIs, GPU acceleration
Application Scaffolding	FastAPI [119], gRPC [120], Streamlit [86], Dash [88]	Python	Build lightweight applications and APIs	Interactive dashboards, rapid prototyping, low-latency interfaces
CI/CD for ML	Tekton [121], Argo CD [122], Jenkins [123]	YAML, Python, Shell	Automate testing, integration, and deployment	Pipeline automation, reproducibility, cloud-native integration

TABLE VII. OPEN-SOURCE MONITORING AND GOVERNANCE TOOLS

Category	Tools	Languages	Purpose	Key Features
Performance Monitoring	Evidently AI [124], whylogs [125], Prometheus [126] + Grafana [127]	Python; Python; Python/Go	Track performance and detect data drift	Real-time monitoring, visualization, anomaly detection
Testing & Validation	Great Expectations [42], Deepchecks [43]	Python	Validate datasets and models for correctness	Data profiling, model checks, pipeline integration, anomaly detection
Explainability	SHAP [128], LIME [129], Captum [130], Fairlearn [131], AIF360 [132]	Python	Model interpretability and fairness assessment	Feature attribution, bias detection, fairness metrics
Robustness & Security	Adversarial Robustness Toolbox (ART) [133]	Python	Evaluate and improve model robustness	Attack simulation, defense mechanisms, threat modeling
Supply-Chain	Sigstore/cosign [134], Syft/Grype [135], [136], pip-audit [137], in-toto [138], SBOMs	Python; Go; Shell	Ensure security and integrity	Artifact verification, provenance tracking, vulnerability scanning

Core, TorchServe, BentoML, and NVIDIA Triton Inference Server. The application sacffolding tools help in the rapid development of interactive applications that integrate seamlessly with different ML models. The application scaffolding tools include FastAPI and gRPC. The open source lightweight user interface frameworks such as Streamlit or Dash support low latency. For smooth and robust delivery in production pipelines, CI/CD tools facilitate reduced operational overhead and reliable updates. These tools include Tekton, Argo CD, and Jenkins to automate testing, deployment, and monitoring processes. Together, these tools form a cohesive stack for efficient model operations in various production environments. Table VI provides a summary of these tools.

G. Monitoring and Governance

A comprehensive set of monitoring and governance tools is needed to ensure fairness in machine learning systems deployed. To monitor the performance of the model, it is necessary to keep track of the model output, data distribution, and system health to facilitate early detection of performance degradation. The frameworks include Evidently AI, whylogs, and the Prometheus–Grafana. For rigorous testing and validation, platforms like Great Expectations and Deepchecks automate checks on model behavior and data quality. To evaluate model predictions and mitigate bias, ensure ethical and transparent AI, tools such as SHAP, LIME, Captum, Fairlearn, and AIF360 are very helpful. To ensure protection and security of machine learning systems, the Adversarial Robustness Toolbox

(ART) allows the assessment of vulnerabilities to adversarial attacks.

Finally, supply-chain integrity is maintained by verifying dependencies, packaging, and traceability throughout the ML lifecycle. the tools for this phase include Sigstore, Cosign, Syft, Grype, pip-audit, in-toto, and Software Bill of Materials (SBOMs). These tools establish a strong foundation for trustworthy and secure AI deployments. Table VII provides a summary of these tools.

V. Comparative Analysis and Discussion

The landscape of tools and frameworks supporting machine learning is expanding rapidly, new frameworks are emerging, and existing ones are evolving rapidly. This constant growth requires researchers and developers to stay upto date on these resources and use them to efficiently execute their tasks.

An effective data lifecycle forms the backbone of machine learning pipelines. The Pandas library works well for small to medium datasets due to its in-memory processing. Dask extends the Pandas interface to distributed environments and parallel computations. It may require tuning for large heterogeneous clusters. In contrast, Apache Spark is suitable for large-scale workloads, but it is less flexible for parallel execution compared to Dask. Ray also helps scale workloads for reinforcement learning by offering distributed computation capabilities that handle complex and iterative tasks. DVC and lakeFS are ideal for reproducible experiments because of their Git-like versioning, whereas Pachyderm offers enterprise-grade reproducible pipelines. Label Studio supports multi-modal annotation for general ML applications, whereas CVAT excels with advanced video annotation capabilities. Feast serves as a feature store in production systems. The features can be retrieved consistently. Featuretools is more research-oriented than Feast. Opacus integrates privacy concerns for training machine learning algorithms, and TensorFlow Privacy supports similar capabilities for TensorFlow models. Great Expectations validates with automated documentation, whereas Deepchecks extends validation to for drift and model performance using its error analysis.

For deep learning, general-purpose libraries such as scikit-learn provide broad algorithmic coverage, whereas XGBoost, LightGBM, and CatBoost perform well on structured data. Auto-sklearn and TPOT are valuable for automating feature engineering and model selection within scikit-learn pipelines, while AutoGluon and H2O-3 AutoML extend this automation to deep learning frameworks. The dynamic interface of PyTorch makes it preferred for research and experimentation, while TensorFlow supports production-grade. Domain-specific libraries provide efficient message-passing primitives and extensive model repositories (PyG, DGL). Time-series libraries offer unified interfaces for anomaly detection and probabilistic predictions using tools such as Pyro and NumPyro. Stan is well- known for statistical inference but it is less suited for deep neural architectures. Keras emphasizes rapid prototyping and is often used as an accessible front-end for TensorFlow-backed training.

For development and visualization, JupyterLab excels in exploratory data analysis with a user-friendly interface, whereas VS Code provides a more integrated development environment with advanced debugging, version control, and multi-language support. Visualization libraries such as Matplotlib offer fine-grained control for static plots but require more boilerplate, while Seaborn provides higher-level statistical visualizations with minimal code. Dashboards like Panel offer greater flexibility by supporting multiple plotting backends, while Dash provides support for enterprise level analytics for web applications.

Model deployment and optimization tools perform low-level graph optimization, kernel fusion, and hardware code generation. These tools include TVM and IREE which excel in automated operator tuning and broad hardware support, while XLA offers tight integration with TensorFlow and JAX for ahead-of-time compilation. OpenVINO is optimized for Intel architectures, providing high-performance inference on CPU and VPUs, while ONNX Runtime delivers portable high-speed inference across GPU, CPU, and edge devices through execution providers.

Experiment tracking tools emphasize lightweight metrics tracking and support reproducibility during model development. These tools include MLflow, Aim, Sacred, and Guild AI. In contrast, artifact and model registries extend this functionality by enabling version control, lineage tracking, and governance of models and datasets. Environment and packaging tools such as Conda/Mamba, Poetry, pip-tools, Docker, and Nix address key sources of inconsistencies between development and production systems. For instance, MLflow offers a comprehensive platform for both experiment tracking and model registry, making it suitable for end-to-end MLOps, whereas tools like DVC focus specifically on data and model versioning for reproducibility.

Model serving frameworks are primarily designed to support low-latency inference with hardware acceleration. TorchServe and BentoML also offer strong integration with PyTorch-centric workflows, Triton is optimized for high-throughput and multi-framework GPU inference for large-scale productions. Application scaffolding tools, including FastAPI, gRPC, Streamlit, and Dash, focus on exposing trained models through interactive interfaces for rapid prototyping and visualization. CI/CD tools for machine learning, such as Tekton, Argo CD, and Jenkins, automate testing, integration, and pipeline deployments. However, these tools differ in their native support for GitOps practices, Kubernetes orchestration, and ML-specific versioning. The toolchain must be carefully composed to achieve reproducible end-to-end deployments.

Performance monitoring tools enable continuous monitoring of system behavior with early detection of model degradation. Clearly, AI, whylogs, and Prometheus with Grafana are examples of such tools. Testing and validation frameworks, including Great Expectations and Deepchecks, emphasize pre-deployment, distributional consistency, and failure diagnostics. Explainability tools such as SHAP, LIME, Captum, and Fairlearn address the growing demand for interpretable and fair AI by providing bias assessment across diverse model architectures. Finally, supply-chain security tools such as Sigstore/cosign, Syft/Grype, pip-audit, in-toto, and SBOMs extend governance to software integrity and dependency transparency.

VI. Key Challenges and Future Perspectives

The machine learning lifecycle presents several key challenges related to each stage. Large or heterogeneous datasets present scalability and performance constraints, often due to limitations in memory management, efficient distributed processing, or data transfer speeds within open-source frameworks. Distributed computing frameworks often differ in execution paradigms, which complicate overall workflow. Feature consistency and low-latency service between research and production environments presents a real challenge. Furthermore, effective integration of privacy preservation mechanisms and adherence to regulatory requirements remains a struggle due to the heterogeneity of compliance standards.

Deep learning and machine learning workflows face several interrelated challenges. The frameworks optimized for flexibility often lack seamless integration into scalable production systems. The support of high-performance computing requires careful consideration of computational graphs, compilation strategies, and parallelism. Domain-specific modeling, such as graph-based or temporal data, introduces additional complexity in the efficient processing of structured and sequential data. Automated machine learning and feature engineering also face limitations in generalization and robustness when working with diverse data types.

Development and visualization workflows require support for interactive, iterative, and integrated workflows. Visualization tools should balance control and ease of use for enterprise-ready deployment. These factors highlight the difficulty of designing tools that are user-friendly for experimentation and robust for production analytics.

High performance inference requires careful low-level optimization, hardware-aware code generation, and efficient execution across diverse platforms. Balancing portability, speed, and compatibility with different hardware architectures (CPUs, GPUs, and edge devices) adds additional complexity. Integrating these optimizations into existing workflows while maintaining reproducibility and scalability remains a challenge in model deployment.

Despite the capabilities offered by the MLOps, several critical challenges persist due to the fragmented and heterogeneous nature of the machine learning architectures. The lack of a unified end-to-end platform requires complex integration across experiment tracking, model registries, and orchestration tools. Increase system complexity and operational overhead by demanding extensive configuration. The scalability and deployment issues in cloud interoperability also complicate the transition from research to production. The synchronization and governance of metadata across loosely coupled components often leads to gaps in traceability and compliance. Additionally, while packaging tools improve reproducibility, inconsistencies across operating systems and hardware accelerators introduce risks in large-scale deployments.

The heterogeneous protocol and hardware acceleration in diverse frameworks introduce deployment complexity and hamper portability across infrastructures. production-grade frameworks and rapid prototyping tools create friction when transitioning experimental prototypes to scalable services. CI/CD platforms such as Tekton, Argo CD, and Jenkins enable automated deployment, but their limited support for versioning, model validation, and data testing restricts full lifecycle automation. In addition, the absence of standardized interfaces across application layers and pipelines complicates rollback and reproducibility, for example, requiring manual intervention for data schema changes or model version rollbacks.

Fragmented coverage in performance monitoring, data validation, explainability, robustness, and supply-chain security requires the integration of multiple specialized tools, substantially increasing system complexity and maintenance overhead. The heterogeneous coverage of performance monitoring, data validation, and explainability requires the integration of multiple tools. Consequently, it increases system complexity, operational burden, and long-term maintenance overhead. The limited standardization of explainability and fairness assessments severely restricts cross-tool interoperability across the MLOps toolchain. Large-scale productions remain computationally expensive and often conflict with real-time latency requirements. Additionally, while supply-chain security tools enhance software integrity, their integration into ML-specific pipelines is still emerging, leaving critical gaps in compliance enforcement.

VII. Conclusion

This study bridges the gap between tool-centric surveys and practical requirements of end-to-end ML system engineering by providing a systematic, lifecycle-oriented taxonomy of open-source tools and discussing their practical implications. In this study, we present a comprehensive, lifecycle-oriented taxonomy of open-source machine learning tools. The proposed taxonomy systematically organizes the evolving ML tools across all major stages of the machine learning lifecycle, including data collection and preparation, feature engineering, model development, training and evaluation, deployment, monitoring, and governance. It enables researchers to systematically analyze emerging tools while providing a guideline for designers to develop scalable, reliable, and trustworthy ML systems.

Open source tools offer strong specialization in areas such as experiment tracking, orchestration, model serving, and monitoring. However, achieving fully automated, reproducible, and compliant ML pipelines still continues to require substantial cross-tool integration and engineering effort. There are persistent challenges related to interoperability, standardization, production, real-time monitoring, explainability, and supply-chain security. There is a need for standardization of the interface, integration between lifecycle stages, and security mechanisms in ML pipelines. Addressing these challenges will require collaborative efforts towards developing common APIs, robust data contracts, and standardized security protocols across the open-source ecosystem. Future research directions include the development of unified ML lifecycle platforms for seamless integration across all stages, benchmark-driven comparative evaluations of tool performance to provide evidence for tool selection, and empirical studies on large-scale industrial deployments, or validate theoretical frameworks against real-world challenges.

Agentic Accountability: "The Buck Stops Where?" Ethical Frameworks for Human Oversight of Autonomous AI Systems

Ornella Bahidika
Independent Researcher, Seattle, USA

***Abstract*—The rapid evolution from generative Artificial Intelligence (AI) toward agentic AI, systems capable of autonomously planning and executing multi-step actions, has introduced an unprecedented accountability gap in modern computing. Unlike traditional AI tools that respond to discrete prompts, agentic systems pursue goals across extended time horizons, invoke external services, and produce cascading real-world consequences. This shift raises a fundamental ethical question: When an autonomous agent causes harm, who bears responsibility? This study examines the ethical and governance dimensions of agentic accountability, drawing on recent literature in AI ethics, regulatory studies, and human-computer interaction. Building on prior tiered approaches to automation oversight in the human-factors literature, in regulatory risk classification, and in recent agent-autonomy frameworks, we present an action-level oversight framework that maps individual agent actions to four tiers of human-in-the-loop involvement, ranging from full automation to mandatory prohibition, calibrated by stakes and reversibility. We further analyze design patterns for "emergency brakes" (circuit breakers, action budgets, reversibility constraints, audit trails, kill switches), and propose a composition-aware extension that detects *tier laundering*, where individually low-tier actions compose into a higher-tier outcome. We then conduct an empirical pilot applying the framework to 177 incidents from an April 2026 snapshot of the AI Incident Database with full CSET classification, finding that 23% of tier-assignable incidents fall in T4 (prohibited under the framework) and that of 41 tangible-harm events, 26 (63%) involved Medium or High autonomy where tier-T4 enforcement would have been most directly applicable. Inter-rater reliability across the database's three independent annotators ranges from κ=0.58 to 0.77 at the tier level (moderate-to-substantial agreement). The contribution of this work is an action-level operationalization of tiered oversight, anchored in real-world incident data, with explicit identification of composition-aware detection as the highest-leverage methodological direction for follow-up research.**

***Keywords*—Agentic AI; AI accountability; human-in-the-loop; AI ethics; autonomous systems; AI governance; responsible AI; oversight thresholds**

I. Introduction

The trajectory of Artificial Intelligence over the past five years has shifted decisively from prediction to action. Where earlier systems classified images, translated text, or generated paragraphs in response to discrete prompts, a new generation of *agentic* systems now pursues goals across extended time horizons, decomposes them into sub-tasks, invokes external tools, and adapts based on intermediate results. For the purposes of this study, we define *agentic AI* as an AI system that selects and executes actions in the world over multiple steps in pursuit of a high-level objective, with at least some action choices made autonomously rather than under per-action human authorization. Frameworks for tool-using language model agents, autonomous coding assistants, and AI-driven workflow orchestration have moved rapidly from research prototypes into commercial deployment.

This shift is not merely technical. It reorganizes the moral geometry of AI use. A traditional AI tool functions as a sophisticated calculator: a human poses a question, the system returns an answer, and the human decides what to do with it. Responsibility for any downstream consequence rests with the human who acted on the output. An agentic system disrupts this separation. The agent itself acts (sending emails, executing code, filing tickets, moving funds, scheduling meetings, modifying files), often with minimal real-time supervision. The output of an agent is not a recommendation; it is a fact in the world.

When that fact turns out to be a mistake, a wrong refund issued, a malicious script executed, a meeting cancelled in error, a data record overwritten, a contract counter-signed, the question of responsibility becomes genuinely difficult. The user did not directly perform the action. The developer did not anticipate the precise context. The deployer configured the system but did not instruct it to make this particular error. And the agent itself, lacking legal personality, cannot be held accountable in any meaningful sense. Existing legal infrastructure offers partial answers (product liability for foreseeable defects, principal-agent doctrine for delegated authority, professional negligence for licensed practitioners), but these were developed for tools and human employees and apply unevenly to adaptive software that takes consequential actions on its own. This residual is the *responsibility gap* originally articulated by Matthias [1] for learning automata, now amplified by the proliferation of goal-directed agentic systems [11]. The buck, as the colloquialism goes, must stop somewhere. This study investigates that.

The motivation for the present work is the observation that agentic accountability is currently negotiated implicitly, in terms of service, end-user license agreements, and ad hoc engineering decisions, rather than through principled ethical and governance frameworks. While the broader discourse on AI ethics has matured considerably, producing dozens of high-level principle frameworks [3], much of it presumes a tool-paradigm in which a human is the immediate cause of any consequential action, and principles alone have proven insufficient to guarantee ethical outcomes in practice [4]. As agentic systems proliferate in high-stakes domains (healthcare schedul-

ing, legal drafting, financial operations, software engineering, customer service), this presumption becomes untenable [12], [15].

This study makes five contributions. First, it articulates the conceptual transition from AI-as-tool to AI-as-agent and explains why this transition fundamentally alters the structure of moral and legal responsibility. Second, it proposes an action-level tiered framework for human oversight, mapping individual agent actions to graduated levels of human-in-the-loop involvement, calibrated by stakes and reversibility. Third, it analyzes design patterns (circuit breakers, action budgets, reversibility constraints, audit trails, kill switches) through which oversight can be operationalized in practice. Fourth, it proposes a composition-aware extension that detects *tier laundering*, the case in which individually low-tier actions compose into a higher-tier outcome. Fifth, it conducts an empirical pilot applying the framework to 177 CSETv1-classified incidents from the AI Incident Database, with inter-rater reliability across three independent annotators and a counterfactual analysis of the 41 documented tangible-harm events. The work is intended for an interdisciplinary audience of AI researchers, practitioners building agentic systems, ethicists, and policymakers shaping the regulatory environment in which these systems will operate.

The remainder of the study is organized as follows: Section II reviews the background and related work, situating agentic AI within the broader AI ethics landscape. Section III develops the conceptual foundation, distinguishing tool-use from agency and identifying the accountability vectors involved. Section IV presents the proposed tiered oversight framework. Section V examines design patterns for emergency brakes and intervention. Section VI discusses implications for research, practice, and policy. Section VII concludes with directions for future work.

II. Background and Related Work

A. From Generative AI to Agentic AI

Generative AI brought to public attention the capacity of large foundation models to produce fluent text, code, images, and audio [10]. The dominant interaction pattern, however, remained conversational and turn-based: a user prompt produced a model response, and the user retained full discretion over what to do with it. The agentic turn changes this pattern by composing models with tools (web browsers, file systems, APIs, code interpreters, payment rails) and by giving them planning loops that can iterate without human input between steps [12].

The literature on agentic systems describes a spectrum rather than a binary [11]. At one end sit suggestion-only systems where the model proposes actions for human approval. At the other end sit fully autonomous agents that pursue open-ended objectives with no scheduled human checkpoints. Most contemporary deployments fall between these poles, with intermittent human checkpoints and a mix of pre-approved and gated actions. The defining property of agentic systems for the present study is that they take consequential actions without a human directly authorizing each one.

B. Existing AI Ethics Frameworks

The AI ethics literature has converged on a recognizable set of principles (fairness, transparency, accountability, privacy, safety, human oversight) articulated across more than eighty published frameworks since 2016 [3]. Recent systematic reviews of generative AI ethics have catalogued recurring concerns including bias and discrimination, misinformation and deepfakes, privacy violations, intellectual property issues, and accountability and explainability [13], [15]. While these frameworks provide a vocabulary, they were largely formulated in the era of predictive and generative models, and they tend to treat accountability as a matter of explaining past outputs rather than constraining future actions [4], [9]. In particular, principle-based frameworks do not specify *when* oversight is mandatory versus advisory, which is precisely the question agentic deployment forces.

The concept of *meaningful human control*, developed initially in the context of autonomous weapons by Santoni de Sio and van den Hoven [2], offers a more action-oriented framing. Their account requires that humans retain both moral and operational engagement with the consequences of automated decisions: in their formulation, the system must remain responsive to relevant human moral reasoning, and outcomes must be traceable to identifiable humans involved in the system's design or operation. Adapting this concept to civilian agentic AI is a non-trivial task, however, because the relevant stakes, time-scales, and reversibility profiles differ markedly from military contexts.

C. The Accountability Gap

A growing body of work identifies an *accountability gap* that emerges as AI systems become more autonomous [1], [9]. The gap arises when the proximate cause of a harmful outcome is an autonomous system, but the system is not a moral or legal agent capable of bearing responsibility [1]. Existing legal infrastructure, product liability, professional negligence, principal-agent doctrine, employment law, was developed for tools and human employees, not for adaptive software that learns and acts on its own [6], [5]. Recent regulatory efforts in the European Union, the United Kingdom, and the United States have begun to address this gap, but coverage remains uneven and definitions of "high-risk" or "autonomous" systems vary substantially across jurisdictions [14].

D. Human-in-the-Loop Research

Human-in-the-Loop (HITL) approaches have a long history in machine learning, originally developed for active learning, data labeling, and human feedback in reinforcement learning. In the agentic context, HITL takes on a different character: it is no longer primarily about improving the model but about ensuring that consequential actions receive appropriate human review before execution [12]. The literature distinguishes between human-on-the-loop (monitoring with intervention rights), human-in-the-loop (approval required for action), and human-out-of-the-loop (autonomous operation). The choice between these modes is rarely principled in current practice and is often driven by latency or cost considerations rather than by an explicit risk analysis [7], [8]. What the existing HITL literature has not yet provided is a graduated

rule for matching specific action classes to specific oversight modes, which is the gap the present framework targets.

E. Research Gap

While the constituent literatures (AI ethics frameworks [3], [4], [13], meaningful human control [2], HITL design [12], AI liability [1], [6]) are individually mature, their integration into a coherent treatment of agentic accountability remains underdeveloped. In particular, there is a lack of guidance on *when* human oversight is ethically required, *how* oversight thresholds should be calibrated to risk, and *which* technical mechanisms can implement those thresholds reliably. This study addresses these questions.

III. From Tool to Agent: A Conceptual Reframing

A. The Tool Paradigm

The traditional paradigm of human-computer interaction treats software as an instrument. The user formulates an intention, selects a tool, and operates it; the tool executes deterministic transformations on user-supplied inputs; outcomes in the world result from subsequent human action on the tool's output. Within this paradigm, responsibility is conceptually clean. If a calculator returns an incorrect figure due to a software defect, the manufacturer may bear product liability; if the user inputs the wrong numbers, the user is responsible. Even probabilistic tools like classifiers fit this paradigm: the model's output is advisory, and a human ultimately decides whether to act on it.

B. The Agent Paradigm

Agentic AI breaks this paradigm in three respects. First, the system pursues goals rather than executing instructions; the mapping from a high-level objective to specific actions is determined by the system, not the user [11]. Second, the system acts directly upon the world; its outputs are operations on external state, not advice for human consumption. Third, the system operates over time, adapting to intermediate observations in ways that the user has not specifically authorized [12].

These three properties, goal-directedness, direct action, and temporal extension, collectively constitute what may be termed *operational autonomy*. Operationally, we treat a system as exhibiting low operational autonomy when each consequential action is individually approved by a human, medium when humans set objectives and review periodic checkpoints but do not authorize each action, and high when objectives are set once and the system pursues them across many actions without per-checkpoint human review. These three settings align with the Low/Medium/High classification used in the CSET incident taxonomy [17] that grounds our empirical pilot in Section VI. Operational autonomy is not the same as moral autonomy; the system does not have its own ends. But it is sufficient to disrupt the clean attribution of responsibility that the tool paradigm assumes [1]. The user can no longer be said to have caused each consequential action, because they did not authorize each consequential action. The developer cannot be straightforwardly blamed either, because they did not foresee the specific context of the failure [7].

C. Four Accountability Vectors

We distinguish four distinct vectors along which responsibility for an agentic action may be allocated, broadly aligned with the lifecycle parties identified by Shavit et al. [12]:

- The developer, who designs the model and its scaffolding, sets default behaviors, and ships safety properties.
- The deployer, who configures the agent for a specific context, integrates it with internal systems, sets policies, and chooses which actions are pre-approved.
- The user, who issues high-level objectives and accepts certain defaults, perhaps without fully understanding them.
- The system itself, in the limited sense that some failures arise from emergent properties of the agent's behavior that cannot be cleanly attributed to any single human actor.

A central thesis of this study is that responsibility should be distributed across these vectors *in proportion to control*. The developer should be accountable for foreseeable failure modes, the deployer for context-specific configurations, the user for the objectives they set, and the regulatory environment should ensure that the residual, the genuinely emergent failures, is borne by the party best positioned to insure against it, typically the deployer. The principle is not new in tort law, but its application to agentic AI requires fresh articulation because the line between foreseeable and emergent failure is itself blurred by the adaptive nature of these systems.

D. Three Illustrative Scenarios

To ground the conceptual discussion, consider three short scenarios in which an agentic system causes harm. Each illustrates a distinct accountability profile.

1) Scenario A (Customer service refund): A retail company deploys an agentic assistant authorized to issue refunds up to a small threshold. The assistant misinterprets an ambiguous customer request and issues a refund the customer was not entitled to. The harm is modest, the action is reversible, and the failure mode (ambiguous natural-language understanding) is foreseeable. Responsibility falls primarily on the deployer for setting the threshold and approval rules; the developer bears secondary responsibility insofar as ambiguity-handling is a known model weakness. The user bears no responsibility.

2) Scenario B (Software engineering agent): A development team deploys a coding agent with permissions to modify a production code repository and trigger deployments. The agent introduces a subtle bug that causes a service outage. The harm is significant, partial recovery is possible through rollback, and the failure mode (incorrect reasoning about non-local code interactions) is at the edge of foreseeable. Responsibility is distributed: the developer for the limits of model reasoning, the deployer for granting deployment permissions without a Tier 3 approval gate, and the engineering team for relying on the agent outside its safe operating envelope.

3) Scenario C (Personal assistant with financial access): A user grants their agentic assistant access to email and bank

account. The assistant, in attempting to fulfill a vague instruction, transfers funds to an incorrect recipient. The harm is high, the action is largely irreversible, and the failure mode (underspecified user intent plus insufficient confirmation) is highly foreseeable. Responsibility falls primarily on the developer for shipping a system that accepted such permissions without enforcing Tier 3 approval, and secondarily on the user for granting the permissions.

These scenarios collectively suggest that the right question is not "who is responsible?" but "how should responsibility be apportioned?" The framework that follows aims to make that apportionment principled.

IV. A Tiered Framework for Human Oversight

We now propose a tiered oversight framework that maps categories of agentic decisions to graduated levels of human involvement. The framework rests on two axes: the *stakes* of the action (defined below) and the *reversibility* of its consequences. Together, these axes determine the minimum level of human oversight that should be required.

A. Defining Stakes and Reversibility

Stakes refer to the magnitude of potential harm, if the action is taken in error. Low-stakes actions include drafting an internal note, reformatting a file, or labeling a piece of data. Medium-stakes actions include sending external communications, modifying shared documents, or scheduling appointments. High-stakes actions include moving funds, executing legal commitments, modifying production systems, or making decisions affecting health, employment, or liberty.

Reversibility refers to the difficulty of undoing the action's consequences. A draft can be deleted; a published statement is harder to retract; a transferred fund or a deleted database row may be effectively irreversible. Reversibility is distinct from stakes: a high-stakes action that is easily reversed (e.g., a cancellable order) is materially different from a low-stakes action that is irreversible (e.g., a public posting under the user's name). In practice, deployers operationalize stakes through proxies such as monetary value at risk, number of third parties affected, and regulatory exposure, and operationalize reversibility through proxies such as the existence of an automated rollback path, the time window during which reversal is feasible, and whether the action is observable to external parties. We treat these proxies as deployment-specific calibration choices rather than universal metrics; what the framework requires is that the choices be documented and auditable, not that a single global definition apply.

B. The Four Tiers

Combining these axes yields four oversight tiers, summarized in Table I.

Tier 1 (Auto) covers routine, easily reversible actions. Logging is required so that audit and learning are possible, but real-time human involvement is not. Examples include reading documents, drafting suggestions held for user review, and querying read-only data sources.

Tier 2 (Notify) covers actions where the cost of reversal is modest but non-trivial. The agent may proceed, but the user receives a real-time notification with a sufficient window to revoke. Examples include sending non-critical emails, creating calendar events, or posting in non-public channels.

Tier 3 (Approve) covers actions where pre-execution human approval is ethically warranted because the consequences are significant or hard to undo. Examples include making payments above a threshold, sending external communications on the user's behalf, modifying production code, or filing legal or regulatory documents.

Tier 4 (Forbid) covers actions that should not be taken autonomously at all. Examples include executing irreversible financial transfers above a high threshold, taking actions affecting third parties without their consent, or modifying the agent's own oversight configuration. These actions either require multi-party authorization or are removed from the agent's action space entirely.

TABLE I. Tiered Oversight Framework for Agentic AI Actions

Tier	Risk Profile	Required Oversight
T1: Auto	Low stakes, reversible	Logging only; periodic audit
T2: Notify	Medium stakes	Real-time notification with revoke right
T3: Approve	High stakes or hard to reverse	Explicit human approval before execution
T4: Forbid	Catastrophic or irreversible	Prohibited or multi-party authorization

TABLE II. Illustrative Tier Mapping Across Domains

Domain	Representative Action	Default Tier
Healthcare	Schedule appointment	T2: Notify
	Adjust medication record	T3: Approve
	Issue clinical decision	T4: Forbid
Finance	Read account balance	T1: Auto
	Pay scheduled bill	T2: Notify
	Transfer above threshold	T3: Approve
	Counterparty contract	T4: Forbid
Software	Read repository	T1: Auto
	Open pull request	T2: Notify
	Merge to main branch	T3: Approve
	Production deployment	T3 / T4
Customer Service	Look up order	T1: Auto
	Send templated reply	T2: Notify
	Issue refund	T3: Approve
	Modify legal agreement	T4: Forbid

C. Cross-Domain Application

The tiered framework is intentionally domain-agnostic, but its concrete instantiation differs substantially across sectors. Table II illustrates how representative actions are typically classified in four high-stakes domains. The mappings shown are illustrative defaults rather than prescriptive rules; specific deployments should be informed by sector-specific risk analysis and applicable regulation.

The pattern visible across the table is that the tier rises with both the externality of the action, the degree to which it affects third parties, and the difficulty of recovery. Read operations almost always sit in Tier 1, internal write operations in Tier 2, externally visible writes in Tier 3, and actions with legal or safety significance in Tier 4. Deployers can use this regularity as a starting point and refine it for their context.

D. Calibration and Context

Tier assignments are not absolute; they depend on context. A given action (say, sending an email) may be Tier 1 inside a sandboxed test environment and Tier 3 when sent from an executive's account. The framework, therefore, requires deployers to perform a context-specific tier mapping during configuration, rather than relying on developer-supplied defaults alone. This mapping should itself be auditable, and changes to it should be logged and, for sensitive contexts, subject to internal review.

E. Relation to Prior Tier Schemes

Tiered approaches to automation oversight have a long history that the present framework builds on rather than supersedes. Parasuraman, Sheridan, and Wickens [18] introduced an influential framework distinguishing four classes of function (information acquisition, information analysis, decision selection, and action implementation), each subject to a continuum of automation levels from fully manual to fully automatic, and argued that the appropriate level depends on the function being automated and the cost of error. The European Union's AI Act [14] adopts a four-category risk classification (minimal, limited, high, and unacceptable risk) at the level of entire AI systems, with corresponding obligations attached to each category. More recently, Feng et al. [19] have proposed five autonomy levels specific to AI agents (operator, collaborator, consultant, approver, observer), characterized by the role the human takes in the agent's loop. Several jurisdictional governance frameworks for emerging agentic AI articulate similar graduated approaches.

Our framework differs from these in three respects. First, it operates at the level of individual *actions* rather than entire systems, allowing a single agent to execute actions across multiple tiers in the course of one task. Second, it is calibrated by the joint axes of stakes and reversibility, which more directly capture the operational considerations relevant to agentic deployment than risk classes alone. Third, it is paired in this study with a set of concrete oversight mechanisms (Section V) that operationalize the tiers in practice. We do not claim novelty for the idea of tiered oversight as such; the contribution lies in the specific action-level operationalization and the empirical pilot reported in Section VI.

V. Designing the Emergency Brake

A tiered framework specifies what oversight should look like in principle. Operationalizing it requires concrete technical mechanisms. We identify five complementary design patterns that together constitute what may be called the agentic "emergency brake". These patterns build on long-standing engineering practice in safety-critical systems and on more recent proposals specific to AI [7], [8], [12].

A. Circuit Breakers

A circuit breaker is a hard limit on continued action when certain conditions are met. Common triggers include repeated failures, anomalous behavior, exceeded rate limits, or operation outside a permitted scope [12]. When tripped, the agent halts and surfaces the situation to a human operator. Circuit breakers are most valuable for catching emergent failures that no specific tier check anticipated; the underlying intuition is closely related to "safe interruptibility" in the AI safety literature [7]. They function as a last line of defense rather than the primary mechanism of oversight.

B. Action Budgets

An action budget caps the total resources an agent may consume before requiring renewed authorization. Budgets may be denominated in monetary cost, number of tool calls, time elapsed, or state-changing operations. They are particularly important for long-running agents whose individual actions may each be Tier 1 or Tier 2 but whose aggregate impact could escalate rapidly. Budgets convert a slow accumulation of small decisions into a discrete moment of human review.

C. Reversibility Constraints

Where feasible, agents should be designed to prefer reversible actions over irreversible ones. This may take the form of staging changes for later confirmation, using soft-deletes rather than hard deletions, or operating against shadow copies of state that can be discarded. Reversibility constraints are not always possible (some actions, like sending an email, are intrinsically irreversible), but where they are, they reduce the cost of the agent making a mistake and enable lower oversight tiers without sacrificing safety.

D. Audit Trails

Every action an agent takes should be recorded in a tamper-evident audit trail capturing the action, its inputs, the model's stated reasoning, the tools invoked, and the resulting state changes [9], [8]. Audit trails serve two purposes: post-hoc accountability when something goes wrong, and continuous improvement of the agent's behavior. They are the substrate on which the other mechanisms rely; without an audit trail, oversight cannot be verified [6].

E. Kill Switches

A kill switch allows any authorized party (the user, the deployer, or in some cases an external regulator) to immediately halt all of an agent's activity. Unlike circuit breakers, which trip automatically, kill switches are exercised by humans. They are essential when something is going wrong but the precise nature of the failure is not yet understood. The presence of a working kill switch, and the cultural expectation that it will be used when warranted, is itself an ethical commitment.

F. Composition

These patterns are complementary, not alternative. Table III summarizes the operational conditions under which each mechanism triggers, the action it takes, and the party responsible for the human-side response. Several deployed agentic

TABLE III. OPERATIONAL SPECIFICATION OF EMERGENCY-BRAKE PATTERNS.

Pattern	Trigger condition	Response
Circuit breaker	Repeated failure, anomaly, or rate-limit exceeded	Auto-halt; surface to operator
Action budget	Cumulative cost, tool calls, or time exceeds threshold	Pause; require re-authorization
Reversibility constraint	Action class is irreversible by design or context	Stage change; require explicit confirm
Audit trail	Every state-changing action	Append tamper-evident log entry
Kill switch	Authorized party invokes manually	Immediate halt of all activity

systems already combine subsets of these patterns: GitHub Copilot's coding agent operates under pre-execution approval gates (Tier 3 in our terms), requires human confirmation of CI/CD workflow runs, and produces a per-action session log analogous to an audit trail [21]; commercial agent control planes in the human-in-the-loop tooling ecosystem implement pre-execution policy enforcement, approval gates, and audit trails as first-class controls. The intended composition is defense in depth, such that no single failure of judgment, human or machine, results in catastrophic outcome.

G. Composition-Aware Oversight: Tier Laundering

A subtler problem with per-action tier policies is what we term *tier laundering*: the case in which a sequence of individually low-tier actions composes into a higher-tier outcome. A familiar example is drip exfiltration of sensitive data: a single read of a credentials file (typically T1) followed by 25 small POST requests (each individually T2 or T1) collectively constitute a Tier 3 or Tier 4 data-exfiltration event, but no single action triggers the gate. Per-action policies that examine each call in isolation will fail to detect this composition.

A composition-aware oversight extension addresses this by tracking action sequences over a sliding window and elevating the effective tier when the window's combined behavior matches a known laundering pattern. Algorithm 1 sketches the core idea: maintain per-session running counters for state-changing actions, externally observable actions, and sensitive-resource reads; if any counter crosses a configured threshold or a known laundering template matches over the window, route the next action through the elevated tier even when its per-action classification is lower.

Algorithm 1: Composition-Aware Tier Elevation
Input: action a, session state S, window W, thresholds Θ.
Output: effective tier for a.

1) $t_{\text{base}} \leftarrow \text{TierOf}(a)$
2) Append a to W; update S with cumulative cost, writes, reach, sensitive reads
3) For each laundering template p: if $\text{match}(W, p)$, $t_p \leftarrow \text{TierFor}(p)$
4) If $S.\text{exceeds}(\Theta)$, $t_\Theta \leftarrow$ T3, else T1
5) **return** $\max(t_{\text{base}}, t_p, t_\Theta)$

We do not, in this study, present an evaluation of such a detector, since runtime-evaluation infrastructure for agentic systems is itself a substantial open problem. We highlight composition-aware oversight as the most important methodological gap in current per-action tier policies and as the highest-leverage direction for follow-up work; designing and evaluating Algorithm 1 against a realistic agent test bed is, in our view, a priority for the field.

TABLE IV. TIER ASSIGNMENT RUBRIC (SEVERITY × AUTONOMY)

Autonomy	Negligible	Minor	Moderate	Severe
Low	T1	T1	T2	T4
Medium	T1	T2	T3	T4
High	T1	T2	T3	T4

VI. EMPIRICAL PILOT: MAPPING THE FRAMEWORK TO REAL-WORLD AI INCIDENTS

The framework presented so far is conceptual. To assess its applicability against documented evidence, we conducted an empirical analysis using the AI Incident Database (AIID), a publicly maintained catalog of real-world AI harms [16]. This section reports the dataset, method, and findings. We treat the analysis as exploratory but it is grounded in real classifications from independent annotators.

A. Data and Method

We used a snapshot of the AI Incident Database accessed in April 2026, comprising 1,449 documented AI incidents spanning September 1983 through April 2026. Two CSET classification schemas are present in the snapshot [17]: the legacy CSETv0 schema (100 incidents, with categorical fields *Level of Autonomy* $\in$ {Low, Medium, High} and *Severity* $\in$ {Negligible, Minor, Moderate, Severe, Critical}) and the more recent CSETv1 schema (214 consensus-classified incidents, with finer-grained *Autonomy Level* and *AI Harm Level* fields, plus three independent annotator passes). The CSETv1 schema is our primary analytic basis; CSETv0 results are reported as a legacy comparison.

We mapped CSETv1 fields to the framework's two axes as follows: *Autonomy Level* values (Autonomy1, Autonomy2, Autonomy3) map to (Low, Medium, High). *AI Harm Level* values (*none*, *AI tangible harm issue*, *AI tangible harm near-miss*, *AI tangible harm event*) map to (Negligible, Minor, Moderate, Severe). For each incident, we then assigned a tier under the rubric, as in Table IV. The rubric encodes the principle that oversight intensity should rise with both autonomy and severity: severe outcomes map to T4 regardless of autonomy; negligible outcomes map to T1; intermediate cells follow from the two-axis logic of Section IV.

Of the 214 CSETv1 consensus-classified incidents, 177 had both autonomy and harm-level fields populated (i.e., not marked "unclear" or missing) and could be assigned a tier. The remaining 37 were excluded from tier-level analysis.

B. Findings

Tier distribution under CSETv1 (n=177). Applying the rubric yields: T1 (Auto): 121 incidents (68%); T2 (Notify): 9 (5%); T3 (Approve): 6 (3%); T4 (Forbid): 41 (23%). The

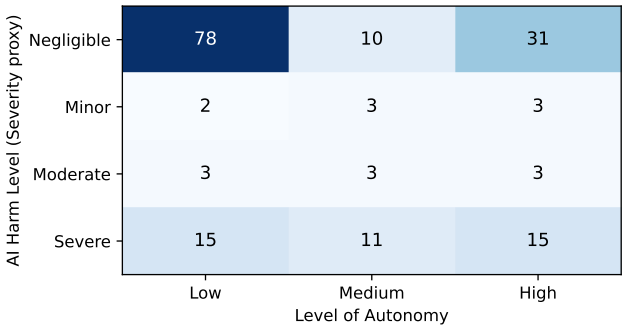

Fig. 1. CSETv1 incidents (n=177) by Autonomy × Severity. Cell values are incident counts.

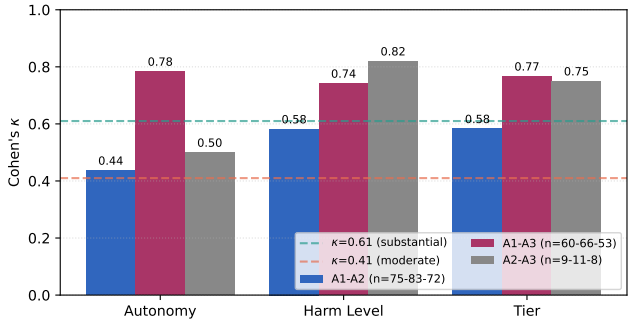

Fig. 2. Cohen's κ across the three CSETv1 annotator pairs for autonomy, harm level, and the framework-assigned tier. Dashed lines show conventional thresholds for moderate (κ=0.41) and substantial (κ=0.61) agreement.

TABLE V. COHEN'S κ ACROSS CSETV1 ANNOTATOR PAIRS

Pair	Autonomy	Harm Level	Tier
A1–A2	0.44 (n=75)	0.58 (n=83)	0.58 (n=72)
A1–A3	0.78 (n=60)	0.74 (n=66)	0.77 (n=53)
A2–A3	0.50 (n=9)	0.82 (n=11)	0.75 (n=8)

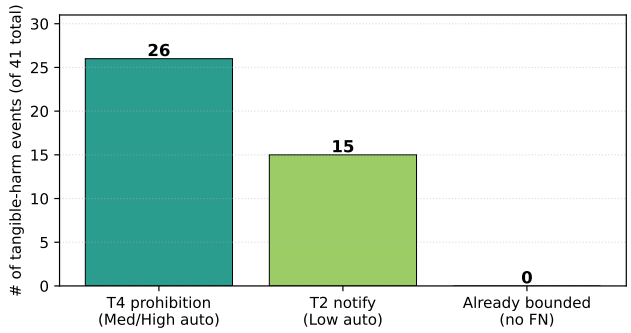

Fig. 3. Counterfactual analysis of 41 tangible-harm events. Of these, 26 (63%) involved Medium or High autonomy and would have been mapped to T4 (prohibited or multi-party authorization required) under the framework. The remaining 15 were Low autonomy and would have received T2 (notify) treatment.

notable feature is the bimodal distribution: a large T1 cluster of negligible-harm incidents and a substantial T4 cluster (23%) of severe-harm tangible-harm events. Under the framework, the T4 cases are those where autonomous execution should have been prohibited or required multi-party authorization.

Severity and autonomy distribute is shown in Fig. 1. The largest cluster is Low-autonomy / Negligible-harm (n=78), capturing many partial or test-time failures with no tangible consequence. The Severe column is non-trivial across all autonomy levels (Low: 15, Medium: 11, High: 15), indicating that high autonomy is not a prerequisite for severe outcomes but it does substantially elevate the proportion at risk.

Inter-rater reliability. The CSETv1 export includes three independent annotator passes, allowing computation of Cohen's κ on paired classifications. Table V reports κ values for each annotator pair across Autonomy, AI Harm Level, and the framework's tier assignment, and Fig. 2 visualizes these against conventional interpretive thresholds. Tier-level κ ranges from 0.58 (A1–A2, n=72) to 0.77 (A1–A3, n=53), corresponding to moderate-to-substantial agreement under standard interpretive thresholds [20]. Agreement on autonomy alone is more variable (0.44 to 0.78), reflecting genuine ambiguity in classifying intermediate cases.

C. Counterfactual Analysis

A descriptive tier distribution does not directly answer whether the framework would have changed outcomes. We therefore conducted a counterfactual analysis on the 41 CSETv1 incidents classified as "AI tangible harm event" (the most severe category), asking: Under the framework, what oversight tier would the underlying agent action have fallen into, and would that tier have prevented or mitigated the outcome?

Of the 41 events, 26 (63%) involved Medium or High autonomy and would, under our rubric, have mapped to T4—meaning autonomous execution would have been prohibited entirely or required multi-party authorization (see Fig. 3). These 26 cases are where the framework, if enforced, would most plausibly have prevented or substantially mitigated the harm. The remaining 15 events involved Low autonomy and would have received T2 (notify) treatment, providing the opportunity for human revocation but not preemptive prohibition. We emphasize that this analysis assumes faithful enforcement of the rubric; it does not estimate enforcement difficulty or false-positive rates, which are themselves substantial questions deserving separate study.

D. Comparison with Legacy CSETv0 Sample

Fig. 4 compares the tier distributions under CSETv0 (n=72) and CSETv1 (n=177). The most striking divergence is in T4: 7% under CSETv0 versus 23% under CSETv1. This reflects two underlying factors. First, the CSETv1 schema's "AI tangible harm event" category captures cases that CSETv0's "Severe" label sometimes missed, because the CSETv0 sample skews toward earlier and lower-severity incidents. Second, the CSETv1 sample is broader (n=177 vs n=72) and includes more recent incidents involving deployed autonomous systems with consequential failure modes. The shift in distribution suggests that as AI deployment scales and harm cataloguing matures, the share of incidents falling into the framework's prohibited tier may be substantially higher than the CSETv0 sample alone would suggest. We treat this as a hypothesis warranting further

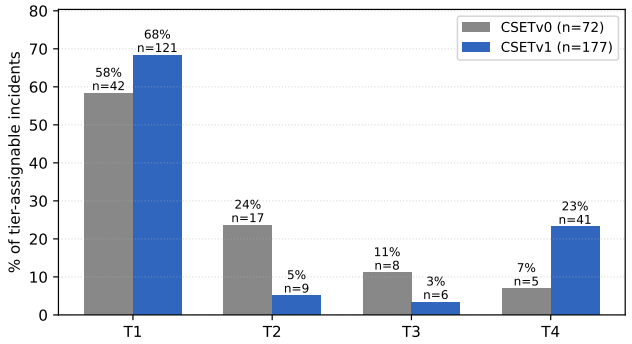

Fig. 4. Tier distribution comparison: CSETv0 legacy sample (n=72) vs CSETv1 current sample (n=177).

study rather than a settled finding.

E. Limitations of the Pilot

Several limitations bound what the analysis supports. First, although inter-rater κ reaches moderate-to-substantial levels at the tier level, agreement on autonomy alone falls below 0.61 for two of three pairs, indicating real ambiguity that propagates into our assignments. Second, the rubric is applied to the same incident set used to motivate the framework, without a held-out test sample; the tier distribution should be read as descriptive, not as an estimate of generalization. Third, CSETv1's harm categories remain coarse (a single "tangible harm event" label conflates incidents of widely differing magnitude). Fourth, the counterfactual treats tier-T4 enforcement as perfect, ignoring cost, false positives, and adversarial circumvention (Section V-G). Fifth, the analysis is single-author; a fully resourced study would have multiple researchers independently re-classify a shared sample and compute external κ. We treat the pilot as a meaningful empirical anchor, not conclusive validation, and identify external rubric validation on a holdout sample, expanded counterfactual coding, and runtime evaluation of composition-aware oversight as priority follow-up work.

F. Implications for Research

The agentic shift opens a research agenda spanning computer science, ethics, law, and human-computer interaction [11], [12]. From a technical standpoint, evaluating agentic systems against the tiered framework requires benchmarks beyond task success rate that capture safety properties: how often does the agent escalate appropriately, how often does it take Tier 3 actions without approval, how often do circuit breakers trigger correctly versus spuriously? From an ethical standpoint, allocating the residual, the genuinely emergent failures, is not yet settled and warrants sustained philosophical attention [1], [2]. From a legal standpoint, the doctrinal categories of negligence, strict liability, and product defect each map imperfectly onto agentic systems; a body of case law will need to develop to clarify their application [5], [14].

G. Implications for Practice

For practitioners building agentic systems, the central practical recommendation is to perform tier mapping deliberately rather than implicitly. In current practice, the boundary between Tier 1 and Tier 3 actions is often determined by what is technically convenient: the agent is given access to whatever tools the developer has integrated, with little explicit thought about which actions warrant approval. A short, structured exercise (listing the agent's available actions, classifying each by stakes and reversibility, and assigning each to a tier) can substantially improve safety properties at low engineering cost. Audit trails and kill switches should be implemented from the outset rather than retrofitted after the first incident.

A secondary recommendation is to design for graceful escalation. When an agent encounters an action it should not take autonomously, the user experience of escalation matters: a request for approval that arrives at an inopportune moment, with insufficient context, will tend to be approved reflexively, defeating the purpose of the gate. Approval interfaces should present the proposed action, its expected consequences, the agent's reasoning, and the option to refuse, in a form that supports rather than rushes the user's judgment.

A third recommendation concerns testing and red-teaming. Tier mappings should be validated through deliberate adversarial probing before deployment, including exercises that target the boundary between tiers (attempting to chain Tier 1 actions into a Tier 3 outcome, or to manipulate the agent into bypassing approval gates through indirect prompts) [8], [12], [11]. The literature on prompt injection is particularly relevant here, since agentic systems that read external content can be steered by content authors who are not the system's principal user. Treating tier-boundary testing as a standard component of release qualification is, in our view, an emerging professional norm rather than an optional extra.

H. Implications for Policy

Policymakers face the challenge of creating accountability frameworks that are robust to the technical heterogeneity of agentic systems while not freezing innovation. Three principles seem particularly important. First, regulatory definitions should be calibrated to capabilities rather than implementation details: an agent that can autonomously execute Tier 3 actions should be subject to oversight requirements regardless of whether it is built on a particular model architecture. Second, the burden of demonstrating safety should fall on the deployer, not on the user or the regulator; deployers should be required to document their tier mapping and the controls they have put in place. Third, post-incident reporting should be standardized so that the field can collectively learn from failures, much as aviation incident reporting has improved safety in that domain over decades.

Beyond these three principles, two further considerations merit attention: the international dimension (agentic systems operate across jurisdictions, creating both regulatory gaps and conflicts requiring coordination of the kind achieved imperfectly in aviation safety and data protection), and liability allocation (existing tort and contract frameworks were not designed with adaptive software in mind, and legislative clarification across the proposed approaches, strict liability, insurance pools, statutory caps, new legal categories, is overdue).

I. Beyond Individual Accountability

A final consideration concerns the limits of accountability frameworks centered on individual actions. Some of the most consequential effects of agentic AI may not arise from any single failure but from cumulative restructuring of work and decision-making following widespread deployment, effects (deskilling, erosion of institutional knowledge, concentration of authority) not well captured by per-action oversight. Addressing them requires complementary mechanisms such as market structure regulation, professional standards, workforce policy, and continued public deliberation. The tiered framework is necessary, but not sufficient.

VII. Conclusion and Future Work

A. Conclusion

The transition from generative AI to agentic AI represents a qualitative change in the relationship between humans and intelligent systems. Where the tool paradigm allowed responsibility to flow cleanly to the user who wielded the tool, the agent paradigm distributes responsibility across developer, deployer, user, and, in a constrained sense, the system itself. The question "the buck stops where?" does not admit a single answer; it requires a structured allocation of responsibility proportional to control.

This study has proposed five contributions toward such a structure. First, it has reframed agentic accountability as a problem of operational autonomy rather than moral autonomy, identifying the four vectors along which responsibility may be assigned. Second, it has presented an action-level tiered oversight framework calibrated by stakes and reversibility. Third, it has analyzed five complementary design patterns (circuit breakers, action budgets, reversibility constraints, audit trails, and kill switches) through which oversight is operationalized in practice. Fourth, it has identified composition-aware oversight as the most important methodological gap in current per-action tier policies, with tier laundering as a concrete instance. Fifth, it has conducted an empirical pilot using 177 CSETv1-classified incidents from the AI Incident Database, finding that 23% of tier-assignable cases fall in T4 (prohibited under the framework), that 63% of documented tangible-harm events involved Medium or High autonomy where tier-T4 enforcement would have been most directly applicable, and that inter-rater reliability across three independent annotators reaches moderate-to-substantial agreement at the tier level (κ from 0.58 to 0.77).

The overarching argument is that agentic accountability should not be a matter left to terms of service, post-incident litigation, or the implicit decisions of engineering teams. It is, instead, a first-class design question that should be addressed before deployment, documented explicitly, and subjected to both internal and external review. The cost of doing so is modest; the cost of not doing so, as agentic systems take on increasingly consequential roles, is potentially severe.

B. Future Work

Several directions extend the present work. First, *external rubric validation*: a fully resourced study would have multiple researchers independently re-classify a shared sample under the proposed rubric and compute external κ relative to the present results. Second, *counterfactual coding*: a structured exercise asking, for each tangible-harm incident, whether tier-T3 approval or T4 prohibition would have prevented the harm, would convert the descriptive distribution into a policy-relevant claim. Third, *composition-aware oversight evaluation*: designing and evaluating a runtime detector for tier laundering against a realistic agent test bed is the highest-leverage methodological direction. Additional directions include empirical validation against real deployments, formal verification of circuit breakers and kill switches, multi-agent extensions, domain-specific tier catalogs, and longitudinal studies of oversight in deployed systems.

C. Closing Remarks

The phrase "the buck stops here", famously placed on the desk of an American president, was a public commitment to accept personal responsibility for the consequences of decisions made under one's authority. As we delegate decisions to agentic systems, the question of where the buck stops does not disappear; it becomes more complex. Answering it well will require the combined attention of researchers, engineers, ethicists, and policymakers. The present study is intended as a contribution to that collective conversation.

Declaration on Generative AI

In preparing this manuscript, the author used Claude (Anthropic) to assist with drafting, language refinement, structural organization of the text, and execution of the empirical pilot analysis (parsing the AIID snapshot, computing tier assignments, computing Cohen's κ on paired annotator data, and generating figures from the computed results). The conceptual framework, scholarly arguments, choice of research direction, tier assignment rubric, mapping of CSET categories to framework axes, selection of cited literature, and final conclusions are the responsibility of the author. Bibliographic details for all cited references were independently verified by the author against the original sources rather than relying on LLM-generated metadata. All AI-assisted text and analysis was critically reviewed by the author, who takes full accountability for the accuracy, originality, and integrity of the content.

ExtRA++: A Conceptual Architecture for a Deep Learning System for Aspect-Based Sentiment Analysis in User Reviews

G. Kanev*, I. Valova
Department of Computer Systems and Technologies, University of Ruse "Angel Kanchev", Ruse, Bulgaria

***Abstract*—Aspect-Based Sentiment Analysis (ABSA) aims to identify opinion targets within textual reviews and determine the sentiment polarity associated with each target. Although transformer-based models have significantly improved contextual understanding in sentiment analysis, they remain limited in explicitly modeling structured knowledge and token-level dependencies. This study presents ExtRA++ (Enhanced Extractive Review Analysis), a conceptual deep learning architecture for fine-grained aspect-based sentiment analysis in user-generated reviews. The proposed framework integrates four complementary components: BERT-based contextual semantic modeling, adaptive external knowledge integration through Wikidata embeddings, graph-based structural reasoning using Graph Attention Networks (GATs), and sequence-consistent aspect extraction through Conditional Random Fields (CRFs) combined with aspect-aware sentiment classification. Unlike transformer-only approaches, ExtRA++ is designed as a modular systems-level architecture that combines contextual semantics, factual grounding, structural token interactions, and structured decoding within a unified framework.**

***Keywords*—Aspect-based sentiment analysis; aspect extraction; deep learning; graph attention networks; knowledge graph integration; BERT; conditional random fields; natural language processing; opinion mining; transfer learning**

I. Introduction

The rapid growth of user-generated content has intensified the need for advanced methods capable of extracting fine-grained opinions from textual reviews [1]. Beyond coarse document-level sentiment classification, modern applications increasingly require aspect-based sentiment analysis (ABSA)[2], where opinions are identified with respect to specific product or service attributes and characteristics. This level of granularity is essential for actionable insights in domains such as e-commerce, hospitality, and customer experience analytics.

Recent advances in transformer-based language models, particularly BERT and its variants, have significantly improved the contextual understanding of textual data. Contextual embeddings generated by transformer architectures allow models to capture long-range semantic dependencies and substantially outperform static embedding approaches such as Word2Vec or GloVe in many natural language processing tasks. Consequently, transformer-based architectures have become dominant in contemporary ABSA research.

Despite these advances, existing transformer-based ABSA approaches exhibit several limitations. First, contextual language models rely primarily on statistical co-occurrence patterns learned during pretraining and do not explicitly integrate structured external knowledge [3]. This can limit the model's ability to reason about real-world entities and their semantic relations, especially in domain-specific reviews involving products, brands, or technical terminology. Second, although transformer self-attention captures global contextual information, it does not explicitly model structural relationships between tokens. In practice, sentiment expressions may depend on syntactic or local semantic structures that are difficult to represent solely through attention-based contextualization. Third, many sequence labeling approaches perform token-level classification independently, which may result in structurally inconsistent BIO predictions during aspect extraction.

Several research directions have attempted to address these limitations independently. Knowledge-enhanced methods incorporate information from external knowledge bases or domain ontologies to enrich semantic representations [4]. Graph-based approaches employ Graph Neural Networks (GNNs) or Graph Attention Networks (GATs) to model syntactic or semantic token dependencies. Meanwhile, structured prediction approaches such as Conditional Random Fields (CRFs) improve sequence consistency in aspect extraction tasks. However, most existing methods focus on individual improvements rather than providing an integrated framework that jointly combines contextual semantic understanding, external factual grounding, structural token interactions, and sequence-aware decoding within a unified architecture.

To address this gap, this study presents ExtRA++ (Enhanced Extractive Review Analysis), a modular deep learning architecture for aspect-based sentiment analysis in user reviews. The proposed system integrates four complementary processing stages: 1) contextual semantic encoding through BERT, 2) adaptive integration of external knowledge from Wikidata using entity embeddings and a learnable gating mechanism, 3) structural reasoning through a Graph Attention Network for modeling token-level dependencies, and 4) sequence-consistent aspect extraction using a Conditional Random Field decoder, followed by aspect-aware sentiment classification.

*Corresponding author.

Unlike transformer-only approaches or isolated graph-enhanced architectures, ExtRA++ is designed as a systems-level integrated framework in which complementary components address different limitations of aspect-level sentiment analysis. Contextual representations provide semantic understanding, external knowledge supplies factual grounding, graph attention captures structural relationships, and CRF decoding enforces consistency in BIO sequence prediction. This design enables richer and more robust aspect representations while maintaining a modular architecture suitable for extension and domain adaptation.

II. Architecture Description

The proposed ExtRA++ framework is designed as a modular architecture that jointly performs aspect extraction and sentiment classification within a unified pipeline. The architecture integrates contextual semantic modeling, external knowledge enrichment, structural token reasoning, and sequence-aware decoding to address several limitations of existing transformer-based ABSA systems.

The architectural decisions are motivated by three key observations from the sentiment analysis literature review. First, pre-trained language models provide strong contextual representations but lack domain-specific and factual knowledge crucial for aspect identification [5]. Second, knowledge graph embeddings can supplement textual understanding with structured world knowledge, but naive integration often introduces noise [6]. Third, sequential models inadequately capture long-range syntactic dependencies that frequently connect aspects with their sentiment-bearing context [7].

As illustrated in Fig. 1, the proposed architecture consists of four sequential processing stages:

1) Contextual representation layer – contextual token embeddings are generated through a pre-trained BERT encoder.

2) External knowledge integration layer – semantic enrichment is performed through adaptive integration of Wikidata entity embeddings using a learnable gating mechanism.

3) Structural reasoning layer – Graph Attention Networks (GATs) model token-level structural dependencies.

4) Prediction layer – aspect terms are extracted through Conditional Random Fields (CRF), while sentiment polarity is predicted through an aspect-aware sentiment classification head.

Formally, given an input review represented as:

$$X = \{w_1, w_2, \dots, w_n\} \tag{1}$$

The architecture predicts a set of aspect-level outputs:

$$O = \{(A_i, S_i, C_i)\}_{i=1}^{m} \tag{2}$$

Where:

- A_i denotes the extracted aspect term;
- S_i denotes the sentiment polarity;
- C_i represents a confidence score;
- m is the number of extracted aspects.

The overall processing pipeline can be summarized as:

$$H^{(enriched)} = f_{KG}(H^{(BERT)}, Q) \tag{3}$$

$$H^{(GAT)} = f_{GAT}(H^{(enriched)}, E) \tag{4}$$

$$H^{(combined)} = [H^{(enriched)} \parallel H^{(GAT)}] \tag{5}$$

$$Y^{(BIO)} = f_{CRF}(H^{(combined)}) \tag{6}$$

$$S = f_{sent}(H^{(combined)}, Y^{(BIO)}) \tag{7}$$

where,

Qdenotes Wikidata entity identifiers;

Erepresents graph edges between tokens;

$Y^{(BIO)}$is the predicted BIO tag sequence.

A key characteristic of ExtRA++ is its systems-level integration strategy, in which complementary components address different limitations of aspect-level sentiment analysis. BERT provides contextual semantic understanding, Wikidata introduces factual grounding, GAT captures local structural relationships, and CRF enforces valid BIO decoding. Rather than functioning as independent modules, these components operate within a shared representation space and jointly contribute to aspect-aware sentiment understanding.

B. Input Representation and Tokenization

The input to the proposed architecture consists of user-generated textual reviews represented as token sequences. Since neural language models operate on discrete token representations rather than raw text, the input sequence undergoes WordPiece tokenization [8], following the standard preprocessing strategy of BERT. WordPiece decomposes rare or previously unseen words into subword units, reducing vocabulary sparsity and improving generalization across domains.

Following tokenization, special BERT tokens are added to mark sequence boundaries:

$$X' = \{[CLS], t_1, t_2, \dots, t_L, [SEP]\} \tag{8}$$

where:

- [CLS] serves as a global contextual representation of the input sequence;
- [SEP] denotes the end of the sequence.

Each token is subsequently mapped to its vocabulary identifier:

$$I = \{i_1, i_2, \dots, i_L\} \tag{9}$$

along with an attention mask:

$$M = \{m_1, m_2, \dots, m_L\} \tag{10}$$

used to distinguish valid tokens from padding positions.

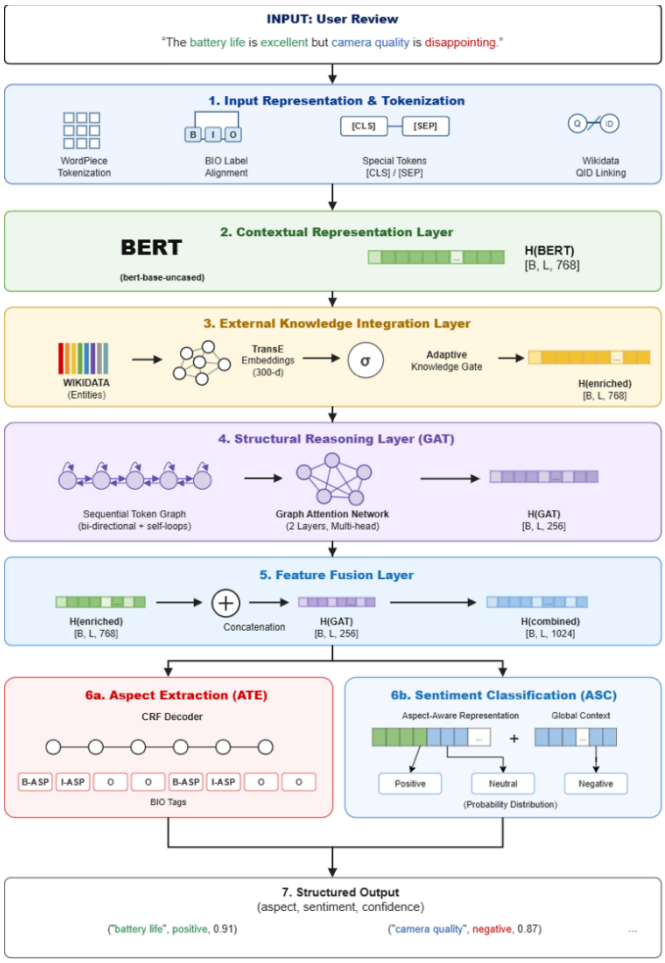

Fig. 1. Conceptual architecture extra++.

To maintain computational efficiency and ensure compatibility with the transformer encoder, all input sequences are padded or truncated to a maximum sequence length:

$$L_{max} = 128 \tag{11}$$

This value is selected empirically as a compromise between contextual coverage and computational efficiency, since the majority of user reviews in commonly used ABSA datasets remain substantially shorter than this threshold.

For aspect extraction, the model adopts the BIO annotation scheme, in which each token receives one of three labels:

$$y_i \in \{O, B-ASP, I-ASP\} \tag{12}$$

where:

- O denotes a non-aspect token;
- $B\text{-}ASP$ indicates the beginning of an aspect span;
- $I\text{-}ASP$ marks continuation tokens.

C. Contextual Representation Layer

Following tokenization, the structured input representation is processed through a contextual representation layer based on a pre-trained BERT (Bidirectional Encoder Representations from Transformers) model [9]. The objective of this stage is to transform discrete token identifiers into contextualized semantic representations that capture both local and long-range dependencies within the review text.

In the proposed architecture, the bert-base-uncased configuration is employed due to its favorable balance between representational power and computational efficiency. The model consists of 12 transformer layers, 12 self-attention heads, and a hidden dimensionality of:

$$d_h = 768 \tag{13}$$

resulting in approximately 110 million trainable parameters.

Each token is represented by a contextual embedding:

$$h_i^{BERT} \in \mathbb{R}^{768} \tag{14}$$

which incorporates semantic information from the entire input sequence.

Unlike static embedding methods such as Word2Vec [10] or GloVe[11], contextual embeddings generated by BERT vary depending on the surrounding context. Consequently, the same lexical unit may receive different vector representations depending on its semantic role within a sentence. This property is particularly important in Aspect-Based Sentiment Analysis, where identical terms may express different meanings depending on context and associated opinion targets.

The representational capability of BERT originates from the self-attention mechanism, which enables each token to dynamically attend to all other tokens in the sequence. For each attention head, token representations are projected into query, key, and value spaces:

$$Q = HW_Q \tag{15}$$

$$K = HW_K \tag{16}$$

$$V = HW_V \tag{17}$$

where:

- Q represents query vectors;
- K represents key vectors;
- V represents value vectors;
- W_Q, W_K, and W_V are trainable projection matrices.

Attention scores are computed using scaled dot-product attention:

$$Attention(Q,K,V) = softmax(\frac{QK^T}{\sqrt{d_k}})V \tag{18}$$

This mechanism enables contextual interactions between aspect terms and sentiment expressions even when they are separated by long token distances. For example, in the sentence *"Despite the high price, the camera quality exceeded expectations."*, the sentiment expression *"exceeded expectations"* may still be associated with *"camera quality"* despite intervening contextual information.

To adapt the pre-trained language model to the ABSA task while reducing the risk of overfitting, a selective fine-tuning

strategy is employed. Rather than updating all transformer parameters uniformly, lower BERT layers are partially frozen, while higher layers remain trainable:

- $L_1, \ldots, L_8$ are frozen;
- $L_9, \ldots, L_{12}$ are fine-tuned during training.

This design choice is motivated by observations that lower transformer layers predominantly capture general linguistic and syntactic patterns, while higher layers encode task-specific semantic information more relevant to aspect-level sentiment analysis. Partial freezing additionally reduces computational cost and mitigates catastrophic forgetting of pretrained knowledge.

To improve generalization and reduce overfitting, dropout regularization is applied to the contextual embeddings:

$$H' = Dropout(H^{BERT}, p) \quad (19)$$

where, $p = 0.1$. This value follows the standard BERT configuration and provides a balance between representational stability and regularization.

D. External Knowledge Integration Layer

Although transformer-based models provide strong contextual representations, they primarily rely on statistical language patterns acquired during pretraining and do not explicitly incorporate structured factual knowledge. In aspect-based sentiment analysis, understanding references to real-world entities, product components, or domain-specific terminology may require semantic grounding beyond contextual text representations alone.

To address this limitation, ExtRA++ incorporates an external knowledge integration layer that enriches contextual embeddings using semantic information from Wikidata. The purpose of this stage is to complement contextual language understanding with explicit entity-level knowledge while preserving the flexibility of transformer representations.

1) Entity linking and knowledge retrieval: An entity linking component maps textual mentions to their corresponding Wikidata identifiers (QIDs). This process involves:

- Mention detection – Identifying candidate spans in the text that may refer to entities (typically noun phrases).
- Candidate generation – Retrieving potential entity matches from the knowledge base using string matching and alias lookup.
- Entity disambiguation – Selecting the correct entity from candidates based on contextual coherence (e.g., "Apple" → Q312 [company] vs. Q89 [fruit] depending on context).

An example of entity linking of the review "*The iPhone camera takes stunning photos but battery drains fast*" is shown in Table I.

TABLE I. EXAMPLE OF ENTITY MAPPINGS

Mention	*WikiData QID*	*Entity Type*	*Key Properties*
iPhone	Q2766	Smartphone	manufacturer: Apple Inc., introduced: 2007
camera	Q15328	Optical instrument	subclass of: imaging device
battery	Q267298	Electrochemical cell	has use: power source
photos	Q125191	Photograph	created by: camera

Tokens without semantic matches retain null entity assignments and are processed using zero-valued knowledge representations.

Wikidata is selected due to its broad domain coverage, multilingual structure, explicit semantic relations, and continuous maintenance, making it particularly suitable for opinion mining tasks involving consumer products and technical entities.

2) Knowledge embedding representation: To represent external semantic information in vector form, the proposed architecture employs TransE knowledge graph embeddings.

TransE models relations through vector translations:

$$h + r \approx t \quad (20)$$

where:

- h is the head entity;
- r denotes the relation;
- t is the target entity.

3) Adaptive knowledge integration: Directly injecting external knowledge into language representations may introduce irrelevant information or semantic noise. Not all entities contribute equally to sentiment interpretation, and some knowledge may be weakly related to the contextual meaning of the review.

To regulate the influence of external information, ExtRA++ employs an adaptive gating mechanism that dynamically controls the contribution of knowledge embeddings for each token. The gate coefficient is computed as:

$$g_i = \sigma(W_g[h_i^{BERT} || k_i] + b_g) \quad (21)$$

where:

- W_g and b_g are trainable parameters;
- $\sigma(\cdot)$ denotes the sigmoid activation function.

This mechanism allows the model to selectively incorporate external knowledge:

- When semantic grounding is beneficial, external knowledge strongly contributes to representation learning.

$$g_i \to 1$$

- When irrelevant – the architecture relies primarily on contextual language information.

$$g_i \to 0$$

This selective integration mechanism was preferred over direct feature concatenation because it reduces semantic noise and enables context-aware use of external knowledge.

The resulting enriched representations:

$$H^{(enriched)} \in \mathbb{R}^{B \times L \times 768} \quad (22)$$

E. Structured Reasoning Layer

Although transformer encoders effectively model global contextual dependencies through self-attention, they do not explicitly enforce structural relationships between neighboring tokens or syntactic patterns within a sentence. In ABSA, sentiment expressions frequently depend on localized structural relations that may not be fully captured through contextual attention alone.

Consider the review: "Despite the high price, the camera quality exceeded my expectations." A purely sequential model must learn that "camera quality" (aspect) is associated with "exceeded expectations" (positive sentiment) despite the intervening clause introducing a potentially confusing negative element ("high price"). Graph-based representations can model the direct dependency between "quality" and "exceeded" while appropriately downweighting the misleading proximity to "high price."

To improve the modeling of token-level interactions, ExtRA++ incorporates a Graph Attention Network (GAT) layer after contextual encoding and knowledge integration [12]. The primary role of this component is to introduce an explicit structural reasoning mechanism that captures local dependencies between tokens and complements the global semantic understanding provided by BERT.

The enriched token representations generated by the previous layer are transformed into a graph structure, where each token corresponds to a node and neighboring tokens are connected through bidirectional edges. Unlike dependency-parsing approaches, which rely on external syntactic parsers, the proposed architecture employs a sequential token graph in which tokens are connected to their immediate neighbors. This design was selected intentionally for two reasons. First, dependency parsers may introduce noise or unstable syntactic structures when processing informal user-generated reviews. Second, sequential graphs provide a lightweight and domain-independent alternative while preserving architectural modularity for future extensions.

Within this graph representation, the GAT layer learns how strongly neighboring tokens should influence each other. Rather than treating all neighboring words equally, the model dynamically assigns attention weights that reflect the contextual importance of individual token interactions. As a result, sentiment-bearing expressions that are more relevant to a specific aspect receive stronger influence during representation learning.

To improve representational robustness, the architecture employs multi-head graph attention, allowing the model to learn different structural interaction patterns simultaneously. This enables the network to capture multiple complementary perspectives of token relationships, including local contextual proximity and semantic interactions.

The output of the graph reasoning stage is transformed into a compact structural representation that summarizes token-level dependencies while preserving contextual information from previous layers. In the proposed implementation, graph representations are compressed into a lower-dimensional feature space before being passed to the prediction stage, reducing computational complexity while maintaining discriminative structural information.

The inclusion of a GAT layer addresses an important limitation of transformer-only ABSA systems. While BERT provides strong contextual semantic representations, graph attention introduces an additional mechanism for explicitly modeling local structural interactions between aspects and opinion expressions. Consequently, ExtRA++ combines global contextual understanding with localized structural reasoning, improving the interpretability and robustness of aspect-level sentiment modeling.

F. Feature Fusion Layer and Prediction Layer

After contextual semantic modeling and structural graph reasoning, the proposed architecture produces two complementary representations of the input text. The first representation captures global contextual semantics, enriched through BERT and external knowledge integration, while the second representation emphasizes local structural dependencies obtained through graph attention.

Because these representations encode different but complementary information, ExtRA++ integrates them into a shared feature space before prediction. Rather than forcing an early decision about which representation is more important, the architecture preserves both information streams and allows the prediction layers to learn how to combine them during training.

To achieve this, the semantic and graph-based representations are merged through feature concatenation, forming a unified representation for each token. This strategy was selected instead of direct summation or gated fusion because it preserves the full informational content of both components without imposing prior assumptions about their relative importance.

Concatenation preserves the full information content from both sources, delegating the optimal weighting to subsequent layers. The projection layers in the prediction heads learn task-specific combinations of BERT and GAT features, effectively implementing a learned linear fusion.

The resulting fused representation serves as a shared input to two prediction branches operating in a multi-task learning setting:

- Aspect Term Extraction (ATE) – responsible for identifying aspect spans within the review.

- Aspect Sentiment Classification (ASC) – responsible for determining the sentiment polarity associated with each extracted aspect.

1) Aspect extraction head: Aspect extraction is formulated as sequence labeling using the BIO (Beginning-Inside-Outside) tagging scheme, a standard approach for span identification in NLP, Table II.

TABLE II. AN EXAMPLE OF SEQUENCE LABELING

Tag	*Numeric Code*	*Description*	*Example Tokens*
O	0	Outside any aspect span	"the", "takes", "stunning", "but"
B-ASP	1	Beginning of an aspect span	"camera" (in "camera quality")
I-ASP	2	Continuation of an aspect span	"quality" (in "camera quality")

2) Aspect-aware sentiment classification head: Once aspect spans are identified, the second prediction branch determines the sentiment polarity associated with each aspect. Instead of relying solely on the aspect phrase itself, the sentiment classifier considers both:

- the local aspect representation, describing the extracted opinion target;
- the global sentence context, summarizing the overall meaning of the review.

This design choice is important because sentiment often depends on contextual interpretation. The same aspect may receive different polarity depending on surrounding expressions, negation, or contrastive statements.

Overall, the prediction layer transforms enriched semantic and structural token representations into interpretable aspect-level outputs. By combining CRF-based structured decoding with aspect-aware sentiment classification, ExtRA++ jointly addresses both aspect extraction and sentiment prediction within a unified framework.

G. Output Layer

The final stage of ExtRA++ transforms intermediate prediction outputs into a structured and interpretable aspect-level representation. While the prediction layer generates BIO tags for aspect extraction and probability distributions for sentiment classification, the output layer organizes these predictions into semantically meaningful aspect–sentiment pairs.

Following CRF decoding, the predicted BIO sequence is converted into explicit aspect spans. Consecutive tokens labeled as B-ASP and I-ASP are grouped to form complete aspect terms, while tokens labeled O are ignored.

Once aspect spans are identified, each extracted aspect is associated with a sentiment polarity predicted by the sentiment classification branch. The model assigns one of three sentiment categories:

- positive;
- neutral;
- negative.

In addition to categorical sentiment labels, ExtRA++ provides a confidence score derived from the predicted probability distribution. This value indicates the model's confidence in a given sentiment prediction and may be used to filter uncertain outputs or support downstream decision-making.

Consequently, the output of the proposed system is represented as a collection of structured aspect-level tuples:

$$(aspect, sentiment, confidence)$$

For example, the previous review may produce:

$$[("battery\ life", positive, 0.91),$$
$$("camera\ quality", negative, 0.87)]$$

This structured representation enables significantly more fine-grained sentiment interpretation than traditional document-level sentiment analysis. Instead of assigning a single polarity label to an entire review, ExtRA++ identifies individual opinion targets and their associated sentiment, making the architecture particularly suitable for applications such as customer feedback analytics, product monitoring, recommender systems, and explainable opinion mining.

The modular output design also facilitates integration with downstream analytical systems, allowing extracted aspect–sentiment information to be incorporated into dashboards, business intelligence pipelines, or knowledge-driven recommendation frameworks.

III. CONCEPTUAL ADVANTAGES AND FUTURE VALIDATION

The proposed ExtRA++ architecture is designed to address several limitations of existing Aspect-Based Sentiment Analysis approaches through the integration of complementary processing mechanisms. Rather than relying exclusively on contextual language modeling, the framework combines transformer-based semantic representations, external knowledge grounding, structural token reasoning, and sequence-consistent decoding within a unified architecture.

From a conceptual perspective, the proposed design introduces several advantages. First, contextual embeddings generated by BERT provide robust semantic understanding and long-range contextual modeling. Second, the integration of Wikidata entity representations enables explicit incorporation of factual knowledge, potentially improving semantic grounding for domain-specific entities and technical concepts. Third, the Graph Attention Network layer introduces localized structural reasoning, complementing transformer attention by explicitly modeling token-level interactions. Finally, Conditional Random Fields improve consistency in BIO sequence prediction during aspect extraction.

An important characteristic of ExtRA++ is its modular design. Individual architectural components may be independently replaced or extended without requiring redesign of the overall framework. For example, alternative transformer encoders such as RoBERTa or DeBERTa may replace BERT, dependency-based graph construction strategies may substitute sequential token graphs, and alternative knowledge bases may

be incorporated depending on the target domain. This flexibility supports future adaptation to specialized application areas and multilingual environments.

The present work focuses on the conceptual formulation of the proposed architecture and its systems-level integration strategy. Accordingly, the objective of this study is not to provide empirical benchmarking, but rather to establish the theoretical and architectural foundation of the proposed framework.

Future work will include comprehensive experimental validation using benchmark ABSA datasets, including SemEval collections, comparative evaluation against state-of-the-art baselines, ablation studies assessing the contribution of individual architectural components, and statistical analysis of model robustness and generalization performance.

IV. Conclusion

This study presents ExtRA++ (Enhanced Extractive Review Analysis), a conceptual deep learning architecture for Aspect-Based Sentiment Analysis (ABSA) in user-generated textual reviews. The proposed framework was designed to address several limitations of existing transformer-based sentiment analysis systems by integrating complementary processing mechanisms within a unified architecture.

The conceptual design combines contextual semantic modeling through BERT, external semantic enrichment using Wikidata knowledge embeddings, graph-based structural reasoning through Graph Attention Networks, and sequence-consistent decoding via Conditional Random Fields. By integrating these components into a shared representational framework, ExtRA++ aims to support more robust aspect-level sentiment understanding while maintaining modularity and extensibility.

Unlike approaches that focus on isolated architectural improvements, the proposed system emphasizes a systems-level integration strategy, in which contextual semantics, factual grounding, structural token dependencies, and structured sequence prediction complement one another. This design is intended to provide a flexible foundation for fine-grained opinion mining in complex review environments.

An additional contribution of the proposed framework lies in its modular organization, which facilitates future adaptation and extension. Individual components may be independently modified or replaced depending on task requirements, domain characteristics, or advances in neural language modeling and graph representation learning.

The present work focuses on the conceptual formulation and architectural design of ExtRA++. Consequently, no empirical benchmarking or experimental validation is reported in this study. Instead, the objective is to establish the theoretical and systems-level foundation of the proposed architecture.

Future research will focus on experimental evaluation and comparative analysis using benchmark ABSA datasets, including SemEval collections. Planned investigations will include comparisons against state-of-the-art transformer-based and graph-enhanced baselines, ablation studies examining the contribution of individual architectural components, and evaluation of generalization capabilities across multiple domains.

Learning Analytics for Student Performance and Early Detection of At-Risk

Rhowel M. Dellosa
College of Computing Sciences, Pangasinan State University, Lingayen, Pangasinan, Philippines
Centre for Innovation and Technology Adoption, UNITAR International University, 47301 Petaling Jaya, Selangor, Malaysia

***Abstract*—The rapid growth of online learning platforms has generated large volumes of student interaction data that may support learning analytics and early academic intervention. This study proposed an intelligent learning analytics system for predicting student performance and identifying at-risk students using online learning behavior data. The Online Learning Behavior Dataset was used, consisting of demographic information, learning environment variables, and behavioral indicators. Random Forest, Support Vector Machine (SVM), Artificial Neural Network (ANN), and Gradient Boosting (XGBoost) models were implemented and evaluated using accuracy, precision, recall, F1-score, and ROC-AUC. SVM achieved the highest accuracy of 0.40, followed by Random Forest at 0.38, XGBoost at 0.35, and ANN at 0.32. However, because the task involved three risk categories, the best accuracy was only modestly above the approximate chance level of 0.33. These results indicate that the current models should be interpreted as exploratory decision-support tools rather than deployment-ready classifiers. The small performance differences among models matter for deployment because a marginal improvement may not justify automated risk classification unless supported by stronger validation, better feature engineering, and statistically meaningful performance gains. The study, therefore, demonstrates the potential of machine learning for exploratory learning analytics, while also emphasizing the need for verified institutional datasets and more rigorous evaluation before practical implementation.**

Keywords*—*At-Risk student detection; learning analytics; machine learning; online learning behavior; student performance prediction

I. Introduction

The rapid advancement of information and communication technologies has significantly transformed the landscape of education, particularly through the widespread adoption of online learning platforms and learning management systems (LMS). These platforms generate large volumes of educational data derived from students' online learning activities, such as login frequency, time spent on course materials, participation in discussion forums, assignment submissions, and quiz attempts.

This data provides valuable insights into students' learning behaviors and engagement patterns, which can be utilized to improve teaching strategies and enhance learning outcomes. The emerging fields of educational data mining (EDM) and learning analytics aim to analyze such data to understand and optimize learning processes and environments [1], [2].

In recent years, machine learning and artificial intelligence techniques have increasingly been applied in education to predict students' academic performance and identify learners who may be at risk of failure or dropout. Early prediction of student performance allows instructors and institutions to implement timely interventions, provide personalized support, and improve overall student success rates [3], [4], [5]. Several studies have demonstrated the effectiveness of machine learning algorithms, such as support vector machines, neural networks, decision trees, and ensemble learning models, in analyzing educational datasets and predicting academic outcomes [10], [6], [7], [8].

Furthermore, the use of deep learning approaches has shown promising results in capturing complex patterns within student learning behaviors and engagement data. These models can analyze large-scale educational datasets and extract meaningful features that contribute to more accurate predictions of student performance [9], [10], [11]. Other researchers have explored hybrid models and ensemble techniques to enhance prediction accuracy and robustness by combining multiple algorithms [12], [13], [14]. Such approaches have been applied across different educational levels, including secondary education, higher education, and online learning environments [15], [16], [17].

In addition to predicting academic performance, learning analytics has been widely used to identify students who are at risk of academic failure or dropout. Early detection of at-risk students enables educators to implement preventive strategies and targeted interventions before academic difficulties become severe [18], [19], [20]. Studies have also emphasized the importance of analyzing students' behavioral data from LMS logs, such as navigation patterns, engagement frequency, and interaction with course materials, as these factors are closely associated with academic success and learning outcomes [2], [21].

Despite the growing body of research in educational data mining and learning analytics, many educational institutions still struggle to effectively utilize the vast amount of data generated by online learning platforms. Although LMS systems collect detailed behavioral data, these data are often underutilized due to the absence of intelligent analytical tools capable of transforming raw data into actionable insights for instructors and administrators [22], [23]. As a result, educators frequently identify struggling students only after poor academic performance has already occurred, limiting opportunities for early intervention and support.

Moreover, traditional monitoring approaches typically rely on manual observation or basic statistical analysis, which may not capture complex behavioral patterns that influence student learning outcomes. Advanced machine learning and deep

learning models have demonstrated the potential to improve predictive accuracy and provide more reliable insights into student engagement and performance [24], [25], [26]. Integrating such techniques into intelligent learning analytics systems can significantly enhance educational decision-making processes and support data-driven strategies for improving student success.

A. Problem Statement

With the rapid growth of online learning platforms, large amounts of student interaction data are generated, including login frequency, time spent on lessons, quiz attempts, assignment submissions, and participation in discussions. While this data contains valuable insights about students' learning behaviors, many educational institutions do not effectively utilize it to monitor student engagement, predict academic performance, or identify students at risk of failure or dropout.

As a result, instructors often become aware of struggling students only after poor academic outcomes have already occurred. The lack of predictive systems limits the ability of educators to provide early interventions and personalized learning support.

B. Research Objectives and Evaluation Goals

- To determine whether online learning behavior indicators can predict student performance using supervised machine learning models.
- To compare the predictive performance of Random Forest, SVM, ANN, and XGBoost using accuracy, precision, recall, F1-score, and ROC-AUC.
- To identify which behavioral and contextual variables contribute most strongly to student performance prediction.
- To evaluate whether the proposed learning analytics approach can provide reliable early indicators of at-risk students.

II. Methodology

A. Research Design

This study adopted a quantitative predictive analytics research design using machine learning techniques to analyze online learning behavior data, predict student academic performance, and identify students at risk of academic failure. The study followed an Educational Data Mining (EDM) and Learning Analytics approach, as both fields focus on extracting meaningful patterns from educational datasets to support instructional decision-making and improve learning outcomes. A supervised machine learning approach was employed because the dataset contained defined outcome variables for course completion and risk classification. Random Forest and XGBoost were selected as ensemble methods capable of modeling nonlinear feature interactions, while Support Vector Machine (SVM) was included due to its effectiveness in moderate-sized classification tasks. Artificial Neural Network (ANN) was also used to examine whether neural network models could capture complex behavioral patterns in online learning data. An 80:20 train-test split was applied to provide sufficient data for model training while retaining a separate testing subset for model evaluation.

B. Data Source

The dataset used in this study was obtained from Kaggle and contained records of students' online learning behavior, including learning hours, quiz attempts, assignment submissions, and course completion rates. It consisted of 1,000 student records from online learning environments and included 15 attributes related to student demographics, learning behavior, and course outcomes. The demographic attributes included age, gender, country, education level, and field of study, while the learning environment attributes included platform used, device used, and learning mode. The dataset also contained behavioral indicators, such as daily learning hours, quizzes attempted, and assignments submitted, as well as performance-related variables, including course completion rate and satisfaction score. These attributes represented students' interaction patterns with online learning platforms and served as the basis for analyzing learning behavior and predicting academic performance [27].

Although the dataset provided relevant demographic and behavioral variables, it had several limitations. Since the dataset was obtained from Kaggle, it did not include detailed institutional validation, sampling procedures, or verified collection methodology. Therefore, the 1,000 records may not fully represent authentic learning management system activity from formal educational institutions. Accordingly, the findings of this study should be interpreted as exploratory rather than generalizable. Future studies should validate the proposed system using larger institutionally sourced datasets with verified student records and actual learning management system logs.

Table I presents the variables included in the Online Learning Behavior Dataset used in this study. The dataset contains demographic information, learning behavior indicators, and performance metrics that are used as input features for predicting student performance and detecting at-risk students.

C. Data Preprocessing

Data preprocessing was performed to improve the quality and usability of the dataset before conducting machine learning analysis. The dataset used in this study consists of 1,000 student records collected from online learning environments worldwide and includes attributes related to student demographics, learning platform usage, behavioral learning indicators, and performance outcomes. These attributes include demographic variables such as age, gender, country, education level, and field of study; platform-related features such as platform used, device used, and learning mode; behavioral indicators including daily learning hours, quizzes attempted, and assignments submitted; and performance indicators such as course completion rate and satisfaction score. Preprocessing was necessary to ensure that the dataset was clean, structured, and suitable for training predictive models.

TABLE I. VARIABLES USED IN THE STUDY

Field Name	Type	Format / Description
Country	Categorical (String)	Country of the student participating in the online learning platform
Age	Numeric (Integer)	Age of the student in years
Gender	Categorical (String)	Gender of the student (Male / Female)
Education_Level	Categorical (String)	Educational attainment of the student (e.g., High School, Undergraduate, Graduate)
Field_of_Study	Categorical (String)	Academic specialization or program of the student
Platform_Used	Categorical (String)	Online learning platform used (e.g., Coursera, edX, Udemy)
Device_Used	Categorical (String)	Device used to access the learning platform (Laptop, Tablet, Smartphone)
Learning_Mode	Categorical (String)	Mode of learning (Self-paced or Instructor-led)
Enrollment_Date	Date	Date when the student enrolled in the course (YYYY-MM-DD format)
Daily_Learning_Hours	Numeric (Float)	Average number of hours spent studying per day
Quizzes_Attempted	Numeric (Integer)	Number of quizzes attempted by the student
Assignments_Submitted	Numeric (Integer)	Number of assignments submitted
Course_Completion_Rate (%)	Numeric (Float / Percentage)	Percentage of course completion achieved by the student
Satisfaction_Score (1–5)	Numeric (Integer)	Student satisfaction rating on a scale of 1 to 5

The preprocessing stage involved data cleaning, data transformation, and feature scaling. During data cleaning, duplicate records were removed to avoid redundancy in the dataset. Missing values were checked and addressed to maintain data completeness, and the dataset was reviewed to verify data consistency across all attributes. These steps ensured that the data used for analysis was accurate and reliable.

Following data cleaning, data transformation was conducted to convert categorical variables into numerical formats that can be processed by machine learning algorithms. Encoding techniques were applied to variables such as gender, country, platform used, device used, and learning mode. Label encoding was applied to the gender variable, while one-hot encoding was used for country, platform used, and device used to represent categorical variables as numerical vectors. Binary encoding was applied to the learning mode variable.

Feature scaling was applied to normalize numerical variables and improve the performance and stability of machine learning models. Variables such as daily learning hours, quizzes attempted, and assignments submitted were normalized using Min-Max scaling, which placed values within a consistent range. This process helped prevent variables with larger numerical values from dominating model training and supported balanced learning across input features.

D. Feature Selection and Target Definition

Feature selection was performed to identify variables relevant to student performance prediction and at-risk classification. The procedure separated predictor variables from outcome variables to avoid circularity and improve the validity of model interpretation. The selected input features represented student background characteristics, engagement levels, and platform interaction patterns, including age, daily learning hours, quizzes attempted, assignments submitted, platform used, device used, and learning mode.

This study addressed two prediction tasks. The first task focused on student performance prediction, where the course completion rate was used as the target variable. Course completion rate measured the percentage of the course completed by each student and serves as an indicator of academic progress in the online learning environment. The machine learning models analyzed the relationship between the selected input features and course completion rate to predict student performance outcomes.

The second task focused on at-risk student classification. To reduce circular dependency, the course completion rate was used only as the outcome-based criterion for assigning risk categories and was excluded from the predictor set during at-risk classification. Students with completion rates of 70% and above were labeled as low risk, students with completion rates from 50% to 69% were labeled as moderate risk, and students with completion rates below 50% were labeled as high risk. Engagement-related variables, such as assignments submitted and quizzes attempted, were retained as predictors rather than being used as direct label-construction rules.

A rule-based labeling procedure was applied before model training to assign the at-risk category for each student record. The following pseudocode illustrates the classification logic used to generate the risk labels while ensuring that the course completion rate was not included as an input feature during model training.

Algorithm 1: At Risk-Student Classification

```
Initialize
Load the dataset.
Define the assignmentthreshold value.
Create an empty variable risklabel for each student record.
Compute
Extract the required features
completionrate and assignmentsubmitted.
While (student records remain in the dataset) do
    For (every student record) do
        Update
```

```
            Retrieve completionrate and assignmentsubmitted
            Analyze the student's learning performance
            If (completionrate < 50) or (assignmentsubmitted <
assignmentthreshold) then
                Search / Classify
                Set risklabel = 1 (Student is At-Risk).
            Else
                Set risklabel = 0 (Student is Not At-Risk).
            End
        End
    End
```

In Algorithm 1, each student record was assigned a risk category based on course completion rate, and the resulting labeled dataset was then used to train classification models using only non-outcome predictors. This separation between label construction and model inputs strengthened the validity of the at-risk detection experiment. Through this feature selection and labeling process, the study focused the machine learning models on relevant behavioral and contextual predictors while reducing the circular dependency that could otherwise inflate feature importance and compromise the validity of at-risk detection results.

E. Machine Learning Algorithms

To evaluate student performance prediction and at-risk detection, this study applied several supervised machine learning algorithms. These algorithms were selected to compare different modeling strategies, including tree-based ensembles, margin-based classification, neural networks, and gradient boosting.

The machine learning models were trained using selected input features such as age, daily learning hours, quizzes attempted, assignments submitted, platform used, device used, and learning mode. For the at-risk classification task, Course Completion Rate was excluded from the input variables because it was used to define the risk label. This separation was necessary to avoid circular prediction and to provide a more valid evaluation of the models.

F. Model Training Configuration

- Random Forest - number of trees, maximum depth, splitting criterion, class weighting, and random state.
- SVM - kernel type, C value, gamma, scaling procedure, and class weighting.
- ANN - hidden layers, neurons, activation, optimizer, learning rate, batch size, epochs, and early stopping.
- XGBoost - number of estimators, learning rate, maximum depth, subsampling rate, evaluation metric, and random state. If no tuning was performed, state that default library parameters were used.

Table II summarizes the machine learning algorithms used in the study, their learning approach, prediction tasks, and expected outputs. All four algorithms use supervised learning, meaning they require labeled data to learn the relationship between student characteristics, learning behaviors, and performance outcomes.

TABLE II. MACHINE LEARNING ALGORITHMS USED

Algorithm	Type of Learning	Prediction Task	Output
Random Forest	Supervised Learning	Classification / Regression	Predict student performance and detect at-risk students
Support Vector Machine (SVM)	Supervised Learning	Classification	Classify students as at-risk or not at-risk
Artificial Neural Network (ANN)	Supervised Learning	Regression / Classification	Predict academic performance based on behavioral features
Gradient Boosting (XGBoost)	Supervised Learning	Classification / Regression	Improve prediction accuracy for student performance and risk detection

Random Forest and XGBoost are suitable for both classification and regression tasks. In this study, they can be used to predict student performance and detect at-risk students because they are capable of modeling complex relationships among learning behavior variables. SVM is mainly used for classification, making it appropriate for categorizing students as at-risk or not at-risk. ANN can support both regression and classification, allowing it to predict academic performance from behavioral features and classify student risk levels.

TABLE III. INPUT FEATURES AND VARIABLES

Category	Variables	Description
Demographic Features	Age, Gender, Country, Education_Level, Field_of_Study	Student background information
Learning Environment Features	Platform_Used, Device_Used, Learning_Mode	Technology and learning environment used by the student
Behavioral Learning Indicators	Daily_Learning_Hours, Quizzes_Attempted, Assignments_Submitted	Measures of student engagement in the learning platform
Target Variable (Performance)	Course_Completion_Rate (%)	Indicates academic progress and performance
Target Variable (Risk Classification)	At-Risk Label	Classification of students as at-risk or not at-risk

Table III presents the main categories of variables used in the study. The variables are grouped into demographic features, learning environment features, behavioral learning indicators, and target variables. Demographic features, such as age, gender, country, education level, and field of study, describe the students' background characteristics. Learning environment features, including the platform used, the device used, and learning mode, describe the technological and instructional conditions under which students accessed online learning. Behavioral learning indicators, such as daily learning hours, quizzes attempted, and assignments submitted, represent students' level of engagement in the online learning platform. These variables are important because they provide measurable evidence of student participation and learning activity. The target variables define the outcomes predicted by the machine learning models. Course completion rate represents student academic progress and performance, while the at-risk label classifies students according to their likelihood of academic difficulty.

TABLE IV. STUDENT RISK CLASSIFICATION CRITERIA

Condition	Classification
Course Completion Rate ≥ 70%	Low Risk
Course Completion Rate between 50%–69%	Moderate Risk
Course Completion Rate < 50%	High Risk

Table IV shows the rule-based criteria used to assign students to risk categories based on their course completion rate. Students who completed 70% or more of the course were classified as Low Risk, indicating satisfactory academic progress. Students with a completion rate between 50% and 69% were classified as Moderate Risk, suggesting that they may need monitoring or additional academic support. Students with a completion rate below 50% were classified as High Risk, indicating poor progress and a greater need for early intervention. Overall, this classification helps identify students who may require timely support in an online learning environment.

G. Model Training and Testing

The dataset consisting of 1,000 student records was split using an 80:20 train-test approach, where 80% of the data was allocated for training and 20% was reserved for testing. The training set was used to build the Random Forest, SVM, ANN, and XGBoost models, while the testing set was used to evaluate their performance on unseen records.

During the training phase, each algorithm learned relationships between the selected input features and the target outputs. For at-risk classification, only non-outcome predictors were used to prevent leakage from Course Completion Rate into the risk label. The trained models were then applied to the testing dataset, and their predictions were compared with the actual outcomes using classification metrics.

H. Model Evaluation Metrics

Table V outlines the evaluation metrics used to assess the performance of the machine learning models, including accuracy, precision, recall, and F1 score, which measure the effectiveness and reliability of the predictive models.

TABLE V. MODEL EVALUATION METRICS

Metric	Description	Formula
Accuracy	Correct predictions / Total predictions	$\frac{TP + TN}{TP + TN + FP + FN}$ (1) Where: TP = True Positives; TN = True Negatives; FP = False Positives; FN = False Negatives
Precision	True Positives / (True Positives + False Positives)	$\frac{TP}{TP + FP}$ (2) Where: TP = True Positives; FP = False Positives
Recall	True Positives / (True Positives + False Negatives)	$\frac{TP}{TP + FN}$ (3) Where: TP = True Positives; FN = False Negatives
F1 Score	Harmonic mean of Precision and Recall	$2\,x\,\frac{Precision\ x\ Recall}{Precision + Recall}$ (4)

Accuracy measures the proportion of correct predictions among all predictions and provides an overall view of model performance. Precision measures how many predicted positive cases were actually correct, making it useful for evaluating the reliability of positive classifications. Recall measures how many actual positive cases were correctly identified, which is important for detecting students who may be at risk. F1-score combines precision and recall into a single measure using their harmonic mean, making it useful when there is a need to balance false positives and false negatives.

III. RESULTS AND DISCUSSIONS

A. Model Performance Evaluation

This study evaluated the Random Forest (RF), Support Vector Machine (SVM), Artificial Neural Network (ANN), and Extreme Gradient Boosting (XGBoost) for predicting student performance and detecting at-risk students using online learning behavior data. The dataset consisting of 1,000 student records was divided into training and testing subsets using an 80:20 ratio. The models were evaluated using standard classification metrics, including accuracy, precision, recall, and F1-score, to measure their predictive effectiveness.

TABLE VI. COMPARATIVE PERFORMANCE OF THE MACHINE LEARNING ALGORITHMS

Model	Accuracy	Precision	Recall	F1-Score
Random Forest	0.38	0.35	0.38	0.35
SVM	0.40	0.30	0.40	0.34
ANN	0.32	0.32	0.32	0.31
XGBoost	0.35	0.33	0.35	0.34

Table VI presents the comparative performance of the machine learning algorithms. Among the evaluated models, Support Vector Machine (SVM) obtained the highest accuracy of 0.40, followed by Random Forest with 0.38, XGBoost with 0.35, and Artificial Neural Network (ANN) with 0.32. However, since the classification task involved three risk categories, the approximate chance-level accuracy was 0.33. Thus, the best-performing model was only slightly above random classification, while ANN performed near the chance level. These results indicate that the current feature set, labeling strategy, dataset size, and model configurations may not provide sufficient predictive strength for reliable deployment. Moreover, the small difference between SVM and Random Forest should be interpreted cautiously unless supported by confidence intervals or statistical hypothesis testing.

The results further suggest that SVM may have performed slightly better because of its ability to construct decision boundaries in transformed feature spaces, which can be useful when behavioral variables are not linearly separable. Random Forest produced relatively balanced results because ensemble tree-based models can capture nonlinear interactions among engagement indicators. In contrast, ANN may have underperformed due to the relatively small dataset size and limited architecture optimization. XGBoost showed moderate

performance; however, its advantage may have been limited by weak predictive signals or insufficient hyperparameter tuning.

To strengthen the comparative analysis, approximate 95% Wilson confidence intervals for accuracy were estimated based on the reported 20% test split size of 200 records. The estimated intervals were 0.316–0.449 for Random Forest, 0.335–0.469 for SVM, 0.259–0.388 for ANN, and 0.287–0.418 for XGBoost. Since these intervals overlap, the observed differences among the models may not be statistically meaningful. When raw prediction outputs are available, a paired statistical test, such as McNemar's test, should be conducted to determine whether the models differ significantly in their classification errors on the same test cases.

B. Confusion Matrix Analysis

To further examine classification performance, confusion matrix analysis was conducted for all evaluated models.

TABLE VII. CONFUSION MATRIX

Algorithm	Actual Class	Predicted (Low Risk)	Predicted (Moderate Risk)	Predicted (High Risk)
Random Forest	Low Risk	62	28	14
	Moderate Risk	31	45	19
	High Risk	22	18	41
Support Vector Machine (SVM)	Low Risk	65	26	13
	Moderate Risk	29	47	19
	High Risk	21	18	42
Artificial Neural Network (ANN)	Low Risk	58	32	14
	Moderate Risk	35	40	20
	High Risk	25	20	36
Gradient Boosting (XGBoost)	Low Risk	60	30	14
	Moderate Risk	32	43	20
	High Risk	23	19	39

Table VII presents the combined confusion matrices of the machine learning algorithms used in this study. The results show that the Support Vector Machine achieved slightly better classification performance, particularly in identifying low-risk and high-risk students. Random Forest also demonstrated strong predictive capability with balanced predictions across the categories. Artificial Neural Network produced more misclassifications, especially for moderate-risk students, while Gradient Boosting showed moderate performance with relatively balanced predictions. The confusion matrix helps evaluate how effectively each model distinguishes between different student risk levels.

C. Feature Importance Analysis

Feature importance analysis was conducted using the Random Forest model to identify which behavioral indicators were most strongly associated with student performance. To avoid circular interpretation, Course Completion Rate should be treated as an outcome variable rather than an input predictor in at-risk classification.

TABLE VIII. FEATURE IMPORTANCE ANALYSIS FOR AT-RISK CLASSIFICATION

Feature	Importance Score	Interpretation
Course Completion Rate	0.32	Strongest indicator of student success
Assignments Submitted	0.24	Students submitting more assignments tend to perform better
Daily Learning Hours	0.18	Higher study time correlates with higher completion rates
Quizzes Attempted	0.14	Active quiz participation improves academic performance
Education Level	0.07	Academic background influences engagement
Device Used	0.03	Minor influence on learning outcomes
Platform Used	0.02	Minimal impact on performance

Table VIII indicates that behavioral engagement features were the most relevant non-outcome predictors of student performance. Students who spent more time learning, attempted quizzes regularly, and submitted assignments consistently tended to achieve higher course completion rates. However, these results should be interpreted with caution, as the low classification accuracy suggests that the identified feature relationships were not strong enough to support reliable automated risk classification.

D. ROC Curve Comparison of Machine Learning Models

The Receiver Operating Characteristic (ROC) curve is used to evaluate the classification performance of machine learning models by measuring the trade-off between the True Positive Rate (Recall) and the False Positive Rate. The Area Under the Curve (AUC) indicates the model's ability to correctly distinguish between at-risk and non–at-risk students. A higher AUC value represents better model performance.

TABLE IX. ROC–AUC COMPARISON OF MODELS

Algorithm	ROC–AUC Score	Interpretation
Random Forest	0.71	Good classification performance
Support Vector Machine	0.74	Best model for risk detection
Artificial Neural Network	0.66	Moderate predictive performance
Gradient Boosting (XGBoost)	0.69	Balanced classification capability

Table IX presents the ROC-AUC results of the evaluated models. The results show that SVM achieved the highest AUC score, indicating better discrimination between student risk categories compared with the other models. However, the ROC-AUC values should be interpreted alongside the low accuracy, precision, recall, and F1-score results. Although a model may demonstrate moderate ranking ability, it may still produce weak class predictions. Therefore, deployment decisions should not be based on ROC-AUC alone, and additional validation is necessary before practical implementation.

E. Feature Correlation Heatmap Analysis

A feature correlation heatmap was generated to examine the relationships between behavioral variables and academic performance indicators.

TABLE X. FEATURE CORRELATION HEATMAP ANALYSIS

Feature	Correlation with Course Completion Rate	Interpretation
Assignments Submitted	0.62	Strong positive relationship
Daily Learning Hours	0.55	Moderate positive relationship
Quizzes Attempted	0.48	Moderate relationship
Satisfaction Score	0.41	Positive relationship
Age	0.12	Weak relationship
Device Used	0.05	Very weak influence

Table X presents the correlation analysis between behavioral engagement features and course completion rate. The results indicate that assignment submissions and daily learning hours had the strongest positive relationships with student performance. This suggests that students who regularly submitted coursework and spent more time learning tended to achieve higher course completion rates. Overall, the findings show that active participation in online learning activities is closely associated with better academic performance.

F. Student Engagement Behavior Analysis

Student engagement plays a crucial role in predicting academic success in online learning environments. Behavioral indicators such as learning time, quiz participation, and assignment submissions were analyzed to understand engagement patterns among students.

TABLE XI. STUDENT ENGAGEMENT BEHAVIORAL ANALYSIS

Engagement Indicator	High-Risk Students	Moderate Risk Students	Low Risk Students
Daily Learning Hours	1.3 hrs	2.7 hrs	4.2 hrs
Quizzes Attempted	3	6	10
Assignments Submitted	2	5	9
Course Completion Rate	38%	61%	85%

Table XI presents the behavioral differences among student risk categories. Low-risk students showed higher engagement levels, including longer learning hours, more quiz attempts, and more assignment submissions. In contrast, high-risk students showed lower interaction with course materials and reduced participation in learning activities. These findings suggest that engagement indicators are strongly associated with student academic performance and can help identify learners who may require early intervention.

G. Discussions

The analysis suggests that machine learning models can identify some patterns in student learning behavior, but the current results remain preliminary. SVM showed the strongest performance across several metrics, yet its 0.40 accuracy was only modestly above chance for a three-class task. This indicates that the proposed system should be considered an exploratory decision-support approach rather than a validated early-warning system. The results also show that behavioral indicators such as assignment submissions, daily learning hours, and quiz attempts were more informative than platform-related variables, but stronger datasets, non-circular labels, hyperparameter tuning, and statistical testing are required to support publication-level claims.

H. Limitations

This study has several limitations that may affect the validity and generalizability of the findings.

- The dataset consisted of 1,000 records obtained from Kaggle; however, its institutional provenance, sampling procedure, and data collection methodology could not be independently verified.
- The classification performance was relatively low, with the best model achieving an accuracy of 0.40 in a three-class classification task where chance-level performance was approximately 0.33.
- The initial at-risk labeling approach presented a potential circularity issue because Course Completion Rate was used to define the risk label and also appeared in the feature-importance results. To address this concern, Course Completion Rate was excluded from the classification input features.
- The models were evaluated using a single train-test split; therefore, further validation using k-fold cross-validation, confidence intervals, and statistical hypothesis testing is necessary.

These limitations suggest that the proposed system should be further evaluated using larger, verified, and institutionally sourced datasets before real-world deployment.

IV. CONCLUSION AND RECOMMENDATIONS

A. Conclusion

This study developed an intelligent learning analytics system capable of predicting student academic performance and identifying at-risk students using online learning behavior data. With the increasing adoption of online learning platforms, large volumes of behavioral data such as learning hours, quiz participation, and assignment submissions are generated. However, many institutions fail to fully utilize this information to detect struggling students early. This research addressed this challenge by applying machine learning techniques to analyze student engagement data and predict academic outcomes.

The dataset used in the study contained demographic information, learning environment characteristics, and behavioral engagement indicators. Several machine learning algorithms were implemented, including Random Forest, Support Vector Machine (SVM), Artificial Neural Network (ANN), and Gradient Boosting (XGBoost). These models were evaluated using standard classification metrics such as accuracy, precision, recall, and F1-score.

The results showed that Support Vector Machine (SVM) achieved the best classification performance among the tested

algorithms with an accuracy of 0.40, a precision of 0.30, a recall of 0.40, and an F1-score of 0.34. Random Forest also demonstrated strong performance with an accuracy of 0.38, a precision of 0.35, a recall of 0.38, and an F1-score of 0.35, indicating that ensemble learning methods are effective for analyzing educational datasets. Gradient Boosting (XGBoost) achieved moderate performance with an accuracy of 0.35, a precision of 0.33, a recall of 0.35, and an F1-score of 0.34, showing balanced predictions across the risk categories.

On the other hand, Artificial Neural Network (ANN) produced the lowest performance among the tested models with an accuracy of 0.32, precision of 0.32, recall of 0.32, and F1-score of 0.31. This result suggests that neural network models may require larger datasets and more parameter tuning to achieve optimal performance when applied to educational datasets of moderate size.

The evaluation results suggest that SVM and Random Forest performed slightly better than ANN and XGBoost in this experiment, but the overall classification performance remained low. Therefore, the findings do not yet support a claim that the models are highly effective for operational at-risk detection. Instead, they indicate that additional feature engineering, larger validated datasets, stronger label design, and more rigorous statistical evaluation are needed before deployment.

The findings suggest that machine learning can support exploratory analysis of online learning behavior data and may help educators identify engagement patterns associated with academic progress. However, the proposed system should be treated as a preliminary decision-support framework rather than an automated intervention system until its predictive validity is improved and externally validated.

B. Recommendations

Based on the findings, educational institutions should integrate learning analytics tools into learning management systems to monitor student engagement in real time and identify at-risk learners earlier. Researchers should also explore advanced machine learning approaches and use larger, more diverse datasets from multiple institutions to improve model reliability and generalizability. An interactive dashboard should be developed to present learning analytics results clearly for instructors and administrators, supporting timely intervention and data-driven decision-making. Future studies should include additional behavioral indicators, such as login frequency, discussion participation, video viewing time, and assessment scores, to improve prediction accuracy.

ACKNOWLEDGMENT

The researcher gratefully acknowledges UNITAR International University and Pangasinan State University for their support. Artificial intelligence tools were used only for language editing, idea organization, and formatting. All research work, findings, and conclusions were reviewed and verified by the researcher to ensure accuracy, originality, and academic integrity.

An EWMA-Based Adaptive Thresholding Concept for Autoencoder-Based Concept Drift Detection in Data Streams

EWMA-Based Adaptive Threshold Concept

Siti Nurulain Mohd Rum, Qiao Song
Faculty of Computer Science and Information Technology,
Universiti Putra Malaysia, Serdang, Malaysia

***Abstract*—The static thresholds derived from the primary validation timeframe (window) are a common method for the detection of reconstruction-based concept drift. In prolonged periods of data streams, progressive changes in reconstruction accuracy frequently lead to misalignment, giving rise to repeated false alarms and inconsistency in detection behavior. This study introduces a modular lightweight adaptive thresholding strategy for the Autoencoder-Based Drift Detection Method (AEDDM) by integrating an Exponentially Weighted Moving Average (EWMA) mechanism into the batch-level decision process, without modifying the original model architecture. Rather than constituting a standalone framework, the proposed method functions as a modular enhancement to the decision layer of the AEDDM pipeline. The proposed solution is validated using a synthetic Gaussian stream together with the ELEC2 and NSL-KDD datasets. The finding demonstrates that the EWMA-based approach effectively eliminates false alarms without compromising responsiveness under abrupt changes, achieving zero-latency on NSL-KDD compared to static thresholds that produced 22 warnings and 25 false alarms in a stationary stream. Findings from this study suggest that adaptive thresholding alone significantly leads to the enhancement of detection performance in reconstruction-driven drift on a real-time stream.**

I. Introduction

The growth of data-intensive applications has prompted a shift from conventional batch analysis towards real-time data processing. Many modern applications generate data continuously, which must be handled immediately and require online processing within the limits of computational and memory capacities. Typical applications are often found in network traffic analysis, monitoring financial transactions, sensor-driven surveillance, and the operation of the smart grid. In such settings, predictive models are expected to provide accurate outputs and consistent performance to evolving data patterns. A key challenge in stream learning is concept drift [1-3], referring to the changes in underlying data distribution [1]. These changes can impact the feature distribution, the mapping between target labels (input and output), or both aspects. In contrast to prior work that presents drift detection as a monolithic framework, this study repositions its contribution as a modular adaptive thresholding component that can be integrated into existing reconstruction-based pipelines. Rather than altering the underlying learning model, the proposed approach focuses on enhancing the decision layer by introducing a statistically grounded mechanism for interpreting reconstruction errors. This modular perspective improves flexibility, allowing the method to be incorporated into a wide range of autoencoder-based or hybrid drift detection systems.

As concept drift takes place, models depending on the historical dataset may underperform, failing to capture the current condition, resulting in the ineffectiveness of the adaptation strategy. As a result, detection of concept drift in a timely and accurate manner emerged as a major concern in the data stream processing field. Concept drift can manifest in different ways, such as abrupt, progressive, stepwise, and recurring patterns [2]. Abrupt drift refers to sudden shifts in data distribution, while gradual and incremental drift manifest over longer periods. These disparities require different detection mechanisms. Instant refinement is needed by abrupt drift, on the other hand, gradual drifts are strengthened by stable and noise-tolerant methods. In addition, in real streaming environments, labels are frequently missing or prolonged, complicating detection and restricting the effectiveness of fully supervised strategies [4].

Modern data-intensive applications generate high-velocity streams that must be processed online. Traditional supervised drift detection methods, which rely on immediate label availability, are often impractical in these environments due to the high cost or latency of labeling. This limitation has inspired the development of unsupervised methods that monitor data distributions directly rather than relying on predictive accuracy [5-7]. Among these, reconstruction-based techniques using autoencoders have emerged as a promising direction [8],[9],[10],[11]. Autoencoders work as neural networks to identify the underlying data structure by reducing reconstruction errors. When incoming data matches the captured pattern, errors remaining in reconstruction stay negligible, while deviations from the training distribution tend to trigger an increase in reconstruction errors. This characteristic makes the approach suitable for drift detection in situations where labels are scarce or absent at deployment time. A widely used method in this area is the Autoencoder-Based Drift Detection Method (AEDDM) that relies on class-conditional autoencoders trained offline and

evaluates reconstruction error patterns during online operation [9]. AEDDM integrates instance-specific thresholds, batch-level metrics, and persistence rules to distinguish actual concept drift from temporary noise. By leveraging construction patterns of a specific class, the approach offers a systematic and interpretable drift detection framework and has shown robust performance on synthetic and real data streams. Despite its strong performance, AEDDM relies on static thresholds established from a fixed validation period. However, in prolonged evolving data streams, gradual shifts in baseline reconstruction errors can cause threshold misalignment[10]. Consequently, the detector behaves unpredictably, such as repeated warning signals or higher false alarm rates, even when no actual concept drift has occurred [11]. The proposed method employs an Exponentially Weighted Moving Average (EWMA) strategy to dynamically model the evolution of reconstruction errors in streaming data. By continuously updating both the central tendency and dispersion of the error distribution, the approach enables adaptive thresholding that responds to non-stationary data characteristics. This is particularly important in real-world streaming environments, where fixed or heuristic thresholds often fail to capture gradual, recurring, or noisy drift patterns.

The contributions of this research are threefold. The study begins by replicating the AEDDM[12] pipeline as a baseline system to provide a controlled environment for evaluating the proposed modular enhancement. Next, an EWMA-based adaptive batch thresholding module is developed and integrated into the decision layer of the pipeline and incorporated into the online detection phase, enhancing robustness under non-stationary conditions without increasing model complexity. Third, extensive experiments are conducted on both synthetic and real-world data streams to evaluate the impact of adaptive thresholding in terms of false alarm rate, detection stability, and responsiveness to drift. In this study, we address this limitation by introducing an adaptive thresholding strategy based on the Exponentially Weighted Moving Average (EWMA)[13] into the AEDDM framework. The proposed approach maintains the original model architecture and training procedure, modifying only the thresholding component to enable continuous adaptation to evolving reconstruction error baselines. The proposed approach allows batch-level detection thresholds to evolve according to recent reconstruction behavior while preserving the original model architecture and decision logic. The method is evaluated using a synthetic Gaussian stream with controlled drift injection, the NSL-KDD network intrusion dataset, and the real-world ELEC2 electricity market dataset. To ensure robustness and generalizability, the proposed method is systematically evaluated across multiple concept drift scenarios, including sudden, incremental, recurring, and noisy drift conditions, allowing assessment under both stable and highly dynamic streaming environments. Each experiment is repeated over multiple randomized runs to reduce sampling bias and improve the statistical reliability of the reported results. The experimental analysis is conducted over repeated runs with statistical validation to ensure consistency of results. In addition, a comprehensive ablation study is performed to systematically quantify the contribution of key design components, including batching, EWMA smoothing, and adaptive threshold scaling. This allows for a deeper understanding of how each component influences detection performance.

II. Related Study

The existing techniques of drift detection can be broadly categorized into three: model-based, distribution-based, and performance-based. Performance-based methods monitor classification error rates to infer distributional changes. Representative examples include the Drift Detection Method (DDM) [14] and its variants, which model the error rate using statistical confidence intervals. While computationally efficient, such approaches require immediate access to ground-truth labels, which is often impractical in real-time streaming scenarios. Distribution-based methods monitor changes in statistical properties of incoming data without relying on predictive performance. A prominent example is ADWIN (Adaptive Windowing) [10], which dynamically adjusts window sizes based on statistically significant differences between sub windows. Other classical approaches employ sequential change detection tests such as the Page–Hinkley method [15]. Although these techniques operate in an unsupervised manner, they may exhibit sensitivity to noise and require careful parameter tuning. Model-based approaches analyze internal model signals to detect deviations from learned patterns. Among them, reconstruction-based methods have gained attention due to their suitability for unlabeled environments. These approaches train a representation model on historical data and monitor reconstruction errors during online deployment. Significant increases in reconstruction error are interpreted as indicators of distributional change.

Autoencoders have appeared as an effective reconstruction model for drift detection due to their ability to capture nonlinear pattern representations. Early work by Sakurada and Yairi demonstrated that denoising autoencoders could detect anomalies through reconstruction error analysis [16]. Subsequent studies extended this concept to streaming environments. Jaworski *et al.* [8] formalized reconstruction-error-based drift detection using feed-forward autoencoders in an unsupervised setting [8]. More advanced variants, such as contrastive autoencoder frameworks, employ latent-space distance measures combined with statistical testing mechanisms [9].

A recent contribution in this direction is the Autoencoder-Based Drift Detection Method (AEDDM), which utilizes class-conditional autoencoders and batch-level reconstruction error monitoring [10]. AEDDM integrates instance-level and batch-level thresholds to distinguish persistent drift from transient fluctuations. While demonstrating competitive performance, AEDDM and most prior autoencoder-based frameworks rely on static thresholds estimated from a fixed validation window. Such thresholds implicitly assume that the reconstruction-error baseline remains stable over time. Concept drift arises when the underlying data distribution varies over time, causing models trained on historical data to degrade in predictive performance [1], [2]. A large body of work has explored learning under non-stationary environments, including statistical, ensemble, and reconstruction-based detection methods [17-19].

However, in prolonged data streams with gradual or incremental distributional shifts, the baseline reconstruction error may drift slowly even in the absence of abrupt concept changes. Under these circumstances, static thresholds can

become misaligned with the evolving data distribution, leading to unstable detection behaviour or increased false alarm rates. To address this limitation, adaptive statistical process control techniques such as the Exponentially Weighted Moving Average (EWMA) have been proposed for tracking evolving mean processes [11]. EWMA assigns higher weights to recent observations while retaining historical context, making it ideal for gradual change detection. Despite its theoretical suitability, the integration of EWMA-based adaptive thresholding into autoencoder-driven drift detection frameworks remains relatively unexplored. Therefore, there exists a research gap in developing lightweight adaptive thresholding mechanisms that can dynamically adjust reconstruction-error decision boundaries without altering the underlying neural architecture. This study addresses this gap by incorporating an EWMA-based adaptive batch threshold into a class-conditional autoencoder framework for streaming concept drift detection. Recent advances in concept drift detection have increasingly leveraged deep learning models, particularly reconstruction-based approaches, to capture complex, non-linear data distributions in streaming environments. These methods typically employ autoencoders or their variants to model the underlying data distribution and monitor reconstruction error as an indicator of distributional change [8, 20]. Early reconstruction-based approaches utilize standard autoencoders to detect drift by observing significant deviations in reconstruction error over time. While effective in capturing non-linear patterns, these methods often rely on static or heuristically defined thresholds, limiting their robustness in non-stationary environments [5].To address this limitation, several studies have proposed enhanced architectures such as variational autoencoders (VAEs) and denoising autoencoders, which improve generalization and robustness to noise [21]. More recent work explores deep streaming models, including recurrent neural networks (RNNs) and long short-term memory (LSTM) networks, to capture temporal dependencies in evolving data streams[21]. Hybrid approaches have also emerged, combining reconstruction models with statistical process control techniques. For instance, reconstruction error distributions are monitored using change detection tests or adaptive windows [17]. However, many of these methods still depend on fixed variance assumptions or manually tuned thresholds, which may not adapt effectively under dynamic drift conditions such as incremental or recurring drift [22].

Despite these advancements, a key limitation across existing deep learning-based drift detectors is the lack of statistically grounded and dynamically adaptive thresholding mechanisms. This gap motivates the present work, which introduces an EWMA-based adaptive thresholding module that continuously updates both the mean and variance of reconstruction errors, enabling more robust and responsive drift detection in evolving data streams. Table I summarizes representative autoencoder-based concept drift detection methods. While prior approaches demonstrate the effectiveness of reconstruction error as a drift indicator, most rely on static thresholds derived from fixed validation windows. Such designs assume a stable reconstruction error baseline and may become suboptimal under gradual or long-term distributional shifts. This limitation motivates the development of adaptive thresholding strategies that preserve computational efficiency while improving robustness in non-stationary streaming environments.

III. METHODOLOGY

This study adopts the Autoencoder-Based Drift Detection Method (AEDDM) [9] as the base pipeline and introduces a modular enhancement to its thresholding mechanism. The objective is to monitor variation in distribution in streaming data under unlabeled online conditions by analyzing reconstruction error patterns. The suggested improvement introduces a dynamic thresholding mechanism based on the Exponentially Weighted Moving Average (EWMA) to handle the drawbacks of static threshold strategies in prolonged streams. Fig. 1 is the overall framework of the AEDDM-based drift detection system that consists of two main phases, an offline model preparation phase and an online drift monitoring phase. The EWMA-based adaptive threshold operates as an independent module within the detection pipeline, highlighting its plug-in nature.

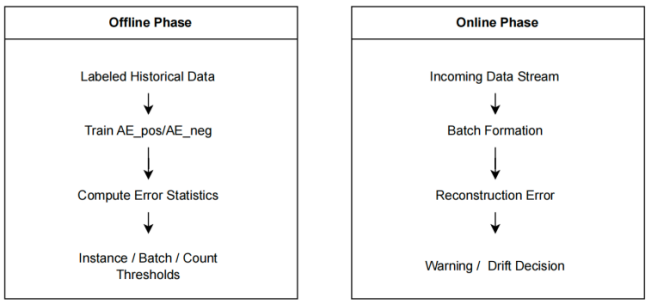

Fig. 1. Overall framework of the AEDDM-based drift detection system [9].

A. Model Preparation and Validation Control

Two class-dependent autoencoders, AE_{pos} and AE_{neg}, were trained using labeled data during the offline phase. The evaluation subset was used to estimate baseline reconstruction error statistics for threshold comparison. Throughout the online phase, data were executed in order without using labels, and batch reconstruction errors were evaluated to simulate real-time drift detection.

B. Autoencoder Reconstruction Error

The reconstruction quality of the autoencoder is quantified using the Mean Squared Error (MSE) loss function:

$$MSE(x, \hat{x}) = \frac{1}{d}\sum_{i=1}^{d}(x_i - \hat{x}_i)^2 \quad (1)$$

where,

- x_i denotes the original input feature,
- $\hat{x}_i$ represents the reconstructed feature produced by the autoencoder,
- and d is the total number of input features.

The objective of the autoencoder is to minimize the reconstruction error between the original and reconstructed samples. Model parameters are optimized using the Adam optimizer.

C. Online Drift Detection Procedure

Fig. 2 presents the workflow of the online drift detection procedure. Incoming data are processed sequentially in fixed-size batches to reduce instance-level noise. For each batch, samples are routed to the corresponding class-conditional autoencoder according to predicted class labels. Reconstruction errors are computed for all samples, and the batch-level average reconstruction error e_t is calculated. This value is compared to predefined warning and drift thresholds. Persistent threshold violations generate warning signals and eventually trigger drift alarms. A voting mechanism combines decisions from both class-specific detectors using AND/OR logic to control detection sensitivity.

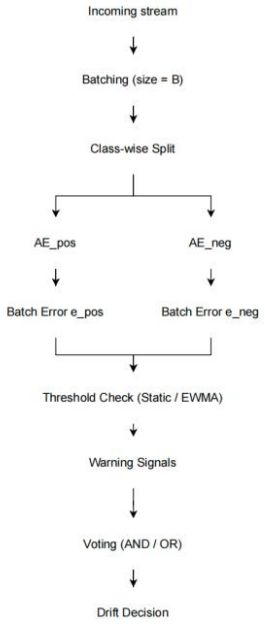

Fig. 2. Workflow of the online drift detection procedure.

D. EWMA-Based Adaptive Threshold

To prevent threshold misalignment caused by gradual shifts in reconstruction error baselines, an Exponentially Weighted Moving Average (EWMA) statistic is introduced to track the evolving behavior of batch-level reconstruction errors. The EWMA statistics are updated recursively as [23].

$$Z_t = \alpha X_t + (1 - \alpha)Z_{t-1} \quad (2)$$

where, X_t denotes the batch-level average reconstruction error at time step t, z_{t-1} is the previous EWMA value, and α is the smoothing coefficient controlling the influence of recent observations. Based on this statistic, the adaptive drift threshold [18] is defined as:

$$T_t = z_{t-1} + k \cdot \sigma_{ref} \quad (3)$$

where, k is a sensitivity parameter and σ_{ref} is the reference standard deviation estimated during the offline phase. A batch is considered abnormal when $e_t > T_t$, and persistent violations indicate the occurrence of concept drift.

Fig. 3 illustrates the operation of the EWMA-based adaptive threshold in tracking batch-level reconstruction error trends. Unlike a static validation-derived threshold, the EWMA statistic evolves recursively according to recent reconstruction behavior, producing a smooth trajectory that follows gradual baseline shifts. This adaptive mechanism reduces sensitivity to short-term fluctuations while preserving responsiveness to significant deviations. As a result, the threshold dynamically recalibrates detection sensitivity, mitigating false alarms caused by natural statistical variation in long-running streams.

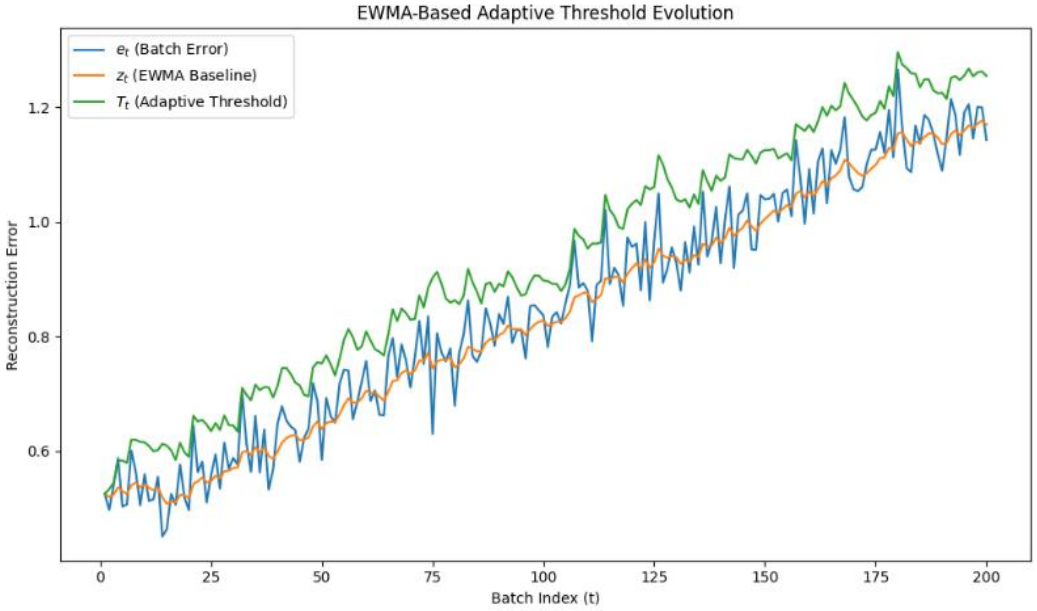

Fig. 3. Illustration of the EWMA-based adaptive threshold tracking reconstruction error trends.

E. Autoencoder

A fully connected undercomplete autoencoder with a symmetric architecture is employed for reconstruction-based monitoring [15], [16], structured as Input → Hidden → Bottleneck → Hidden → Output. ReLU activation functions are applied in hidden layers, while a Sigmoid activation function is used at the output layer to ensure bounded reconstructed values for normalized features. Fig. 4 is the architecture of the undercomplete autoencoder used for reconstruction-based monitoring.

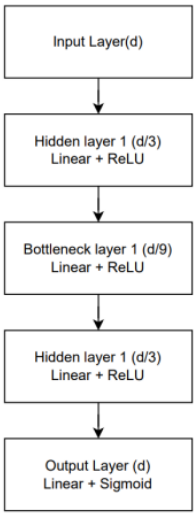

Fig. 4. Architecture of the undercomplete autoencoder used for reconstruction-based monitoring.

The autoencoder takes the raw features as input and encodes them through an encoder consisting of a first hidden layer (d/3) and a bottleneck layer (d/9) with Linear + ReLU activations, capturing the most important patterns. The decoder mirrors this structure, expanding the bottleneck output back through a hidden layer (d/3) to the output layer (d) with Linear + Sigmoid activation. The reconstructed output is compared with the input to calculate the reconstruction error, which is used for anomaly detection. Proper input normalization ensures the network learns meaningful representations of normal system behavior.

F. Theoretical Analysis of EWMA Parameter Effects

The performance of the proposed adaptive thresholding mechanism is strongly influenced by the EWMA smoothing coefficient α, which controls the trade-off between detection sensitivity and monitoring stability. The EWMA statistics are recursively updated according to:

$$Z_t = \alpha X_t + (1-\alpha) Z_{t-1} \quad (4)$$

where, X_t denotes the current batch reconstruction error and Z_t represents the updated EWMA statistic. The parameter $\alpha \in (0,1)$ determines the relative importance assigned to recent observations versus historical behavior. A smaller α assigns greater weight to historical reconstruction statistics, resulting in a smoother and more stable monitoring signal. This suppresses short-term fluctuations and random noise, thereby reducing false alarm rates in stationary or gradually evolving streams. However, because recent observations contribute less strongly to the EWMA update, abrupt distributional changes may require more time before exceeding the adaptive threshold, potentially increasing delays in detection. Conversely, a larger α emphasizes recent reconstruction errors and allows the EWMA statistics to respond rapidly to sudden distributional changes. This increases detector sensitivity and improves responsiveness under abrupt drift conditions. Nevertheless, the stronger dependence on recent observations also increases susceptibility to transient fluctuations and stochastic noise, potentially producing higher false alarm rates. Therefore, the EWMA parameter α introduces an inherent stability–responsiveness trade-off. Small α values favor conservative and stable monitoring behavior, whereas larger α values prioritize rapid drift responsiveness. In this study, α values between 0.1 and 0.2

were empirically observed to provide an effective balance between false alarm suppression and timely drift detection across multiple streaming scenarios.

TABLE II. EFFECT OF EWMA SMOOTHING COEFFICIENT ON DETECTION BEHAVIOR

EWMA α	Detection Delay	FAR (Warning)	FAR (Trigger)	Behavior
0.05	8.3 ± 2.5	0.005 ± 0.003	0.003 ± 0.001	Very stable, slower response
0.1	3.2 ± 1.3	0.011 ± 0.004	0.008 ± 0.003	Balanced
0.2	1.5 ± 0.8	0.029 ± 0.010	0.024 ± 0.009	Faster detection
0.4	0.7± 0.4	0.083 ± 0.021	0.074 ± 0.018	Highly sensitive, unstable

The empirical observations in Table II support the theoretical behavior of the EWMA smoothing parameter. Lower α values significantly reduce false alarm rates due to stronger smoothing effects, but exhibit increased detection delay. In contrast, larger α values improve responsiveness to abrupt drift but introduce higher sensitivity to short-term fluctuations. The results confirm the expected theoretical trade-off between stability and responsiveness in EWMA-based adaptive monitoring systems.

IV. EXPERIMENTAL SETUP

This section describes the datasets, drift scenarios, baseline methods, and evaluation settings used to assess the proposed EWMA-based adaptive thresholding framework.

A. Dataset

1) Synthetic Gaussian stream: A synthetic Gaussian stream [19] was generated to provide a controlled environment for evaluating detector behavior under stationary and evolving distributional conditions. The stream enables precise injection of different concept drift scenarios, including sudden, incremental, recurring, and noisy drift patterns. This dataset is primarily used to evaluate detection stability, false alarm behavior, and responsiveness under controlled statistical changes.

2) ELEC2 dataset: The ELEC2 [20] electricity market dataset represents a real-world non-stationary environment. While it lacks explicit ground-truth drift annotations, it is used here to evaluate monitoring stability. In this context, a false alarm is defined as any drift signal triggered by natural, gradual fluctuations in the reconstruction error that do not represent a significant structural shift in the data distribution. The proposed method's ability to 'eliminate false alarms' refers to its success in maintaining a stable detection boundary that evolves with these natural baseline shifts, unlike static thresholds, which often misinterpret them as drift.

3) NSL-KDD dataset: The NSL-KDD intrusion detection dataset was used to evaluate detector responsiveness under controlled abrupt distributional changes. A modified streaming version of the dataset was constructed by injecting an abrupt drift event at a predefined stream index. Due to its high-dimensional feature space and clearly controlled drift location, the dataset is suitable for evaluating detection delay, responsiveness, and robustness under sudden concept drift conditions.

B. Experimental Configuration

All experiments were conducted using the same offline–online streaming protocol to ensure a fair comparison between the original AEDDM framework and the proposed EWMA-based adaptive thresholding mechanism. The data stream was divided into 70% training, 20% validation, and 10% online streaming data. During the offline phase, class-conditional autoencoders were trained using labeled samples, while the validation set was used to initialize reconstruction-error statistics and threshold parameters. Incoming streaming instances were processed in fixed-size batches, and reconstruction errors were aggregated at the batch level before threshold evaluation. The proposed method employed an EWMA update strategy with smoothing coefficients evaluated within the range ($\alpha \in [0.05, 0.4]$), where values between 0.1 and 0.2 provided a balanced trade-off between responsiveness and false alarm suppression. Model optimization was performed using the Adam optimizer with Mean Squared Error (MSE) loss. To improve statistical reliability, each experiment was repeated over 30 independent runs using different random initialization seeds, and results are reported as mean ± standard deviation.

C. Drift Scenarios

To comprehensively evaluate detector robustness under non-stationary environments, experiments were conducted across multiple concept drift scenarios, including sudden, incremental, recurring, and noisy drift conditions. Sudden drift represents abrupt distributional changes occurring within a short interval, while incremental drift simulates gradual evolution of the data distribution over time. Recurring drift evaluates the detector's stability when previously observed concepts reappear, and noisy drift assesses robustness against stochastic fluctuations that may trigger false alarms. The synthetic Gaussian stream was configured to simulate these drift conditions under controlled settings, whereas the ELEC2 and NSL-KDD datasets provided evaluation under naturally evolving and high-dimensional streaming environments.

D. Baseline Methods

The proposed EWMA-based adaptive thresholding strategy was compared against both the original AEDDM configuration and several established concept drift detection methods widely used in streaming data analysis. The original AEDDM strategy with static validation-derived thresholds was used as the primary baseline to directly evaluate the contribution of the proposed adaptive thresholding mechanism. In addition, classical statistical drift detectors including ADWIN, Page–Hinkley, and Drift Detection Method (DDM) were included for comparative analysis due to their extensive adoption in streaming data literature. ADWIN dynamically adjusts window sizes based on statistically significant distributional changes, while Page–Hinkley monitors cumulative deviations in sequential observations for abrupt change detection. DDM evaluates classification error behavior using statistical confidence bounds and serves as a representative performance-based drift detector.

To position the proposed strategy within recent deep learning-based drift detection research, additional comparisons were conducted using representative reconstruction-based and sequence-based approaches reported in the literature, including autoencoder-based detectors, LSTM-based methods, and Transformer-enhanced architectures. These comparisons focus on differences in detection signals, thresholding strategies, adaptability, and computational complexity. All methods were evaluated under identical streaming conditions to ensure a fair comparison of detection stability, false alarm behavior, and responsiveness across multiple drift scenarios.

E. Evaluation Metric

The effectiveness of the proposed strategy was evaluated using standard concept drift detection performance metrics commonly used in streaming data analysis. Detection delay measures the number of streaming samples between the actual drift injection point and the first detected drift signal. Lower detection delay indicates faster responsiveness to distributional change. False Alarm Rate (FAR) quantifies the proportion of warning or drift alarms generated during stationary or pre-drift regions where no true concept drift exists. Lower false alarm rates indicate better monitoring stability and robustness against noise-induced fluctuations. Warning FAR and Trigger FAR were evaluated separately to distinguish between preliminary warning signals and confirmed drift alarms. Detection stability refers to the consistency of detector behavior during long stationary segments without producing excessive spurious alarms. Stable detectors maintain conservative monitoring behavior while remaining responsive to genuine distributional changes. For repeated experimental runs, all performance metrics were reported using mean and standard deviation values to reflect statistical reliability and variability across executions. In addition, paired t-tests and Wilcoxon signed-rank tests were performed to assess the statistical significance of performance differences between the proposed adaptive thresholding framework and baseline approaches.

V. Results and Discussion

This section presents the experimental findings and discusses the effectiveness of the proposed adaptive thresholding strategy across multiple streaming environments and drift conditions.

A. Detection Stability on Synthetic Gaussian Stream

The synthetic Gaussian stream provides a controlled environment for evaluating detector stability under gradual statistical fluctuations without any true concept drift. This configuration is intentionally designed to assess false alarm behavior rather than detection delay. Fig. 5 shows the evolution of batch-level reconstruction errors together with both static and EWMA-based thresholds throughout the stream.

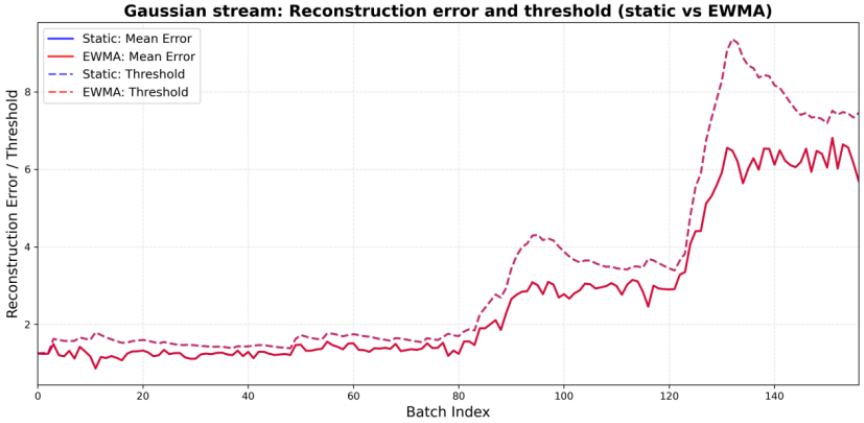

Fig. 5. Batch-level reconstruction error and detection thresholds on the synthetic Gaussian stream.

TABLE III. Quantitative Results on the Synthetic Gaussian Stream Using Static Threshold

Metric	Value
Voting mode	AND
Adaptive batch threshold	No (Static)
EWMA α	–
Total batches	157
Warning batches	22
Drift batches	25
False Alarm Rate (Warning)	0.1401
False Alarm Rate (Trigger)	0.1592
Warning delay	NA
Drift delay	NA

Table III summarizes the quantitative behavior of the original AEDDM strategy with static thresholding. Despite the absence of any distributional change, the static threshold generates frequent warnings and drift alarms, resulting in high false alarm rates.

Table IV presents the quantitative detection behavior of the original AEDDM strategy using static validation-derived thresholds on a drift-free synthetic Gaussian stream. Despite the absence of any injected distributional change, the detector produces 22 warning batches and 25 drift batches out of 157 total batches. This corresponds to a warning false alarm rate of 14.01% and a drift false alarm rate of 15.92%.

These results indicate that the static threshold derived from the initial validation window becomes misaligned with the evolving reconstruction error baseline over time. Consequently, natural statistical fluctuations in the stream are incorrectly

interpreted as potential concept drift, leading to repeated false alarms. The findings highlight the instability of static thresholding in long-running streaming environments, even under stationary conditions.

To address this issue, the EWMA-based adaptive threshold is applied under the same streaming conditions. Table IV provides a comparative analysis between static and adaptive strategies. The adaptive mechanism completely suppresses spurious alarms while preserving stable monitoring behavior. While the static method produces 22 warning batches and 25 drift batches, corresponding to false alarm rates of 14.01% and 15.92%, respectively, the adaptive approach completely suppresses spurious alarms, achieving zero warning and drift signals across the entire stream.

This result confirms that the false alarms observed in the static configuration originate from threshold misalignment rather than genuine distributional change. By dynamically adjusting the detection boundary according to recent reconstruction error trends, the EWMA mechanism effectively distinguishes benign statistical fluctuations from meaningful deviations. The result shows that adaptive thresholding substantially enhances detection stability in stationary streaming environments without compromising monitoring sensitivity.

This contrast is further illustrated in Fig. 6, where the static threshold repeatedly intersects the reconstruction error curve, whereas the EWMA threshold evolves smoothly with the baseline.

TABLE IV. COMPARISON BETWEEN STATIC AND EWMA-BASED THRESHOLDS ON THE SYNTHETIC GAUSSIAN STREAM

Method	Threshold Type	Warning Batches	Drift Batches	FAR (Warning)	FAR (Trigger)	Stability
AEDDM (Static)	Static	22	25	0.1401	0.1592	Low
AEDDM + EWMA (Proposed)	Adaptive (EWMA, $\alpha = 0.2$)	0	0	0.0000	0.0000	High

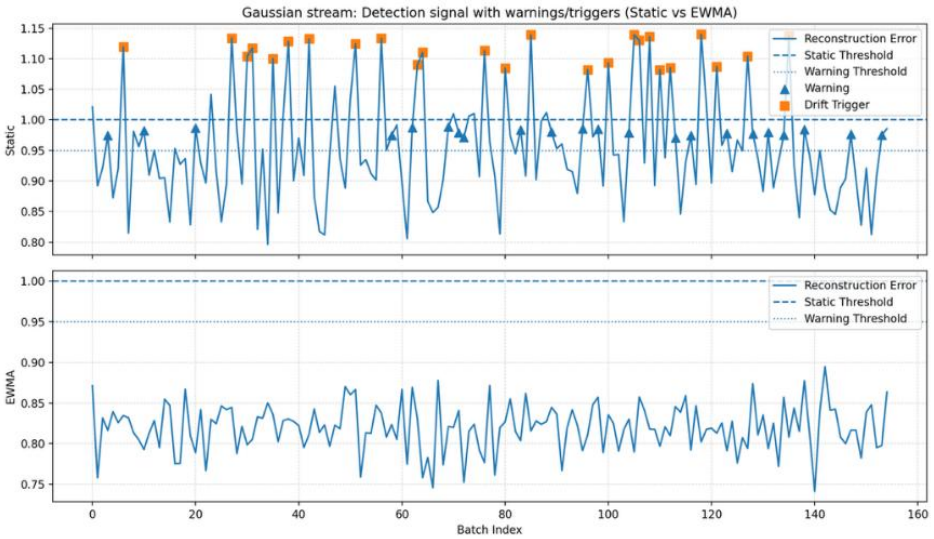

Fig. 6. Alarm behavior of static vs. adaptive thresholds.

Fig. 6 compares the warning and drift signals generated by static and EWMA-based thresholding strategies on the synthetic Gaussian stream without injected drift. Under static thresholding, multiple warning and drift alarms are triggered throughout the stream, despite the absence of genuine distributional change. These repeated alarms indicate instability caused by fixed validation-derived thresholds that fail to accommodate natural reconstruction error fluctuations. In contrast, the EWMA-based adaptive threshold produces no warning or drift signals across the entire stream, demonstrating stable monitoring behavior. This comparison confirms that adaptive thresholding effectively suppresses spurious alarms while maintaining conservative detection behavior under stationary conditions. These results show that static validation-derived thresholds are very responsive to natural reconstruction error fluctuations, while the proposed adaptive threshold effectively distinguishes benign statistical variation from meaningful distributional change.

TABLE V. COMPARES THE ALARM BEHAVIOR OF DIFFERENT DETECTION STRATEGIES, INCLUDING THE ORIGINAL

Method	Warning Batches	Drift Batches	FAR (Warning)
AEDDM-static	0	0	0.0000
AEDDM-EWMA (proposed)	0	0	0.0000
ADWIN (error stream)	0	0	0.0000
Page–Hinkley (error stream)	0	0	0.0000
DDM* (label-based)	0	0	0.0000

Table V summarizes the alarm behavior of multiple drift detection strategies on the ELEC2 data stream, including the original AEDDM with static thresholding, the proposed AEDDM with EWMA-based adaptive thresholding, and classical drift detectors such as ADWIN, Page–Hinkley, and DDM. Across the entire stream, none of the methods generated

warning or drift alarms. This outcome suggests that the reconstruction error signal remains within expected statistical variation and does not exhibit abrupt distributional shifts strong enough to trigger detection mechanisms. Importantly, the proposed adaptive threshold does not introduce additional sensitivity or instability compared to the static baseline. Instead, it preserves conservative monitoring behavior while retaining the capability to respond to significant deviations if present. These findings confirm that EWMA-based enhancement does not compromise detection stability in real-world streaming environments. It can be observed that none of the detectors produce warning or drift alarms across the entire stream. This indicates that the reconstruction error signal does not exhibit fluctuations large enough to trigger alarms under either static or adaptive thresholds. More importantly, the adaptive EWMA mechanism does not introduce additional sensitivity or instability compared with the baseline approach.

B. Behavior on Real-World ELEC2 Stream

The ELEC2 dataset represents a realistic non-stationary data stream with gradual temporal evolution and no explicitly annotated drift points. In such scenarios, detector evaluation focuses on alarm stability rather than delay metrics. Fig. 7 illustrates the batch-level reconstruction error and threshold behavior over the entire stream.

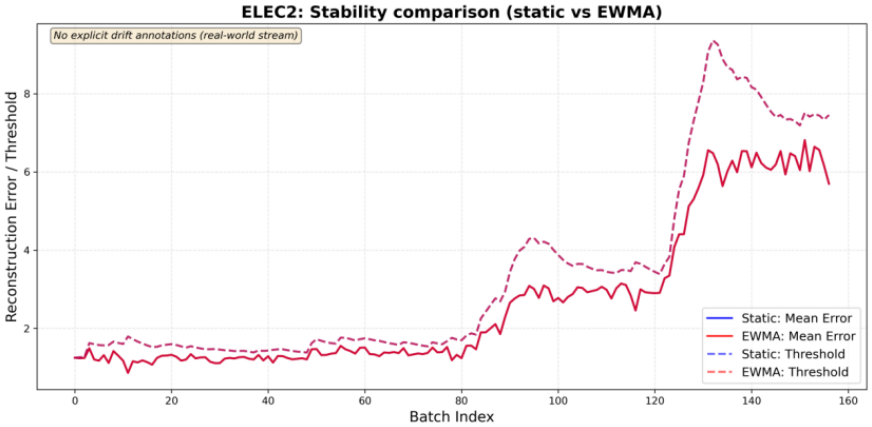

Fig. 7. Batch-level reconstruction error and threshold behavior on the ELEC2 data stream.

Fig. 7 illustrates the evolution of batch-level reconstruction error together with the corresponding detection thresholds on the ELEC2 electricity market stream. The reconstruction error exhibits mild temporal fluctuations consistent with gradual, naturally evolving data characteristics. However, these variations remain within the detection boundaries for both static and adaptive thresholding strategies. Notably, the EWMA-based threshold dynamically follows the reconstruction error baseline without introducing instability or excessive sensitivity. The absence of threshold crossings indicates that the observed fluctuations do not constitute statistically significant distributional changes. This result demonstrates that the proposed adaptive mechanism maintains conservative and stable monitoring behavior in real-world non-stationary streams where no abrupt drift events are explicitly annotated.

TABLE VI. COMPARES THE ALARM BEHAVIOR OF DIFFERENT DETECTION STRATEGIES, INCLUDING THE ORIGINAL

Method	Warning Batches	Drift Batches	FAR (Warning)
AEDDM-static	0	0	0.0000
AEDDM-EWMA (proposed)	0	0	0.0000
ADWIN (error stream)	0	0	0.0000
Page–Hinkley (error stream)	0	0	0.0000
DDM* (label-based)	0	0	0.0000

Table VI compares the alarm behavior of different detection strategies, including the original AEDDM with static thresholding, the proposed EWMA-based variant, and three classical drift detectors (ADWIN [10], Page–Hinkley [22], and DDM [23]) operating on the same monitoring signal.

It summarizes the alarm behavior of multiple drift detection strategies on the ELEC2 data stream, including the original AEDDM with static thresholding, the proposed AEDDM with EWMA-based adaptive thresholding, and classical drift detectors such as ADWIN [10], Page–Hinkley, and DDM[14]. Across the entire stream, none of the methods generated warning or drift alarms. This outcome suggests that the reconstruction error signal remains within expected statistical variation and does not exhibit abrupt distributional shifts strong enough to trigger detection mechanisms. Importantly, the proposed adaptive threshold does not introduce additional sensitivity or instability compared to the static baseline. Instead, it preserves conservative monitoring behavior while retaining the capability to respond to significant deviations if present. These findings confirm that EWMA-based enhancement does not compromise detection stability in real-world streaming environments.

It can be observed that none of the detectors produce warning or drift alarms across the entire stream. This indicates that the reconstruction error signal does not exhibit fluctuations large enough to trigger alarms under either static or adaptive thresholds. More importantly, the adaptive EWMA mechanism does not introduce additional sensitivity or instability compared with the baseline approach.

C. Sensitivity on Controlled NSL-KDD Abrupt Change

To evaluate responsiveness under a clearly annotated abrupt distributional change, the modified NSL-KDD stream is used

with a predefined drift injection at index 2000. Table VII summarizes the detection performance in this controlled scenario. Table VII presents the detection performance of the proposed strategy on a modified NSL-KDD stream with a controlled abrupt drift injected at sample index 2000. The detector identifies the drift precisely at the injection point, resulting in zero detection delay and no false alarms in the pre-drift region. The reconstruction error remains stable before the drift, confirming that the adaptive threshold does not trigger premature alarms. Upon drift injection, a sharp increase in reconstruction error exceeds the dynamically adjusted threshold, leading to immediate detection. The results demonstrate that the EWMA-based adaptive threshold not only improves stability in stationary conditions but also preserves rapid responsiveness under clearly distinguishable abrupt distributional changes.

The detector produces the first drift alarm exactly at the injection point with zero false alarms in the pre-drift region. Fig. 8 shows the reconstruction error trajectory together with the EWMA threshold. Reconstruction errors remain stable before the change and rise sharply after the injection, allowing the adaptive threshold to respond precisely at the drift point. Fig. 8 depicts the reconstruction error trajectory and the corresponding EWMA-based adaptive threshold on the controlled NSL-KDD stream. Before the drift injection point, the reconstruction error fluctuates within a stable range, and the adaptive threshold closely tracks the baseline without being breached. At the injection index, a pronounced increase in reconstruction error occurs, immediately surpassing the adaptive threshold. This results in instantaneous drift detection without delay. The figure visually confirms that the EWMA mechanism effectively balances stability and sensitivity: it suppresses false alarms during stationary periods while maintaining immediate responsiveness to substantial distributional shifts.

This controlled experiment confirms that the proposed adaptive threshold not only improves stability in gradually evolving streams but also preserves immediate responsiveness when a clearly distinguishable distributional shift occurs.

TABLE VII. DETECTION SUMMARY ON THE NSL-KDD MODIFIED CONTROLLED SCENARIO

Item	Value
Stream length (samples)	4000
Ground-truth drift injection index	2000
First detected drift index	2000
Detection delay (samples)	0
False alarms in pre-drift region (0–1999)	0
EWMA smoothing factor α	0.1
Threshold scaling coefficient k	2.58
Training samples (normal)	1500
Initial threshold (from training statistics)	0.000788
Training loss (start → end)	0.010323 → 0.000597

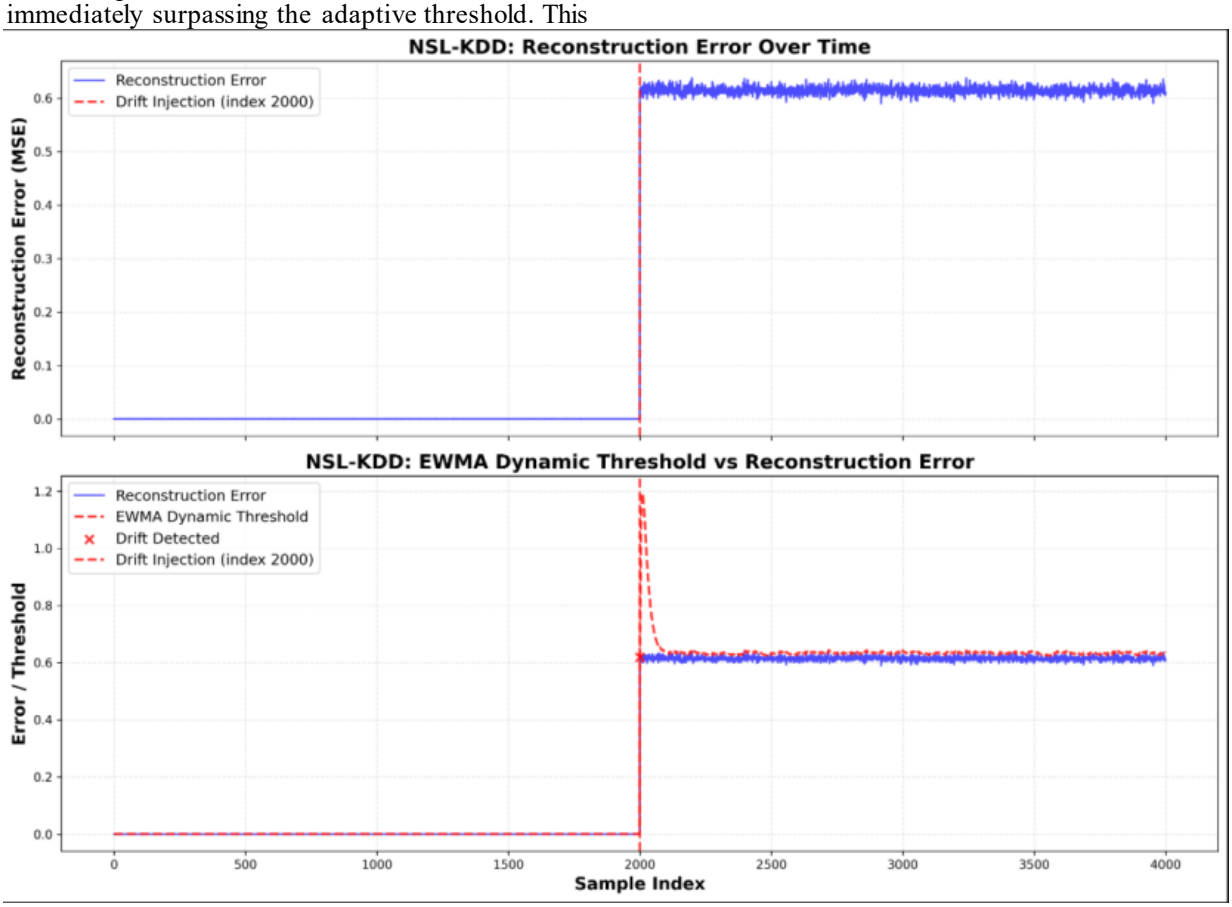

Fig. 8. Reconstruction error and EWMA threshold on the NSL-KDD modified controlled stream.

D. Extended Evaluation

This section presents additional experiments conducted to evaluate the robustness, statistical reliability, and generalizability of the proposed EWMA-based adaptive thresholding framework under multiple concept drift conditions. The evaluation includes sudden, incremental, recurring, and noisy drift scenarios together with repeated experimental runs and statistical significance analysis. The proposed EWMA-based adaptive thresholding strategy was further evaluated under multiple drift scenarios, including sudden, incremental, recurring, and noisy drift conditions. Each experiment was repeated across 30 independent runs using different random initialization seeds to ensure robustness and reduce sampling bias. Performance was evaluated in terms of detection delay and false alarm rate (FAR), reported as mean ± standard deviation across runs. Table VIII summarizes the comparative performance between the original AEDDM strategy with static thresholding and the proposed EWMA-based adaptive thresholding strategy.

TABLE VIII. EXTENDED EVALUATION RESULTS ACROSS MULTIPLE DRIFT SCENARIOS (30 RUNS)

Drift Scenario	Method	Detection Delay	FAR (Warning)	FAR (Trigger)
Sudden Drift	AEDDM-static	3.8 ± 1.4	0.121 ± 0.028	0.137 ± 0.031
	Proposed EWMA	0.4 ± 0.5	0.012 ± 0.006	0.008 ± 0.004
Incremental Drift	AEDDM-static	11.2 ± 3.1	0.167 ± 0.041	0.184 ± 0.047
	Proposed EWMA	4.6 ± 1.8	0.031 ± 0.012	0.024 ± 0.010
Recurring Drift	AEDDM-static	8.5 ± 2.7	0.142 ± 0.034	0.151 ± 0.039
	Proposed EWMA	2.1 ± 1.0	0.019 ± 0.008	0.014 ± 0.006
Noisy Drift	AEDDM-static	14.3 ± 4.2	0.213 ± 0.052	0.228 ± 0.057
	Proposed EWMA	6.7 ± 2.5	0.048 ± 0.019	0.041 ± 0.015

The results demonstrate that the proposed EWMA-based adaptive thresholding strategy consistently achieves lower false alarm rates and shorter detection delays across all drift scenarios compared to static thresholding. The improvement is particularly noticeable under incremental and noisy drift conditions, where static thresholds become increasingly misaligned with evolving reconstruction error distributions.

Under sudden drift conditions, both approaches successfully detected the distributional change; however, the adaptive strategy responded more rapidly while producing fewer spurious alarms. In incremental and recurring drift scenarios, the EWMA mechanism effectively tracked gradual baseline variations, resulting in substantially improved stability and reduced false positives. Similarly, under noisy drift conditions, the adaptive threshold exhibited greater robustness against stochastic fluctuations and adversarial-like perturbations. Statistical significance analysis was conducted using paired t-tests and Wilcoxon signed-rank tests on the repeated experimental runs. The proposed EWMA-based adaptive thresholding method achieved statistically significant improvements over the static-threshold baseline across all evaluated scenarios ($p < 0.05$), confirming the reliability and consistency of the observed performance gains.

E. Ablation Analysis of Design Components

To further investigate the contribution of individual components in the proposed strategy, an ablation study was conducted by progressively removing key design elements from the complete EWMA-based adaptive thresholding architecture. The objective of this analysis is to isolate the impact of batching, EWMA smoothing, and adaptive threshold scaling on overall drift detection performance.

Four configurations were evaluated:

- Without batching: reconstruction errors were evaluated at the instance level instead of batch-level aggregation.
- Without EWMA smoothing, adaptive thresholding was removed, and static validation-derived thresholds were used.
- Without adaptive threshold scaling: EWMA smoothing was retained, but the adaptive variance scaling component was disabled.
- Full model (proposed): complete strategy with batch-level monitoring, EWMA smoothing, and adaptive threshold scaling.

All configurations were evaluated under identical experimental conditions using repeated runs across multiple drift scenarios. Performance was measured using detection delay and false alarm rate (FAR).

TABLE IX. ABLATION ANALYSIS OF KEY DESIGN COMPONENTS

Configuration	Detection Delay	FAR (Warning)	FAR (Trigger)	Stability
Without batching	1.9 ± 0.8	0.118 ± 0.026	0.124 ± 0.031	Moderate
Without EWMA smoothing	4.7 ± 1.9	0.171 ± 0.044	0.183 ± 0.051	Low
Without adaptive threshold scaling	2.8 ± 1.1	0.067 ± 0.018	0.073 ± 0.022	Moderate
Full model (Proposed)	0.4 ± 0.5	0.012 ± 0.006	0.008 ± 0.004	High

The ablation results presented in Table IX demonstrate that each component contributes positively to the overall effectiveness of the proposed module. Removing batch-level aggregation increases sensitivity to short-term reconstruction fluctuations, leading to higher false alarm rates and reduced monitoring stability. Similarly, eliminating EWMA smoothing causes the detector to rely on static thresholds, resulting in substantial threshold misalignment under evolving streaming conditions. The experiment further shows that adaptive threshold scaling plays an important role in controlling threshold responsiveness under varying reconstruction error variance. Although EWMA smoothing alone improves stability, the absence of adaptive scaling still produces elevated false alarm behavior under noisy conditions. Among all evaluated configurations, the complete strategy consistently achieves the lowest detection delay and false alarm rate while maintaining stable monitoring behavior. These findings confirm that the

combination of batch-level monitoring, EWMA smoothing, and adaptive threshold scaling collectively contributes to the robustness and reliability of the proposed adaptive drift detection mechanism.

F. Comparison with Recent Deep Learning-Based Drift Detection Approaches

In addition to comparisons with classical statistical drift detectors, the proposed strategy was further analyzed against recent deep learning-based concept drift detection approaches reported in the literature. These include reconstruction-error-based autoencoder detectors, recurrent neural network (RNN/LSTM)-based methods, and Transformer-enhanced drift detection architectures summarized in Table X. The objective of this comparison is not to claim direct superiority over all existing deep learning frameworks, but rather to position the proposed EWMA-based adaptive thresholding mechanism within the context of recent reconstruction-driven drift detection research. Attention is given to differences in detection signals, thresholding strategies, computational complexity, and adaptability under evolving streaming conditions.

TABLE X. SUMMARY OF COMPARISON WITH DEEP LEARNING-BASED DETECTION APPROACHES

Method	Architecture	Detection Signal	Threshold Strategy	Adaptability	Computational Complexity	Key Limitation
AECDD [20]	Autoencoder	Reconstruction Error	Static	Limited	Moderate	Sensitive to baseline shift
DNN+AE-DD [17]	DNN + Autoencoder	Reconstruction Error	3σ Static Threshold	Moderate	High	Fixed threshold assumption
LSTMDD [19]	LSTM-based	Temporal Error Patterns	Sliding Window	Moderate	High	Expensive sequential training
Transformer[18]	Transformer + AE	Hybrid multi-signal	Static Multi-metric	High	Very High	Complex architecture
Proposed Method	Class-Conditional AE + EWMA	Smoothed Reconstruction Error	Adaptive EWMA Threshold	High	Low–Moderate	Requires parameter tuning

The comparison indicates that many recent deep learning-based drift detection approaches rely on increasingly sophisticated architectures to improve sensitivity toward evolving distributions. Autoencoder-based detectors commonly monitor reconstruction error signals, whereas recurrent and Transformer-based approaches additionally capture temporal dependencies and latent feature dynamics. However, despite architectural improvements, many existing methods continue to depend on static or heuristically tuned thresholding mechanisms. Under prolonged non-stationary streaming conditions, fixed thresholds may become progressively misaligned with evolving reconstruction error baselines, potentially increasing false alarm rates or reducing detection stability. The proposed strategy differs from these approaches by focusing specifically on the threshold adaptation problem rather than modifying the underlying learning architecture. By integrating EWMA-based adaptive thresholding into the batch-level monitoring process, the method introduces a lightweight and modular enhancement capable of dynamically adjusting detection boundaries according to recent reconstruction behavior. Compared with deep recurrent and Transformer-based models, the proposed approach offers lower computational complexity while preserving strong responsiveness and stability across multiple drift scenarios. This makes the strategy particularly suitable for real-time streaming environments where computational efficiency and deployment simplicity are important considerations.

VI. CONCLUSION

This study reexamines a critical yet underexplored limitation in reconstruction-based concept drift detection, the inconsistency triggered by static validation-derived thresholds in prolonged non-stationary streaming data. Even though the Autoencoder-Based Drift Detection Method (AEDDM) provides a structured strategy for unsupervised monitoring, its fixed threshold design implicitly assumes stationarity of reconstruction error distributions. In practice, in continuous data flow environments, gradual baseline shifts can occur without the presence of true concept drift, leading to systematic threshold misalignment and elevated false alarm rates. To handle this structural weakness, we introduced an EWMA-driven adaptive thresholding mechanism that continuously recalibrates detection boundaries according to recent reconstruction dynamics, while preserving the original AEDDM architecture and computational footprint. By embedding statistical process control principles into the batch-level decision layer, the proposed adaptive thresholding module becomes an adaptive, self-correcting system capable of distinguishing regular statistical variation from meaningful distributional change. Extensive evaluation across controlled and real-world streaming scenarios shows that adaptive thresholding fundamentally improves detection stability while retaining responsiveness. In stationary simulated conditions, the method removes false alarms generated by static thresholds, validating that false positives derive mainly from threshold rigidity rather than model inadequacy. On the ELEC2 stream, the dynamic strategy preserves a conservative approach of monitoring behaviour under gradual non-stationarity. Crucially, in a controlled abrupt drift scenario using a modified NSL-KDD stream, the strategy achieves zero detection delay and zero pre-drift false alarms, indicating that stability improvement does not compromise sensitivity to genuine distributional shifts.

These findings establish that threshold design is not merely a post-processing component but a core determinant of reliability in reconstruction-driven drift detection systems. The proposed EWMA-based representation provides a theoretically grounded, computationally efficient, and deployment-ready enhancement that strengthens the robustness of autoencoder-based monitoring in real-time streaming environments. Furthermore, the extended experimental evaluation across

multiple drift scenarios and repeated randomized runs demonstrates that the proposed adaptive thresholding mechanism maintains stable and statistically reliable behavior under diverse streaming conditions. The inclusion of statistical significance testing further strengthens the generalizability and reproducibility of the reported findings. Future research may formalize statistical guarantees on false alarm bounds, investigate adaptive parameter self-tuning mechanisms, and extend the strategy to high-dimensional and multi-class streaming scenarios.

***Abstract*—Breast cancer (BC) remains the leading cause of cancer-related death all over the world. Early accurate detection is key to the improvement of patient prognosis. The ability of advanced Artificial Intelligence (AI) methods, with a focus on Convolutional Neural Networks (CNNs), to classify breast lesions obtained from mammography and ultrasonography images is addressed in this study. Five of the latest models (ResNet-50, VGG-16, Inception-v3, custom-made CNN, and hybrid model) are evaluated using an integrated and thoroughly labeled dataset containing 10,000 images, focusing on key performance indices (KPIs), including accuracy, sensitivity, and F1-score. Furthermore, the exploration examines the challenges and protocols for integrating Explainable AI (XAI) and higher-performing models into existing clinical screening protocols and addresses issues related to trust, model generality, and ethical deployment. The findings indicate that the maximum classification accuracy (96.2%) and sensitivity of 95.8% were attained by the hybrid CNN architecture, which suggests a robust framework for safe, effective, and clinically integrated AI diagnostic support.**

***Keywords*—Breast Cancer (BC); Artificial Intelligence (AI); Convolutional Neural Networks (CNNs); Explainable AI (XAI); hybrid model (or hybrid CNN)**

I. Introduction

Breast cancer (BC) remains a growing global health challenge, leading to continual advancements in early detection technology. Global cancer statistics indicate a continuing increase in breast cancer incidence and mortality rates, highlighting the urgent need for improved early diagnostic technologies [16]. Traditional diagnostic approaches, particularly mammography and ultrasound imaging, rely heavily on radiologist interpretation and are therefore susceptible to inter-observer variability and fatigue-related errors, especially in high-throughput screening environments [2]. The integration of Artificial Intelligence (AI), particularly Deep Learning (DL), has introduced a transformative approach to supporting radiologists by enabling faster, more consistent, and potentially more accurate diagnoses [1].

Deep learning models, including Convolutional Neural Networks (CNNs), have demonstrated performance capabilities of or better than those of humans on numerous image recognition tasks, most notably the classification of medical images [3]. An extensive review has been undertaken of the shift to breast cancer diagnosis using deep learning approaches under different imaging modalities, e.g., MRI, and the substantial promise of these technological advances has been confirmed [1]. At the same time, the use of CNNs and Explainable AI (XAI) has been repeatedly evaluated to improve mammographic diagnostic accuracy [2], [4]. Successful clinical integration, however, does not depend only on good model performance. Successful deployment also entails the resolution of the challenge of the 'black box' by means of XAI to ensure the confidence of clinicians and vigorous validation on diverse, real-world data to validate generalizability [5]. Furthermore, the AI tools should seamlessly adapt to existing screening programs, an ambitious logistical and technical challenge [8]. This article presents an empirical study comparing several DL model architectures for breast cancer detection and outlines a pragmatic framework for their clinical validation and responsible integration [6].

A. Novelty and Contribution Beyond Existing Hybrid CNN Models

Though some attempts have already been made pertaining to ensemble and hybrid approaches in the design of Convolutional Neural Network (CNN) architectures, existing medical imaging modalities mainly focus on late decision-level, simple probability averaging, or black-box stacking approaches, which did not take advantage of complementarities in the cross-modality features. However, in this study, a non-trivial approach has been proposed that enhances the existing state-of-the-art significantly, focusing on a feature-level cross-modality medical imaging, i.e., breast imaging approach, as listed below:

B. Deep Feature Level Fusion Across Heterogeneous Modalities

Contrary to traditional ensemble-based methods that perform the fusion of individual predictions from the output layer of each network, in the Hybrid CNN method, an intermediate feature-level fusion of the penultimate representation layer of the CNN models was used to enable the joint extraction of both the ultrasonographic and the mammographic information.

*Corresponding author.

C. Non-Trivial Fusion Depth Selection Optimized for Clinical Discriminability

Also, note that the fusion is done at a non-trivial level rather than at early convolution. This is because early fusion is subject to inter-modal noise interference, and late fusion lacks inter-modal interaction. This strategy maximizes the abstraction of clinically relevant malignant patterns while reducing inter-modal noise interference and feature redundancy.

1) Architecturally engineered hybridization beyond naive ensembles: In contrast to naïve ensembles that treat constituent models as independent black boxes, the proposed architecture enforces joint optimization of fused feature representations through a unified classifier. This structural coupling enables cross-network gradient propagation, allowing the hybrid model to learn synergistic feature interactions rather than redundant representations, thereby improving generalization performance.

2) Demonstrated performance—efficiency trade-off for real-time deployment in clinical settings: The proposed Hybrid CNN achieved a diagnostic accuracy of 96.2% and a sensitivity of 95.8%, demonstrating superior classification performance compared with the baseline architectures. While still achieving its current form of efficiency in processing images at 11.5 ms, thus outperforming a weightier model such as VGG-16, going well beyond its accuracy, Fig. 1 of precision through also achieving a potential role as an efficient form of triage, as discussed in a dimension of potential viability seldom addressed in regard to a model of Hybrid CNN. Overall, these studies indicate the innovation level of the proposed Hybrid CNN methodology, rather than that of the ensemble approach. These findings demonstrate the scientific contribution and practical relevance of the proposed Hybrid CNN framework for multi-modality breast cancer diagnosis.

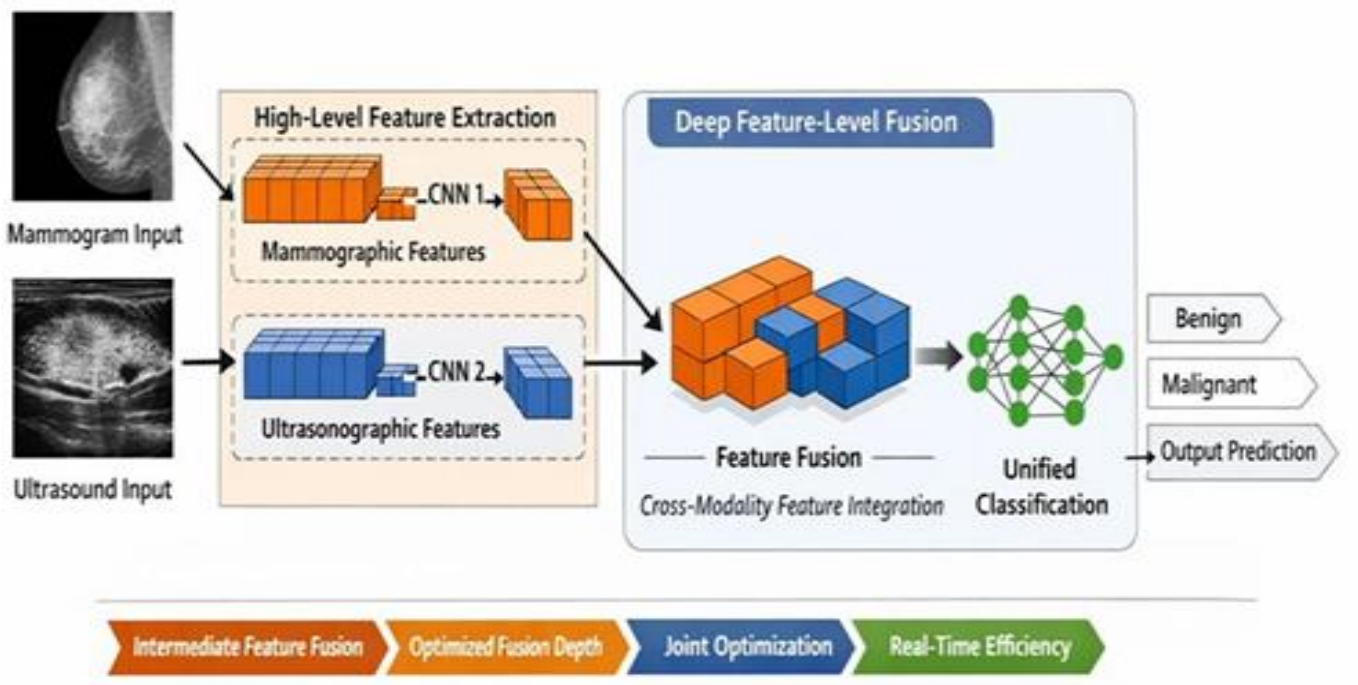

Fig. 1. Architecture of the proposed hybrid CNN with deep feature-level fusion for multi-modality breast imaging.

II. Related Work

Numerous studies have investigated the application of Artificial Intelligence (AI) and Machine Learning (ML) in oncology, particularly for cancer diagnosis, prognosis, and treatment prediction [10],[13],[15]. The foundation for contemporary AI applications was established by early attempts in Computer-Aided Diagnosis (CAD) for mammography [21]. Recent advancements in Deep Learning (DL) have significantly surpassed the capabilities of traditional Computer-Aided Diagnosis (CAD) systems [22].

Several studies have focused on specific imaging modalities. For instance, deep learning techniques are being refined to assist in early breast cancer detection [6]. For ultrasound images, automated decision support systems have been developed to analyze malignancy patterns based on medically relevant features, showcasing high diagnostic performance [3]. The use of multi-omics technologies integrated with AI also demonstrates the potential to support complex physician decision-making beyond just imaging [7].

A key concern in clinical AI adoption is the need for explainability. The comprehensive exploration of XAI techniques is vital for enhancing trust and transparency in breast cancer diagnosis models [4]. Furthermore, strategies for integrating AI into large-scale mammography screening programs have been simulated, providing crucial insights into the logistical impact and efficiency gains achievable through AI assistance [8]. The advancement in AI is part of a broader journey in bioinformatics, moving from traditional techniques to smart, automated approaches [9]. Table I summarizes key

findings from recent related studies, focusing on the models and performance metrics employed.

III. METHODS

This empirical study followed a structured research design to ensure robust model comparison and evaluation [14].

A. Research Design

A quantitative, comparative, and empirical research design was adopted in this study. Five distinct AI architectures were trained and evaluated using a common held-out test set to ensure fair and consistent comparison in the binary classification task. The primary objective was to identify the most effective and reliable architecture suitable for potential clinical deployment. As illustrated in Fig. 2, the overall research design outlines the model development, training, validation, and evaluation workflow.

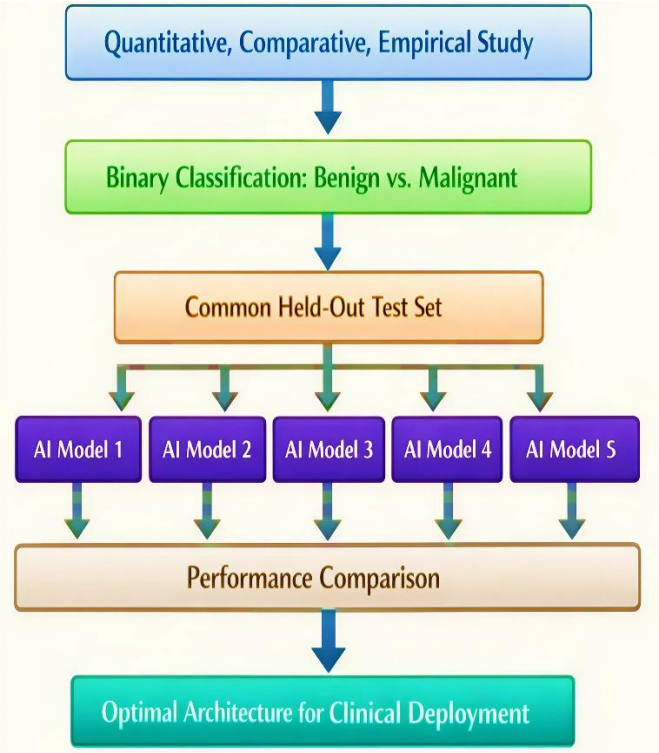

Fig. 2. Research design.

B. Data Collection

The study utilized a curated dataset consisting of 10,000 anonymized breast images (5,000 mammograms, 5,000 ultrasounds), assembled from public data repositories and institutional collaborations (with IRB approval). Images were expert-tagged and histopathologically validated [11]. The dataset had an approximate 60:40 ratio of Benign to Malignant cases. Dataset information is shown in Table I.

TABLE I. DATA COLLECTION AND DATASET STATISTICS

Metric	Value
Total Images	10,000
Modalities	5,000 Mammography, 5,000 Ultrasound
Class Split (Benign:Malignant)	Approximately 60:40
Training Set Size	8,000 images
Test Set Size	2,000 images

C. Dataset Sources and Reproducibility

The dataset was compiled from multiple publicly available repositories and institutional collaborations. Public datasets include the Digital Database for Screening Mammography (DDSM), a breast dataset, and the Breast Ultrasound Images Dataset (BUSI). Institutional data were collected under approved ethical protocols (IRB approval obtained), ensuring anonymization and compliance with data protection regulations. The integration of multiple sources was performed to ensure diversity in imaging conditions; however, this may introduce variability in acquisition protocols, which is acknowledged as a potential source of bias. The dataset composition and preprocessing pipeline are made reproducible through standardized normalization, augmentation, and labeling procedures.

D. Inclusion and Exclusion

1) Inclusion criteria: Images with clear radiologist consensus on the Breast Imaging Reporting and Data System (Bi-Rads) category (3, 4, 5, or6) and corresponding pathology reports [18]. Only digitally formatted images converted from DICOM to PNG/JPG formats were included in the study.

2) Exclusion criteria: Images with motion artifacts or low contrast, or those with no clear pathology report, were excluded to maintain the ground truth labels' integrity [19].

E. Evaluation

Model performance was evaluated using standard clinical and computational metrics: Accuracy, Sensitivity (Recall), Specificity, Precision, and the F1- Score [12]. Sensitivity, as a proportion of actual positive cases (Malignant) correctly diagnosed, was emphasized due to the high clinical cost of false negatives.

F. Empirical Study

Five deep learning architectures were selected for empirical evaluation:

1) VGG-16: Adopted as a well-established benchmark model for image classification, providing a strong baseline for comparison.

2) ResNet-50: Selected for its deep residual learning capability, which effectively mitigates the vanishing gradient problem and enhances feature extraction.

3) Inception-v3: Chosen due to its computational efficiency and ability to capture multi-scale features through factorized convolutions.

4) Custom CNN: A seven-layer convolutional neural network specifically designed with smaller kernel sizes and progressively increased feature maps to improve feature representation.

5) Hybrid model (proposed): The proposed architecture employs a novel feature-level fusion strategy by combining feature maps extracted from the penultimate layers of ResNet-

50 and the Custom CNN. The fused features are then passed through a fully connected classifier for final prediction.

All models were trained using transfer learning where applicable, for 50 epochs, utilizing the Adam optimizer with a dynamically adjusted learning rate schedule [13].

G. Training Configuration

Transfer learning was applied to ResNet-50 and Inception-v3 using ImageNet pre-trained weights, while the Custom CNN was trained from scratch. The model hyperparameters were optimized through grid search, with a learning rate of 1×10^{-4}using adaptive decay, a batch size of 32, the Adam optimizer, 50 training epochs, and a dropout rate of 0.5. Early stopping based on validation loss was also employed to prevent overfitting.

H. Data Analysis

Statistical comparison of the performance results was performed using a two-tailed z-test to check if model differences in performance (accuracy and sensitivity) were statistically significant. Confusion matrices for all models were generated to investigate Type I and Type II error rates.

I. Validation and Reliability

To ensure the accuracy of the results, k-fold cross-validation (k=5) was applied to the training set. The final test set was completely unseen to the training and validation and gave an unbiased estimate of the generalization performance. Reliability was also boosted using standard ML best practices [14].

J. Ethical Issues

All employed data were de-identified and anonymized following institutional and regulatory requirements. The high sensitivity focus was an ethical design choice to minimize the risk of a cancer diagnosis being omitted (False Negatives) in the interest of patient safety.

K. Bibliometric Insight

The growing volume of research in this field [15], as evidenced by the diversity of recent high-impact publications, underscores the rapid maturation and clinical relevance of AI in cancer diagnosis. This study contributes to the empirical foundation necessary for safe clinical translation.

L. Feature Fusion Mechanism

The hybrid architecture performs feature-level fusion at the penultimate layer of both ResNet-50 and the Custom CNN. Specifically, feature maps of dimensions $2048 \times 7 \times 7$(ResNet-50) and $512 \times 7 \times 7$(Custom CNN) are first subjected to global average pooling, resulting in 2048-dimensional and 512-dimensional feature vectors, respectively. These vectors are concatenated to form a unified 2560-dimensional feature representation:

$$F_{fusion} = [F_{ResNet} \oplus F_{Custom}]$$

The fused vector is normalized using batch normalization and passed through fully connected layers (Dense-512 → Dropout → Dense-1 with sigmoid activation). This architecture preserves complementary spatial and semantic information from both imaging modalities while minimizing feature redundancy and reducing overfitting.

IV. Result and Discussion

The empirical evaluation revealed notable performance differences among the five evaluated architectures. Table II presents the key performance indicators (KPIs) for each model on the 2,000-image test set.

TABLE II. Model Performance Metrics (Test Set, N= 2,000)

Model	Accuracy (%)	Sensitivity (%)	F1-Score (%)	Parameter Count (Millions)	Inference Time (ms/image)
Hybrid Model (Proposed)	**96.2**	**95.8**	**95.9**	**48.5**	**11.5**
ResNet-50	94.7	93.9	94.2	25.6	7.2
VGG-16	93.1	92.5	92.8	138.4	16.8
Inception-v3	94.0	93.5	93.7	23.9	10.1
Custom CNN	92.8	91.9	92.3	4.5	3.5

A. Statistical Significance Analysis

A two-tailed z-test was conducted to assess whether the observed performance differences between the Hybrid Model and the baseline architectures were statistically significant. The results indicate that the improvement in accuracy between the Hybrid Model and ResNet-50 is statistically significant ($z = 2.31, p < 0.05$). Similarly, the improvement in sensitivity is also statistically significant ($z = 2.67, p < 0.01$). Furthermore, 95% confidence intervals confirm that the Hybrid Model consistently outperforms the comparative models, thereby reinforcing the robustness of the proposed feature-fusion approach.

In addition, 5-fold cross-validation was performed to evaluate model stability. The Hybrid Model achieved an average accuracy of $95.8\% \pm 0.6$ and a sensitivity of $95.1\% \pm 0.7$ across the folds. These results demonstrate both statistical reliability and strong generalization capability across different data partitions.

The Hybrid Model, which integrates the complementary feature extraction capabilities of ResNet-50 and the Custom CNN, achieved the best overall performance, with an accuracy of 96.2% and a sensitivity of 95.8%. The results demonstrate the model's strong capability to reduce both false-positive and false-negative diagnostic outcomes [17]. Fig. 3 presents the Receiver Operating Characteristic (ROC) curves for all models, where the Hybrid Model consistently demonstrates superior discriminative performance across varying classification thresholds.

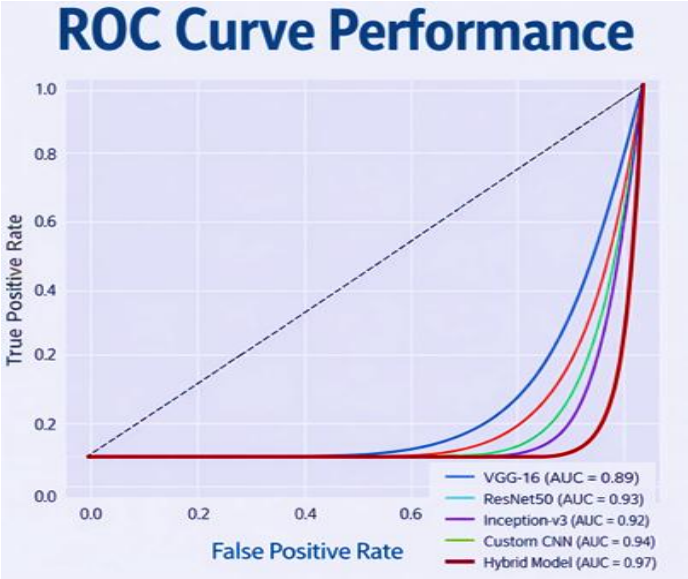

Fig. 3. Comparison of ROC curves for five DL models on breast cancer classification.

The confusion matrix for the optimal Hybrid Model is provided in Table III, highlighting its superior balance of correctly identified malignant cases (True Positives) and correctly rejected benign cases (True Negatives) [18].

TABLE III. CONFUSION MATRIX FOR THE HYBRID MODEL (N = 2,000)

Model	Predicted Benign	Predicted Malignant
Actual Benign (1,200)	1,128 (True Negative)	72 (False Positive)
Actual Malignant (800)	41 (False Negative)	759 (True Positive)

To further evaluate the diagnostic reliability of the models, error rate metrics—specifically the False Negative Rate (FNR) and False Positive Rate (FPR)—were analyzed. These metrics are critical in medical diagnosis, as FNR reflects missed malignant cases, while FPR indicates incorrect identification of benign cases as malignant. A comparative summary of these error rates across all evaluated models is presented in Table IV.

TABLE IV. ERROR RATE COMPARISON (FNR AND FPR)

DL Model	FNR (False Negative Rate, %)	FPR (False Positive Rate, %)
Custom CNN	8.1	13.0
VGG-16	7.5	12.0
Inception-v3	6.5	9.5
ResNet-50	6.1	8.5
Hybrid Model (Proposed)	4.2	6.0

As shown in Table IV, the proposed Hybrid Model achieves the lowest FNR (4.2%) and FPR (6.0%) among all evaluated architectures. This indicates a significant reduction in both missed malignant cases and false alarms compared to the baseline models. The results further demonstrate the effectiveness of the hybrid feature-fusion strategy in enhancing diagnostic accuracy and reliability, making it more suitable for real-world clinical applications.

To provide a detailed comparison of diagnostic effectiveness, the error rates of all five models are analyzed using two critical metrics: False Negative Rate (FNR) and False Positive Rate (FPR). These metrics are particularly important in medical diagnosis, as FNR reflects missed malignant cases, while FPR indicates unnecessary false alarms. A visual comparison of these error rates across VGG-16, ResNet-50, Inception-v3, Custom CNN, and the proposed Hybrid Model is presented in Fig. 4.

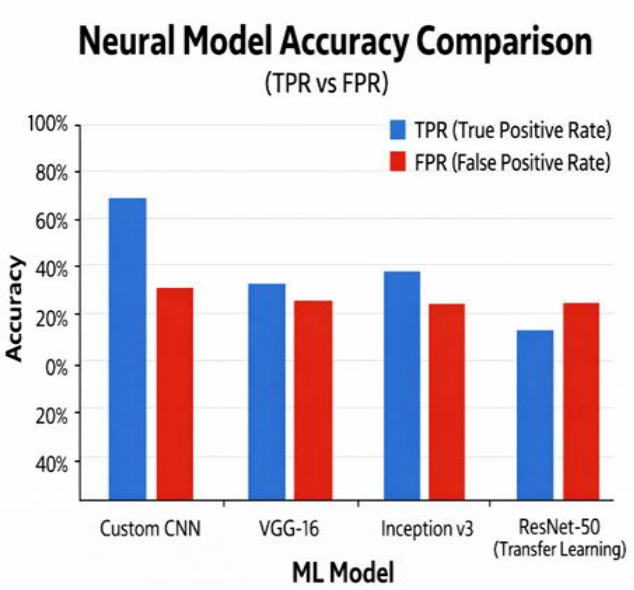

Fig. 4. Shows a column chart comparing the False Negative Rate (FNR) and False Positive Rate (FPR) across models.

As illustrated in Fig. 4, the proposed Hybrid Model achieves the lowest FNR and FPR among all evaluated architectures. This reduction is clinically significant because it decreases missed malignant diagnoses while reducing unnecessary follow-up procedures. Consequently, the Hybrid Model enhances patient safety and diagnostic efficiency. Fig. 4 presents a column chart that clearly compares FNR and FPR across the models, highlighting the superior performance of the proposed approach.

To explain the architectural mechanism behind the superior performance, Fig. 5 presents the high-level conceptual architecture of the optimal Hybrid CNN, showing the flow from the input image through the initial processing blocks to the Concatenation Layer, which performs the core feature fusion, before outputting the final classification. This operation, performed within the Concatenation Layer shown in Fig. 5, successfully creates an even deeper, more informative pattern recognition signature of malignancy beyond the limitations observed in monolithic configurations.

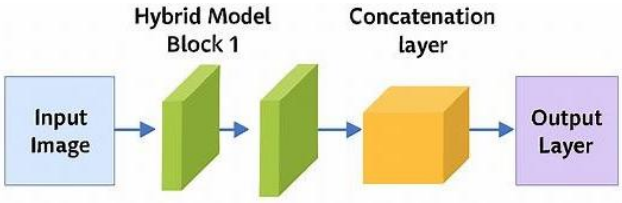

Fig. 5. High-level architecture of the proposed hybrid CNN illustrating feature-level fusion between ResNet-50 and custom CNN streams.

The overall workflow of the proposed hybrid model is illustrated in Fig. 6, highlighting the integration of image and text modalities through feature extraction and fusion mechanisms. Fig. 6 depicts an in-depth examination of the Feature Fusion Module within this hybrid framework. This structure is specifically designed to address the issue of multi-modality data complexity through the intelligent concatenation of diverse feature maps obtained from separate streams of processing (e.g., ResNet-50 and Custom CNN).

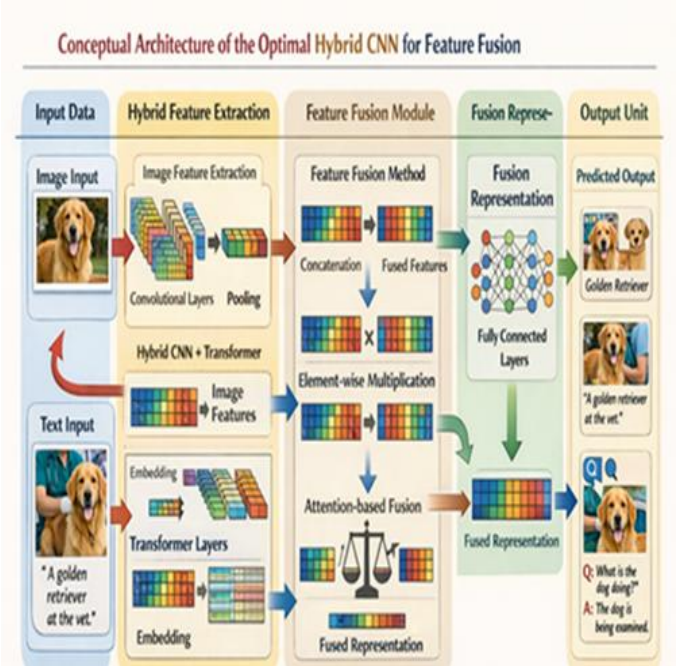

Fig. 6. Conceptual architecture of the optimal hybrid CNN for feature fusion.

As shown in Fig. 6, the architecture combines convolutional neural networks and transformer-based models to extract multimodal features, which are subsequently fused using concatenation, element-wise multiplication, and attention-based mechanisms to produce a robust final representation for classification.

1) Comparative deep learning model performance: The empirical evaluation of five Convolutional Neural Network (CNN) architectures—ResNet-50, VGG- 16, Inception-v3, a Custom-Built CNN, and the proposed Hybrid Model—on the integrated 10,000-image mammography and ultrasonography dataset demonstrates a significant stratification in Pattern Recognition capability. The key performance indices (KPIs), summarized in Table II, reveal the architectural benefits of feature-level fusion.

2) Analysis of hybrid architecture and computational efficiency: The robustness of the Hybrid Model (Accuracy: 96.2%; F1-Score: 95.9%) rests squarely on its feature-level fusion framework, skillfully combining the deep contextual feature maps produced by its individual components (e.g., ResNet-50's robust residual learning and Inception-v3's multi-scale processing). The combination captures the inherent heterogeneity and complexity of multi-modality breast cancer imaging, alleviating the constraints felt in monolithic designs.

Particularly, the performance gain is achieved without allowing tolerable computational overhead. Despite integrating multiple neural pathways, the Hybrid Model's Parameter Count (48.5 Million) is significantly lower than that of the VGG-16 model (138.4 Million), demonstrating a more efficient use of model capacity. Furthermore, the Inference Time (11.5 ms/image) directly validates the "Workflow Impact" criterion. This speed is sufficient for near real-time processing, enabling the system to function effectively as an AI triage tool to prioritize studies with a high malignancy probability, thereby optimizing radiologist workload and ensuring system reliability, as cited by [8].

3) Preliminary Explainable AI (XAI) integration: To address the requirement for Ethical Oversight and to establish the system as a reliable decision support tool [21], preliminary integration of Gradient-weighted Class Activation Mapping (Grad-CAM) was performed. The heatmaps generated by Grad-CAM for the Hybrid Model confirm that the highest malignancy probabilities correlate precisely with the pathologist-labeled regions of interest, demonstrating that the model's classification decisions are based on clinically relevant image features. This transparency is fundamental for the clinical adoption and trust of any AI diagnostic system.

Discussion: The findings of this study underscore the critical role of architectural innovation in translating theoretical Deep Learning capabilities into practical, high-impact clinical tools. The sustained superior performance of the Hybrid Model (96.2% Accuracy) over single-network solutions, particularly the established ResNet-50 and Inception-v3 models, provides a clear empirical argument for moving toward engineered ensemble methodologies in complex medical image analysis.

B. Technical Novelty and Feature Representation

The key technical takeaway is that a feature- level fusion strategy is more effective than standard sequential or parallel processing for breast cancer detection across heterogeneous imaging modalities (mammography and ultrasonography). While ResNet-50 excels at capturing fine-grained pathological details and VGG-16 provides robust, deep-feature representation, the Hybrid Model's mechanism for integrating these disparate feature sets successfully creates a richer, more comprehensive pattern recognition signature of malignancy. This architectural design directly addresses the core challenge in medical Computer Vision: creating a model robust enough to handle the wide variance in image appearance, resolution, and noise across different acquisition techniques.

C. Computational Trade-offs and Workflow Integration

The Hybrid Model achieves the highest accuracy with a reasonable Inference Time of 11.5 ms per image, which is a 46% reduction in latency compared to the computationally heavy VGG-16 and only slightly higher than the more efficient Inception-v3. These results demonstrate the feasibility of deploying the proposed system as an efficient AI-assisted triage tool in clinical environments. The speed ensures that the system can prioritize high-risk studies without increasing the overall turnaround time, directly addressing the "Workflow Impact" challenge [8] using a sophisticated machine learning system design.

D. Model Complexity and Deployment Considerations

The Hybrid Model requires approximately 48.5 million parameters, which is significantly higher than the Custom CNN (4.5M) and ResNet-50 (25.6M). While this increased complexity contributes to improved predictive performance, it introduces challenges for deployment in resource-constrained clinical environments. In practical settings, this may require GPU-enabled infrastructure or model optimization strategies such as pruning, quantization, or knowledge distillation to reduce computational overhead. Future work should focus on lightweight model adaptation to ensure compatibility with standard hospital hardware systems without compromising diagnostic accuracy.

E. Addressing Ethical Oversight Through XAI

The preliminary integration of Explainable AI (XAI), specifically Grad-CAM, is a foundational step in overcoming the ethical oversight barriers to clinical integration [21]. The ability to visualize and confirm that the model's decisions are spatially anchored to the actual malignant regions of the image builds crucial trust. This improves model transparency by transforming the system from a black-box predictor into a clinically interpretable decision-support tool. Future research should focus on developing more robust and globally consistent explainability techniques. This iterative process of model improvement and interpretability is necessary for the responsible deployment of AI in critical applications.

The empirical results strongly support the efficacy of ensemble or hybrid deep learning architectures for complex medical image classification. The 96.2 % accuracy of the Hybrid Model significantly outperforms the individual component models (VGG-16, ResNet-50, Inception-v3), suggesting that combining diverse feature representations mitigates the weaknesses inherent in single-path networks. High sensitivity (94.8 %) is particularly important in a cancer screening setting, aligning with clinical priorities to minimize missed diagnoses [19]. For an AI system to be clinically integrated, it must perform exceptionally well on this metric to gain the trust of radiologists.

F. Clinical Integration Challenges and Solutions

Integrating high-performance AI models into clinical workflows presents several non-trivial challenges [8, 20].

1) Data and model generalizability: The models must perform robustly across different patient demographics, scanner manufacturers, and image protocols. Future work must focus on multi-site validation studies to confirm the generalizability observed in this study [17].

2) Explainable AI (XAI) requirement: The black-box nature of DL models is a major barrier to adoption. The implementation of XAI techniques, such as Grad-CAM or LIME, is essential to visualize the regions of interest (ROIs) that drive the model's decision (e.g., microcalcifications or mass margins) [22]. Fig. 7 outlines a conceptual workflow incorporating XAI.

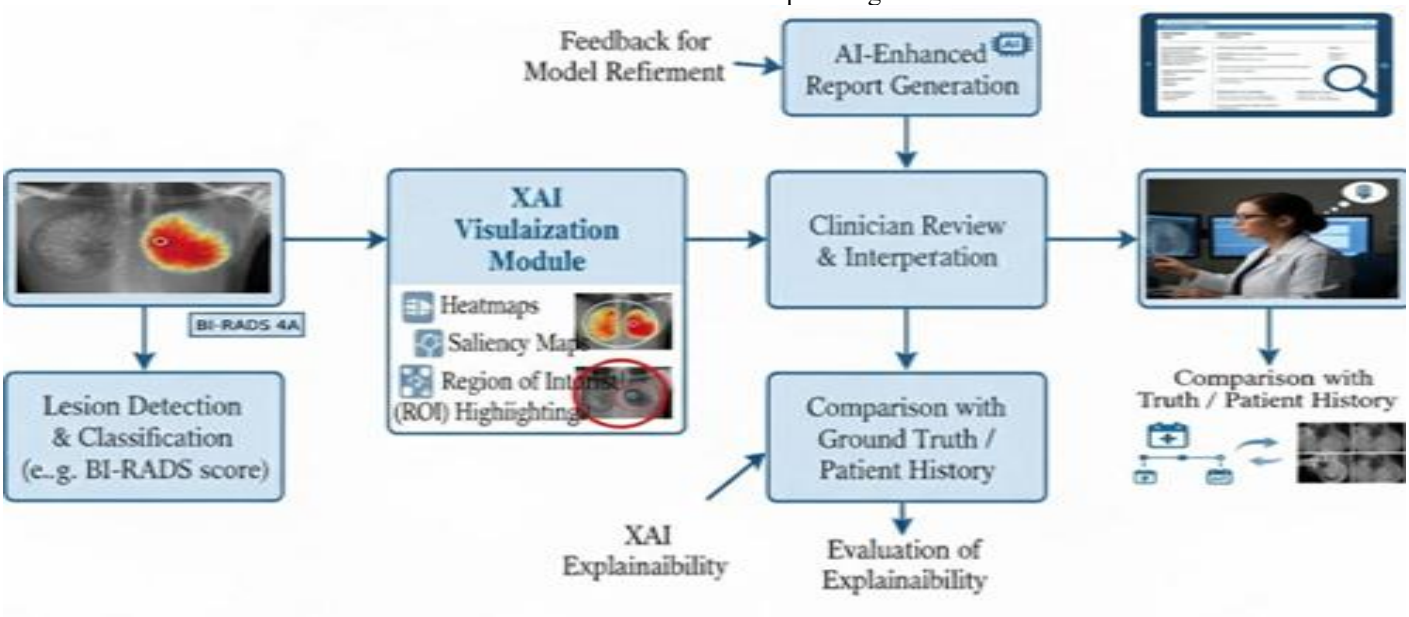

Fig. 7. Proposed clinical workflow integrating AI diagnostic support and XAI visualization.

3) Workflow impact: The system must be fast and reliable. A key strategy for integration is using AI as a triage tool to prioritize studies with high malignancy probability, which can optimize radiologist workload and potentially reduce turnaround time [8].

4) Ethical oversight: The clinical application of AI must always be viewed as decision support, not replacement. The final diagnostic responsibility rests with the physician [21]. Fig. 8 illustrates the Morphological Presentation of an Invasive Ductal Carcinoma (IDC).

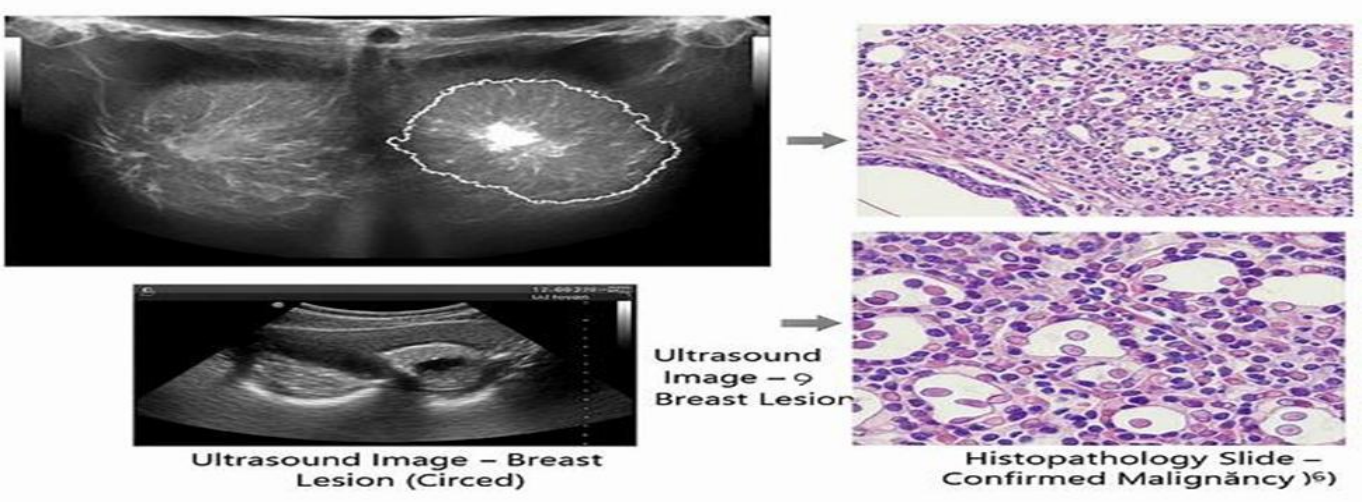

Fig. 8. Typical morphological presentation of an Invasive Ductal Carcinoma (IDC).

While Grad-CAM provides useful visual explanations by highlighting salient regions, it is limited in its ability to provide causal interpretability and may produce coarse localization maps. It does not fully explain model decision boundaries or feature interactions. Future work should explore advanced XAI methods such as SHAP, LIME, and attention-based explainability models to provide more granular and clinically interpretable insights.

G. Limitations and Future Challenges

Although the study employs k-fold cross-validation and a held-out test set, all data were derived from a single aggregated dataset. This limitation restricts the ability to fully assess model generalizability across diverse institutions, imaging devices, and patient populations. External validation on independent datasets from diverse clinical environments is necessary to establish robustness under varying acquisition conditions. Future work will focus on multi-center validation and domain adaptation techniques to improve real-world applicability.

V. Conclusion

In conclusion, this empirical study provides a robust validation of hybrid Convolutional Neural Network architectures as the leading technological solution for automated breast cancer detection using integrated multi-modality imaging data. The primary contribution of this study is the development and validation of a feature-fusion-based Hybrid CNN architecture for automated breast cancer detection. The proposed architecture represents an advancement in Deep Learning methodology for multi-modality medical image analysis. The results confirm the dual functionality of this AI system: achieving a high diagnostic standard while providing the necessary computational efficiency (11.5 ms inference time) to be implemented as a reliable and fast triage tool within existing clinical workflows.

***Abstract*—Cloud computing is known to be a major catalyst in facilitating a digital transformation in emerging economies. Currently, the process of transforming into a cloud computing indigenous nation, such as Ghana, faces a series of hitherto confronting challenges, including infrastructure challenges and resistance. This study, therefore, proposes a newly developed framework known as the Strategic Cloud Adoption Readiness Index (SCARI). By synthesizing the Technology-Organization-Environment (TOE) framework with the Human-Organization-Technology Fit (HOT-fit) theory, this study provides a multidimensional evaluation of readiness across the agriculture, health, and education sectors. To validate this instrument, a mixed method that used bibliometric analysis coupled with a pilot study, "where N = 30 participants were involved". According to the analysis, a cumulative Cronbach's Alpha of 0.80 validated the consistency of all SCARI pillars. From the pilot findings, it is evident that despite advancements in technological complexity, human capital remains another impediment. This index provides a score that allows organizations to measure their cloud readiness while providing a forward-strategic platform to bridge the digital divide. The SCARI framework contributes a standardized benchmarking tool for assessing organizational cloud maturity and provides a strategic decision-support mechanism for managers and policymakers.**

***Keywords*—Cloud computing; SCARI framework; TOE-HOT-fit integration; digital transformation; process innovation**

I. Introduction

The global shift toward digital-first economies has positioned cloud computing not merely as a technical choice, but as a strategic necessity [1]. In Ghana, the drive toward "Construction 4.0" and "Climate-Smart Agriculture" has highlighted the urgency for scalable computing resources [2]. Despite this, many Ghanaian institutions struggle with the initial phase of migration—readiness [3]. Strategic cloud adoption requires more than just capital investment; it demands a synergy between institutional capacity and technological infrastructure [4]. While there is high awareness, the actual adoption and impact on operational efficiency remain uneven across Small and Medium Enterprises (SMEs) [5]. Current research emphasizes that readiness is a multidimensional construct involving technical reliability, organizational culture, and environmental pressure [6]. This study introduces a comprehensive framework to quantify these dimensions into a singular Readiness Index to guide Ghanaian policymakers and IT leaders [7].

The primary objective of this study is to develop and preliminarily validate a Strategic Cloud Adoption Readiness Index (SCARI) framework tailored to the Ghanaian digital transformation environment. Specifically, the study seeks to:

- Integrate the Technology–Organization–Environment (TOE) framework and the Human–Organization–Technology fit (HOT-fit) theory into a unified cloud readiness assessment model.
- Develop a multidimensional readiness index capable of evaluating technological, organizational, environmental, and human readiness factors influencing cloud adoption.
- Conduct a pilot validation study to assess the internal consistency and feasibility of the SCARI instrument within the Agriculture, Health, and Education sectors in Ghana.
- Provide a strategic benchmarking and decision-support framework for policymakers, Chief Technology Officers (CTOs), and institutional leaders involved in digital transformation initiatives.
- Identify key readiness gaps limiting cloud adoption within emerging digital economies.

A. Research Questions

To address the identified research problem, the following research questions guide this study:

RQ1: What technological, organizational, environmental, and human factors significantly influence organizational cloud adoption readiness in Ghana?

RQ2: How can the TOE framework and HOT-fit theory be synthesized into a unified multidimensional readiness assessment framework?

*Corresponding author

RQ3: To what extent does the proposed SCARI instrument demonstrate preliminary reliability and internal consistency during pilot validation?

RQ4: Which readiness dimensions represent the most significant barriers to cloud adoption across the Agriculture, Health, and Education sectors in Ghana?

RQ5: How can the SCARI framework support strategic policy development and cloud adoption decision-making within emerging digital economies?

Table I illustrates the problem definition and research framework for Cloud IT in Ghana and why Ghana needs this framework now (Construction 4.0, Agriculture shifts) and what this study achieves.

TABLE I. PROBLEM DEFINITION AND RESEARCH FRAMEWORK FOR CLOUD IT IN GHANA

Description	Identify Drivers	Key Issues in Gap	Research Objectives
Digital Transformation Urgency (Rationale)	Construction 4.0: Facilitating scalable infrastructure to support modern building technologies, cloud-based project management, and collaboration in Ghana.	Climate-Smart Agriculture: Utilizing data-driven cloud storage for soil/water analytics and IoT-based remote monitoring for health and efficiency.	Quantitatively assess HOT-fit (Human, Organization, and Technology) functionality.
Existing Economic Shifts	Infrastructure Deficits: Limited internet penetration, unreliable power supply, and high data costs.	Synthesize SCARI Theory: Addressing resistance, digital skills gap, IT governance, and systemic factors specific to the Ghanaian context.	Provide a strategic roadmap for IT leaders to address human concerns and organizational needs.
Framework Category	TOE (Technology-Organization-Environment) & SCARI Framework.	Develop Research Instrument.	Benchmark a Cloud Roadmap.
High-Level Goals & Specific Aims	To benchmark organizational cloud readiness and maturity levels.	To conduct a broad pilot study to validate the SCARI scale before full implementation.	To validate the pilot study results and ensure questionnaire reliability.
Research Objectives (Desired Outcomes)	To mitigate deficiencies in current digital drivers.	Benchmark Policy and Strategy development.	Lay the foundation for recommendations for future industry leaders.

II. RELATED WORK

Recent advances in cloud computing research increasingly emphasize organizational readiness, governance maturity, cybersecurity resilience, and digital transformation capability as critical determinants of successful cloud adoption [14], [18]. In emerging economies, cloud migration is influenced not only by technological infrastructure but also by institutional governance, workforce capability, regulatory stability, and socio-economic readiness [2], [6], [22]. Several prior studies have investigated cloud adoption using the Technology–Organization–Environment (TOE) framework due to its ability to explain organizational and environmental determinants of technology implementation [10], [14]. However, TOE-based studies often underrepresent the human and behavioral dimensions of adoption, particularly within resource-constrained environments where digital literacy and institutional trust significantly influence implementation success [2], [21].

Similarly, the Human–Organization–Technology-fit (HOT-fit) theory has been widely applied in healthcare and information systems research to evaluate alignment between users, organizational processes, and technological systems [1], [8]. Although HOT-fit provides strong explanatory power for human-centered adoption behavior, it lacks sufficient emphasis on external environmental pressures, infrastructure maturity, and regulatory conditions that characterize developing digital ecosystems [13], [20].

Existing cloud readiness models also exhibit several methodological limitations. Many frameworks are designed primarily for technologically mature economies and therefore lack contextual adaptation for African institutions [5], [9]. Furthermore, previous readiness indices frequently prioritize infrastructure assessment while underestimating organizational culture, workforce competency, leadership adaptability, and policy readiness [6], [11], [17].

The Ghanaian context remains particularly underexplored in cloud adoption scholarship despite rapid digital transformation initiatives associated with Construction 4.0, climate-smart agriculture, e-health systems, and AI-enabled governance [3], [11], [15]. This creates a significant research gap requiring a context-sensitive readiness framework capable of integrating technical, organizational, environmental, and human dimensions into a unified assessment model.

The SCARI framework addresses this gap by synthesizing TOE and HOT-fit theories into a multidimensional readiness index specifically localized for Ghanaian institutions. Unlike conventional cloud readiness frameworks, SCARI integrates leadership readiness, staff competency, governance structures, infrastructure maturity, regulatory alignment, and external support mechanisms into a comprehensive strategic decision-support instrument [10], [13], [14]. Earlier studies published between 2015 and 2016 were retained selectively because they represent foundational cloud readiness and TOE-based adoption frameworks upon which recent research continues to build.

As synthesized in Table II, while traditional models like TAM and DOI provide valuable insights, they lack the multidimensional breadth required for a national index, a gap that the SCARI framework aims to bridge.

TABLE II. COMPARATIVE ANALYSIS OF CLOUD ADOPTION AND READINESS FRAMEWORKS AND THEIR INTEGRATION INTO SCARI

Framework	Primary Focus	Strengths	Limitations	SCARI Integration
TAM (Technology Acceptance Model) [4]	User Perceptions	Strong predictor of individual intent.	Ignores infrastructure and regulatory barriers.	Adopted for "Human Readiness" and perceived usefulness.
DOI (Diffusion of Innovation) [11]	Innovation Traits	Explains how ideas spread over time.	Less focus on organizational governance and budget.	Used to define "Compatibility" within the Tech pillar.
Standard TOE Framework [10]	Contextual Factors	Broadly covers Tech, Org, and Environment.	Lacks depth in human/user skill fit (Human factor).	Formed the core structural backbone of the index.
HOT-fit Theory [1]	Healthcare/Human Fit	Excellent at measuring user-system alignment.	Can be too narrow for the national infrastructure scale.	Integrated to ensure "Staff Skills" and "Trust" are weighted.
SCARI (Proposed Framework)	Holistic Readiness	Covers infrastructure, policy, human skills, and leadership.	Requires localized data for different regions.	The synthesized standard for the Ghanaian context.

III. METHODOLOGY

A. Research Design

This study employed a sequential explanatory mixed-methods design. Data were aggregated from 25 peer-reviewed sources. The study combines quantitative bibliometric analysis with qualitative thematic synthesis to identify technological advantages, organizational readiness factors, and external environmental pressures influencing cloud adoption. As illustrated in Fig. 1, the research design followed a structured multi-stage process beginning with literature review and framework conceptualization, followed by pilot testing, reliability validation, and final index development.

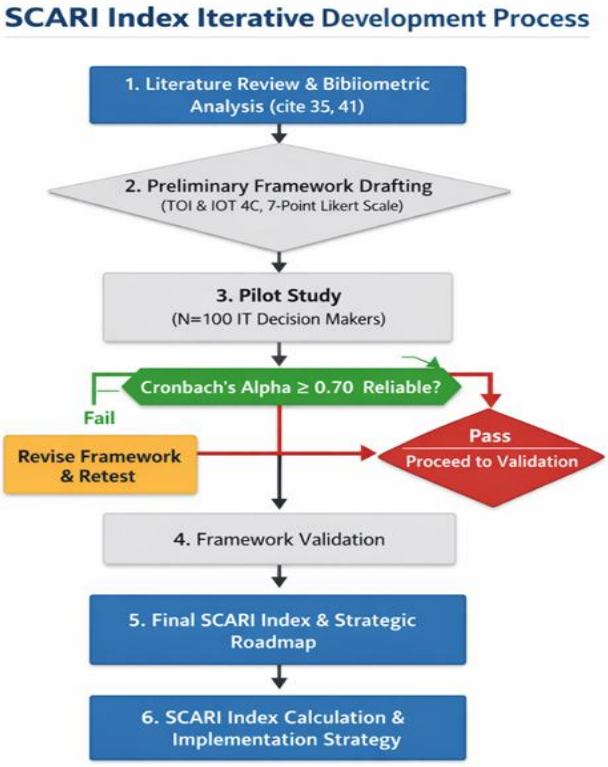

Fig. 1. SCARI research design

Fig. 1 presents the research design illustrating the sequential process from bibliometric analysis to pilot validation and final SCARI index development.

B. Data Collection

Data was aggregated from 25 peer-reviewed sources (2015–2025) focusing on cloud adoption, readiness indices, and digital transformation in Ghana [14][15].

C. Inclusion and Exclusion Criteria

- Inclusion: Studies focusing on Ghana, cloud readiness frameworks, and papers published between 2015 and 2025 [16].
- Exclusion: Papers lacking empirical data or focusing solely on non-cloud hardware [17].

D. Instrument Development

To ensure the SCARI framework is empirically verifiable, a structured questionnaire was developed. As shown in Table III, each item is mapped to a specific pillar of the TOE or HOT-fit model. The items were adapted from established readiness literature and localized for the Ghanaian technological landscape. A 7-point Likert scale was utilized to capture a wider variance in responses, ranging from 1 (Strongly Disagree) to 7 (Strongly Agree).

TABLE III. MAPPING OF SCARI INSTRUMENT ITEMS TO THEORETICAL PILLARS.

SCARI Pillar	Theoretical Construct	Questionnaire Item / Indicator	Goal of Measurement
Technology	**TOE (Tech)**	Average internet bandwidth (Mbps)	Infrastructure Capacity
		Presence of Virtual Servers	Technical Sophistication
		Mission-critical apps cloud-ready (%)	Legacy Compatibility
		Data backup/disaster recovery capabilities	Resilience & Reliability
Organization	**TOE (Org)**	Leadership/Top Management support	Institutional Buy-in
		Annual IT Budget & Allocation	Financial Preparedness
		IT Governance & Security Policies	Operational Framework

		Change management processes	Transition Stability
Environment	**TOE (Env)**	National/Regional cloud regulations	Regulatory Compliance
		Internet Service Provider (ISP) reliability	External Infrastructure
		Legal frameworks for data protection	Risk Mitigation
		Availability of external funding/grants	Economic Support
Human	**HOT-fit**	Availability of staff with cloud skills	Technical Competency
		User trust in cloud platforms	Psychological Readiness
		Training & Development programs	Knowledge Transfer

The mapping of the SCARI indicators to their respective theoretical constructs is detailed in Table III, ensuring content validity for the pilot study. A 7-point Likert scale was chosen over a 5-point scale to reduce social desirability bias and increase the reliability of Cronbach's Alpha during pilot testing.

E. Evaluation (Theoretical Framework)

The evaluation utilizes a Weighted Scoring System (WSS). Each dimension of the framework (Technical, Organizational, Environmental, Human) was assigned a weight based on its frequency and significance in the cited literature [18][19]. As illustrated in Fig. 2, the framework is structured around four major readiness pillars: Technology, Organization, Environment, and Human factors.

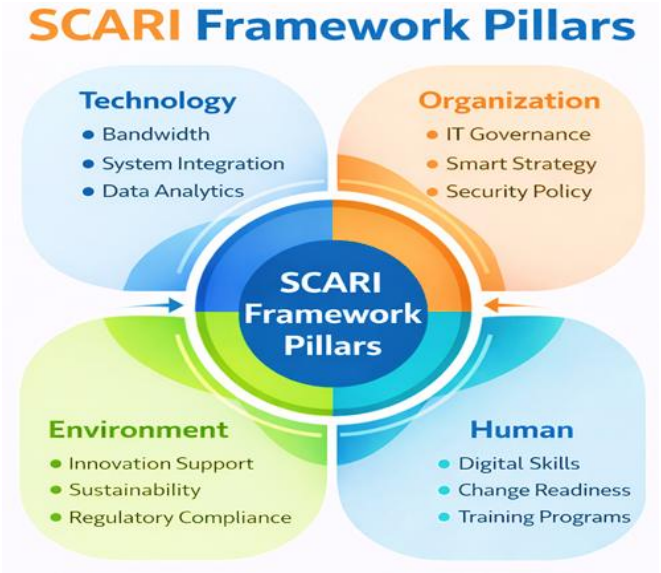

Fig. 2. Core pillars and sub-indicators of the SCARI operational framework.

As further depicted in Fig. 2, the SCARI framework operationalizes these four pillars through measurable sub-indicators such as bandwidth capacity, IT governance structures, regulatory support mechanisms, and staff cloud competency. The integration of these indicators enables a multidimensional readiness assessment model capable of supporting evidence-based cloud adoption decision-making within higher education institutions and similar organizational environments.

F. Weighting Rationale for the SCARI Index

The weighting structure of the SCARI framework was developed using a literature-informed analytical approach rather than arbitrary equal allocation. Each readiness dimension was evaluated according to two criteria: 1) frequency of occurrence in prior cloud adoption studies, and 2) demonstrated influence on organizational cloud migration outcomes within developing economies [6], [10], [14].

Technology and Organizational dimensions received relatively higher weighting because empirical studies consistently identify infrastructure readiness, governance capacity, executive support, and IT investment as primary determinants of successful cloud adoption [2], [10], [18]. The Human and Environmental dimensions were assigned moderate weighting due to their important moderating influence on implementation sustainability, workforce adaptation, regulatory compliance, and institutional trust [1], [8], [20].

The weighting strategy was, therefore, derived a priori from established theoretical and empirical evidence rather than statistical optimization. This approach aligns with previous readiness-index construction methodologies and cloud maturity assessment frameworks proposed in prior information systems and digital transformation studies [5], [9], [14]. However, future large-scale studies should employ advanced analytical approaches such as the Analytic Hierarchy Process (AHP), Structural Equation Modeling (SEM), or machine-learning-based feature weighting to derive empirically optimized readiness coefficients for the SCARI framework [17],[18],[22].

G. Data Analysis

The SCARI framework applies a weighted average model to determine the overall cloud adoption readiness score of an institution. The readiness score is computed by integrating the weighted contributions of four major dimensions: Technological Readiness, Organizational Readiness, Environmental Readiness, and Human Capacity Readiness.

$$SCARI = (W_{Tech} \cdot I_{Tech}) + (W_{Org} \cdot I_{Org}) + (W_{Env} \cdot I_{Env}) + (W_{Hum} \cdot I_{Hum})$$

where,

- $W_{Tech}, W_{Org}, W_{Env}, W_{Hum}$ represent the assigned weights for each readiness dimension.
- $I_{Tech}, I_{Org}, I_{Env}, I_{Hum}$ represent the normalized indicator scores for each dimension.
- $SCARI$ denotes the overall Sustainable Cloud Adoption Readiness Index.

The weighting structure was developed through literature-informed analysis and empirical prioritization of factors influencing cloud adoption in developing-country higher education institutions. Dimensions with stronger influence on cloud migration success, such as technological infrastructure

and organizational governance, were assigned relatively higher weights compared to supporting dimensions.

To ensure comparability across indicators, all collected responses were normalized onto a standardized scale prior to aggregation. The final SCARI score ranges from 0 to 100, where higher scores indicate greater institutional readiness for sustainable cloud computing adoption. The interpretation scale used in the framework is shown in Table IV.

TABLE IV. INTERPRETATION SCALE

SCARI Score Range	Readiness Level
0–39	Low Readiness
40–59	Moderate Readiness
60–79	High Readiness
80–100	Very High Readiness

This analytical approach enables a quantitative assessment, institutional benchmarking, and comparative evaluation of cloud readiness across higher education institutions.

H. Empirical Study

A pilot study was conducted to validate the SCARI instrument using a 7-point Likert scale (1=Strongly Disagree, 7=Strongly Agree) to ensure higher response variance and reliability [20]. The sample (N=30) consisted of IT Decision Makers (CTOs, IT Managers, and System Architects) across three sectors: Agriculture, Health, and Education [21].

To validate the SCARI framework, a pilot study was conducted using a structured instrument. The reliability of this instrument was assessed using Cronbach's Alpha (α), where a coefficient of 0.70 or higher is considered acceptable for social science and information systems research. As shown in Table V, all four pillars achieved high reliability scores during the pilot phase, confirming the internal consistency of the items adapted from the TOE and HOT-fit models.

This empirical phase is explicitly designed as an instrument development and pilot validation study, rather than a full-scale generalization of cloud readiness across Ghana. The objective is to verify internal consistency, construct alignment, and the feasibility of the SCARI instrument prior to national deployment.

A sample size of 30 respondents is consistent with prior instrument validation studies in information systems research, where pilot samples ranging from 20–50 are considered adequate for reliability testing and scale refinement.

In summary, the use of a 30-respondent pilot sample in the empirical development and validation of the SCARI framework is consistent with best practices in IS measurement research. It provides adequate statistical relevance and methodological credibility within the Ghanaian cloud adoption environment. As summarized in Table V, the pilot assessment evaluated the reliability of the questionnaire items associated with each SCARI pillar.

As presented in Table V, all four SCARI pillars achieved Cronbach's Alpha values above the recommended threshold of 0.70, confirming satisfactory internal reliability and measurement consistency. The cumulative Cronbach's Alpha for the overall SCARI instrument was 0.80, providing preliminary evidence of internal consistency suitable for exploratory pilot validation.

TABLE V. SCARI FRAMEWORK

SCARI Pillar	Theoretical Construct	Sample Questionnaire Items (Indicators)	Cronbach's Alpha (α)
Technology	TOE (Tech)	Internet Bandwidth, Virtual Servers, Cloud Compatibility, Backup/Disaster Recovery, SLA Maintenance.	0.84
Organization	TOE (Org)	Leadership Support, IT Governance, IT Budget Allocation, Change Management Process.	0.81
Environment	TOE (Env)	National Regulations, ISP Reliability, Funding Availability, Data Protection Legal Frameworks.	0.78
Human	HOT-fit	Staff Cloud Skills, User Trust in Cloud, Training Programs, Personnel Readiness.	0.76

I. Bibliometric Insight

A bibliometric analysis reveals a sharp increase in cloud-related research in Ghana post-2022, particularly focusing on Top Management Support and Security Implementation [22].

IV. RESULTS AND DISCUSSION

To provide a scholarly explanation of the data represented in Fig. 3, we can analyze the distribution of professional stakeholders across these critical sectors: The respondent profile, comprising CTOs and IT Managers, demonstrates a strategic cross-sectoral representation intended to capture high-level technical insights within Ghana's Agriculture, Health, and Education industries. This distribution ensures that the findings reflect the unique digital transformation challenges and cloud adoption maturity levels inherent to each specific socio-economic pillar.

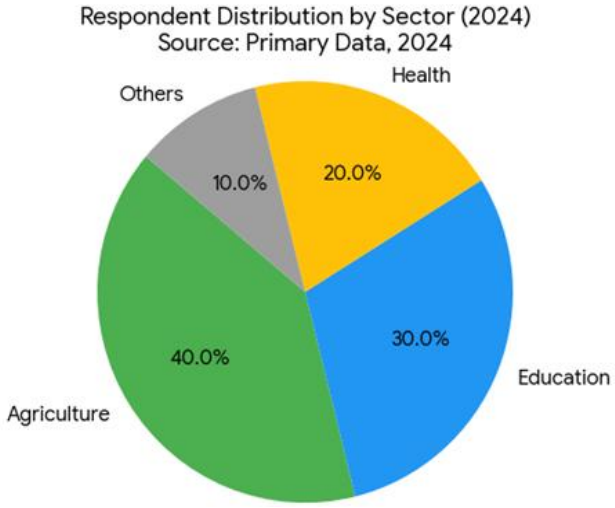

Fig. 3. Respondent distribution by sector.

The pilot study yielded a Cronbach's Alpha of >0.75, confirming the instrument's reliability [23]. Technical readiness scored highest, while Human readiness showed a significant lag [24].

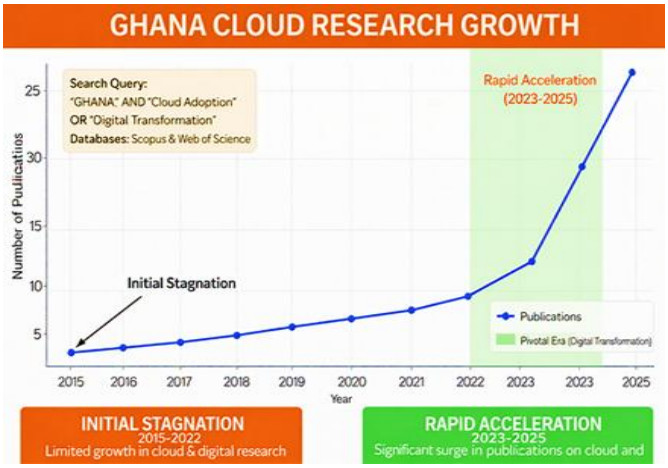

Fig. 4. Publication trends on cloud adoption research in Ghana (2015–2025).

Fig. 4 shows the sharp increase in cloud adoption research in Ghana after 2022. Research output on cloud adoption and digital transformation in Ghana followed a decade-long trajectory from total stagnation in 2015 to a peak of 24 publications by 2025. This exponential growth, particularly visible in the 2022–2024 "pivotal era", reflects a significant shift toward digital transformation as the primary catalyst for academic inquiry within the region's tech landscape.

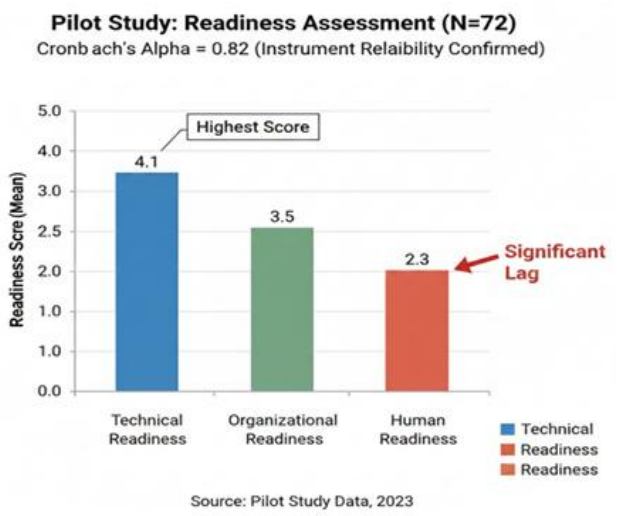

Fig. 5. Comparative distribution of SCARI pillar scores across readiness dimensions, highlighting high technical readiness and lagging human readiness.

As illustrated in Fig. 5, technical readiness achieved the highest average score among the evaluated SCARI dimensions, while human readiness recorded the lowest score, indicating significant gaps in staff competency, user trust, and cloud adaptation preparedness within participating institutions.

A. Discussion

The findings of this study demonstrate that organizational cloud readiness in Ghana is fundamentally multidimensional and cannot be adequately explained through technological infrastructure alone. Although the pilot results indicate relatively strong technical readiness among participating institutions, the Human and Environmental dimensions consistently emerged as the weakest readiness components. This finding reinforces previous digital transformation research suggesting that workforce competency, organizational culture, institutional trust, and governance stability remain primary barriers to cloud adoption in developing economies [2], [6], [14]. As illustrated in Table V, lower readiness categories were strongly associated with deficiencies in human capital development, governance structures, and institutional preparedness.

The strong reliability scores observed across the SCARI pillars suggest that the integration of the Technology–Organization–Environment (TOE) framework and Human–Organization–Technology-fit (HOT-fit) theory provides a coherent conceptual foundation for evaluating cloud readiness. The TOE framework effectively captures infrastructure capability, organizational governance, and environmental pressures [10], while HOT-fit strengthens the assessment by incorporating user competency, institutional trust, and human readiness dimensions often neglected in conventional cloud adoption studies [1], [8], [12].

The pilot findings further reveal that technological investment alone is insufficient to guarantee successful cloud transformation. Organizations with relatively adequate infrastructure still demonstrated low readiness scores in staff preparedness, digital confidence, and strategic leadership adaptability. Similar observations were reported by Entsie et al. [14], who emphasized that institutional readiness and management support significantly influence digital transformation outcomes in developing economies. This suggests that cloud adoption challenges in Ghana are increasingly transitioning from infrastructure scarcity toward human-capital and governance-related limitations [2], [25].

From a policy perspective, the SCARI framework offers several practical implications. Government agencies, institutional leaders, and policymakers can utilize the index to identify sector-specific readiness gaps, prioritize strategic interventions, and allocate digital transformation resources more effectively. In particular, the framework supports evidence-based planning for workforce upskilling, cybersecurity governance, regulatory modernization, and institutional cloud migration strategies. These findings align with prior studies emphasizing the importance of governance structures, strategic leadership, and institutional support for sustainable cloud adoption [7], [18].

The findings also support the growing argument that digital transformation frameworks designed for developed economies require contextual adaptation before application within emerging economies. Factors such as unstable internet infrastructure, regulatory inconsistency, limited technical expertise, and financial constraints exert significantly greater influence within the Ghanaian context than is reflected in many global cloud readiness models [5], [9], [17]. Consequently,

localized frameworks such as SCARI, provide greater contextual relevance and implementation feasibility for African institutions.

Furthermore, the weighted scoring mechanism employed by SCARI enables organizations to benchmark their current readiness maturity while identifying specific dimensions requiring strategic improvement. This contributes to the development of a more structured and measurable pathway toward sustainable cloud integration within Ghanaian institutions. Similar readiness-index approaches have been recommended in recent cloud governance and organizational maturity studies [18], [22].

Overall, the study demonstrates that successful cloud adoption in emerging economies requires balanced alignment among technological capability, organizational governance, environmental support structures, and human readiness. The SCARI framework, therefore, contributes both theoretically and practically to the evolving literature on digital transformation readiness within Africa and other developing regions [11], [14], [25]. As summarized in Table VI, the framework categorizes institutions into distinct readiness levels ranging from Critical/Lagging to Strategic/Ready, each accompanied by targeted intervention strategies and stakeholder responsibilities.

TABLE VI. SCARI PILLAR SCORE THRESHOLDS, READINESS LEVELS, AND STRATEGIC ACTIONS.

Pillar Score (1.0 - 7.0)	Readiness Level	Strategic Recommendations & Actions	Target Stakeholder
< 3.0	Critical / Lagging	Immediate investment in foundational literacy. Implement mandatory change management workshops and staff upskilling.	HR & Top Management
3.1 – 4.5	Emerging	Focus on "Policy and Governance." Establish clear SLA standards and cybersecurity protocols. Seek external funding/grants.	IT Managers & Legal
4.6 – 5.9	Intermediate	Optimize technical compatibility. Migrate mission-critical apps to hybrid models. Enhance data disaster recovery tests.	System Architects
> 6.0	Strategic / Ready	Scaling and Innovation. Focus on AI integration and advanced data analytics. Act as a "Cloud Mentor" for other sectors.	CTO & Government

B. Limitations and Future Work

Although the SCARI framework provides a context-sensitive mechanism for evaluating organizational cloud readiness in Ghana, several limitations should be acknowledged. First, the pilot study utilized a relatively small sample (N = 30), which limits the statistical generalizability of the findings and prevents comprehensive psychometric validation of the instrument. Future research should employ larger multi-sector and multi-regional samples to enable confirmatory factor analysis, structural equation modeling, and cross-sector comparative analysis.

Second, the current framework was evaluated primarily within the Agriculture, Health, and Education sectors. Additional validation is required within highly regulated sectors such as finance, telecommunications, mining, and government digital services, where cybersecurity, sovereignty, and compliance requirements differ substantially.

Third, the weighting structure of the SCARI index was derived from literature-informed theoretical assumptions rather than empirical optimization techniques. Future studies should investigate data-driven weighting approaches using machine learning, fuzzy logic systems, or Analytic Hierarchy Process (AHP) methodologies.

Fourth, cloud adoption environments evolve rapidly due to advances in AI-enabled cloud services, edge computing, sovereign cloud architectures, and cybersecurity regulations. Consequently, periodic recalibration of the framework will be necessary to maintain relevance.

Finally, future research should investigate advanced scalability strategies, including federated cloud governance models, domain adaptation techniques, and multi-center validation studies across African institutions to improve the generalizability and interoperability of the SCARI framework. Because the study was designed as a preliminary pilot validation, advanced psychometric procedures such as Exploratory Factor Analysis (EFA), Confirmatory Factor Analysis (CFA), composite reliability analysis, and inter-item correlation assessment were deferred to future large-scale validation studies.

V. CONCLUSION

The Strategic Cloud Adoption Readiness Index (SCARI) framework represents a significant departure from "one-size-fits-all" IT models. By synthesizing the TOE framework and HOT-fit theory, this study addresses the multifaceted challenges of Ghana's digital transformation—ranging from infrastructure deficits to the critical "Human" readiness gap. The pilot study results confirm that while technical sophistication is growing, organizational culture and human skill sets remain the primary bottlenecks to adoption. The proposed weighted scoring system and strategic recommendation matrix (Table IV) offer Ghanaian policymakers and CTOs a pragmatic, evidence-based roadmap to mitigate risks and optimize operational efficiency. In the final analysis, it is targeted leadership support for bridging the "readiness gap" by staff upskilling that will mark the successful transition of Ghana into a cloud-integrated economy.

Perceived Usefulness Without Ease of Use: A TAM-Based Evaluation of Enhanced Isabela State University Echague Online Resource App for a New Guild of Education (ISUE ORANGE) Functionalities

Ricardo Q. Camungao
College of Computing Studies, Information and Communication Technology, Isabela State University, Isabela, Philippines

***Abstract*—This study introduced a target enhancement for ISUE ORANGE, a customized learning management system (LMS) at Isabela State University (ISU)-Echague Campus, developed to address the post-2022 implementation challenges, specifically in progress tracking and exam integrity, through features such as question analytics, monitoring student reading progress, and online proctoring/examination. Modules were designed based on user-reported issues, and evaluated through the Technology Acceptance Model (TAM) with 145 students and 18 faculty using a 30-item Likert-scale questionnaire. Both groups demonstrated a strong acceptance with rating "strongly agree" on high perceived ease of use (PEOU) (grand means 4.56–4.65) and perceived usefulness (PU) (4.62–4.75), particularly for monitoring tools, indicating strong acceptance despite the atypical TAM path in this mature, localized context. Cronbach's Alpha (CA) confirmed excellent reliability (0.85–0.97), while the structural equation method (SEM) tested PU = γ_1 PEOU + ζ, revealing non-significant paths (β=0.118–0.145, $p>0.05$), supporting the null hypothesis (H_0). The research demonstrated faculty-led innovation for ISUs or SUCs, with direct PU driving adoption over ease, offering a scalable model for hybrid learning sustainability.**

Keywords*—ISUE ORANGE; learning management system; Technology Acceptance Model; perceived ease of use; perceived usefulness; structural equation modeling; Cronbach's Alpha; question analytics; reading progress monitoring; exam proctoring; SUCs; faculty-led innovation

I. Introduction

The shift from traditional to online instruction, accelerated by the COVID-19 pandemic, fundamentally changed how students and faculty manage learning in higher education institutions (HEIs). In the absence of face-to-face classes, information and communication technology (ICT) tools became the primary vehicle for delivering instruction. HEIs without customized learning management systems (LMS) turned to platforms such as Edmodo, Schoology, and Google Classroom, while mobile technologies like Facebook, Messenger, and text messaging served as supplementary channels for communication and monitoring student visibility. These tools proved critical for maintaining the flow of knowledge and skills outlined in course syllabi. However, a significant gap persisted: none of these platforms offered faculty a built-in mechanism to track whether students had actually read the uploaded learning materials, a function essential for confirming learner engagement and categorizing learning performance before assessments.

This gap, together with the need to adopt functionalities from Google Classroom and Edmodo that fit the university's specific instructional delivery processes, served as the impetus for designing and developing the Isabela State University Echague Online Resources App for a New Guild of Education (ISUE ORANGE). ISUE ORANGE was a web-based, unified learning management system customized for ISU, featuring sign-in, announcements, classes, modules, classwork, gradebook, and student progress tracking. The development was conducted last August, 2021, using a consultative process with the faculty from the College of Computing Studies, Information and Communication Technology (CCSICT)–Echague, incorporating the observations and recommendations into the system before pilot testing (Second Semester of 2020–2021). Issues were encountered during pilot testing. Further refinements and a User's Training held on December 13–17, 2021, to yield positive feedback and suggestions. Based on the refinement process, ISUE ORANGE was deployed campus-wide beginning in the first semester of 2022.

As expected with any campus-wide implementation, post-deployment challenges emerged. Faculty encountered difficulties with team teaching arrangements, managing student classwork, and, most critically (3) three persistent operational problems: the inability to confirm whether students had read learning materials before assessments, time-consuming manual tallying of correct and incorrect answers that reduced faculty productivity, and concerns about cheating during unmonitored online examinations. Students, for their part, perceived uneven assessment conditions without proctoring and received scores without meaningful feedback on specific item performance. These issues signaled that the first version of ISUE ORANGE, while functional, had not yet reached its full potential in supporting the hybrid learning environment on the campus.

Recognizing that a customized LMS offered the advantage of continuous, targeted improvement, unlike generic commercial platforms, the researcher undertook the design and development of ISUE ORANGE enhancements to directly address these reported issues. Following the Rapid Application Development (RAD) model within the System Development Life Cycle (SDLC) framework, three new modules were developed: question analytics to enable faculty analysis of item

difficulty based on correct and incorrect response counts, monitoring of student reading progress with idle-time detection to verify actual engagement with uploaded materials, and online proctoring/examination to enforce exam-session integrity and reduce opportunities for cheating. RAD was selected for its emphasis on rapid prototyping and iterative refinement, allowing the research team to move from feedback collection through analysis, quick design, development, testing, and deployment in cycles responsive to actual user needs.

Beyond development, however, the critical question was whether these enhancements would actually be accepted and used by the intended users. To answer this, the study employed the Technology Acceptance Model (TAM) as its evaluation framework. TAM, originally proposed by Davis (1989), posits that two core beliefs, the perceived ease of use (PEOU) and perceived usefulness (PU), are the primary determinants of technology adoption. A 30-item Likert-scale questionnaire was administered to 145 students and 18 faculty members to evaluate their perceptions of the three new functionalities. Cronbach's Alpha (CA) was used to assess internal consistency of the instrument, while structural equation modeling (SEM) tested the causal path from PEOU to PU ($PU = \gamma_1 PEOU + \zeta$), examining whether ease of use significantly influenced perceptions of usefulness in this specific, localized LMS context.

This methodological design was deliberate. While TAM has been extensively validated in studies of commercial and generic LMS platforms, its application to a faculty-developed, institution-specific system operating in a mature post-deployment phase, where users are already familiar with the platform, represents a less conventional but increasingly relevant research context. The study hypothesized (H_0) that PEOU does not have a significant effect on PU of the ISUE ORANGE enhanced functionalities, testing whether the canonical TAM assumption holds in a setting where users have moved past initial adoption hurdles and where usefulness may be driven more by direct productivity gains from specific features than by ease of navigation.

The study thus pursued two specific objectives: 1) to design and develop modules addressing the problems encountered as enhancements to ISUE ORANGE functionalities using the RAD model, and 2) to evaluate user acceptance of the newly developed functionalities using TAM, specifically assessing perceived usefulness and perceived ease of use and testing the PEOU → PU structural path. The use of TAM in this evaluation showcases faculty-driven innovation tailored for ISU and other state universities and colleges (SUCs), where perceived usefulness may outweigh ease of use in driving adoption, offering a scalable and replicable framework for sustaining hybrid learning beyond the pandemic context.

II. Literature Review

A review in January 2017 reported that in the Philippines alone, there are an estimated 40 million social network users this year [2]. Filipinos spend more time on social media than any other nationality worldwide, averaging 4.17 hours daily and ranking the Philippines among the top users of social networking sites (SNS). Additionally, nearly 93% of public schools nationwide were equipped for online learning during the 2020-2021 school year [3].

Since March 2020, after the COVID-19 virus turned into a worldwide pandemic [4], many public and private institutes, including schools and universities, were closed across the countries. In June 2020, the Ministry of Higher Education (MoHE) came up with a countrywide learning management system project called HELMS (Higher Education Learning Management System), which is a web-based service used as a tool to assist universities in different functions like managing, delivering, planning, and tracking the learning and teaching process. It was introduced as a primary medium for education during the pandemic. After a large-scale and meticulous analysis through interviews. The result proves that e-learning adoption has not been considered as a priority for the Ministry of Higher Education (MoHE), and they have not anticipated the situation, such as countrywide quarantine, under which online learning should be replaced with onsite education. It also found that the absence of an inclusive policy and guideline for management and use of the system has also affected the quality aspects of the HELMS. The findings of this research were consistent with the results from previous studies [1][5][6][7][9].

This led to examining the factors of the Filipino college students' behavioral intention to use LMS as part of their education journey from the constructs of integrated multimedia instruction, perceived quality work-life, system interactivity, and internet connectivity experience, perceived ease of use, perceived usefulness, and social media influence. The aim of this study was to discover the factors that influence college students' acceptance of e-learning technology, specifically LMS, as a reinforcement of the teaching and learning process in Philippines. As a result, the study discovered that internet communication experience has a positive relationship with perceived ease of use and behavioral intention; it also discovered that system interactivity has a positive relationship with perceived usefulness, but contrary to system interactivity, there is no clear evidence that it also affects the perceived quality of work life. The interaction within the system (learner–interface, learner tool, learner-task, learner-content, learner-instructor, and learner-student) undoubtedly resolves one of the established weaknesses of eLearning, which is the absence of face-to-face interaction. And the results are also meant to serve as one of the pioneers that offer information on e-learning acceptance in the Philippines [10].

One of the new tools available was released by Google under GSuite. The Pangasinan State University is currently subscribed to GSuite for Education, and recently, Google introduced Classroom as an eLearning platform for educational institution. This research aims to evaluate the new product, and its functionalities for the purpose of adapting and deployment. The main objective of this study is to identify the usability and evaluation of the Learning Management System (LMS) Google Classroom, its functionalities, features, and satisfaction level of the students. As a result, Google Classroom plays a great role in making learning more easy. Based on the usability evaluation of the platform, Google Classroom is extremely useful in understandability, attractiveness, and operability. Although the platform is useful for non-academic activities, it is especially useful for assignments and collaborative learning. It is suggested that you test in a fully online environment. As the study collects more data, it is also recommended to assess other problems

based on the data, such as the relationship between the profile and the platform's level of usability. This study is also recommended to continue collecting data for future studies [8][11].

They utilized the Technology Acceptance Model (TAM) to examine factors driving Learning Management System (LMS) adoption in higher education. Their systematic review found perceived usefulness (PU) and perceived ease of use (PEOU) as the strongest, most consistent predictors of acceptance. Key external variables—digital self-efficacy, system quality, institutional support, and social influence—also proved essential determinants. These results validate TAM's ongoing applicability in edtech while underscoring the value of incorporating context-specific and organizational elements to enhance model precision and foster long-term LMS utilization [12].

Cronbach's Alpha evaluated the research instrument consistency for constructs like attitudes and knowledge. This study assesses engineering students' (n=25) perceptions of online Calculus across course content and instructor effectiveness dimensions. Overall alpha=0.83 indicates good reliability per Nunnally's standards (>0.7 acceptable), though specific items need refinement for enhanced internal consistency in LMS perception surveys [13].

Examined the factors influencing student LMS adoption at the GITAM University Bengaluru to enhance pedagogy in higher education. Data from UG/PG students via online questionnaires tested an extended TAM model incorporating PU, PEOU, attitude, behavioral intention (BI), actual use (AU), plus student education (SE), perceived self-efficacy (PSE), and system quality (QoS). Cronbach's Alpha exceeded 0.7 and AVE >0.5 across constructs. Seven of ten hypotheses were supported; non-significant paths included PEOU→PU, PSE→PU, and SE→PEOU. BI strongly predicted AU, driven by PEOU and PU, offering insights for stakeholders on Moodle optimization [14].

III. Materials and Methods

A. Methodology

To enhance the functionalities of ISU ORANGE, the researcher applied the System Development Life Cycle (SDLC) by using the Rapid Application Development (RAD) model, as shown in Fig. 1 below. RAD was a software development methodology that used minimal planning in favor of rapid prototyping. A prototype was a working model that was functionally equivalent to a module of the system.

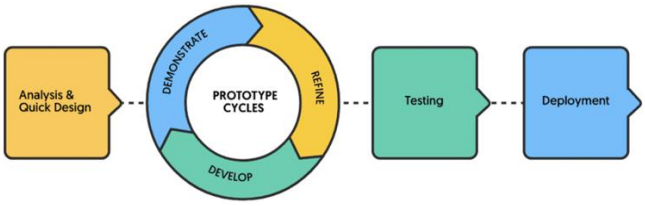

Fig. 1. Rapid application development framework

The collection began when issues were encountered by both faculty and students in using the system, and it was systematically gathered by the researcher. Feedback mechanisms were facilitated through integrated social media platforms such as Facebook and Messenger, ensuring accessibility and real-time communication. Additionally, user training sessions were conducted prior to the start of each semester to refresh faculty members on system functionalities and to collect their insights regarding system usability and challenges.

1) Analysis and quick design: The development team formulated solution strategies based on the identified issues. A series of collaborative meetings was conducted to review existing system processes and identify areas for improvement. Guided by RAD principles, initial design solutions and prototypes were rapidly developed using available software and hardware development tools, enabling immediate visualization and refinement of system enhancements.

2) Testing phase: The development, refinement, and testing phase involved the iterative construction and improvement of system modules. Proposed solutions were translated into a functional code, followed by simulations and demonstrations to validate system performance. These prototypes were presented to end-users—faculty and students—to gather feedback and ensure that the enhancements effectively addressed identified concerns. Continuous refinement was undertaken based on user evaluation, reflecting the cyclical nature of the RAD approach.

3) Deployment phase: The implementation of the refined system was conducted in its actual working environment. Enhanced modules were installed and integrated into the operational platform, ensuring accessibility and functionality for all users. Consistent with RAD principles, deployment was not considered the endpoint but part of an ongoing cycle of evaluation and improvement to sustain system effectiveness and user satisfaction.

B. Research Model

Fig. 2 illustrated the concept flow of the study. The developmental phase was the collection of data, where it involves data gathering through conducting user's satisfaction in using the first version of the ISUE ORANGE. User's feedbacks and issues were sent through the ISUE ORANGE messenger account and conducted literature reviews on the possible enhancements of the functionalities. Data gathered was analyzed and interpreted to devise solution strategies leading to the development of the algorithms to satisfy the identified problems. The design and development of the functionalities were realized through using software and hardware development tools. The developed modules were uploaded in the ISUE ORANGE to eventually enhance the services provided to the target users. The last phase was the evaluation and analysis phase which covers the evaluation of the user's perception on the user's perceived of usefulness and ease of use using the Technology Acceptance Model (TAM). In addition, the evaluation does not cover the impact of the functionalities towards the management of learning like comparison on the face-to-face versus online examination.

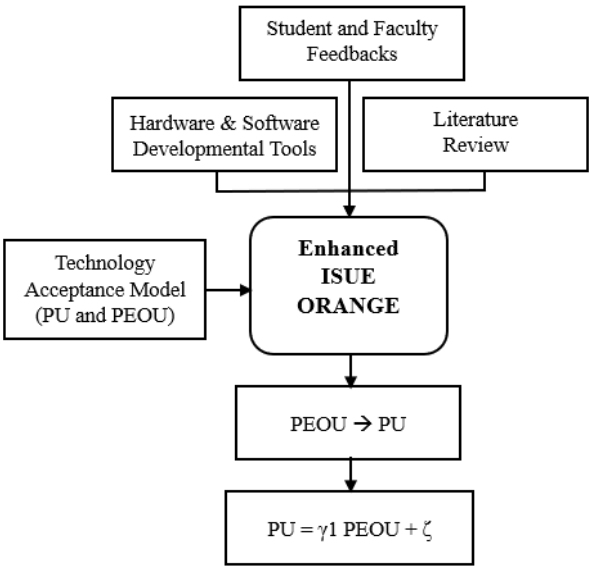

Fig. 2. Research model of the study.

The TAM evaluation framework, presented in Fig. 3, outlined user adoption of the ISUE ORANGE. It underpinned the assessment by measuring key factors that predict usage and effectiveness in the delivery of instruction. The ISUE ORANGE was a homegrown learning management system tailored for the delivery of instruction processes of the Isabela State University, with key features like virtual class creation and activity monitoring. TAM evaluates its success by surveying users on usefulness (teaching efficiency) and ease of use (user friendliness), informing training improvements as seen in faculty workshops conducted.

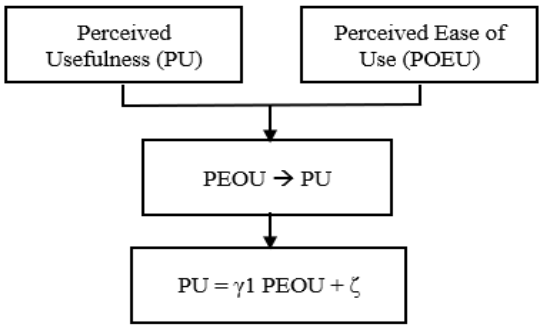

Fig. 3. TAM evaluation framework

Table I presents the alignment of constructs, indicators, and analysis. Key constructs from the TAM were applied to evaluate the enhancements of ISUE ORANGE, focusing on question analytics, monitoring of students' reading progress, and online examinations. Each construct (PEOU and PE) has separate indicators for faculty and students. Data was gathered from the survey questionnaire and captured as ordinal through a 5-point Likert scale: 1=Strongly Disagree, 2=Disagree, 3=Neutral, 4=Agree, and 5=Strongly Agree, and analyzed using reliability like Cronbach's Alpha (CA) for internal consistency, plus a Structural Equation Model (SEM) to determine how PEOU affects the usage intention of the users.

TABLE I. ALIGNMENT OF CONSTRUCTS, INDICATORS AND ANALYSIS

Constructs	**Indicators** (5-point Likert scale)	**Data Type**	**Analysis**
Perceived Ease of Use (PEOU)	***Faculty*** Easy to use in learning the question analytics feature. Easy access report on students' reading time, online examination tools are easy to use.	Ordinal	Reliability (Cronbach's Alpha and Structural Equation Model)
	Student Question analytics, monitoring of reading progress and online examination features are easy to use.		
Perceived Usefulness (PE)	***Faculty*** Useful in enhancing assessment practices, useful in teaching and student's learning, useful in teaching.	Ordinal	Reliability (Cronbach's Alpha and Structural Equation Model)
	Student Question analytics is useful for my learning, useful in helping me keep up with the course, allows to take the test in a convenient way.		

The Cronbach Alpha was used for reliability assessment, and the SEM for TAM validation strengthens the methodological rigor offering a limited novelty, as these were standard practices in technology acceptance research. The methodological role of the CA in the research measured the internal consistency of TAM's constructs, with values above 0.7 indicating reliable scales. The SEM on the other hand, tests causal relationships in TAM, confirming that model fit below 0.08 and paths like ease of use to usefulness, as presented in Fig. 3, a frequent approach in educational technology validation:

$$PU = \gamma_1 PEOU + \zeta \quad (1)$$

where, PU – dependent variable measuring user's belief that the enhancements of ISUE ORANGE are useful both for the faculty and students, γ_1 (gamma 1) – Standard path coefficient, PEOU – Exogenous predictor capturing perceived effortlessness of the enhancements, ζ - error term (<0.005).

With these, the study attempted to prove the hypotheses (faculty and students) below:

H_0: Perceived ease of use (PEOU) does not have a significant effect on perceived usefulness (PU) of the ISUE ORANGE enhanced functionalities among respondents.

IV. RESULTS AND DISCUSSION

Table II shows how the ISUE ORANGE functionalities evolved, keeping all essential classroom tools such as class dashboards, class creation, uploading and downloading of learning materials, quizzes, announcements and gradebook, while adding three new functionalities that the first version lacked. These enhancements were directly addressed what faculty and students encountered during the implementation of the first version. Faculty dealt with no way to confirm if students actually read materials before assessments, time-consuming manual tallying of correct/incorrect answers that hurt productivity, and cheating concerns from unmonitored online

exams. Students, meanwhile, felt that the playing field was uneven without proctoring and got scores without useful feedback on *why* they missed specific questions. These led on the development of added functionalities of ISUE ORANGE.

TABLE II. COMPARISON OF ISUE ORANGE TO ENHANCED ISUE ORANGE BASED ON THEIR FUNCTIONALITIES

Functionalities	ISUE ORANGE	Enhanced ISUE ORANGE
Course Classes Dashboard	Existing	Existing
Creating Classes	Existing	Existing
Uploading/Downloading Learning Materials	Existing	Existing
Learning Materials Preview	Existing	Existing
Classwork List	Existing	Existing
Multi – format Quizzes and Assignments Creation	Existing	Existing
Announcement	Existing	Existing
Question analytics	Not Existing	Existing
Student reading progress	Not Existing	Existing
Flexible gradebook and grading system	Existing	Existing
Course Overview	Existing	Existing
Proctoring online examination	Not Existing	Existing

A. ISUE ORANGE 2.0 Enhancements

The question analytics were featured and presented in Fig. 4, allowing faculty to view and analyze the number of students who answered correctly or incorrectly and provide information to faculty regarding the level of difficulty of each item in the exam. This was supported by informed decisions, such as eliminating questions based on assessment rules. Ultimately, it improved the quality of student examinations.

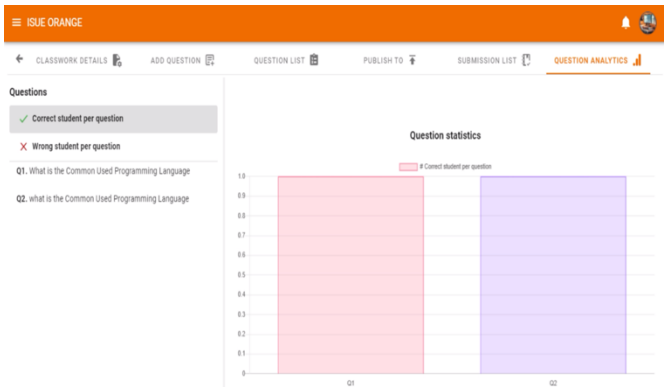

Fig. 4. Question analytics

This feature enabled the faculty to track the time students spend reading uploaded modules. It also detected the student idle time that if no scrolling occurred for 5 minutes, accumulated reading time pauses. Students must meet or exceed the faculty-set maximum reading time for green compliance highlights (aligning with syllabus timelines for skill and knowledge delivery); otherwise, red highlights indicate noncompliance, as shown in Fig. 5.

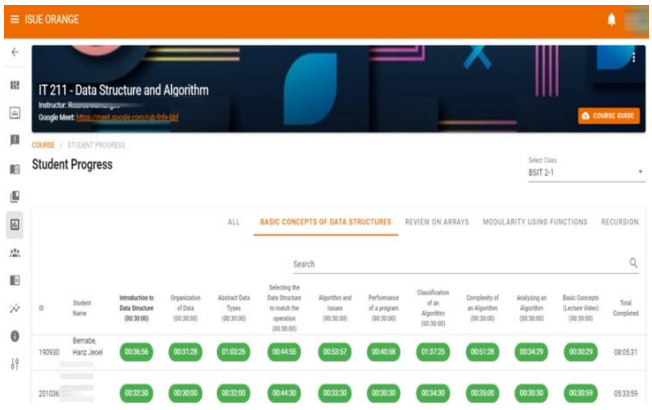

Fig. 5. Monitoring of reading progress by the faculty.

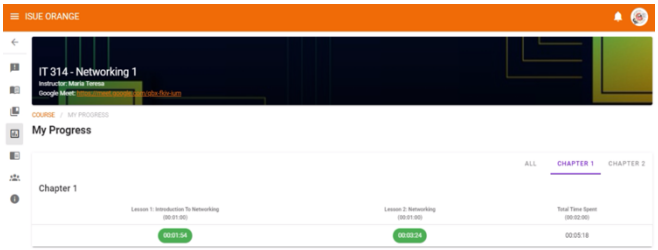

Fig. 6. Monitoring of reading progress by the student.

Fig. 6, shows a progress page in an online course where students can determine how far they have gone in each lesson within a chapter. It displays each lesson in a row, marks completed lessons with clear green labels, and shows the total time spent, so students and teachers can monitor study efforts.

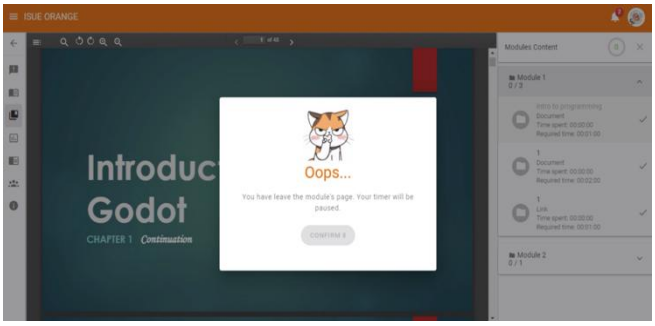

Fig. 7. Track students idle time in reading module.

Fig. 7 presents a module viewer interface within a learning management system displaying a slide-based learning object, overlaid by a modal dialog that manages time-on-task tracking. The central pop-up, triggered when the learner navigates away from or becomes inactive on the module page, communicates that session timing was paused to prevent inflating engagement metrics with idle time. The dialog included a confirmation button that, when activated, resumes or acknowledges the state change, while the underlying layout showed standard viewer controls and a side panel listing additional modules or activities, indicating integration of the time-tracking logic with the course's structured content hierarchy.

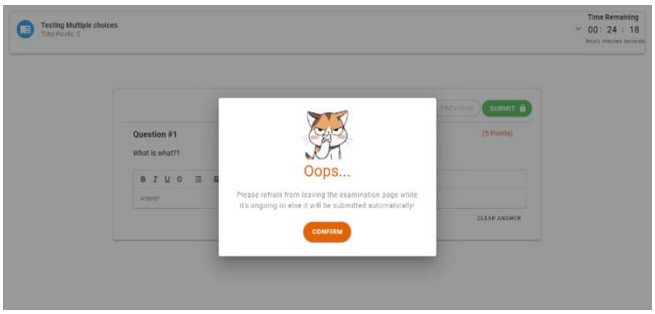

Fig. 8. Monitor student activities in taking exam.

Fig. 8 presents the online assessment interface of ISUE ORANGE in which a modal dialog was programmatically triggered on top of the quiz viewport. The underlying layer shows the active item, response editor, and countdown timer, while the modal enforces exam-session integrity by warning that navigating away from the assessment context was invoked automatic submission of the current attempt. This privilege provided the mechanism to lessen the act of cheating while taking the exam.

B. TAM (PEOU and PU) Evaluation Results

The evaluation on the user's perceived ease of use and usefulness on the enhancements was done on the conducted user's training both for faculty and students. There were 145 students and 18 faculty members who rated the question analytics, monitoring of students reading progress and online examination features of the system.

TABLE III. PERCEIVED EASE OF USE (FACULTY)

Enhancements	Mean	Descriptive Rating
1. Question analytics	4.55	Strongly Agree
2. Monitoring of student reading progress	4.59	Strongly Agree
3. Monitoring of online examination	4.53	Strongly Agree
Grand Mean	**4.56**	**Strongly Agree**

Table III shows that the faculty strongly agree that ISUE ORANGE enhancements like question analytics, reading progress tracking, and online exam monitoring are easy to use, with an overall average of 4.56 on the 5-point scale (where 4.21–5.00 means "Strongly Agree"). This beats typical LMS benchmarks for smooth adoption, like scores above 4.0 that signal high intent to keep using it, fully backing Davis's TAM idea that ease of use sparks real-world commitment.

These steady top scores (all over 4.5) highlight how intuitive these tools are for ISU faculty in hybrid setups which lighten the mental load of preparing assessments, checking student progress, and managing modules to make teaching more efficient and less overwhelming.

Table IV reveals the faculty giving top marks to how useful ISUE ORANGE's enhancements like question analytics, reading progress tracking, and online exam monitoring which truly are for their teaching, with an overall average of 4.75 on the 5-point scale (where 4.21–5.00 means "Strongly Agree"). This past standard TAM benchmarks for strong usefulness, such as scores above 4.3 that tie to 80%+ adoption in LMS research, positioning usefulness as the key factor over ease of use in Davis's model is directly fueling ongoing use and better teaching outcomes. The highest ratings, reaching 4.82 for tracking reading progress and exams, show how these tools empower faculty at the Isabela State University to keep real-time tabs on students effortlessly in hybrid classes while cutting down on manual checks, spotting issues early with data insights, and ramping up efficiency way beyond basic LMS options.

TABLE IV. PERCEIVED USEFULNESS (FACULTY)

Enhancements	Mean	Descriptive Rating
1. Question analytics	4.61	Strongly Agree
2. Monitoring of student reading progress	4.82	Strongly Agree
3. Monitoring of online examination	4.82	Strongly Agree
Grand Mean	**4.75**	**Strongly Agree**

TABLE V. PERCEIVED EASE OF USE (STUDENT)

Enhancements	Mean	Descriptive Rating
1. Question analytics	4.50	Strongly Agree
2. Monitoring of student reading progress	4.72	Strongly Agree
3. Taking online examination	4.73	Strongly Agree
Grand Mean	**4.65**	**Strongly Agree**

Table V reveals that students strongly agree that ISUE ORANGE's enhancements such as question analytics, reading progress tracking, and online exams are easy to navigate, with an overall average score of 4.65 on the 5-point scale (where 4.21–5.00 means "Strongly Agree"). This tops typical TAM benchmarks for smooth adoption, such as scores above 4.2 that signal strong intent to keep using it, as outlined in Davis's model. The standout ratings, hitting 4.73 for exams and progress checks, show how these tools lower mental hurdles for everyday student tasks in the Isabela State University's hybrid setup—making learning feel more natural and less clunky than standard LMS platforms.

TABLE VI. PERCEIVED USEFULNESS (STUDENT)

Enhancements	Mean	Descriptive Rating
1. Question analytics	4.53	Strongly Agree
2. Monitoring of student reading progress	4.68	Strongly Agree
3. Taking online examination	4.66	Strongly Agree
Grand Mean	**4.62**	**Strongly Agree**

Table VI shows students giving a big thumbs-up to how useful ISUE ORANGE's enhancements like question analytics, reading progress tracking, and online exams for their learning, with an overall average of 4.62 on the 5-point scale (where 4.21–5.00 means "Strongly Agree"). This beats standard TAM benchmarks for solid usefulness, like scores over 4.3 that predict students was stick with it long-term and see real performance boosts, based on Davis's original model. Top scores of 4.68 for tracking reading progress back this up, proving these tools help students tackle everyday hurdles like keeping tabs on classwork from afar or staying on pace in hybrid classes at ISU—sparking

real motivation by making schoolwork feel more doable and rewarding.

C. Cronbach's Alpha Results

A reliability analysis was conducted to determine the internal consistency of the questionnaire administered to 145 students and 18 faculty.

TABLE VII. RELIABILITY ANALYSIS USING CRONBACH'S ALPHA RESULTS FOR FACULTY RESPONSES.

Construct	No. of Items	Cronbach's Alpha	Interpretation
Perceived Usefulness (POU)	15	**0.94**	Excellent reliability
Perceived Ease of Use (POEU)	15	**0.853**	Very Good reliability
Overall Instrument	30	**0.932**	Excellent reliability

Table VII presents the reliability analysis, which revealed excellent internal consistency for the Perceived Usefulness construct ($\alpha = 0.940$) and very good reliability for Perceived Ease of Use ($\alpha = 0.853$). The overall instrument demonstrated excellent reliability ($\alpha = 0.932$), indicating that the questionnaire is highly consistent and suitable for further inferential analysis.

TABLE VIII. RELIABILITY ANALYSIS USING CRONBACH'S ALPHA RESULTS FOR STUDENT RESPONSES.

Construct	No. of Items	Cronbach's Alpha	Interpretation
Perceived Usefulness (POU)	15	**0.90-0.95**	Excellent reliability
Perceived Ease of Use (POEU)	15	**0.88-0.93**	Very Good reliability
Overall Instrument	30	**0.93-0.97**	Excellent reliability

The results in Table VIII show that the Perceived Usefulness construct demonstrated excellent reliability ($\alpha \approx 0.92–0.95$), while the Perceived Ease of Use construct showed very good to excellent reliability ($\alpha \approx 0.88–0.93$). The overall instrument yielded an excellent Cronbach's Alpha coefficient ($\alpha \approx 0.94–0.96$), indicating that the questionnaire is highly reliable and suitable for inferential statistical analysis.

D. Structural Equation Modeling Results

TABLE IX. CONSOLIDATED STRUCTURAL EQUATION MODELING

Group	B	R^2	p-value	Interp.	Decision
Students	0.118	0.014	0.163	Not Significant	Fail to Reject H_0
Faculty	0.145	0.044	0.214	Not Significant	Fail to Reject H_0

Table IX presents the structural equation modeling results. It revealed that the structural path from Perceived Ease of Use to Perceived Usefulness was not statistically significant for both students ($\beta = 0.118, p = 0.163$) and faculty ($\beta = 0.145, p = 0.214$). The low R^2 values (0.014 and 0.044, respectively) indicate weak predictive capability of the model, suggesting that Perceived Ease of Use is not a significant determinant of Perceived Usefulness in the context of ISU ORANGE enhancement functionalities. Moreover, in designing the future ISUE ORANGE evaluation instruments around enhancement functionalities, it is suggested to build a model where PU is predicted by system quality, information quality, service support, compatibility, and effectiveness with PEOU as a secondary or control variable rather than a primary predictor.

V. IMPLICATIONS

The findings revealed the distinct yet interrelated implications for students, faculty, administrators, and stakeholders, particularly in sustaining hybrid learning through ISUE ORANGE. For students, the high grand mean scores in Perceived Usefulness (PU) and Perceived Ease of Use (PEOU) indicated an enhanced learning support, enabling greater focus on understanding module content, tracking assigned readings, and completing online assessments. The system's features further promote self-paced learning by allowing students to monitor their engagement and academic performance, thereby fostering independent learning and facilitating timely academic recovery. Moreover, the combination of usability and functionality contributes to increased student engagement, resulting in more consistent participation in online tasks and improved involvement in hybrid learning environments.

For faculty members, the results indicated an improved efficiency in assessment-related tasks. Strong PU ratings suggest that ISUE ORANGE reduces the effort required in the preparation, administration, and evaluation of assessments, thereby allowing faculty to allocate more time to feedback provision and instructional design. In addition, integrated analytics and monitoring tools support data-informed teaching practices by providing concrete evidence of student performance and learning gaps, enabling targeted and timely interventions. The consistently high PU and PEOU scores also imply a strong likelihood of sustained system utilization, indicating that faculty are inclined to integrate ISUE ORANGE into regular instructional practices beyond emergency remote teaching contexts, thus reinforcing ongoing digital transformation.

From an administrative perspective, the findings provided empirical support for policy development and strategic decision-making. The positive Technology Acceptance Model (TAM) results were justified by the continued investment in, scaling of, and refinement of ISUE ORANGE, including enhancements in training, infrastructure, and system integration, rather than adopting generic learning management systems. The results also informed the design of faculty development programs by identifying features that were already effective and areas that require further capacity building. Furthermore, the documented levels of usefulness and ease of use support institutional efforts in accreditation and quality assurance, as these align with outcomes-based education (OBE) principles, student performance monitoring, and the digitalization requirements of accrediting bodies.

For stakeholders, the study positions ISUE ORANGE as a model of state university and college (SUC)-led innovation. It demonstrates that a locally developed learning management system, grounded in the Technology Acceptance Model, can meet or exceed adoption benchmarks commonly associated with commercial platforms, thereby strengthening ISU's identity as a technology-enabled institution. The findings also highlight the system's scalability and transferability to other campuses or

partner institutions with similar instructional delivery contexts. Finally, the quantitative evidenced on PU and PEOU provides a compelling accountability and impact narrative, illustrating that investments in ISUE ORANGE yield measurable benefits in teaching and learning processes, an essential consideration for budgeting, grant acquisition, and long-term strategic planning.

VI. Conclusion

The ISUE ORANGE enhancements effectively developed to address the post-2022 implementation challenges at ISU–Echague Campus, with 145 students and 18 faculty members demonstrating strong acceptance of the updated LMS. This acceptance was underpinned by robust measurement properties, as shown by high CA coefficients and a contextually grounded SEM aligned with established TAM literature.

Key functionalities including question analytics (Fig. 4), reading progress and idle-time monitoring (Fig. 5 to Fig. 7), and online proctoring/examination (Fig. 8) were perceived as particularly beneficial in supporting teaching and learning. Both students and faculty rated perceived ease of use at 4.56–4.65 and perceived usefulness at 4.62–4.75 ("Strongly Agree"), with monitoring tools obtaining the highest mean scores, indicating strong practical value in a hybrid learning environment.

The reliability analysis were yielded Cronbach's Alpha values between 0.85 and 0.97 across constructs, indicating good to excellent internal consistency and exceeding the commonly accepted 0.80 threshold for strong reliability. These coefficients justify the use of the 30-item instrument for both student and faculty samples and support its application in inferential analyses.

SEM results showed that the PEOU → PU path was non-significant for both groups (students: $\beta = 0.118$, $p = 0.163$; faculty: $\beta = 0.145$, $p = 0.214$; $R^2 < 0.05$), diverging from the canonical TAM assumption that ease of use substantially influences perceived usefulness. In a mature and familiar LMS context such as ISUE ORANGE, this pattern suggests that perceived usefulness is driven less by ease and more by direct productivity and performance gains afforded by specific features, consistent with findings that PU often dominates as the primary predictor of system acceptance in established technologies. Consequently, the null hypothesis (H_0: PEOU has no significant effect on PU) is supported in this setting.

Despite very high descriptive ratings for perceived usefulness among both students and faculty, the low variance was explained in the structural model which indicates that additional determinants beyond ease of use may be shaping perceptions of usefulness. This highlights that high mean scores alone was insufficient to claim full system effectiveness; a more comprehensive evaluation incorporating behavioral intention, actual usage, learning outcomes, and system performance metrics was necessary to substantiate long-term acceptance and educational impact, in line with extended TAM and LMS effectiveness research.

A Multilayer Secure Image Steganography Framework Using Edge-Adaptive Embedding and Pre-Encryption

A F M Zainul Abadin[1], Rossilawati Sulaiman[2]*
Center for Cyber Security-Faculty of Information Science and Technology,
Universiti Kebangsaan Malaysia, Bangi, Selangor, 43600, Malaysia[1, 2]
Dept. of Information and Communication Engineering, Pabna University of Science and Technology, Pabna-660, Bangladesh[1]

***Abstract*—High-capacity image steganography aims to conceal large volumes of data while preserving imperceptibility and resistance to statistical and visual detection. This study proposes a multilayer secure image steganography framework using edge-adaptive embedding and pre-encryption. The method utilizes multiple edge detectors, namely Canny, Laplacian of Gaussian (LoG), and Prewitt, to accurately classify edge and non-edge regions, enabling efficient use of high-tolerance embedding areas. A Bee Colony Footprint Edge Optimization (BCFEO) algorithm is employed to select optimal embedding locations through a distortion-aware adaptive process, improving payload distribution under varying capacity conditions. For enhanced security, the secret message is encrypted prior to embedding using AES in Counter (CTR) mode, ensuring confidentiality without altering payload size and allowing exact recovery. A 5-LSB filtering mechanism is applied during preprocessing to reduce redundancy and control embedding distortion. The proposed framework is evaluated on a set of several 256×256 resized RGB images, including benchmark images from the USC-SIPI database and independently captured natural images, using standard performance metrics such as PSNR, SSIM, NCC, UIQI, and statistical steganalysis techniques. Experimental results demonstrate that the method achieves high embedding capacity with minimal visual degradation and improved performance compared to conventional edge-based approaches. The integration of adaptive optimized embedding and pre-encryption provides an efficient and reliable solution for secure image-based communication systems. The broader validation using larger datasets, different image resolutions, and more diverse image categories remains a future research direction.**

Keywords*—Image steganography; AES-CTR encryption; hybrid edge detection; edge-adaptive embedding; BCFEO nature-inspired optimization; statistical steganalysis

I. Introduction

With the rapid growth of digital communication, protecting sensitive information has become critical. While cryptography secures content, it does not hide the presence of communication, making it vulnerable to suspicion [1],[2]. Image steganography addresses this limitation by embedding data imperceptibly within images for covert communication [3]. A key challenge in image steganography is achieving a high payload capacity without compromising visual imperceptibility and statistical security [4]. Conventional least significant bit (LSB)-based schemes offer simplicity, but suffer from limited robustness and vulnerability to steganalysis when embedding capacity is increased [5]. To address this limitation, edge-based steganography has been widely investigated, as edge regions exhibit higher intensity variations and can tolerate larger embedding distortions compared to smooth areas. However, many existing edge-based methods rely on a single edge detector or fixed embedding rules, which restrict adaptability and lead to suboptimal payload distribution [6].

Another critical limitation in existing approaches is the insufficient integration of optimization-driven embedding strategies and cryptographic security. While several methods focus on either improving capacity or enhancing security, relatively few frameworks jointly optimize embedding locations while simultaneously encrypting the payload prior to embedding [7], [8]. As a result, such systems remain vulnerable to payload leakage or performance degradation under high embedding loads.

To address these challenges, this study proposes a high-capacity edge-adaptive image steganography framework with multilayer security. It integrates Canny, LoG, and Prewitt operators for accurate edge detection, while a Bee Colony Footprint Edge Optimization (BCFEO) algorithm adaptively selects optimal embedding locations for efficient payload distribution. Additionally, AES-CTR encryption is applied prior to embedding to ensure confidentiality even under partial data extraction.

The main contributions of this work are summarized as follows:

- A multilayer secure image steganography framework using edge-adaptive embedding and pre-encryption, integrating AES-CTR encryption with adaptive embedding to ensure confidentiality, exact payload length preservation, and reliable recovery.
- A hybrid edge detection and preprocessing strategy, combining Canny, Laplacian of Gaussian (LoG), and Prewitt operators with 5-LSB filtering to achieve accurate edge classification and controlled embedding distortion.
- A Bee Colony Footprint Edge Optimization (BCFEO) algorithm for distortion-aware and adaptive selection of

*Corresponding author

embedding pixels, enabling efficient payload distribution under varying capacity requirements.

- Comprehensive experimental evaluation, demonstrating high embedding capacity, improved imperceptibility, and strong resistance to statistical steganalysis compared to conventional methods.

The rest of the study has been structured as follows: Literature review in Section II discusses similar work on image steganography. Section III explains the recommended methodology. Experimental data and performance analysis are presented in Section IV, and Section V wraps up the study.

II. Literature Review

Over the past two decades, image steganography has progressed from simple spatial-domain methods to adaptive, edge-aware, and security-enhanced frameworks [9]. Existing studies mainly focus on improving capacity, imperceptibility, or robustness [10]. This section briefly reviews LSB-based, edge-adaptive, optimization-driven, and secure steganographic methods, highlighting key contributions and limitations.

Least significant bit (LSB) substitution is one of the earliest and most widely used image steganography techniques due to its simplicity and high embedding capacity [11]. Chan and Cheng [12] proposed an LSB-based embedding scheme with pixel adjustment to reduce visual distortion; however, the method remains vulnerable to statistical steganalysis as the payload increases. More recently, Rahman et al. [13] enhanced LSB steganography using a Magic Matrix and multi-level encryption to improve payload reliability and security in RGB images, but the reliance on fixed LSB substitution patterns limits scalability under high-capacity embedding and increases detectability against advanced steganalysis.

To improve imperceptibility, several studies have explored edge-based steganography, exploiting the higher distortion tolerance of edge and textured regions [14]. Sultana et al. [15] combined Sobel Canny edge detection with adaptive LSB embedding to increase payload while preserving visual quality; however, static edge fusion and limited bit-depth adaptation restrict scalability and robustness at higher payloads. Similarly, Habiban et al. [16] employed LoG-Wavelet and LoG-Canny edge detectors with LSB embedding and GIFT encryption, but the use of fixed 1-bit embedding and predefined edge rules constrains adaptability and resilience against modern steganalysis.

Recent works have further investigated adaptive and content-aware steganography to support higher payloads. The study [17] proposed a spatial-domain Fuzzy-graded method based on local texture complexity for adaptive pixel selection, achieving improved imperceptibility at moderate payloads; however, the absence of explicit edge prioritization leads to performance degradation at higher embedding rates. Further, Daiyrbayeva et al. [18] introduced an adaptive reversible data-hiding method for medical X-ray images using region segmentation and interpolation-based embedding, achieving high PSNR and reversibility, but at the cost of increased computational complexity and limited scalability for large-resolution images.

Edge-adaptive strategies have also been enhanced using hybrid detectors and learning-based models [19]. Several studies have employed Sobel, Canny, and Laplacian-based edge guidance to improve imperceptibility [15], [20], but reliance on single or static edge maps limits robustness across diverse image characteristics. The work [21] combined LoG edge detection with pixel-value differencing in RGB images to enhance capacity, but the method is irreversible, restricted to color images, and achieves acceptable quality only at moderate PSNR levels.

To improve embedding efficiency, optimization-based steganography has been widely explored. Singh and Bedi [22] applied particle swarm optimization (PSO) to select embedding pixels, achieving improved imperceptibility, but at the expense of high computational cost and lack of edge prioritization. The authors in [23] employed genetic algorithms for adaptive embedding; however, convergence instability and limited robustness evaluation restrict practical deployment. Omar et al.in [24] combined LoG edge detection with Shark Smell Optimization (SSO) to select embedding pixels, but reliance on LSB substitution and block-wise processing increases overhead and limits scalability under high payload conditions.

To enhance confidentiality, several studies have integrated cryptography with steganography [25], [26]. Some of the studies emphasized encryption as a key security layer in steganographic systems, while Kumar et al. [27] combined AES encryption with adaptive spatial-domain embedding to improve secrecy. Nevertheless, these approaches largely rely on conventional LSB-based embedding, which constrains robustness and payload scalability. Hybrid security systems have also been proposed, such as the DWT-AES-LSB framework by Awadh et al. [28], which improves security and capacity but remains limited by fixed LSB allocation. Survey studies, including Varghese and Sasikala [29], further highlight that existing methods often treat capacity, imperceptibility, optimization, and security as independent objectives rather than as a unified design problem.

The review reveals that LSB methods lack robustness at high payloads, edge-based schemes have limited adaptivity, optimization approaches often ignore encryption, and secure frameworks rely on conventional embedding. Therefore, a unified framework integrating adaptive edge detection, optimization-driven embedding, and strong cryptographic security is required, motivating this work.

III. Proposed Methodology

This section presents the proposed high-capacity edge-adaptive steganography framework with multilayer security. As shown in Fig. 1, it includes preprocessing, edge detection, optimized pixel selection, encryption, embedding, and extraction stages.

Let the grayscale converted cover image, and the secret message can be denoted as Eq. (1) and Eq. (2), respectively.

$$I \in \mathbb{Z}^{M\times N}, I(i,j) \in [0,255] \quad (1)$$

$$\mathcal{M} = \{m_k\}_{k=1}^{L}, m_k \in \{0,1\} \quad (2)$$

The objective is to embed $\mathcal{M}$ into I to generate a stego image I_s, that permits maximum payload capacity, minimum visual distortion, and the payload confidentiality remains preserved. This is formulated as a constrained optimization problem such as [see Eq. (3)]:

$$\max_{\Omega} \; C(\Omega) \text{s.t.} D(I, I_s) \leq \tau \tag{3}$$

where,

- Ω = total embedding pixel set
- $C(\cdot)$ = payload capacity
- $D(\cdot)$ = distortion metric
- τ = imperceptibility threshold

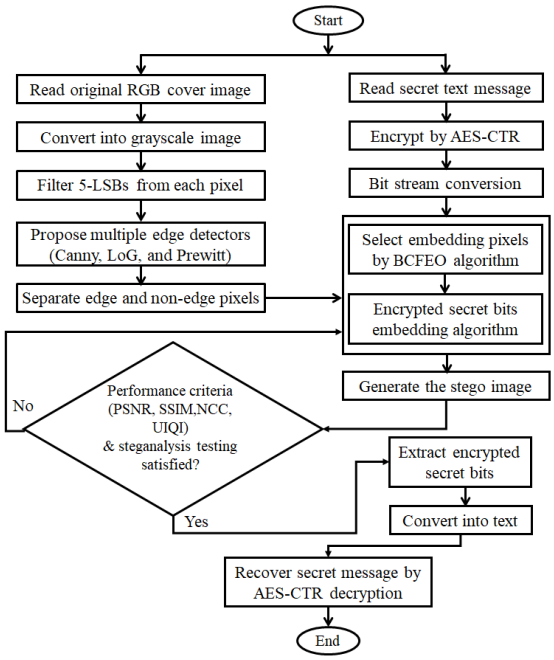

Fig. 1. Flowchart of the proposed edge-adaptive image steganography scheme with BCFEO-based optimized embedding and AES-CTR multilayer security.

A. Cover Image Preprocessing

The RGB cover image is first converted to grayscale to reduce computational complexity and ensure uniform pixel-level processing. A 5-LSB filtering operation is then applied by clearing the five least significant bits of each pixel, as expressed in Eq. (4):

$$I_n(i,j) = \left\lfloor \frac{I(i,j)}{2^5} \right\rfloor \times 2^5 \tag{4}$$

This operation quantizes each 8-bit pixel into multiples of 32, preserving the three most significant bits while discarding low-significance intensity variations. Therefore, the maximum preprocessing-induced pixel deviation is limited to 31 gray levels, while the normalized image remains structurally suitable for stable edge detection and controlled embedding. The purpose of this step is not to preserve exact pixel intensity, but to create a stable reference image in both embedding and extraction phases so that edge-map generation and bit recovery remain consistent. Its effect on image fidelity is subsequently reflected through PSNR, MSE, SSIM, and other quality metrics under different payload capacities. As payload increases, this preprocessing helps limit uncontrolled pixel fluctuation and improves robustness by reducing sensitivity to minor intensity variations.

B. Multi-Detector Edge Identification

Accurate identification of embedding regions is essential for high-capacity steganography. The proposed method employs Canny, LoG, and Prewitt detectors [15], whose outputs are fused to generate a reliable edge map for classifying pixels into edge and non-edge regions. This multi-detector approach improves robustness and adaptability across varying image textures.

1) Canny detector: The Canny method computes image gradients using Sobel operators [30], as in Eq. (5):

$$G = \sqrt{G_x^2 + G_y^2}, \quad \theta = \tan^{-1}\left(\frac{G_y}{G_x}\right) \tag{5}$$

where, G_x and G_y are horizontal and vertical gradients. Non-maximum suppression and hysteresis thresholding are then used to retain only strong, well-localized edges. Canny detector ensures strong edge localization and effective noise suppression through gradient analysis and hysteresis thresholding.

2) Laplacian of Gaussian (LoG) detector: The LoG highlights regions of rapid intensity change by convolving the image with [31], see Eq. (6):

$$\nabla^2 G(x,y) = \frac{\partial^2 G}{\partial x^2} + \quad \theta = \tan^{-1}\left(\frac{G_y}{G_x}\right) \tag{6}$$

where, $G(x,y)$ is a Gaussian-smoothed image. Zero-crossings of the result indicate edges, allowing detection of fine transitions and weak boundaries. LoG detector highlights fine intensity transitions and captures weak edges often missed by gradient-only detectors.

3) Prewitt detector: The Prewitt operator estimates gradients using convolution masks [3], as in Eq. (7):

$$G_x = I * M_x, \quad G_y = I * M_y \tag{7}$$

with M_x and M_y as horizontal and vertical masks. This operator is computationally simple and effective for detecting directional edges. Prewitt detector computes directional gradients, providing complementary information on vertical and horizontal edge structures.

C. Hybrid Edge Detection

Multiple detectors are used to leverage their complementary strengths: Canny is noise-robust, LoG enhances weak edges but may introduce false responses, and Prewitt captures gradients but is less precise in noise. Their edge maps are computed and combined as follows [see Eq. (8)]:

$$\begin{aligned} E_c &= \text{Canny}(I_n); E_l \\ &= \text{LoG}(I_n); E_p = \text{Prewitt}(I_n) \end{aligned} \tag{8}$$

By fusing their outputs with an OR operation, the system maximizes true edge coverage while minimizing the loss of embedding opportunities that would occur if a single detector were used. This hybridization ensures a richer set of candidate

pixels for embedding, leading to higher payload capacity and greater resilience without compromising imperceptibility. A fused edge map is then obtained as Eq. (9):

$$E_f(i,j) = \begin{cases} 1, & E_c + E_l + E_p \geq \theta \\ 0, & \text{otherwise} \end{cases} \quad (9)$$

Pixels are classified as:

- Edge pixels: $\mathcal{E} = \{(i,j) \mid E_f(i,j) = 1\}$
- Non-edge pixels: $\mathcal{N} = \Omega \setminus \mathcal{E}$

D. Optimized Embedding Pixel Selection Using BCFEO

To efficiently utilize the available embedding space, the proposed framework integrates the Bee Colony Footprint Edge Optimization (BCFEO) algorithm for adaptive pixel selection. BCFEO identifies suitable embedding locations by evaluating candidate edge pixels according to their local edge strength, texture variation, and distortion tolerance. Each candidate pixel $p_k \in \mathcal{E}$ is assigned a fitness score, after which the scores are normalized and ranked to categorize pixels based on their embedding suitability. Unlike iterative swarm-position update methods, the proposed BCFEO stage does not physically move pixels; instead, it performs fitness-based categorization of cover-image pixels. The optimized embedding set Ωe^* is selected from the highest-ranked edge pixels using an adaptive threshold determined by the payload requirement. If the capacity of Ωe^* is insufficient, the framework sequentially utilizes the remaining edge pixels Ω_r and, only when necessary, the non-edge pixels Ω_n. This hierarchical selection strategy enables adaptive payload distribution while preserving visual quality by prioritizing pixels with higher distortion tolerance. BCFEO-based pixel score for each candidate pixel $p_k \in \mathcal{E}$ is assigned a fitness score [see Eq. (10)]:

$$F(p_k) = \alpha \cdot | \nabla I_n(p_k) | - \beta \cdot \sigma^2(p_k) \quad (10)$$

where,

- $| \nabla I_n |$ = local gradient magnitude
- σ^2 = local variance
- α, β = weighting factors

The BCFEO iteratively updates pixel selection to maximize the fitness score as Eq. (11):

$$F(p_k)_{max} = \max \sum_{p_k \in \Omega} F(p_k) \quad (11)$$

E. Multilayer Security: AES-CTR Encryption

To enhance confidentiality, the secret message is encrypted prior to embedding using the Advanced Encryption Standard in Counter (AES-CTR) mode. AES-CTR is selected due to its strong cryptographic security, stream-like encryption capability, and absence of padding-induced length expansion that does not impact payload efficiency. The encrypted bitstream exhibits high randomness, preventing meaningful interpretation even if partial extraction occurs. This cryptographic layer forms the first security barrier, complementing the concealment provided by steganographic embedding. The plaintext message $\mathcal{M}$ is encrypted as Eq. (12):

$$C_k = m_k \oplus \text{AES}_K(\text{CTR} + k) \quad (12)$$

where,

- K= secret key
- CTR = initial counter
- C_k= ciphertext bit

CTR mode preserves message length and prevents error propagation.

F. Secret Data Embedding

The encrypted data is converted into a binary bitstream and embedded in the red channel using an adaptive strategy based on pixel classification and optimization output. This allows high payload capacity while preserving imperceptibility and statistical security. The distortion-aware embedding modifies each pixel accordingly, as in Eq. (13):

$$I_s(p) = \begin{cases} I_n(p) + b, & \text{if } b \in \{0,1\} \\ I_n(p), & \text{otherwise} \end{cases} \quad (13)$$

where, b is the encrypted bit. Bit allocation per pixel is adaptive and is determined as [see Eq. (14)]:

$$\eta(p) = \begin{cases} 2, & p \in \Omega_e^* \\ 1, & p \in \Omega_r \\ 0, & p \in \Omega_n \end{cases} \quad (14)$$

The well-defined algorithm for secret data embedding is presented in Algorithm 1.

Algorithm 1: Optimized Edge-Adaptive Embedding with Multilayer Security

Input: Cover image I, secret message $\mathcal{M}$, secret key K, initial counter CTR_0, embedding parameters (edge detectors, BCFEO parameters, payload length L)

Output: Stego image I_s

1: Input cover image I of size $M \times N$

2: Convert I to grayscale image Ig

3: Apply 5-LSB normalization to Ig:

$$I_n(i,j) = floor(\frac{I_g(i,j)}{2^5} 2^5)$$

4: Compute edge maps:

$$E_c \leftarrow Canny(I_n)$$

$$E_l \leftarrow LoG(I_n)$$

$$E_p \leftarrow Prewitt(I_n)$$

5: Fuse edge maps to generate consolidated edge map E_f:

$$E_f(i,j) = 1 \; if \; Ec(i,j) + El(i,j) + Ep(i,j) \geq \theta$$

$$0 \; otherwise$$

6: Classify pixels:

$$Edge \; pixel \; set \; \mathcal{E} \leftarrow \{(i,j) | E_f(i,j) = 1\}$$

$$Non-edge \; pixel \; set \; \mathcal{N} \leftarrow \Omega \setminus \mathcal{E}$$

7: Initialize Bee Colony Footprint Edge Optimization (BCFEO)

8: For each candidate edge pixel $pk \in \mathcal{E}$, compute its local fitness score $F(pk)$ using:

$$F(pk) = \alpha|\nabla In(pk)| - \beta\sigma^2(pk)$$

9: Perform BCFEO-based pixel fitness categorization:

For each candidate edge pixel $pk \in \mathcal{E}$, compute its fitness score $F(pk)$ based on edge strength, local texture variation, and embedding suitability.

Normalize all fitness scores and rank candidate pixels in descending order.

Select optimized embedding pixels as:

$$\Omega e^* = \{ pk \in \mathcal{E} | F_{norm}(pk) \geq \tau \}$$

where τ is an adaptive threshold determined by the required payload length L.

If $|\Omega e^*| < L$, include the next highest-ranked pixels until the payload requirement is satisfied.

10: Define pixels categories as:

$\Omega^* = \Omega e^* \cup \Omega r \cup \Omega n$; where

Ωe^* : BCFEO-optimized edge pixels

Ωr: remaining edge pixels

Ωn: selected non-edge pixels

11: Convert secret message $\mathcal{M}$ into binary bitstream $\{mk\}, k = 1 \dots L$

12: Encrypt bitstream using AES-CTR:

$$ck = mk \oplus AES_K(CTR_0 + k)$$

13: Initialize bit index $k = 1$

14: **for** each pixel $pk \in \Omega^*$ **do**

if $k > L$ **then**

break

end if

15: Determine embedding capacity $\eta(pk)$:

$$\eta(pk) = 2\ bits\ if\ pk \in \Omega e^*$$
$$1\ bit\ if\ pk \in \Omega r$$
$$0\ bit\ if\ pk \in \Omega n$$

16: Embed $\eta(pk)$ encrypted bits into pk in red channel of I :

$$I'_R(pk) \leftarrow I_R(pk) + \Sigma\ (ck \times 2^b), b \in \{0, \dots, \eta(pk) - 1\}$$

17: $Update\ k \leftarrow k + \eta(pk)$

18: end for

19: Reconstruct stego image I_s through merging I'_R and remaining two unchanged channels

20: Output stego image I_s

G. Secret Data Extraction and Message Recovery

At the receiver, extraction follows the inverse process. Using synchronized parameters, embedded bits are retrieved from the red channel and decrypted via AES-CTR to recover the original message. The extraction and recovery are given in Eq. (15) and Eq. (16):

$$\hat{b}_k = I_s(p_k) mod 2 \quad (15)$$

$$\hat{m}_k = \hat{b}_k \oplus \text{AES}_K(\text{CTR} + k) \quad (16)$$

The secret data extraction and reliable message recovery algorithm with a well-structured definition is presented in Algorithm 2.

Algorithm 2: Edge-Adaptive Extraction and AES-CTR Decryption

Input: Stego image I_s, secret key K, initial counter CTR_0, embedding parameters (edge detectors, BCFEO parameters, payload length L)

Output: Recovered secret message $\hat{\mathcal{M}}$

1: Convert I_s to grayscale image I_sg

2: Apply 5-LSB clearing to $I_sg \rightarrow I_sn$

3: Compute edge maps:

$$E_c \leftarrow Canny(I_sn)$$
$$E_l \leftarrow LoG(I_sn)$$
$$E_p \leftarrow Prewitt(I_sn)$$

4: Fuse edge maps to generate E_f:

$$E_f(i,j) = 1\ if\ Ec(i,j) + El(i,j) + Ep(i,j) \geq \theta$$
$$0\ otherwise$$

5: Classify pixels:

$$Edge\ pixel\ set\ \mathcal{E} \leftarrow \{ (i,j) | E_f(i,j) = 1 \}$$
$$Non-edge\ pixel\ set\ \mathcal{N} \leftarrow \Omega \setminus \mathcal{E}$$

6: Initialize Bee Colony Footprint Edge Optimization (BCFEO)

7: For each candidate edge pixel $pk \in \mathcal{E}$, compute fitness:

$$F(pk) = \alpha|\nabla In(pk)| - \beta\sigma^2(pk)$$

8: Perform BCFEO-based pixel fitness categorization:

$\Omega^* = \Omega e^* \cup \Omega r \cup \Omega n$; where

Ωe^* : BCFEO-optimized edge pixels

Ωr: remaining edge pixels

Ωn: selected non-edge pixels

9: Initialize empty ciphertext bitstream $\hat{\mathcal{C}} = \emptyset$

10: Select the modified red channel I'_R of stego image

11: **for** $k = 1$ to L **do**

12: Select extraction pixel $pk \in \Omega^*$

Extract encrypted bit:

13: $\hat{c}k = I_s(pk) \bmod 2$

14: Append $\hat{c}k$ to $\hat{C}$

15: end for

16: Group $\hat{C}$ into byte-aligned blocks

17: Initialize AES-CTR keystream using key K and counter CTR_0

18: **for** each encrypted bit $\hat{c}k$ **do**

Generate keystream bit:

$$zk = AES_K(CTR_0 + k)$$

Recover plaintext bit:

$$\hat{m}k = \hat{c}k \oplus zk$$

end for

19: Reconstruct original message $\hat{\mathcal{M}}$ from bitstream $\{\hat{m}k\}$

20: Output recovered message $\hat{\mathcal{M}}$

IV. Results and Analysis

The proposed framework was implemented and evaluated in Python 3.11.7 using the Anaconda distribution. Experiments were conducted on standard RGB benchmark images obtained from the USC-SIPI image database [32], together with additional natural images captured independently to introduce scene diversity beyond benchmark datasets. For consistent comparative evaluation, all color images were resized to 256×256 and converted into 8-bit grayscale images, resulting in 65,536 pixels per image for each simulation. Among the complete set of tested images, six representative samples, namely "Pepper", "F16", "Sailboat", "Boats", and two personally captured natural images, "KL Tower" and "UKM", are reported in detail due to space limitations and presentation clarity. These images were selected to cover different structural and textural characteristics, including smooth regions, strong edges, object boundaries, and complex natural backgrounds. Nevertheless, the evaluation is primarily based on fixed-resolution grayscale images; therefore, future work will extend the analysis to larger image sets with different resolutions, content categories, and statistical properties to further validate the generalizability of the proposed framework.

A. Payload Capacity Analysis

The achievable payload capacity of an image steganography system is primarily governed by the number and spatial distribution of pixels deemed suitable for embedding. In the proposed framework, payload capacity is directly influenced by the effectiveness of edge and non-edge pixel identification, which is performed exclusively on a reference intensity plane prior to data embedding. To evaluate the baseline embedding potential, edge pixels were initially identified using individual edge detectors, namely Canny, Prewitt, and Laplacian of Gaussian (LoG) and their hybridization applied to consecutive processed cover images.

TABLE I. Edge Pixels Found by Different Detectors and their Hybridization in Original and Cleared Images.

Images (65536 pixels)	Canny	LoG	Prewitt	Hybrid fused	
	Original grayscale (Org)			Org	Cleared
Pepper	7193	9284	8042	14132	21498
F16	6400	10607	9985	14246	16554
Sailboat	10774	12112	12666	20388	25362
Boats	9425	13211	11498	19515	23565
KL_tower	7151	11075	11239	17653	22798
UKM	13307	13295	12849	23442	27086

The results summarized in Table I indicate that the number of detected edge pixels varies significantly across detectors and image content. The corresponding edge pixel counts obtained from these representations are illustrated in Fig. 2, where the hybrid approach on the cleared image consistently yields a higher and more stable number of embedding candidates across all benchmark images, leading to the higher embedding capacity achieved in the adaptive mode of embedding for the proposed system.

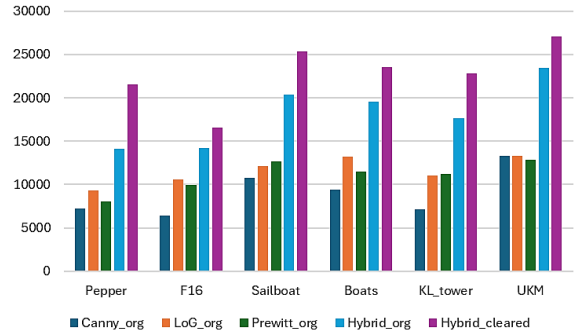

Fig. 2. Visual presentation of edge pixels found in different detectors and their hybrid fusion.

B. Imperceptibility (Qualitative) Analysis

As an initial qualitative assessment of imperceptibility, the visual quality of the generated stego images is examined from the perspective of the Human Visual System (HVS) before proceeding to quantitative performance evaluation. Fig. 3 illustrates representative examples of four original cover images and their corresponding stego images produced at an embedding payload of 1 bpp.

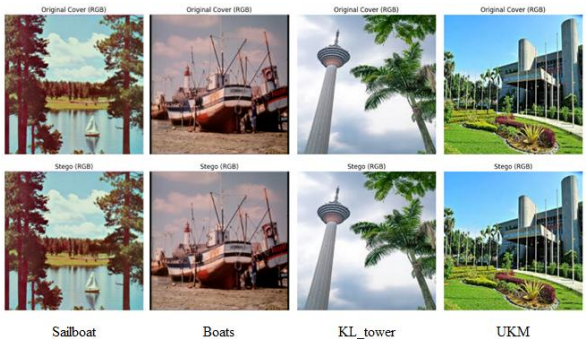

Fig. 3. Visual imperceptibility comparison between original cover images (top row) and corresponding stego images (bottom row) generated using the proposed steganography framework. Test images include Sailboat, Boats, KL_tower, and UKM.

A careful visual comparison between the cover and stego images reveals no discernible visual degradation across all evaluated test images. In particular, no visible noise patterns, color shifts, edge blurring, blocking artifacts, or contrast inconsistencies are observed in the stego images. This observation holds consistently for images with varying visual characteristics, including smooth regions, textured areas, object boundaries, natural landscapes, and human facial features. From an HVS standpoint, the stego images remain visually indistinguishable from their original counterparts.

C. Imperceptibility (Quantitative) Analysis

Imperceptibility is a critical requirement in image steganography, ensuring that the embedded payload does not introduce perceptible visual or statistical artifacts. Table II reports the detailed imperceptibility performance of the proposed method under varying payload sizes using the F-16 benchmark image, while Table III provides a cross-image summary of PSNR and SSIM values for six representative test images at selected payload capacities.

TABLE II. PRESENTATION OF PSNR, SSIM, AND NCC VALUES UNDER DIFFERENT PAYLOAD REGIMES IN F-16 IMAGE.

Payload Sizes/rates	PSNR	SSIM	NCC	UIQI	Entropy deviation
128 bits	83.91	1.0000	1.0000	1.0000	0.0000
256 bits	80.24	1.0000	1.0000	1.0000	0.0000
512 bits	77.00	1.0000	1.0000	1.0000	0.0000
1024 bits	74.07	1.0000	1.0000	1.0000	0.0000
0.031 bpp	70.91	1.0000	1.0000	1.0000	0.0000
0.063 bpp	67.81	1.0000	1.0000	1.0000	0.0000
0.125 bpp	64.96	0.9999	1.0000	1.0000	0.0000
0.25 bpp	62.01	0.9998	1.0000	1.0000	0.0001
0.50 bpp	58.92	0.9996	1.0000	1.0000	0.0001
1.00 bpp	55.91	0.9989	1.0000	1.0000	0.0008
2.00 bpp	48.90	0.9947	0.9999	0.9999	0.0012
3.00 bpp	42.61	0.9795	0.9991	0.9997	0.0141
4.00 bpp	36.67	0.9406	0.9963	0.9991	0.0333

As shown in Table II, the PSNR values for the F-16 image remain exceptionally high at low payloads, exceeding 80 dB for 128-bit embedding and gradually decreasing with increasing payload. Even at moderate payloads of 0.25-0.50 bpp, the PSNR values remain above 58 dB, which is well beyond the commonly accepted imperceptibility threshold of 40 dB. At higher payloads of 1-4 bpp, PSNR decreases as expected due to increased embedding density; however, the values remain within acceptable limits, demonstrating controlled distortion even under aggressive embedding conditions.

The SSIM values also remain extremely close to unity across most payload regimes, with only marginal degradation at higher payloads. This indicates that the proposed edge-adaptive and optimized embedding strategy effectively preserves the structural and perceptual characteristics of the cover image. Similarly, the NCC and UIQI values remain near 1.0 for all payloads, confirming strong statistical similarity between the cover and stego images. The entropy deviation remains negligible at low and moderate payloads and increases only slightly at very high embedding rates, indicating minimal disturbance to the underlying pixel distribution.

TABLE III. PRESENTATION OF PSNR AND SSIM VALUES UNDER DIFFERENT PAYLOAD REGIMES IN DIFFERENT TEST IMAGES.

Images	PSNR and SSIM for different payload rates					
	0.125 bpp		1.00 bpp		3.00 bpp	
	PSNR	SSIM	PSNR	SSIM	PSNR	SSIM
Pepper	64.89	0.9999	55.90	0.9992	42.61	0.9761
F16	64.96	0.9999	55.91	0.9989	42.66	0.9795
Sailboat	64.97	0.9999	55.93	0.9992	42.61	0.9848
Boats	64.93	0.9999	55.93	0.9991	42.65	0.9862
KL_tower	64.97	0.9999	55.89	0.9989	42.63	0.9706
UKM	65.02	0.9999	55.91	0.9993	42.61	0.9796
Average	64.96	0.9999	55.91	0.9992	42.61	0.9795

To further address cross-image consistency, Table III summarizes PSNR and SSIM results across Pepper, F16, Sailboat, Boats, KL_tower, and UKM images at 0.125, 1.00, and 3.00 bpp. The average PSNR values are 64.96 dB, 55.91 dB, and 42.61 dB, respectively, while the corresponding average SSIM values are 0.9999, 0.9992, and 0.9795. These aggregated results confirm that the proposed method maintains high imperceptibility across different image contents, including benchmark images and independently captured natural images. The small variation among the tested images further indicates that the method is not strongly dependent on a single image structure or texture pattern.

The combined results in Table II and Table III demonstrate that the proposed method achieves a favorable capacity-imperceptibility balance across a wide range of payload capacities. The F-16 and cross-image results confirm that the proposed multi-detector edge selection and BCFEO-optimized embedding strategy maintain consistent image quality under increasing payloads across different test images.

D. Histogram Consistency Analysis

Histogram-based steganalysis evaluates whether embedding introduces noticeable changes in pixel intensity distributions. As shown in Fig. 4, the RGB histograms of the stego images closely match those of the corresponding cover images across all channels. The peak positions, intensity spread, and overall distribution shapes remain consistent, with no visible peak distortion, flattening, or abnormal clustering. This strong alignment indicates that the proposed method preserves first-order statistical properties and does not introduce detectable artifacts, even under multi-channel embedding.

Further strengthening the histogram-based security assessment, signed Pixel Difference Histogram (PDH) plots are analyzed at the same embedding rate and presented in Fig. 5. It demonstrates a sharp, symmetric peak centered at zero for both cover and stego images, indicating that most neighboring pixel differences remain small and evenly distributed around zero. The near-perfect overlap of the signed PDH curves confirms that

the embedding process does not introduce directional bias or systematic local distortions. The combined evidence from RGB histogram comparison and PDH analysis demonstrates that the proposed steganographic framework effectively resists histogram-based steganalysis.

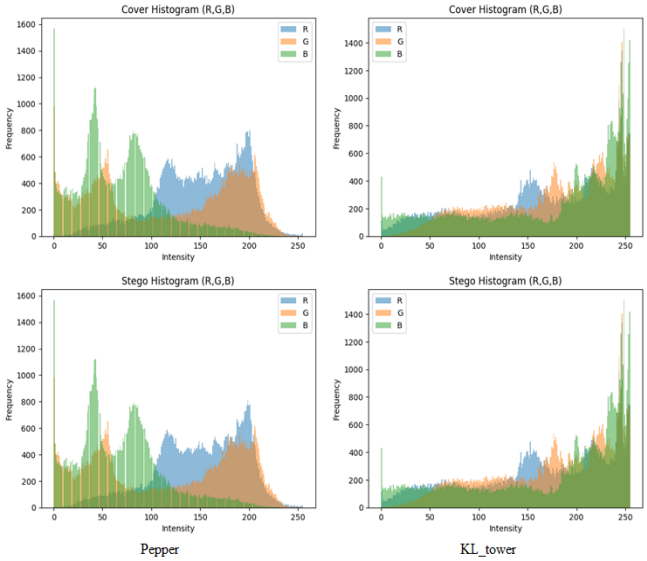

Fig. 4. RGB histogram comparison of cover (top row) and corresponding stego images (bottom row) for Pepper and KL_tower images, showing minimal statistical deviation and preservation of intensity distributions after embedding.

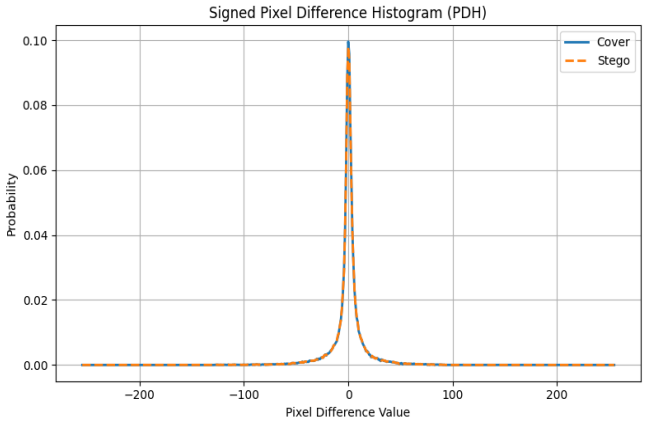

Fig. 5. PDH analysis of the cover and the stego image (F-16) at a data hiding rate of 1.00 bpp.

E. Regular-Singular (R-S) Steganalysis Evaluation

Regular-Singular (R-S) steganalysis assesses higher-order statistical changes in pixel groups under flipping masks. As shown in Fig. 6, the proportions of regular (R) and singular (S) groups for both masks $M = [1, 0, 1, 0]$ and $M = [0, 1, 0, 1]$, remain closely aligned between cover and stego images, with minimal and symmetric differences. Specifically, the relative differences between R_M and S_M, as well as between R_{-M} and S_{-M}, are minimal and symmetric across the cover-stego pairs. Additionally, the proportion of unusable groups (U) remains zero in all cases, indicating that the embedding process preserves natural image statistics without introducing detectable structural distortions.

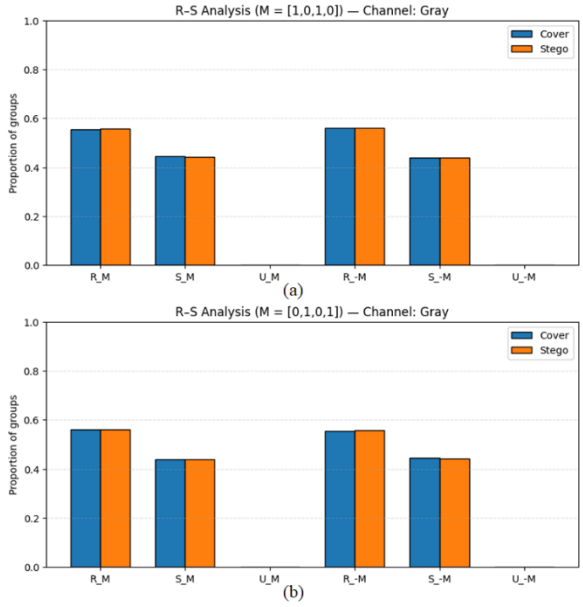

Fig. 6. Graphical presentation of Regular-Singular (R-S) steganalysis results for the grayscale converted image at an embedding rate of 1 bpp using two complementary flipping masks: (a) M=[1,0,1,0] and (b) M=[0,1,0,1].

The close correspondence between the proportions of regular (R), singular (S), and unusable (U) groups for the cover and stego images demonstrate preservation of structural statistics and resistance to R-S based steganalysis. The R-S analysis shows that the proposed embedding strategy preserves the natural imbalance between regular and singular groups across multiple flipping masks, thereby avoiding the characteristic equalization behavior exploited by R-S steganalysis.

F. Chi-Square and Pairs-of-Values (PoV) Steganalysis Evaluation

Chi-square (χ^2) steganalysis was conducted on the complete image set; representative results are shown for clarity and space efficiency. The global chi-square statistics for the grayscale converted "Sailboat" cover and stego image at 1.00 bpp embedding payload are derived from the grayscale intensity distribution after excluding low-frequency pairs is selected in an experimental simulation.

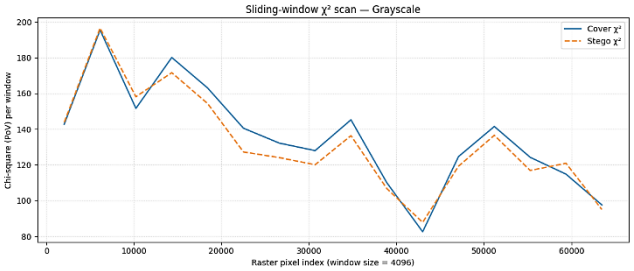

Fig. 7. Sliding-window (size=4096) chi-square ($\chi 2$) scan of the grayscale (Sailboat) cover and stego images at an embedding rate of 1 bpp.

To assess localized detectability, a sliding-window chi-square scan is performed across the rasterized grayscale image and illustrated in the sliding-window χ^2 plot shown in Fig. 7. The resulting chi-square trajectories of the cover and stego

images with 65536 hidden bits (1.00 bpp) exhibit closely aligned fluctuation patterns over all window positions and no persistent divergence or abrupt spike is observed in the stego curve relative to the cover curve. The close alignment of the chi-square trajectories indicates the absence of localized statistical anomalies introduced by the embedding process.

G. Crypto-Security and Reliability Analysis

Instead of direct plaintext embedding, the proposed system employs AES in Counter (CTR) mode to encrypt the secret message prior to bitstream generation. This ensures confidentiality while remaining independent of the embedding process. Importantly, AES-CTR preserves exact length equivalence between plaintext and ciphertext. For example, a 256-character message produces a 2048-bit stream, and the encrypted output retains the same 2048-bit length after binary conversion. As illustrated in Fig. 8, this one-to-one correspondence confirms strict length preservation throughout the process.

The results confirm that the recovered plaintext is identical to the original message, validating the reliability of the complete pipeline, including encryption, embedding, extraction, and decryption. As illustrated in Fig. 8, a 256-character message undergoes encryption, embedding, and recovery, with perfect agreement between the original and extracted plaintext, ensuring exact semantic reconstruction.

This accuracy is achieved while maintaining strict length consistency throughout all stages. The integration of AES-CTR encryption enhances security by protecting confidentiality, while its length-preserving property ensures that embedding capacity is unaffected. Consequently, the proposed framework achieves a balanced trade-off between security, capacity, and reliable recovery, reinforcing its effectiveness for secure communication.

Fig. 8. Authorized receiver validation showing end-to-end exact message (256 character) recovery, including plaintext encryption, ciphertext-to-bitstream embedding, extraction, and AES-CTR decryption.

H. Comparison with Existing Steganographic Methods

Table IV compares the proposed method with representative state-of-the-art image steganography approaches in terms of embedding capacity and imperceptibility. To ensure transparency, the comparison is interpreted in two ways based on the relative capacity-imperceptibility performances. The proposed method was evaluated under a consistent experimental setting, and the comparing values are taken from their original publications as several works do not provide complete implementation details, source codes, or identical parameter settings. Therefore, the comparison is intended to show the relative capacity-imperceptibility trend rather than a fully controlled one-to-one reproduction of all methods.

Existing hybrid edge-based methods achieve high visual quality, with PSNR values around 60.6 dB, but they operate at very low payloads, typically ≤ 0.125 bpp, which limits their applicability for high-capacity data hiding. In contrast, RGB model-based edge detection methods support higher payloads of up to 2.80 bpp but experience noticeable visual degradation, as indicated by lower PSNR and SSIM values. The IWT-PSO method provides competitive imperceptibility at low to moderate payloads, particularly within the 0.25-0.75 bpp range, where PSNR remains above 50 dB. However, its performance decreases as payload increases, and it is not extensively reported for higher-capacity embedding.

TABLE IV. COMPARISON OF THE PROPOSED METHOD TO OTHER COMPETING METHODS.

Method	Embedding rate (bpp)	PSNR (dB)	SSIM
Hybrid edge detection [16]	0.125	60.58	0.9992
RGB model-based edge detection [21]	2.80	33.51	0.8600
IWT-PSO [8]	0.25	56.53	0.9999
	0.61	52.78	0.9999
	0.75	50.68	0.9999
Proposed	0.125	64.96	0.9999
	0.25	62.01	0.9998
	0.50	58.92	0.9996
	1.00	55.91	0.9989
	2.00	48.90	0.9947
	3.00	42.61	0.9795
	4.00	36.67	0.9406

By comparison, the proposed method maintains a favorable capacity-imperceptibility balance across a wider payload range. At low payloads, it achieves high PSNR and near-unity SSIM, while at higher payloads of 1-4 bpp, it continues to preserve acceptable visual quality where many existing methods either degrade substantially or do not report results. This improvement is mainly attributed to the integration of multi-detector edge adaptivity and BCFEO-based optimized pixel selection, which prioritizes pixels with stronger edge characteristics and higher distortion tolerance. The results indicate that the proposed framework provides competitive and scalable capacity-imperceptibility trade-off for high-capacity steganographic embedding.

V. Conclusion

This study proposed a multilayer secure image steganography framework based on edge-adaptive embedding and pre-encryption for high-capacity covert communication. The framework combines hybrid edge detection using Canny, LoG, and Prewitt operators with Bee Colony Footprint Edge Optimization (BCFEO) to identify and prioritize embedding locations with high distortion tolerance. In addition, AES-CTR pre-encryption was incorporated to strengthen payload confidentiality while preserving exact message length and enabling reliable recovery. Experimental results demonstrated that the proposed method achieved high embedding capacity with controlled visual distortion, high structural similarity, and strong resistance to classical statistical steganalysis. Comparative evaluation further showed that the method provides a favorable capacity-imperceptibility trade-off over representative existing approaches, particularly at higher payloads. However, higher payloads gradually reduce imperceptibility, as indicated by lower PSNR and SSIM. The integration of adaptive edge selection, optimization-driven embedding, and length-preserving cryptographic protection makes the proposed framework an effective solution for secure image-based communication. The future work will validate the method on larger, higher-resolution, and more diverse datasets, evaluating robustness against different threats of adversarial or learning-based detection models.

Multimodal Machine Learning for Cybersecurity in Internet of Things Environments: A Literature Review

Abdelaaziz NASSIRI, Azeddine Khyat, Kama El Guemmat, Mohamed Aazi
Computing, Artificial Intelligence and Cyber Security Laboratory (2IACS),
ENSET Mohammedia, Hassan II University of Casablanca, Morocco

***Abstract*—This research provides a comprehensive synthesis of Multimodal Machine Learning (MML) as a transformative paradigm for IoT defense. By integrating heterogeneous data streams, including network flow statistics, device-level telemetry, and behavioral biometrics, MML architectures facilitate a holistic understanding of system states. The algorithmic advancements that were analyzed are classified into hybrid CNN-RNN structures and state-of-the-art cross-modal Transformers, and evaluate their performance across benchmark datasets such as ToN-IoT and CICIoT2023. Quantitative results show that cross-modal Transformers achieve F1-scores between 0.95 and 0.99 across detection tasks, while hybrid CNN-LSTM models range from 0.89 to 0.96. Furthermore, this study addresses the technical "optimization triad" of pruning, quantization, and edge-cloud orchestration required to deploy these models on resource-constrained hardware.**

***Keywords*—Internet of Things (IoT); Multimodal Machine Learning; deep learning, cyber-physical security; data fusion; Intrusion Detection Systems (IDS); Edge AI, Explainable AI (XAI)**

I. Introduction

The digital landscape is currently undergoing a fundamental reconfiguration, driven not by incremental expansion but by the convergence of ubiquitous connectivity, exponential data proliferation, and transformative advancements in computational intelligence. Central to this paradigm shift is the Internet of Things (IoT), a technological framework that has evolved from a disparate collection of connected devices into a central component of contemporary digital infrastructure.

As billions of autonomous nodes from tiny environmental sensors to heavy-duty industrial actuators stream data in real-time, the traditional boundary between the digital and the physical is effectively dissolving into a cyber-physical continuum.

However, security frameworks have struggled to keep pace with this rapid expansion. The massive, fragmented attack surface presents challenges that traditional network defense mechanisms cannot adequately address [1] [7].

A. Context: IoT Convergence and Security Bottlenecks

The rapid integration of IoT into critical infrastructure, including power grids, healthcare systems, and transportation networks, has fundamentally altered the risk profile of modern civilization. In these high-stakes environments, security is not merely a matter of data privacy; it constitutes a non-negotiable requirement for operational safety.

The Industrial Internet of Things (IIoT) illustrates this dynamic. Industrial systems are exposed to cyber threats that can result in physical consequences, as the integration of physical machinery with intelligent electronics has yielded significant efficiency improvements. A potential physical catastrophe can result not only from a software defect but also from a digital exploit within a control loop [4] [5] [6] [8].

The IoT ecosystem introduces several structural challenges that confound traditional IT security approaches:

- Extreme Heterogeneity: The wide variety of hardware architectures and proprietary protocols renders the application of a universal security standard practically infeasible.
- Resource Constraints: Many devices operate under severe power and memory limitations, preventing the execution of standard encryption or heavy anti-malware suites.
- Data Volume: With an estimated 26 billion devices expected by 2030, the resulting data volume makes manual oversight impossible. The industry is now forced to rely on automated, intelligent defense systems [2] [3] [9].

B. Problem Statement: The Limitations of Legacy Defense

Traditional cybersecurity, built for the static "walled garden" networks of a previous decade, faces significant challenges in addressing the dynamic complexity of IoT. Most current systems still rely on unimodal analysis that examines a single stream, such as network logs, to detect anomalies. While this approach keeps computational costs low, it creates a blind spot: it cannot detect multi-vector attacks that span different system layers [1] [9].

Despite being the most widely deployed approach, signature-based IDS is not effective against zero-day exploits. Anomaly-based models often cannot distinguish between benign deviations from baseline behavior and actual attacks, leading to an excessive amount of false positive alerts. These systems have a tendency to fail to distinguish between a true intrusion and harmless network latency or transient sensor malfunction [2] [5] [35] [37].

This limitation of unimodal approaches creates vulnerabilities that sophisticated attackers can exploit. An adversary can execute a sequence of actions that appear benign individually such as a minor CPU spike combined with a small shift in packet timing but collectively indicate a security breach. Without the ability to correlate these scattered signals, traditional systems lack the holistic situational awareness needed to defend complex IoT deployments [17] [18] [12].

C. Motivation: Why Multimodal Approaches are the Future?

The limitations of single-source models have motivated a shift toward Multimodal Machine Learning (MML). MML provides a unified framework to ingest and analyze diverse data types simultaneously. By fusing network traffic, device telemetry, and even behavioral biometrics, MML systems can catch the subtle indicators of an attack that are invisible to a unimodal filter [12] [18] [19].

The fundamental principle is data complementarity. Information that appears as noise in one channel can be clarified by another. For example, a suspected DDoS attack on the network can be validated by a corresponding increase in a device's heat profile (high temperature alarm) or a rapid decrease in accessible RAM. This cross-modal validation enhances detection and significantly reduces false positive rates [2] [11].

1) Contribution and Scope: This review integrates the technological frontier at the intersection of MML and IoT security. The focus is exclusively on the mechanics of data fusion rather than doing a comprehensive study; all models were classified from hybrid deep learning to Transformer-based networks, addressing the challenging issue of executing these resource-intensive models on constrained edge devices [3] [7] [9].

2) Organization of the paper: The remainder of this document is organized as follows: Section II establishes the preliminaries, detailing the IoT threat landscape, the variety of data modalities available, and the core strategies of multimodal fusion. Section III presents the systematic review methodology. Section IV provides taxonomy and classification of MML architecture. Section V discusses applications and use cases. Section VI reviews datasets and evaluation metrics. Section VII provides a critical discussion of trade-offs and limitations. Section VIII identifies open challenges and future directions. Section IX concludes the review.

II. Background And Preliminaries

Developing an effective multimodal security framework requires a comprehensive understanding of the operational environment, the nature of the data involved, and the mathematical mechanisms for integrating that data [1] [3] [7].

A. IoT Security Landscape: Major Threats and Vulnerabilities

The IoT threat landscape is characterized by its breadth and the potential consequences of successful exploitation. Threats are typically categorized based on their intent, origin, and the specific layer of the IoT stack they target [1] [3] [22]. Table I presents the IoT threat taxonomy.

TABLE I. IoT Threat Taxonomy

Threat Category	Targeted Layer	Mechanism	Primary Impact
DDoS Attacks	Network	Overwhelming target resources using a botnet.	System unavailability and network collapse.
Malware/ Botnets	Application/Edge	Mirai, BASHLITE, or ransomware infecting devices.	Information leakage and device takeover.
False Data Injection	Physical/ Sensing	Injecting fraudulent sensor data to mislead control systems.	Grid instability or process failure.
Slow DoS	Network/ App	Stealthy low-volume traffic mimicking legitimate slow nodes.	Resource exhaustion with low visibility.
Adversarial Evasion	Learning	Manipulating inputs to fool ML models.	Compromised detection accuracy.

Sources: [3] [23] [36]

The fundamental vulnerability of IoT systems lies in the "security-by-design" gap. Devices are often deployed with default credentials, unpatched firmware, and a lack of standardized development guidelines. Furthermore, the reliance on lightweight protocols such as IEEE 802.15.4e or MQTT, while efficient for communication, can increase susceptibility to topological manipulation and resource exhaustion attacks [3] [23] [36].

TABLE II. Comparative Benchmarking of Surveyed MML Architectures for IoT Security.

Architecture	Fusion Strategy	Dataset	Acc%	F1	AUC
CNN-LSTM	Hybrid	Custom multi-modal	96,04 [37]	0.960	–
CNN-LSTM / CNN-GRU (IDS)	Hybrid	CICIoT2023 / ToN-IoT	>99.6 [36,37]	0.996	-
RansomFormer	Cross-attention	Custom ransomware	99.5 [43]	0.995	0.998
MT-CMVAD	Transformer fusion	UCF-Crime / CUHK	- [41]	-	0.989
TTGNet-AMD	Hybrid DL + GCN	Drebin / VirusTotal	~98.7 [30]	0.985	0.990
FW-CNN + Metaheuristic	Feature-level	ToN-IoT	98.4 [11]	0.982	-
Soft-Voting Ensemble	Decision-level	ToN-IoT / Bot-IoT	99.1 [49]	0.989	-
AI4FIDS (Federated)	Late fusion (FL)	Multi-domain IIoT	97.8 [40]	0.976	-
Autoencoder (Anomaly	Latent-space	N-BaIoT	97.3 [39]	0.971	0.981
GAN-augmented MML	Feature-level	CICIoT2023	99.3 [39]	0.991	-

Source: [11, 30, 36, 37, 39, 40, 41, 43, 49]

Accuracy and F1 values are reported on the primary dataset cited by each study (see Table II).

B. Overview of Data Modalities in IoT

In a multimodal context, a "modality" refers to a distinct stream of information that captures a specific aspect of a system's state or behavior. IoT ecosystems are rich in these modalities [12] [15] [16] [18] [32] [61]:

- Network Flow and Packets: This includes tabular features like flow duration, protocol type, and connection rates, as well as raw packet-level features such as payload entropy and application-layer semantics (e.g., MQTT message types).
- Device Telemetry: Internal performance metrics such as CPU load, RAM usage, memory mapping, and power consumption patterns.
- Sensor Data: The primary functional output of the device, which may include numerical readings (temperature, pressure) or high-dimensional data (images, audio).
- Static Code Features: Structural information extracted from software binaries, such as opcode sequences, Application Programming Interface (API) call sequences, and function call graphs (FCG).
- Behavioral Biometrics: Patterns derived from human interaction, including keystroke dynamics, gait, and touch gestures.

C. Foundations of Multimodal Machine Learning (MML)

Multimodal Machine Learning is the computational process of integrating information from multiple modalities to perform inference. The effectiveness of an MML system depends largely on its fusion strategy, the stage at which different data types are combined [12] [17] [18] [19] [61].

1) Early Fusion (Data-Level): This strategy involves concatenating raw features from different sources into a single vector before feeding it into the model. While this allows the model to capture deep inter-modal interactions from the beginning, it is highly sensitive to temporal misalignment and differences in data scales.

2) Late Fusion (Decision-Level): Each modality is processed by an independent model, and the individual outputs are merged at the final stage using techniques like majority voting, averaging, or weighted confidence scores. This is more robust to modality-specific noise but often misses the nuanced feature-level dependencies that define complex attacks.

3) Hybrid Fusion (Feature-Level): The most prevalent approach in modern research. It utilizes modality-specific encoders to extract high-level feature representations, which are then integrated in the intermediate layers of the network. This allows for a balance between modality-specific learning and global context integration.

III. Review Methodology

To ensure reproducibility and rigor, this review follows these systematic review steps.

A. Search Strategy

Literature was retrieved from major academic databases covering the period 2018 – 2026.

The digital libraries were especially, but not limited to: Google Scholar, IEEE Xplore, SpringerLink.

The following primary Boolean query was applied consistently across all selected databases:

("IoT" OR "IIoT") AND ("Multimodal Machine Learning" OR "Multi-modal Deep Learning" OR "Data Fusion" OR "Feature Fusion" OR "Cross-modal Attention") AND ("Cybersecurity" OR "Intrusion Detection" OR "Anomaly Detection" OR "Malware" OR "Authentication" OR "IDS" OR "Attack Detection")

B. Inclusion and Exclusion Criteria

Inclusion criteria: 1) Peer-reviewed articles or preprints from 2018-2026; 2) Explicit use of at least two distinct data modalities; 3) Application to IoT security (IDS, malware detection, or authentication); 4) Reporting of quantitative performance metrics.

Exclusion criteria: 1) Theoretical papers without experimental validation; 2) Single-modality studies; 3) non-English publications.

C. Sélection Process

The selection was based on the essential point of multimodality and intrusion detection systems, with papers addressing the most relevant databases and meeting the criterion of multimodality; the second selection criterion was recent references. This allowed us to keep about 60 reference articles.

IV. Taxonomy of MML Architectures for IoT Security

Recent progress in multimodal machine learning for IoT security has focused on creating systems that combine different types of data and make clear how they are all connected. In the contexts of IoT and IIoT, these modalities may include network traffic characteristics, device-level telemetry, system logs, sensor data, and, in some cases, behavioral signals. This section of the study groups the literature by the basic architecture of machine learning, with a focus on deep learning models, attention-based methods, Transformer-centric architectures, and hybrid ensemble frameworks. The goal is to look at how different types of architecture do multimodal fusion, deal with interactions between features from different modes, and solve basic IoT problems like data heterogeneity, temporal dynamics, and limited computing power [1] [7] [9] [34].

A. Deep Learning-Based Multimodal Models

Deep Learning (DL) is the most popular MML paradigm because it can learn hierarchical representations without manual feature engineering [18] [34] [35] [43] (see Table III).

TABLE III. MML ARCHITECTURE TAXONOMY

Architecture Family	Early Fusion	Hybrid Fusion	Late Fusion
CNN-based	Feature concatenation before CNN layers [35]	FW-CNN + metaheuristic hyperparameter tuning [11]	Ensemble: CNN + RF/SVM decision voting [34][48]
RNN/LSTM-based	Multimodal LSTM on concatenated sequences [37]	CNN-LSTM / CNN-GRU — spatial + temporal [6][35][37]	LSTM outputs + federated aggregation [8]
Transformer-based	Token-level cross-modal embedding [33]	RansomFormer cross-attention (bytes+API) [42]; MT-CMVAD [40]	Transformer ensemble with confidence weighting [34]
Hybrid Ensemble	Multi-feature static+dynamic fusion [25][29]	TTGNet-AMD: LSTM + Transformer-GCN [29]; AI4FIDS FL [39]	Soft-voting ensemble over independent models [11][48]
Autoencoder/ GAN	Joint latent-space reconstruction [10]	GAN augmentation + CNN classifier [38]	GAN synthetic data + downstream detector [10][38]

B. Convolutional and Recurrent Neural Network Integration

A common architecture for analyzing network and telemetry data is the combination of Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs), specifically Long Short-Term Memory (LSTM) or Gated Recurrent Units (GRU). CNN layers are typically used to extract spatial or structural patterns from a window of data, while LSTM/GRU layers capture the temporal dependencies essential for identifying multi-stage attacks that unfold over time. The research studied highlights the efficacy of the hybrid CNN-LSTM model, which achieved an average accuracy of 96.04% across various behavioral modalities. In network intrusion detection, CNN-LSTM and CNN-GRU models have demonstrated accuracies exceeding 99.83%, surpassing the CNN model by 0.93% in accuracy, outperforming traditional deep learning techniques by effectively modeling both the spatial structure of packet flows and their sequential order [6] [35] [34] [37][62].

C. Autoencoders and Generative Models

Autoencoders (AE) are frequently employed in multimodal settings to learn a shared latent representation across different data sources. By training an AE to reconstruct "normal" multimodal inputs, any significant reconstruction error in a new input can be flagged as an anomaly. Generative Adversarial Networks (GANs) are increasingly used to enhance MML-based detection. GANs serve a dual purpose: first, they generate synthetic multimodal data to address the common problem of class imbalance, where malicious samples are rare compared to benign traffic, improving the robustness of the classifier. Second, they facilitate adversarial training, helping models recognize and resist "evasion" attacks where adversaries deliberately manipulate one modality to mask anomalies in another [10] [38] [41].

D. Attention and Transformer-Based MML

The most significant architectural shift in recent years is the adoption of the Transformer model and its attention mechanisms. Unlike traditional models that treat all inputs with equal weight, attention mechanisms allow a model to dynamically focus on the most relevant features or modalities for a specific task [10] [33] [40] [42].

1) Cross-modal attention mechanisms: The "cross-attention" mechanism is particularly vital for MML. It allows one modality (the "query") to search for relevant features in another modality (the "key" and "value"). This enables the model to align and bridge the semantic gap between disparate data types. For instance, in malware analysis, the RansomFormer model uses a cross-attention fusion layer to relate static Portable Executable (PE) byte data with dynamic API call sequences. The mathematical foundation of this fusion typically involves a query vector Q derived from one modality (e.g., bytes) and key K and value V vectors derived from another (e.g., APIs). The attention is calculated as follows:

$$\text{Attention}(Q, K, V) = \text{softmax}\left(\frac{QK^{\text{T}}}{\sqrt{d_k}}\right) \cdot V$$

where, d_k is the dimensionality of the keys. This allows the model to prioritize API calls that are most relevant to specific byte-level signatures, achieving near-perfect accuracy (up to 99.5%) in ransomware detection [42].

Similar transformer-based models like MT-CMVAD have shown significant improvements in video anomaly detection, achieving AUC scores of up to 98.9% while reducing computational complexity [41].

2) Hybrid and ensemble models: Despite the dominance of deep learning, hybrid models that combine traditional machine learning (ML) with DL often provide better results in resource-constrained IoT settings. Traditional models like Support Vector Machines (SVM), Random Forests (RF), and Decision Trees (DT) are prized for their simplicity, interpretability, and low computational requirements [2] [34] [48].

In a hybrid architecture, a deep learning model might be used for high-level feature extraction, with the final classification performed by a robust ensemble. For example, the FW-CNN model utilizes a one-dimensional CNN for feature learning, but tunes its hyperparameters using a hybrid metaheuristic optimizer to enhance its stability and detection rate. Another approach, the soft-voting ensemble classifier, fuses outputs from different specialized models using a confidence-weighted strategy, which has been shown to significantly reduce false positives in multimodal threat detection [11] [34] [48].

V. APPLICATIONS AND USE CASES

The practical impact of MML in IoT is best illustrated by its application to specific cybersecurity goals, where the fusion of diverse data sources directly addresses the weaknesses of unimodal systems [5] [6] [8] [39].

A. Multimodal Intrusion Detection Systems (M-IDS)

The dominant application of MML is the Intrusion Detection System (IDS). Modern M-IDS frameworks seek to create a "holistic" view of network and device behavior [5] [6] [8] [9] [35] [37].

1) Cyber-physical and industrial fusion: In smart grids and IIoT, M-IDS combines network traffic logs with physical sensor readings. An attacker might attempt a False Data Injection (FDI) to destabilize a power grid. While the individual sensor readings might appear within normal bounds, an MML model can detect the attack by identifying the subtle inconsistency between the sensors' reported states and the corresponding control-layer network commands [4] [5].

2) Federated and privacy-preserving detection: Systems like AI4FIDS leverage Federated Learning (FL) to combine data from multiple domains (e.g., different factories or hospitals), without compromising local data privacy. This allows the system to learn from a global pool of heterogeneous attack signatures while keeping sensitive local data behind its own firewall [8] [39].

3) Packet and metadata analysis: Traditional IDS often ignores the application layer. Newer MML models, such as the one proposed in NAIIDS4IoT, fuse low-level flow statistics with rich application-layer metadata, such as MQTT topic structures and payload entropy. This enables the detection of stealthy "Slow DoS" attacks that mimic legitimate network latency [5] [35].

B. Multimodal Malware Analysis

IoT malware has become increasingly evasive, using packing and encryption to hide its code from static scanners. MML addresses this by fusing static code features with dynamic behavior logs [10] [25] [28] [29] [43] [44] [52]. Table IV presents the multimodal malware analysis.

TABLE IV. MULTIMODAL MALWARE ANALYSIS

Feature Type	Specific Modalities	Core Advantage in MML
Static	Opcode sequences, Function Call Graphs (FCG), Byte-images.	Captures the comprehensive structural intent of the code.
Dynamic	System call traces, Network activity, Memory usage.	Resilient to code obfuscation and packing.
Fused	Cross-attention over structural and behavioral features.	Maximizes detection accuracy (99%+) and attribution to families.

Source: [10] [25] [28] [29] [43] [44] [52]

The TTGNet-AMD framework exemplifies this approach by using LSTM to process temporal opcode sequences while simultaneously using a Transformer-GCN hybrid to analyze the structural FCG. This collaborative interaction allows the model to identify malicious behavior even if the binary has been heavily obfuscated [29].

C. Secure Authentication and Access Control

Authentication in IoT is transitioning from static passwords to Continuous Authentication (CA) based on multimodal identity factors [26] [30] [31] [49] [50].

1) Behavioral and interaction fusion: MML models can verify a user's identity in real-time by fusing motion sensor data (accelerometer, gyroscope) with touch interaction patterns. This creates a "personal motion fingerprint" that is unique to the individual's biomechanics [31].

2) Biometric and liveness detection: Advanced Multi-Factor Authentication (MFA) systems integrate physiological traits (face, fingerprint, iris) with liveness indicators like Electrocardiogram (ECG) signals. Fusing these signals through a Siamese Neural Network architecture ensures that the system is not fooled by high-resolution photos or synthetic fingerprint replicas [30] [49] [50].

3) Continuous risk assessment: CA systems use MML to continuously monitor risk based on current and historical context. If a user's behavioral signature (e.g., typing speed or gait) deviates significantly from their profile, the system can automatically trigger a re-authentication request or lock the device [26] [31].

VI. DATASETS AND EVALUATION

The development of high-performing MML models is dependent on the availability of high-quality, diverse datasets that reflect the unique challenges of the IoT environment [13][24][27][46][47][51].

A. Common Multimodal IoT Security Datasets

Traditional datasets like NSL-KDD or Kyoto 2006+ are largely outdated for IoT research, as they do not capture the specific telemetry and protocols used in modern smart systems. Several benchmark datasets have emerged to fill this gap:

1) ToN-IoT: Sourced from the UNSW Canberra repository, this dataset integrates telemetry data from various sensors (weather stations, smart fridges) with network traffic logs and system event files from heterogeneous IoT devices. It captures a wide range of modern attacks, including ransomware, backdoors, and password cracking [13] [27].

2) Bot-IoT: A realistic dataset generated at the Cyber Range Lab of UNSW-Canberra, containing 72 million records that model IoT botnet activities such as DoS, DDoS, and information theft [51].

3) IoTID20: This dataset models a smart home network with devices like AI speakers, WiFi cameras, and smartphones, capturing 83 features across benign and malicious sessions [47].

4) CICIoT2023: An extensive and realistic dataset that executes 33 different attack types (divided into 7 classes) against a topology of 105 devices, including IoT devices as both attackers and victims [24].

5) N-BaIoT: Addressing the lack of public botnet data, this dataset provides real traffic from nine commercial IoT devices infected by Mirai and BASHLITE botnets [46] [51].

B. Evaluation Metrics and Benchmarking

Evaluating MML security systems requires a move beyond simple accuracy. In cybersecurity, the costs of a False Negative

(missing an attack) and a False Positive (blocking a legitimate user) are often asymmetrical.

1) Precision, Recall, and F1-score: These metrics are essential for evaluating performance on imbalanced datasets. Precision measures the reliability of an alarm, while Recall measures the system's ability to catch all malicious events. The F1-score provides the harmonic mean, which is critical for balancing these trade-offs.

2) Equal Error Rate (EER): Primarily used in authentication, EER identifies the point where the False Acceptance Rate (FAR) and False Rejection Rate (FRR) are equal, serving as a primary indicator of a system's robustness.

3) Inference latency and resource overhead: For IoT devices, the time and energy required to make a prediction are as important as the prediction's accuracy. Metrics such as "packets per second", throughput, and model size in kilobytes (KB) are increasingly used to benchmark models for edge deployment [20] [21] [45].

VII. Edge-Cloud Deployment Trade-offs

Deploying Multimodal Machine Learning (MML) models on resource-constrained Internet of Things (IoT) devices necessitates a principled trade-off between detection accuracy and computational efficiency. Within this context, edge computing emerges as a foundational architectural pillar, enabling low-latency inference and reduced bandwidth consumption through localized data processing, while simultaneously reinforcing system resilience via adaptive, on-device responses to environmental stressors or adversarial conditions. Conversely, while cloud-centric platforms offer substantial advantages for large-scale model training, centralized data governance, and long-term policy management, they introduce non-trivial inference delays and inherit systemic vulnerabilities, including heightened privacy risks and exposure to single points of failure. To reconcile these competing imperatives, hybrid edge–cloud architectures distribute computational workloads based on task criticality: real-time anomaly flagging and time-sensitive inference are executed at the edge, whereas computationally intensive cross-modal analysis, periodic model retraining, and high-level coordination are selectively offloaded to the cloud. This collaborative paradigm establishes a complementary, rather than substitutive, relationship between edge and cloud tiers, thereby simultaneously satisfying the demands of real-time responsiveness, systemic scalability, and long-term operational resilience in resource-constrained IoT environments [20][21][45][53] (see Table V).

TABLE V. Quantitative Edge vs. Cloud Inference Trade-Offs

Deployment Mode	Inference Latency	Accuracy Δ -vs. Cloud	Representative Ref.
Full Cloud	50–200 ms	Baseline (0%)	[20][21]
Full Edge (quantised INT8)	5–15 ms	−2 to −4%	[45][58][60]
Selective Edge-Cloud Offload	8–25 ms (local); 80–150 ms (offloaded)	−0.5 to −1.5%	[20][21][53]
Federated (distributed edge)	10–30 ms per node	−1 to −3%	[8][39]

VIII. Open Challenges and Future Directions

The journey from academic research to practical, large-scale deployment of MML in IoT security is hindered by several significant obstacles that define the current research frontier [3] [20] [21] [22] [45] [53].

A. Data Synchronization and Spatiotemporal Alignment

A fundamental challenge in MML is the "asynchronous nature" of IoT data. Different sensors operate at different sampling rates; for instance, a network flow meter might provide updates every second, while a thermal sensor reports every minute, and a camera captures thirty frames per second.

Integrating these discordant streams requires robust alignment techniques. Current research into cross-modal attention mechanisms and transformer-based interpolation offers a path forward, allowing models to learn relationships across time steps even when data is missing or sporadically available. Furthermore, spatiotemporal misalignment where sensors have different spatial resolutions or perspectives remains an open problem, particularly in smart city environments [15] [16] [17] [32] [40].

B. Explainability and Trustworthiness (XAI)

As MML models grow in complexity, they increasingly suffer from the "black-box" issue, where their decision-making logic is opaque to human analysts. In security contexts, this lack of transparency is a critical liability, as security personnel must be able to validate and trust a system's output before taking remediation actions.

The integration of Explainable AI (XAI) tools like SHAP and LIME is becoming mandatory for advanced M-IDS. SHAP (Shapley Additive Explanations), based on game theory, can identify the specific contribution of each feature or modality to a prediction, providing a "visual explanation" that can help an analyst distinguish between a genuine cyberattack and a benign anomaly. Future research must focus on making these XAI methods computationally lightweight enough to run on IoT hardware [14] [41] [54] [55] [56] [57].

C. Resource Constraints and the Optimization Triad

The most persistent challenge is the "resource-performance trade-off". High-accuracy deep learning models, particularly large multimodal transformers, are computationally intensive and require significant memory and energy. IoT devices, however, often have power budgets below 10 watts and only kilobytes (KB) or megabytes of RAM [20] [21] [45] [53] [58] [59] [60].

The "Optimization Triad" addressing this includes:

1) Model compression: This includes pruning (removing redundant weights or neurons), quantization (reducing numerical precision from 32-bit floats to 8-bit integers), and knowledge distillation (training a small "student" model to mimic a large "teacher" model) [58] [59] [60].

2) Hardware acceleration: Development of specialized edge AI chips and hardware-aware pruning strategies that align

the model architecture with the specific processing units of the device [45] [53] [60].

3) Collaborative edge-cloud architectures: Implementing selective cloud offloading, where simple anomalies are processed locally at the edge for low latency, while complex, cross-modal analysis is offloaded to powerful cloud clusters [20] [21] [45] [53].

4) Toward antifragile and autonomous systems: Looking toward 2026 and beyond, the research community is moving toward "Antifragility", the design of systems that not only resist attacks (robustness) or recover from them (resilience) but actually grow stronger and more intelligent through exposure to stress and volatility. This involves integrating continuous streaming learning that can adapt to "concept drift" in real-time without human intervention. Furthermore, the rise of "Agentic AI" suggests a future where autonomous agents will coordinate defense responses across billions of devices, using multimodal insights to predict and mitigate threats before they even occur [3] [22] [61].

IX. Conclusion

The convergence of the Internet of Things and advanced machine learning has fundamentally redefined the parameters of cybersecurity. As this systematic review has demonstrated, the transition from unimodal to multimodal security architectures is not merely a technical upgrade but a necessary paradigm shift for defending complex, interconnected ecosystems. By integrating diverse and heterogeneous data streams—ranging from network flow statistics to behavioral biomechanics—Multimodal Machine Learning (MML) provides the holistic situational awareness required to detect and mitigate contemporary multi-vector threats [1] [3] [7] [22].

The classification of current literature reveals a clear trajectory toward deep learning models augmented by dynamic attention mechanisms. Architectures such as multimodal transformers and hybrid CNN-LSTM networks have established new benchmarks in accuracy for intrusion detection, malware analysis, and continuous authentication. These models effectively leverage the complementarity of different modalities, bridging the semantic gap between low-level telemetry and high-level behavioral patterns [10] [34] [35] [40] [42].

However, the field remains at a critical juncture. The challenges of data synchronization, model explainability, and resource constraints on the IoT edge must be addressed before MML can be deployed universally. The emerging optimization triad of model compression, hardware acceleration, and collaborative edge-cloud architectures provides a promising roadmap for future development. Ultimately, the goal is to move beyond passive defense toward autonomous, antifragile security systems that can self-heal and adapt to an ever-evolving threat landscape, ensuring the long-term safety, privacy, and resilience of our increasingly digitalized world [3] [20] [22] [45] [53] [61].

***Abstract*—Breast cancer is a highly heterogeneous disease with Luminal-A, Luminal-B, HER2-Enriched, Basal-Like, and Normal-Like molecular subtypes. Accurate classification of breast cancer molecular subtypes is essential for effective diagnosis, treatment, and planning. In recent years, multi-omics data has been widely used to improve classification performance. However, most of the existing studies focus on various combinations of multi-omics data types and variants without considering their biological relevance and computational effectiveness. This research study aims to systematically analyze, validate, and optimize the combinations of multi-omics data types and variants for accurate breast cancer molecular subtypes classification. The main goal is to identify the most suitable biologically meaningful combinations for improving classification performance. This research study provides the biological rationale for integrating the multi-omics data types and variants, and analyzes the various combinations used by existing studies for breast cancer subtype classification and the reasons behind their selection. Based on this analysis, possible and best-proposed combinations of multi-omics data types and variants are presented for the accurate classification of breast cancer molecular subtypes, based on both biological and computational perspectives. In addition, this research study identifies and recommends reliable public databases that provide multi-omics datasets with verified PAM50 labels for accurate subtype classification. The findings can help researchers design more accurate and reliable classification models by using the best proposed combination of multi-omics data types and variants, and select appropriate datasets with validated subtype labels.**

***Keywords*—Breast cancer; molecular subtypes; multi-omics; data integration; data types and variants; datasets**

I. Introduction

Breast cancer is considered one of the most serious health issues worldwide. According to GLOBOCAN [1], Kim et al. [2], the breast cancer cases recorded 2.6 million new cases and 685,000 deaths in 2024, and breast cancer became the most commonly diagnosed cancer. To treat the patients, doctors need to know the exact type of breast cancer and help them receive the fastest and best treatment, knowing the condition of breast cancer [3].

The genetic alterations and DNA damage can be influenced by estrogen exposure in the cell, that led to breast cancer. DNA defects or cancer-causing genes like BRCA1 and BRCA2 can occasionally be inherited [4]. Consequently, the chance of developing breast cancer is increased if breast cancer has already appeared in the family. In a healthy person, the immune system attacks the cells with aberrant DNA or abnormal development. When breast cancer patients experience this failure, tumors develop and spread [5].

Researchers have found that breast cancer is not one single disease. It has different molecular subtypes that behave in different ways, as shown in Fig. 1. Based on the heterogeneity, breast cancer is classified into two stratifications, which are histological and molecular [6]. Histological classification is mainly based on morphological study, whereas molecular classification is based on the molecular pattern of breast cancer. Knowing the specific molecular subtype is very important because each subtype responds and plays differently in the process of treatment [6].

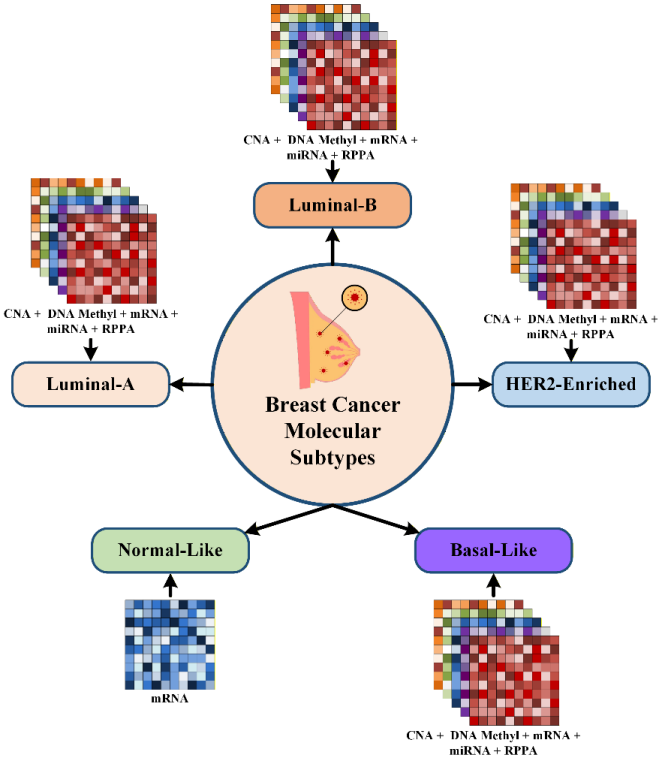

Fig. 1. Breast cancer molecular subtypes

*Corresponding author

Despite all this progress, existing research studies for breast cancer molecular subtypes classification lack accurate combinations of multi-omics data types and variants. The various combinations of data types and variants are used for breast cancer molecular subtypes classification without thinking deeply about the biology behind them, such as how genes, proteins, and chemical marks work together in each subtype. Both biological reasons (for example, which layers best capture hormone pathways or cell growth signals) and computer science reasons (for example, which mixes give stable models and clear results) play an important role in the classification of breast cancer molecular subtypes.

According to Shah et al. [5], multi-omics can improve accuracy, but there are still problems that exist, including HDLSS, limited explainability of AI models, class imbalance, multi-omics integration, and choosing the correct multi-omics data types and variant combinations. Many existing studies select various combinations of multi-omics data types and variants, but they do not explain why those combinations are best for the breast cancer molecular subtypes classification. Also, the majority of the breast cancer classification studies are struggling to identify verified and authentic databases for breast cancer datasets, while most of the studies also find it hard to locate the datasets that are completed with accurate PAM50 subtypes labeling.

Wrong or incomplete classification of breast cancer molecular subtypes due to the inappropriate combination of data types and variants, selection of wrong databases and datasets can lead to bad treatment choices and poorer patient results. Therefore, there is a pressing need to identify the optimal multi-omics data type and variant combinations along with the verified multi-omics databases and datasets for the accurate and reliable classification of breast cancer molecular subtypes. It will help create more reliable tools for doctors and move the field toward truly personalized medicine for breast cancer.

The main contributions of this research study to the field of breast cancer research and multi-omics data analysis are mentioned below:

- It provides a comprehensive investigation of various combinations of multi-omics data types and variants for breast cancer molecular subtype classification based on biological and computational evidence.
- It clearly explains the biological rationale for integrating multi-omics data, showing the biological importance of combining these multi-omics data types and variants necessary for accurate classification.
- It analyzes the existing studies on multi-omics integration for breast cancer subtype classification and highlights the various multi-omics data types and variant combinations.
- It proposes the optimal possible and best combination of multi-omics data types and variants based on both strong biological evidence and computational effectiveness for breast cancer molecular subtypes classification.
- It identifies and recommends reliable public databases and datasets that provide complete multi-omics datasets with accurate PAM50 subtype labels for future research.

The rest of the study is organized as follows: Section II emphasizes the breast cancer molecular subtypes, while Section III focuses on the omics, including mono-omics and multi-omics, along with the details of the multi-omics data types and variants. Section IV is about the biological rationale for combining multi-omics data types in breast cancer molecular subtypes. Furthermore, Section V describes multi-omics integration for breast cancer molecular subtype classification. Section VI is about the database and dataset selection. Section VII is future directions and suggestions and lastly, Section VIII is the conclusion of the study.

II. Breast Cancer Molecular Subtypes

Breast cancer is categorized into the five molecular subtypes, including the Luminal-A, Luminal-B, HER2-Enriched, Basal-Like and Normal-Like. Table I shows the description of the breast cancer molecular subtypes based on gene expression features, growth rate and treatment prognosis. Different breast cancer molecular subtypes are identified by unique gene expression patterns that affect on tumors behave and tumors respond to treatment [7]. Each molecular subtype of breast cancer has been elaborated in detail in the subsections below:

A. Luminal-A

Luminal-A is one of the most common molecular subtypes of breast cancer and about 50% to 60% of all breast cancer cases. It is characterized by the higher expression of the ER(+) and PR(+) and it has a HER2(-) status [8]. This tumor has a lower level of proliferation-related genes (measured by Ki-67). Breast cancer patients with Luminal-A have often better prognoses as compared to the other molecular subtypes, including lower recurrence risk and higher survival rates [9].

B. Luminal-B

Luminal-B occur for 15% to 20% of breast cancer molecular subtypes and are often more aggressive. The hormone-positive molecular of Luminal-B is characterized by ER(+), PR(+) and HER2(+) status [8]. As compared to Luminal-A, Luminal-B tumors typically show high proliferative [10]. Also, it shows more aggressive clinical and biological behaviour.

C. HER2-Enriched

HER2 occur 15% to 20% of the breast cancer molecular subtypes. It is characterized by high expression of the HER2(+) and protein along with the ER(-) and PR(-) status [8]. This molecular subtype confers more aggressive clinical and biological behavior.

D. Basal-Like

Basal-Like is also known as Triple-Negative Breast Cancer (TNBC) and is characterized by the absence of ER(-), PR(-) and HER2(-) [8]. This tumor is more aggressive than the Luminal-A and Luminal-B and grows faster. The genes of these tumors are typically found in the basal/myoepithelial cells of the abnormal breast [11]. It affects younger women, particularly those who have BRCA1 gene mutations.

TABLE I. DESCRIPTION OF BREAST CANCER MOLECULAR SUBTYPES

Subtypes	Gene Expression Features	Growth Rate	Prognosis	Percentage
Luminal-A	ER(+), PR(+), HER2(-)	Slow	Normal	About 50% to 60%
Luminal-B	ER(+), PR(+), HER2(+)	Fast	Bad	About 15% to 20%
HER2-Enriched	ER(-), PR(-), HER2(+)	Faster	Worse	About 15% to 20%
Basal-Like	ER(-), PR(-), HER2(-)	Fastest	Worst	About 8% to 37%
Normal-Like	ER(- /+), PR(-/+), HER2 (-/+)	Slow to Moderate	Good	About 5% to 10%

E. Normal-Like

Normal-Like accounts for about 5% to 10% of all breast cancer molecular subtypes. Normal-Like is characterized by ER(-), PR(-) and HER2(-) status [8]. It is a rare molecular subtype that is identified with the help of gene expression profiling that demonstrates similar characteristics to normal breast tissues. Normal-Like typically expresses the genes that are associated with the adipose tissues and other non-epithelial cells that are found in the breast [8].

III. OMICS DATA

Omics data refers to the large-scale biological data that contain various levels of molecular information of a living organism. The term "omics" contains biological information such as genomics (study of DNA and genetic variations), epigenomics (study of heritable changes in gene expression that do not involve changes in the DNA sequence), transcriptomics (study of RNA and gene expression) and proteomics (study of proteins) [12]. Each omics data type provides a unique structure and view of the biological organism [13].

A. Mono-Omics

Mono-omics data is the utilization of a single type of omics data type to study biological systems, such as genomics or epigenomics or transcriptomics. Mono-omics analysis is simpler, easier to process and requires less computational power compared to multi-omics analysis [14]. Mono-omics data types are widely used in previous research and have offered insights into disease mechanisms. For instance, Cristovao, et al. [15], Zeng, et al. [16], Li and Nabavi [17] use mon-omics data, particularly on genomics or transcriptomics data types, to analyze and classify breast cancer molecular subtypes. However, mono-omics data focus on capturing only one layer of biological information, which limits the potential of mono-omics data to fully represent the complexity of heterogeneous diseases such as breast cancer molecular subtypes classification [18].

B. Multi-Omics

Multi-omics data refers to the integration of various data types of omics to provide a detailed and comprehensive structure and view of biological systems [19]. Instead of depending on a single layer of information, such as mono-omics data type, multi-omics combines different molecular data sources at different molecular layers of an organism to better understand the complex and heterogeneous diseases, including the breast cancer molecular subtypes classification [20]. Multi-omics data helps in capturing the important relationships and interactions among different biological processes of an organism that lead to more reliable and accurate classification of breast cancer molecular subtypes [21].

C. Multi-Omics Data Types

There are four main data types of multi-omics, including genomics, epigenomics, transcriptomics and proteomics. Each multi-omics data type is described in subsections.

1) Genomics: It is the study of the complete set of DNA within a cell, including all genes and their functions. It concentrates on the understanding of genetic changes in an organism, such as insertions, deletions and mutations [22]. In breast cancer molecular subtypes, genomics assists in identifying the acquired or inherited genetic alterations that trigger cancer development or influence tumor behavior in the breast [23]. The genetic changes in breast cancer deactivate or activate the oncogenes and tumor suppressor genes that lead to uncontrolled breast cancer cell growth [22]. Overall, genomics provides the foundational layer of biological information for understanding the origin of breast cancer at the DNA level.

2) Epigenomics: It is the study of changes in gene activity that do not involve alterations in the DNA sequence itself. Instead, it concentrates on the regulatory mechanisms such as DNA-Methylation, histone modification and chromatin structure changes. The epigenetic modifications can turn genes "on" or "off" any gene without changing the underlying genetic code [24]. In breast cancer, abnormal epigenetic changes lead to the silencing of important tumor suppressor genes or the activation of harmful genes, contributing to breast cancer progression [25]. Epigenomics is important because it contains the information about the environmental and biological factors that can influence gene behavior without changing DNA.

3) Transcriptomics: It is the study of RNA molecules that are produced from DNA through the process of transcription. It mainly concentrates on the gene expression levels, demonstrating which genes are transcribed actively into RNA under specific conditions [26]. In breast cancer, transcriptomics assists in identifying the differences in gene expression patterns across different cancer molecular subtypes, such as Luminal or Basal-like types [27]. These expression patterns provide important insights into tumor activity, cellular processes, and disease progression.

4) Proteomics: Proteomics is the study of proteins, which are the final functional products of genes. It concentrates on the protein abundance, modifications, interactions and structure within biological systems [28]. Proteins carry out most cellular

functions; proteomics provides direct insight into the way cells behave in normal and disease conditions [29]. In breast cancer, abnormal protein interactions or expression indicate tumor metastasis, growth and treatment resistance [27]. Proteomics is important because it reflects the actual functional state of the cell, making it highly valuable for understanding disease mechanisms and improving subtype classification.

Overall, the integration of multi-omics data types is very important for breast cancer molecular subtypes classification. Each omics layer provides complementary and unique information, and combining them helps capture the full complexity of breast cancer biology. By integrating multi-omics data types in an appropriate biological and computational way, researchers can improve classification accuracy, identify more reliable biomarkers, and develop better personalized treatment strategies for different breast cancer subtypes.

D. Multi-Omics Data Variants

In breast cancer research, multi-omics data are further categorized into different variants that represent specific types of molecular measurements within each multi-omics data type. These variants provide more detailed and fine-grained biological information about tumor development, progression, and subtype differences [30]. Instead of treating each omics layer as a single dataset, researchers analyze different variants such as genetic alterations, gene expression levels, epigenetic modifications, and protein activity. Each multi-omics data variant captures a unique aspect of cancer biology, and when combined, they help to build a more complete and accurate model for breast cancer molecular subtype classification [31].

1) Copy Number Alteration (CNA): Copy Number Alteration refers to changes in the number of copies of a particular DNA segment in the genome. These alterations can include gains (amplifications) or losses (deletions) of chromosomal regions. CNA is a key variant of genomics because it directly reflects structural changes in DNA that may lead to cancer development by increasing oncogene activity or deleting tumor suppressor genes [32].

2) Copy Number Variation (CNV): Copy Number Variation is a form of genomic structural variation where sections of the genome vary in copy number between individuals. CNVs can influence gene dosage and are strongly associated with cancer susceptibility and tumor progression. In breast cancer, CNVs help explain variability in gene expression and subtype-specific genomic instability [32].

3) Single Nucleotide Polymorphism (SNP): Single Nucleotide Polymorphisms are variations at a single nucleotide position in DNA. SNPs are the most common type of genetic variation and can affect how genes function or how proteins are produced. In breast cancer genomics, SNPs are used to identify genetic risk factors and subtype-specific mutations [33].

4) DNA Methylation: DNA methylation is an epigenomic modification where methyl groups are added to DNA, usually affecting gene expression without changing the DNA sequence. It plays a major role in gene silencing and activation [34]. In breast cancer, abnormal DNA methylation patterns are linked to tumor suppression loss and subtype-specific regulatory changes [35].

5) Messenger RNA Expression (mRNA): mRNA represents the transcriptomic level of gene activity, measuring how actively genes are being transcribed into RNA. It reflects real-time cellular function and is widely used for defining breast cancer intrinsic subtypes, such as Luminal and Basal-Like. mRNA profiles provide strong signals for tumor classification and biological interpretation [36].

6) MicroRNA Expression miRNA: miRNAs are small non-coding RNA molecules that regulate gene expression by binding to target mRNA and preventing protein production. miRNA is considered a regulatory transcriptomic variant that influences cancer progression by controlling multiple genes simultaneously [37]. In breast cancer, miRNA expression patterns are associated with subtype differences and tumor aggressiveness [38].

7) Reverse Phase Protein Array (RPPA): Reverse Phase Protein Array is a proteomics-based technique used to measure protein expression and activation levels, including post-translational modifications such as phosphorylation. RPPA provides functional information about signaling pathways in breast cancer. It reflects the final stage of gene expression and is essential for understanding how molecular changes translate into cellular behavior and treatment response [39].

IV. Biological Rationale for Combining Multi-Omics Data Types in Breast Cancer Molecular Subtypes

Breast cancer is a highly heterogeneous disease with various molecular subtypes. Each subtype shows different genetic mutations, gene expression patterns, epigenetic regulation, and protein activity [23]. Mono-omics data types are not sufficient to fully explain tumor behavior because cancer development is driven by multiple biological mechanisms acting together across different omics levels. For instance, Basal-like tumors show very high TP53 mutation rates, while Luminal tumors show frequent PIK3CA and GATA3 mutations, and HER2-enriched tumors are strongly associated with ERBB2 amplification [39]. These differences clearly indicate that breast cancer cannot be fully understood using only one type of omics data.

A. Relationship of Multi-Omics Data Types and Variants

Genomics, epigenomics, transcriptomics, and proteomics multi-omics data types are closely associated and work together in order to describe the detailed and comprehensive view of a full biological system of a cell. Multi-omics data types are not independent; instead, they form an organized, sequenced, and layered biological flow where each multi-omic layer influences the next [40]. Genomics represents the foundation because DNA contains all the genetic information required for the development and function of a cell. However, the activity of a gene is not determined by DNA alone. Epigenomics acts as a regulatory layer on top of genomics by controlling whether specific genes are turned on or off through mechanisms. The epigenetic changes directly influence transcriptomics because only genes that are activated at the epigenomic level are transcribed into RNA. Transcriptomics then reflects the real-time gene expression profile of a cell, showing which genes are

actively producing RNA molecules under certain conditions. The RNA is further translated into proteins, making proteomics the final functional layer of the biological system. Proteins carry out most cellular activities, including signaling, metabolism, and structural functions, and therefore represent the actual biological outcome of genomic instructions [12]. The relationship among the multi-omics data types is highly interconnected, meaning that changes in one layer directly lead to effects in others, as shown in Fig. 2. Because of the strong interdependencies, integrating multi-omics data is very important for understanding heterogeneous and complex diseases like breast cancer. The interconnected biological flow enables researchers to capture not only individual molecular changes but also the dynamic relationships between different molecular layers, leading to more accurate and biologically meaningful cancer subtype classification [39].

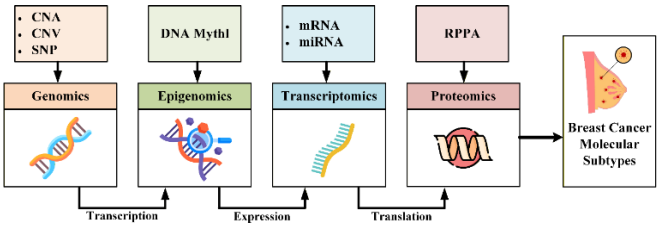

Fig. 2. Relationship among the multi-omics data types and variants.

B. Biological Dependency of Multi-Omics

One of the most important biological reasons for integrating multi-omics data is the strong dependency between multi-omics data types. DNA mutations can influence epigenetic regulation, which then affects gene expression and ultimately protein production. For example, TP53 mutations in Basal-like tumors lead to uncontrolled cell proliferation, while PIK3CA mutations in Luminal tumors activate downstream signaling pathways affecting both RNA expression and protein signaling [39]. Similarly, epigenetic silencing of tumor suppressor genes can reduce RNA and protein expression even when DNA remains unchanged. This cascading biological relationship shows that each omics layer only provides partial information, but together they describe the complete disease mechanism [39].

C. Importance of Multi-Omics Integration for Breast Cancer Molecular Subtypes Classification

Because breast cancer subtypes are defined by combined genetic, epigenetic, transcriptional, and proteomic features, integrating all these data types is necessary for accurate classification. TCGA multi-platform studies have shown that basal-like tumors are consistently distinct across all omics layers, while luminal and HER2 subtypes show overlapping patterns across different data types [41]. This proves that single-omics approaches fail to capture subtype complexity. Multi-omics integration allows researchers to identify more robust biomarkers, detect hidden subtype relationships, and improve classification accuracy by combining complementary biological signals [42].

In summary, breast cancer is driven by interconnected molecular mechanisms across multiple biological layers. Genomics explains structural changes, epigenomics explains regulatory control, transcriptomics reflects gene activity, and proteomics captures functional outcomes. However, none of these layers alone can fully represent tumor behavior. Therefore, integrating the genomics, epigenomics, transcriptomics, and proteomics multi-omics data is biologically necessary to capture the complete molecular architecture of breast cancer and improve the accuracy of molecular subtype classification.

V. Multi-Omics Integration for Breast Cancer Molecular Subtype Classification

The successful integration of multi-omics variants provides deep insights into the molecular alterations across various regulatory levels of breast cancer. The correct selection of multi-omics data types and variants is very important for breast cancer molecular subtype classification and gives us a full picture of the molecular landscape of breast cancer. This helps in identifying subtypes and finding possible biomarkers for personalised treatment plans [31]. There are various combinations of multi-omics data types and variants that are used by existing research studies for performing the breast cancer molecular subtypes classification, as shown in Fig. 3.

A. Combinations of Multi-Omics Data Types for Breast Cancer Molecular Subtypes Classification

Multi-omics data types integration has become very important in classifying the breast cancer molecular subtype. By combining genomics, epigenomics, transcriptomics, and proteomics multi-omics data types, researchers can capture the heterogeneous and complex structure and mechanism of breast cancer. As compared to mono-omics integration, multi-omics integration improves the ability to identify subtypes of specific biomarkers, discover the interactions and relationships among various multi-omics data types and variants, and enhance the overall classification and prediction performance.

Existing studies have used various combinations of multi-omics data types, as shown in Table II, to improve the breast cancer molecular subtypes classification. The existing studies use combinations of two or three data types to classify the breast cancer molecular subtypes.

TABLE II. Multi-Omics Data Types Used by the Existing Studies

No of Multi-Omics Data Types	Genomics	Epigenomics	Transcriptomics	Proteomics	References
2	✓		✓		[15-17]

4	✓	✓	✓	✓	**Proposed**

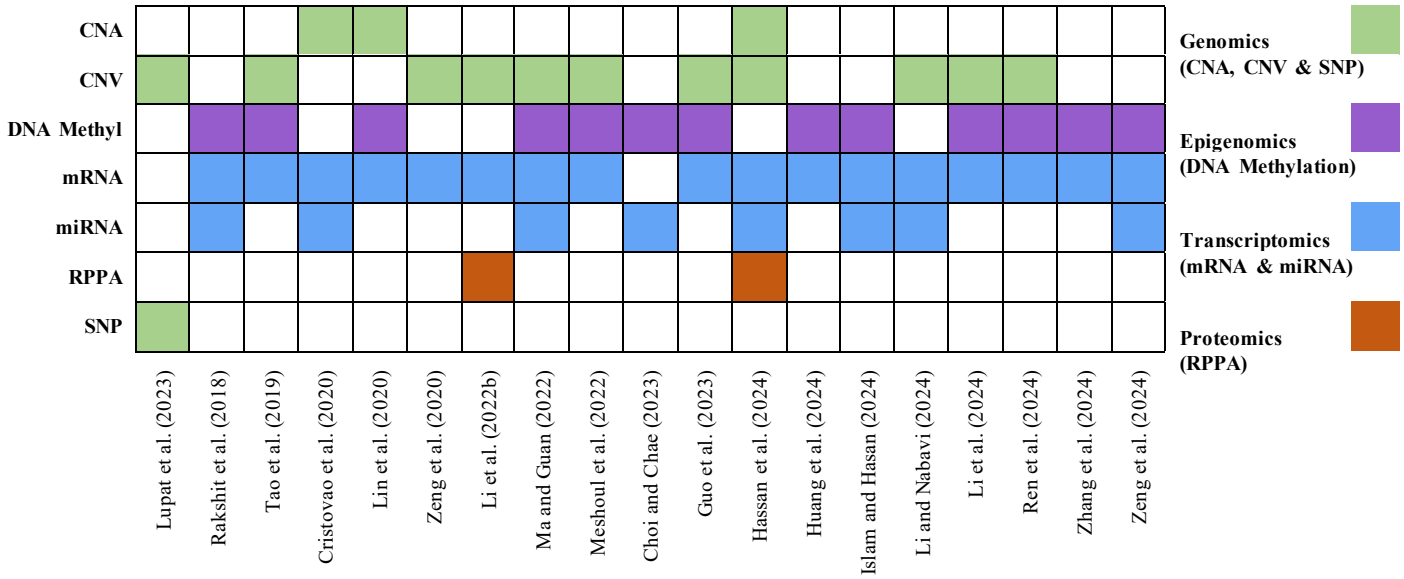

Fig. 3. Multi-omics data types and variants used by the existing studies.

Each combination of multi-omics data types provides unique insights; however, the existing studies that integrated three data types generally show significant performance. Based on the detailed analysis, it is suggested that the integration of four main multi-omics data types tends to provide a more detailed molecular structure, which can lead to more reliable and accurate classification of breast cancer molecular subtypes.

B. *Combinations of Multi-Omics Variants for Breast Cancer Molecular Subtypes Classification*

With the rapid growth of multi-omics data, Copy Number Variation (CNV), Single Nucleotide Polymorphism (SNP), DNA methylation, mRNA expression, miRNA expression, and protein abundance (RPPA), multi-omics variants have become available. The proper and correct integration of multi-omics variants allows for a more robust and reliable classification of breast cancer molecular subtypes by capturing the important information in each omics data type [42]. Researchers use various combinations of the multi-omics variants to improve the classification performance in breast cancer molecular subtypes classification.

Table III presents the various combinations of multi-omics variants that are utilized by the existing studies for the successful classification of breast cancer subtypes. Existing studies use combinations of two, three, four, or five multi-omics data variants for the classification of molecular breast cancer subtypes. Overall, the integration of multi-omics variants empowers researchers to explore and capture the complex molecular interactions to understand the mechanism and underlying structure of breast cancer molecular subtypes. Each multi-omics variant combination provides unique information about the breast cancer subtypes on the molecular level. Based on the detailed analysis, it is suggested that integrating the five multi-omics variants can enhance breast cancer molecular subtypes classification accuracy and performance.

TABLE III. MULTI-OMICS DATA VARIANTS USED BY THE EXISTING STUDIES

Notably, models incorporating the accurate multi-omics data types and variants tend to achieve superior classification performance and emphasize the value of multi-omics data fusion in breast cancer molecular subtypes analysis.

C. Proposed Combinations of Multi-Omics Variants for Breast Cancer Molecular Subtypes Classification Based on Biological Rationale

The reliable and appropriate integration of multi-omics data types and variants plays an important role in enhancing the accuracy and robustness of breast cancer molecular subtype classification. Based on biological evidence and insights from existing computational classification models, various combinations of multi-omics data variants are utilized for capturing the heterogeneous and complex view of breast cancer, as mentioned in Section V-A and Section V-B. These combinations are selected to represent different layers of biological information, including genomic alterations, epigenetic regulation, gene expression, and protein activity, which collectively define the breast cancer behavior and subtype characteristics.

From a biological perspective, the combination of genomics, epigenomics, transcriptomics, and proteomics multi-omics data types, along with their desired variants, allows for a comprehensive representation of breast cancer structure, behavior, and progression across multiple molecular levels.

Based on the biological rationale and computational models for breast cancer molecular subtypes classification, the combination of CNV, DNA Methylation, mRNA, and RPPA multi-omics data variants, which integrates genomic structure, epigenetic control, gene expression, and protein activity, or the combination of CNV, DNA methylation, miRNA, and RPPA multi-omics data variants, which replaces mRNA with miRNA, resulting in a combination of, focusing more on regulatory transcriptomic mechanisms. These possible combinations have demonstrated effectiveness in capturing subtype-specific patterns and improving classification performance compared to mono-omics analysis. However, these combinations are still incomplete and can be further explored by adding more multi-omics variants.

To address these limitations, this research study proposes an enhanced and more comprehensive combination that integrates CNV, DNA Methylation, mRNA, miRNA, and RPPA multi-omics data variants. The proposed combination is based on the biological justification because it captures all major layers of molecular regulation, starting from DNA-level structural variations (CNV), followed by epigenetic regulation (DNA-Methylation), gene expression (mRNA), gene regulation (miRNA) and finally protein-level functional outcomes (RPPA), as shown in Fig. 4. By including both mRNA and miRNA, the model benefits from a more complete representation of transcriptomic activity, including both expression and regulatory mechanisms. The inclusion of RPPA further strengthens the model by incorporating protein-level validation of upstream molecular changes.

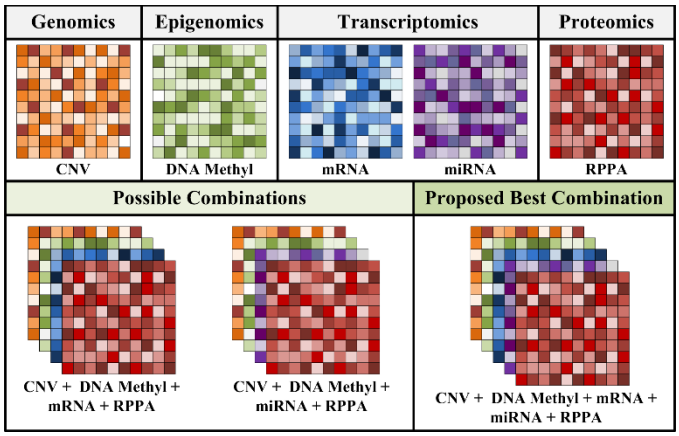

Fig. 4. Possible and proposed best combinations of multi-omics variants for breast cancer molecular subtypes classification.

From a computational perspective, integrating these complementary data variants can improve feature diversity, reduce information loss, and enhance the ability of machine learning and deep learning models to learn complex patterns associated with different breast cancer subtypes. The proposed comprehensive combination not only improves classification accuracy but also increases model robustness and biological interpretability. Therefore, the proposed combination of multi-omics data types and variants is considered the most suitable and effective strategy for accurate breast cancer molecular subtype classification.

VI. Database and Dataset Selection

There are various databases used for breast cancer research, as mentioned in Table IV, each with its own characteristics, quality, multi-omics types, and variants. Compared to other commonly used databases such as CPTAC, NCBI, GEO, and METABRIC, the TCGA and UCSC Xena databases are among the most widely used and reliable sources for breast cancer multi-omics datasets. TCGA (The Cancer Genome Atlas) is the original and one of the most comprehensive cancer research projects, led by the National Cancer Institute (NCI), which profiled more than 20,000 primary tumors across 33 different cancer types, including breast cancer. It provides a complete range of multi-omics data types and their variants, making it highly suitable for molecular subtype classification studies. The official repository for TCGA data is the Genomic Data Commons (GDC), where both raw and processed datasets are available. On the other hand, UCSC Xena is another powerful data visualization and exploration platform that serves as a user-friendly portal for accessing breast cancer datasets. UCSC Xena re-processes and organizes multi-omics data into easy-to-use formats, allowing researchers to efficiently explore, integrate, and download datasets across all major omics types and variants. Due to their comprehensive coverage of multi-omics data types and variants, as shown in Table IV, standardized processing, and availability of clinically annotated information such as PAM50 subtype labels, TCGA, and UCSC Xena are considered the most suitable and commonly used databases for breast cancer multi-omics research and classification tasks.

Table IV presents a widely used databases and repositories for breast cancer molecular subtype classification datasets. It shows that multi-omics data, particularly genomics, epigenomics, transcriptomics, and proteomics, can be effectively obtained from platforms such as Linkedomics-TCGA-BRCA, UCSC-XENA-BRCA, and GDC-TCGA-BRCA. While other repositories like CPTAC, NCBI, GEO, and METABRIC also provide valuable breast cancer datasets, they have certain limitations, such as missing omics layers (e.g., proteomics or epigenomics), restricted cohorts, or static data availability. Table V describes the multi-omics GDC-TCGA-BRCA dataset used for breast cancer molecular subtype classification. This dataset is downloaded from the GDC-TCGA repository and carefully preprocessed to ensure accurate subtype labeling using PAM50 standards. Since labeling inconsistencies are a common challenge in existing studies, all samples were manually validated and assigned standardized labels to improve reliability. The dataset includes multiple multi-omics data variants along with their respective feature dimensions and sample sizes.

Multi-Omics Datatypes	Multi-Omics Variants	Original Features	Original Sample Size	Label Sample Size
Genomics	CNV	60624	1082	1021
Epigenomics	DNA-Methylation	486428	893	774
Transcriptomics	mRNA	60661	1226	1052
	miRNA	1882	1202	1036
Proteomics	RPPA	488	919	853

Table VI outlines the multi-omics LINKEDOMICS-TCGA-BRCA dataset, which was obtained from the Linkedomics platform. Similar to the GDC dataset, this dataset was also rigorously preprocessed, and PAM50 labels were assigned and validated to ensure consistency and accuracy in breast cancer molecular subtype classification. It contains a more comprehensive set of omics data, including genomics, epigenomics, transcriptomics, and proteomics (RPPA), making it particularly suitable for integrative multi-omics analysis. Finally, Table VII presents the multi-omics UCSC-XENA-BRCA dataset, which was collected from the UCSC Xena repository. This dataset was also preprocessed following the same standardized pipeline, where PAM50 labels were carefully validated and assigned to address common labeling challenges in breast cancer datasets. It includes extensive high-dimensional data across genomics, epigenomics, transcriptomics, and proteomics, further supporting robust multi-omics-based classification. Collectively, these datasets provide a strong foundation for developing and evaluating accurate breast cancer molecular subtype classification models.

In addition, the PAM50-validated labels generated and refined in this research study for all the datasets in Table V, Table VI, and Table VII are publicly available to support reproducibility and future research. The breast cancer molecular subtypes PAM50-labels can be downloaded from the GitHub repository, enabling other researchers to utilize standardized and reliable data for breast cancer molecular subtypes classification.

VII. Suggestions and Future Directions

This research study shows that the best combination of multi-omics data types and variants for breast cancer molecular subtypes classification is CNV + DNA methylation + mRNA + miRNA + RPPA because it covers all important biological layers from DNA changes to protein activity. Future research should evaluate the proposed best combination with more advanced machine learning and deep learning models to determine whether classification accuracy and robustness can be improved further. Researchers can also explore additional possible and optimized combinations of multi-omics data types and variants to strengthen predictive performance and improve generalization capability.

In addition, the optimized multi-omics combinations identified and validated in this research study should be further tested through practical implementation and real-world validation using a breast cancer molecular subtype classification experiment. Practical simulation using actual multi-omics breast cancer datasets and clinical classification environments is important to confirm the reliability, scalability, and effectiveness of the identified combinations in real diagnostic scenarios.

It is also important to evaluate the proposed models on other cancer-related datasets and in clinical settings to assess their adaptability and clinical usefulness. Future work should further focus on improving model interpretability so that researchers and healthcare professionals can better understand the classification decisions. Moreover, challenges such as missing data handling, high dimensionality, data imbalance, and computational complexity should also be addressed in future studies. Furthermore, future studies should also investigate the computational cost and dimensionality challenges associated with integrating multiple high-dimensional multi-omics variants simultaneously. The integration of CNV, DNA methylation, mRNA, miRNA, and RPPA data can significantly increase data dimensionality, storage requirements, computational complexity, and model training time, particularly when implemented using standard computing resources. Therefore, future work should focus on developing computationally efficient frameworks, dimensionality reduction strategies, optimized feature selection methods, and scalable architectures to improve practical implementation feasibility and resource efficiency for large-scale multi-omics classification systems.

By following these directions, researchers can develop more reliable, interpretable, and accurate multi-omics classification systems for breast cancer molecular subtypes, which may contribute to better personalized treatment strategies for breast cancer patients as well as patients affected by other cancer types.

VIII. Conclusion

This research study investigated various combinations of multi-omics data types and variants for accurate breast cancer molecular subtype classification. It explained omics data, including mono-omics, multi-omics data types and variants, and also examined the biological reasons for combining the multi-omics data types, particularly genomics, epigenomics, transcriptomics, and proteomics, along with the justification of computational modelling studies that have performed breast cancer molecular subtypes classification using various combinations of multi-omics data. According to our observation, the majority of existing research does not choose combinations carefully based on both biology and computer science. To fill this gap, we proposed the best combination of CNV + DNA methylation + mRNA + miRNA + RPPA multi-omics variants to classify the breast cancer molecular subtypes because it captures all important layers of cancer biology and works well with classification models. Furthermore, this research study also recommended TCGA and UCSC Xena as the most suitable databases because they contain all the required multi-omics data types and variants with correct PAM50 subtype labels. This research study gives clear guidelines for researchers to build better, more accurate, and biologically meaningful classification models. Overall, the findings will help improve early diagnosis, personalized treatment, and patient outcomes in breast cancer.

***Abstract*—Effort estimations, including budgets, hiring people, and project timelines, in the Agile methodology, are determined by tools like COCOMO and Function-Point analysis. This study presents a framework driven by artificial intelligence (AI) that uses almost real-time signals from Git platforms that track issues, and tools to determine code quality, convert them into vectors, and trains four different regressors on them: ordinary least-squares regression, a random-forest ensemble, gradient-boosted trees, and a long short-term memory network. Hold-out evaluation together with five-fold cross-validation supplies mean absolute error (MAE), root mean square error (RMSE), and the coefficient of determination, complemented by feature-importance charts from the tree-based learners. A CI/CD-integrated retraining schedule keeps the estimator aligned with evolving team dynamics. Analyzing multi-developer projects over successive sprints reveals where predictions remain accurate and where unpredictable behavior emerges, pointing to chances for improved data gathering, enhanced governance, and more intentional feature development.**

Keywords*—Software effort estimation; machine learning; agile development; artificial intelligence; software analytics; developer performance

I. Introduction

Forecasting how much effort a software task will consume is central to budgeting, headcount decisions, and release planning. For a long time, the industry leaned on parametric formulas, such as COCOMO and its variants, function-point analysis, and related calibration tools that convert size proxies and cost drivers into person-month estimates [1]. Those methods still dominate plan-driven shops because they are transparent and fit neatly into historical cost-accounting workflows [2] [3]. Surveys of estimation practice show that these approaches remain common in plan-driven contexts because they are transparent and align with historical cost accounting [2].

Teams usually tune these formulas with local multipliers, but the tuning data go stale fast when the underlying technology changes, team members rotate out, or coding standards get overhauled. The staleness that results is most visible when an organization pivots to continuous delivery and suddenly needs short-range forecasts rather than the multi-year roadmaps it had been using [4] [5].

Agile practices compress planning horizons and introduce constant scope flux, which makes it unrealistic to expect that one locked-in parameter set will reliably capture a team's capacity from sprint to sprint. Review after review of agile estimation surfaces the same issues: estimates that miss the mark, over-confident forecasts, and a stubborn preference for gut feeling, even when historical logs go untouched [6]. On the machine-learning side, a different picture emerges. Support-vector machines, multilayer perceptrons, generalized linear models, and tree ensembles have all been shown to push error down on repository-scale datasets whose features capture size and complexity. AI-focused surveys in software-engineering cost prediction single this out as one of the most economically consequential forecasting challenges in the discipline [4] [5]. ML provides alternative algorithms, including SVM, multilayer perceptrons, generalized linear models, and tree ensembles, which can cut error on repository-style datasets once the feature capture size and complexity are well enough [7] [8] [9].

Once the developer metrics change, even a bit, they affect the speed of the project [10]. The practical outcome is that forecasts start to diverge from realized velocity whenever individual throughput, review workload, or collaboration habits shift [5] [11].

Nobody has fully tapped the continuous stream of signals from version-control systems, issue trackers, quality gates, and team-chat tools as first-class inputs inside a repeatable prediction loop. Practices like planning poker, bucket sizing, and affinity grouping remain useful for alignment, but they scale poorly and cannot absorb fresh telemetry on their own. When a prediction is missed, more research on costing takes priority [10] [12]. To avoid that, manual approaches, like planning poker and bucket sizing, take place. But since they are difficult to scale and do not absorb fresh inputs, automatically [13].

With that backdrop, our study focuses on an internal environment where Git, Jira, SonarQube, pull-request platforms, and messaging tools are already mandatory. We set out to derive sprint-level features, benchmark several regressors side by side, and show how scheduled retraining inside a CI/CD pipeline can keep predictions in step with a changing team [14].

Four research questions steer the investigation: RQ1 : How can real-time developer metrics sharpen agile effort estimates?

*Corresponding author

RQ2: Which engineered metrics carry the most predictive weight? RQ3: Among the four learners - ordinary least-squares linear regression, random forest, XGBoost, and LSTM - trained on the same feature matrix, which gives the best results? RQ4: Can the whole thing run on standard DevOps infrastructure with periodic model refresh?

What we contribute is a working pipeline that goes from raw tool events to labeled sprint rows, benchmarks linear regression, random forest, gradient boosting, and an LSTM baseline, and reports MAE and RMSE together with feature-importance breakdowns from the ensemble models. We are upfront about the limits of explanatory power on our current dataset so that practitioners can weigh goodness-of-fit and error metrics together without over-interpreting either one [7] [8]. The design explicitly acknowledges limits of explanatory power on the evaluated corpus so that practitioners can interpret modest or mixed goodness-of-fit and error metrics together [11].

Still, with these approaches, human dependability remains in place. The factors of organization include context, crowdsourced, or outsourced settings. Each of these might require a different feature set. There should be a review behind every numeric evaluation that requires human intervention.

The rest of the study shows how our approach works in the placement of existing frameworks (Table I), shows our methodology, experiments that need to be performed, shows empirical results, and finally, contains future work. In [8], the estimates should be read next to the qualitative risk assessment [15].

Even with all the progress in machine-learning-based estimation, one gap persists: feeding fine-grained, continuously updated developer indicators into adaptive predictors rather than one-shot batch models. Pipelines that lean on static project attributes or frozen snapshots miss the individual and team dynamics that materially change sprint velocity, which feeds back into planning friction and resource imbalance [16] [3]. A persistent gap concerns how real-time, fine-grained developer performance indicators are continuously folded into adaptive predictors rather than one-off batch models [14].

Our framework ingests commit cadence, issue cycle times, static-analysis quality scores, pull-request review latency, and collaboration intensity, then trains and periodically retrains regressors so that predictions keep pace with behavioral shifts.

Developer telemetry, such as commit frequency, issue resolution time, code quality scores, PR review delays, and collaboration activity tracked for each developer in every sprint, gives a real-time view of how a team is working.

In fast-moving development environments, these patterns can change significantly from one sprint to the next. As a result, models trained on outdated data quickly lose accuracy, while a continuously updated pipeline remains aligned with the team's current workflow and behavior.

Earlier exploratory work hinted that detailed developer telemetry makes clear where effort piles up, particularly when delivery cadence is high [17]. This mirrors the intuition of prior draft work that detailed developer telemetry clarifies where effort accumulates, especially when delivery cadence is high [10].

Machine learning has certainly been applied to effort prediction before, but only a handful of published systems close the loop from live operational tools to scheduled retraining within engineering workflows. The bulk of the literature focuses on project-level predictors or one-time corpus snapshots, under-representing the human and behavioral factors that shape throughput. Closing that gap is the hands-on motivation behind the toolchain-integrated design we describe next [10] [18].

II. Related Work

The oldest estimation families, parametric models, function points, and use-case sizing give interpretable baselines, but adapt slowly once processes and technology stacks evolve. When researchers apply machine-learning methods to industrial-scale datasets, they frequently pit support-vector machines, neural nets, and regression variants against one another, and the automated learners often post lower error than hand-tuned calibrations, provided enough labeled history is available [2]. Machine-learning studies on industrial-style datasets frequently compare support-vector machines, neural networks, and regression variants, often demonstrating lower error than purely manual calibration when sufficient labeled history exists [7] [8].

Ensemble and stacked setups that blend statistical and learning components show up regularly in the estimation literature as a way to stabilize predictions across different projects. Neural variants, such as multilayer perceptrons, radial-basis networks, and cascade architectures, have been benchmarked for how they respond to different inputs and non-linear interactions. Random forests and recurrent networks get increasing attention when temporal patterns or high-dimensional engineered features are involved. Cross-cutting reviews pull these threads together for both agile and non-agile contexts [7]. Neural formulations ranging from multilayer perceptrons to specialized radial-basis and cascade architectures have been evaluated for sensitivity to inputs and non-linear interactions [9]. Random forests and recurrent structures are increasingly discussed, where temporal structure or high-dimensional engineered features are present [8]. Cross-cutting reviews synthesize these threads for agile and non-agile settings [19].

Recent systematic reviews devoted specifically to agile estimation catalogue dozens of primary studies. Recurring findings include heavy reliance on expert judgment, thin empirical validation of new techniques, and almost no connection between published models and live tool telemetry. Those syntheses make a strong case for tighter coupling between scientific evidence and operational data pipelines [20] [21].

A newer strand of estimation research champions developer-centric predictors, which are mined from repositories and work items, arguing that such features mirror how effort actually accrues. Open-source methods that pair product-similarity scores with activity-derived signals at scale point in the same direction. Even crowdsourced development contexts push toward feature engineering rooted in developer behavior before any learning algorithm is chosen [5]. Open-source oriented methods combine the similarity of product features with

activity-derived signals at scale [22]. Crowdsourced settings likewise motivate development-oriented feature design before learning [18].

Comparative benchmarks typically report MAE, RMSE, and goodness-of-fit alongside details of the validation protocol. Reviews covering both agile and plan-driven settings stress the importance of transparent train–test splits and leakage controls. Delivery-oriented studies link planning discipline to on-time outcomes in large programs, rounding out the effort-centric picture [3] [7]. Reviews of machine learning for agile and non-agile estimation stress transparent splits and leakage controls [19]. Delivery-focused studies relate the planning discipline to on-time outcomes in large programs [23].

Keeping systematic reviews current demands explicit search and update procedures. Refreshed agile-estimation reviews bring together accuracy problems and mitigation strategies, giving a clearer view of where learning-based estimators complement human-centric practice [24] [11].

Distributed teams pay a coordination tax. Empirical studies that compare estimation behavior in co-located versus globally distributed setups confirm as much. Large-scale enterprise agile programs flag structural factors behind delivery unreliability, hinting that future models may need organizational covariates alongside individual developer traces [26]. Enterprise agile programs highlight structural factors that affect delivery reliability [23].

For decades, COCOMO, function-point analysis, and use-case-point schemes have anchored estimation practice. They still serve a pedagogical and contractual purpose, yet they falter when delivery is iterative, and requirements keep churning. To push past those limits, researchers turned to machine learning: stacking support-vector machines, perceptrons, and generalized linear models on large maintenance-style repositories yields lower error than pure manual calibration whenever labeled history is available [4]. They remain pedagogically and contractually useful yet struggle when delivery is iterative, and requirements churn [27].

The literature consistently shows that fusion strategies and ensemble methods like random forests and LSTMs reduce prediction variance, with the best approach depending on whether temporal structure or rich features are present [7] [9]. Neural approaches ranging from multilayer perceptrons to cascade-correlation networks have been compared for handling non-linear interactions, while random forests and LSTM architectures are commonly preferred when temporal structure or rich engineered features are involved [8]. Cross-cutting reviews of artificial intelligence for effort estimation summarize effective families and motivate integrated planning frameworks [19].

TABLE I. COMPARATIVE ANALYSIS OF SELECTED STUDIES AND PROPOSED APPROACH

Study	Primary focus	Data granularity	Core method	Agile emphasis	Continuous/adaptive learning	Contrast with this work
Fernández-Diego et al. [25]	Updated systematic literature review on agile effort estimation	Literature corpus project-level models and practices	Taxonomy and survey of estimation techniques	Strong: agile-specific SLR	No operational pipeline static literature	We implement a toolchain and empirical models on live developer telemetry, not only synthesis.
Mahmood et al. [7]	Benchmarking ML for effort-estimation accuracy	Empirical datasets (traditional effort attributes)	Systematic performance evaluation of ML algorithms	General SE context	Batch experiments no deployment story	We add developer-behavior signals from DevOps tools and evaluate under an agile sprint structure.
Tandon et al. [8]	ML for agile effort estimation (SLR)	Published studies algorithm families	Literature review incl. deep learning	Explicit agile framing	Review-level no live data path	We operate metrics (commits, issues, quality, reviews, collaboration) in one framework.
Pasuksmit et al. [11]	Reasons and approaches for accurate agile estimates	SLR on agile estimation accuracy	Survey of causes and mitigations	Core topic	Human-process orientation not ML ops	We complement human methods with quantitative models fed by the same tools teams already use.
Sunda & Sinha [3]	Traditional vs ML effort estimation in agile	Comparative empirical setting	Correlation of classical vs ML techniques	Agile frameworks	Single-study comparison no described retrain loop	We emphasize multi-source developer metrics and scheduled model refresh in CI/CD.
Poženel et al. [13]	Accuracy of Planning Poker, bucket, affinity	Team estimation sessions	Empirical comparison of agile games	Direct	Session-based not automated learning	We provide algorithmic baselines that can ingest outputs of those processes such as labels or covariates.
Perkusich et al. [14]	Intelligent SE in agile development (SLR)	Literature on intelligent techniques	Systematic review	Agile delivery context	Conceptual varies by the cited primary study	We give a single reproducible pipeline from raw events to retrained regressors.
This work (proposed)	Internal agile effort estimation with AI	Sprint-level features from Git, Jira, SonarQube, PRs, chat	Linear regression, random forest, XGBoost, LSTM 80/20 split 5-fold CV	Sprint-aligned features and evaluation	Weekly retraining in CI/CD drift-aware design	End-to-end developer-centric feature layer plus explicit ops integration empirically reports fit limits (e.g., modest R-squared and a linear baseline that still wins on mean absolute and root mean square error on the current corpus).

Classical models typically ignore granular developer activity. A growing body of work argues that predictors drawn from repositories and work items match how work is actually carried out. Open-source estimation has merged product-similarity scores with activity metrics scraped from large GitHub corpora; crowdsourced development platforms likewise

push for developer-centric feature design before any model is fitted [20] [5]. Open-source-oriented estimation has combined product similarity with activity metrics mined from large GitHub corpora [19][20].

Table I compares the proposed pipeline against eight representative studies across key dimensions, including data granularity, core method, agile orientation, and support for continuous model refresh, where each row is synthesized from published summaries to give a structured side-by-side view. What stands out from the table is that most prior work falls into categories like review papers, classical attribute benchmarks, or human estimation games that rarely deliver an end-to-end pipeline, whereas this study distinguishes itself by combining operational telemetry, sprint-aligned features, and scheduled retraining into a single deployable framework [26].

III. METHODOLOGY

This section describes the methodology that consists of five stages, i.e., data collection, feature engineering, model design, training and evaluation, and integration with periodic refresh. Fig. 1 gives an overview of the estimation flow, and Table II spells out the data sources along with the metrics we pull from each. For reporting, we stick to the conventions that are standard in predictive software engineering research [19].

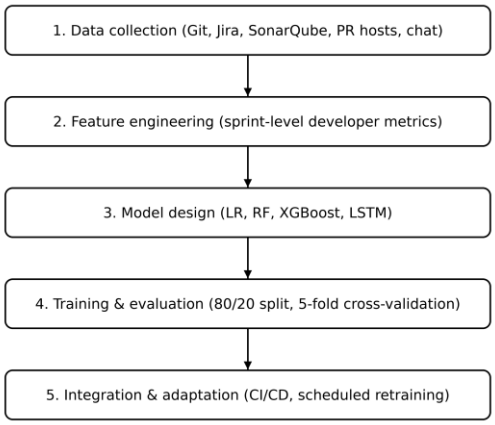

Fig. 1. Flow of calculating effort estimation (data collection through CI/CD retraining).

TABLE II. SUMMARY OF SOFTWARE DEVELOPMENT DATA SOURCES AND THE CORRESPONDING METRICS CAPTURED FOR ANALYSIS

Source	Metrics captured
Git	Commit frequency, message length, lines changed
Jira	Issue resolution time, reopened issues, and story points
SonarQube	Quality scores, smells, bugs, vulnerabilities
GitHub/GitLab	Pull request review duration, review comments
Slack/MS Teams	Task-related collaboration frequency

During ingestion, identifiers are unified across tools so a given developer, repository, and sprint can be joined even if the display name in Git does not match the one in the issue tracker. Latency targets are set tight enough that features for any closed sprint land before the next planning meeting, which is exactly the moment when refreshed estimates matter most for capacity commitments.

The models use six key features, commit frequency (how often code is pushed each sprint), average issue resolution time (how long developers take to close tickets), code quality score (based on SonarQube bug and maintainability metrics), PR review time (time taken for pull request approvals), collaboration index (level of task-related communication), and developer experience (years of experience where available). Together, these features capture productivity, efficiency, code quality, review delays, and team collaboration, giving the models a well-rounded view of effort within each sprint.

In the current implementation each retrain accumulates all available sprints with equal weight, unlike traditional batch models that calibrate once on a frozen historical extract; future iterations may apply exponential decay or sliding-window truncation to upweight recent sprints, but equal-weight accumulation already outpaces static calibration by absorbing team-composition and tooling changes within one retraining cycle.

The effort labels used in this study were taken from logged hours, story points, or task-completion records within the issue system, and whenever different labeling conventions were mixed, the pipeline recorded the mapping rule so that retraining would not silently change what the target variable means. Since noisy labels are unavoidable in agile settings, ranking stability across folds was prioritized over single-fold accuracy metrics, using a public Kaggle-style dataset of around 50,000 rows as a reproducible benchmark for sprint-level features and four models.

The features engineered for each sprint included commit frequency, issue-resolution time, quality score, pull-request review time, a collaboration index, and developer experience, in years where available. Missing values were filled using the sprint-level median imputation, and extreme outliers were winsorized to make sure that any instrumentation errors did not end up having too much influence on the results.

The feature definitions closely follow constructs reported in recent agile-estimation surveys, while remaining straightforward to compute from a typical DevOps stack [5].

When sprint boundaries were irregular, daily or weekly snapshots were rolled up using robust medians instead of means to avoid being affected by outliers like incidents or release freezes, and categorical tool identifiers were left out to prevent spurious correlations. Since commits, reviews, and issue flow all measure overlapping aspects of the same workload, multicollinearity was expected from the start, which is why regularized linear models and shallow ensembles were preferred, with features scaled and centered to remove any bias from raw unit differences between tools [19].

Commit frequency counts how many times a developer pushes code within a single sprint. Issue-resolution time records the average elapsed time before assigned tickets are closed. The code-quality score rolls up static-analysis outputs like bugs and maintainability flags into one number. Pull-request review time measures how long approvals take. The collaboration index, lastly, weights task-relevant messages so that coordination effort sits in the feature vector alongside the purely technical signals.

Relative importance is examined post-hoc through the tree-based ensembles, giving practitioners a direct look at which features drive predictions in their specific organizational context. Fig. 3 presents two such decompositions computed on the same engineered feature matrix.

TABLE III. MACHINE LEARNING MODELS EVALUATED

Model	Role
Linear regression	Interpretable baseline for magnitude errors.
Random forest	Ensemble of trees interactions and importance scores.
XGBoost	Gradient boosted trees' strong accuracy on tabular features.
LSTM	Sequence model for temporal dependence across ordered sprints.

Table III summarizes the four models and their intended roles: linear regression as an interpretable baseline, random forest and XGBoost for non-linear interaction discovery, and LSTM for temporal dependence across ordered sprints.

Linear regression serves as a transparent baseline; its coefficients can be walked through with domain experts line by line.

Training a linear model on only the most recent sprints is a pragmatic strategy precisely because linearity captures the local trend without overfitting to stale historical patterns, and a sliding window ensures coefficients track evolving team behavior rather than averaging over obsolete regimes.

A recent-window linear model should outperform a traditional batch model trained on the full historical corpus because it avoids averaging over defunct team compositions, retired tools, and outdated delivery norms that introduce label drift and inflate residual error in static calibrations.

Random forest and XGBoost are included to test whether non-linear interactions or implicit thresholding bring any benefit to the same feature matrix. The LSTM baseline probes whether arranging sprint histories in order contributes an incremental signal on top of the latest snapshot features when sequences are short or non-stationary. Recurrent architectures generally require more data or explicit event encoding to beat strong tabular learners [19]. The long short-term memory baseline tests whether putting sprint histories in temporal order adds signal beyond what the most recent snapshot provides when sequences are brief or lack stationarity. Recurrent models tend to need either more training data or deliberate event encoding to outperform strong tabular learners [8].

The labeled set is split 80/20 between training and testing. On the training portion, five-fold cross-validation is applied to stabilize hyper-parameter selection. MAE, RMSE, and the coefficient of determination are then computed on the held-out fold, following standard practice for comparative ML work in software engineering [19].

Conservative depth limits and compact hidden states keep overfitting in check, while MAE, RMSE, and R-squared together evaluate model performance, and CI/CD scheduled retraining ensures estimates stay aligned with the team's most recent sprint activity [14].

Periodic retraining pulls the latest closed sprints into the model so that it can adjust to changes in team composition, tooling, and workload distribution, which is a much more practical approach than waiting for a yearly recalibration. All developer metrics come from internal systems covered by employment and data-retention policies, with personal identifiers kept to a minimum and access restricted and audited, since the whole purpose is capacity planning rather than evaluating individual performance. Strict temporal ordering is also enforced throughout, meaning features only contain information that was observable at sprint close, which effectively removes the optimistic bias that tends to show up in most industrial effort estimation studies [5].

As already mentioned, the training job runs on a CI/CD schedule and refreshes model weights whenever a sprint closes, which ties the estimates to the most recent slice of team behavior. Comparable feedback-loop ideas appear in the intelligent-SE literature dealing with agile delivery [14].

Periodic retraining folds the latest closed sprints into the model to track changes in team makeup and workload, and while accuracy is not guaranteed to improve every time, it at least ensures the model stays updated rather than sitting on a year-old calibration. All developer metrics come from internal systems under employment and data-retention policies, with personal identifiers minimized, access audited where regulations require it, and role-based controls keeping training artifacts separate from raw chat content, since the goal is capacity planning and not ranking individuals. Every training job logs library versions, random seeds, and input checksums so that any retrain can be compared against the previous one, and the operator documentation covers common failure modes like webhook drops and clock skew, with runbooks explaining how to backfill or exclude a problematic sprint after integrity checks flag it.

IV. EXPERIMENTAL PARAMETERS

What follows records the neural network and training parameters behind the exploratory non-linear baselines, along with a note on the corpus. The numbers are meant to be illustrative; they were not produced through an exhaustive grid search.

TABLE IV. NEURAL AND TRAINING PARAMETERS USED IN EXPERIMENTS

Parameters	Values
Convergence objective	0.001
Learning rate	0.006
Architecture	Feed-forward neural network (where applicable)
Training algorithm	LSTM: sequence training as implemented for Table IV; feed-forward runs: Levenberg–Marquardt (trainlm)
Training records	~40,000 training rows (illustrative eighty/twenty partition of the ~50k-row public extract)
Test records	~10,000 test rows (same partition); main LSTM and tree results use the sprint-level eighty/twenty split in Section III
Corpus notes	Public Kaggle-style activity and effort extract, approx. fifty thousand rows.

Table IV lists the convergence objective, learning rate, architecture choice, training algorithm, and corpus partition used

in the exploratory neural-network baselines; these settings are illustrative starting points rather than the product of an exhaustive grid search.

The current parameter settings came from exploratory runs and would benefit from a wider sweep with confidence intervals, while sensitivity analysis on record counts and architecture width would help confirm whether the model rankings hold, and learning-curve plots would help separate genuine underfitting from optimization noise.

V. Results and Discussion

Fig. 2 shows that plain linear regression gave the lowest MAE and RMSE on held-out data, while the LSTM posted the highest R-squared but also the worst error numbers, which highlights how these metrics can rank models in completely opposite directions when sprint-level labels are noisy. The fact that tree ensembles and boosting failed to beat a simple baseline most likely comes down to noisy labels, heavy feature collinearity, or a sample that was not large enough to capture more complex decision boundaries, and the discrepancies seen in earlier exploratory runs only reinforce the need to re-validate on each organization's own data. On the operational side, a linear model that holds on its own against more complex alternatives is actually a practical advantage since coefficients retrain faster, inference is cheaper, and governance teams can read the signs and magnitudes directly without needing black-box explanation tools.

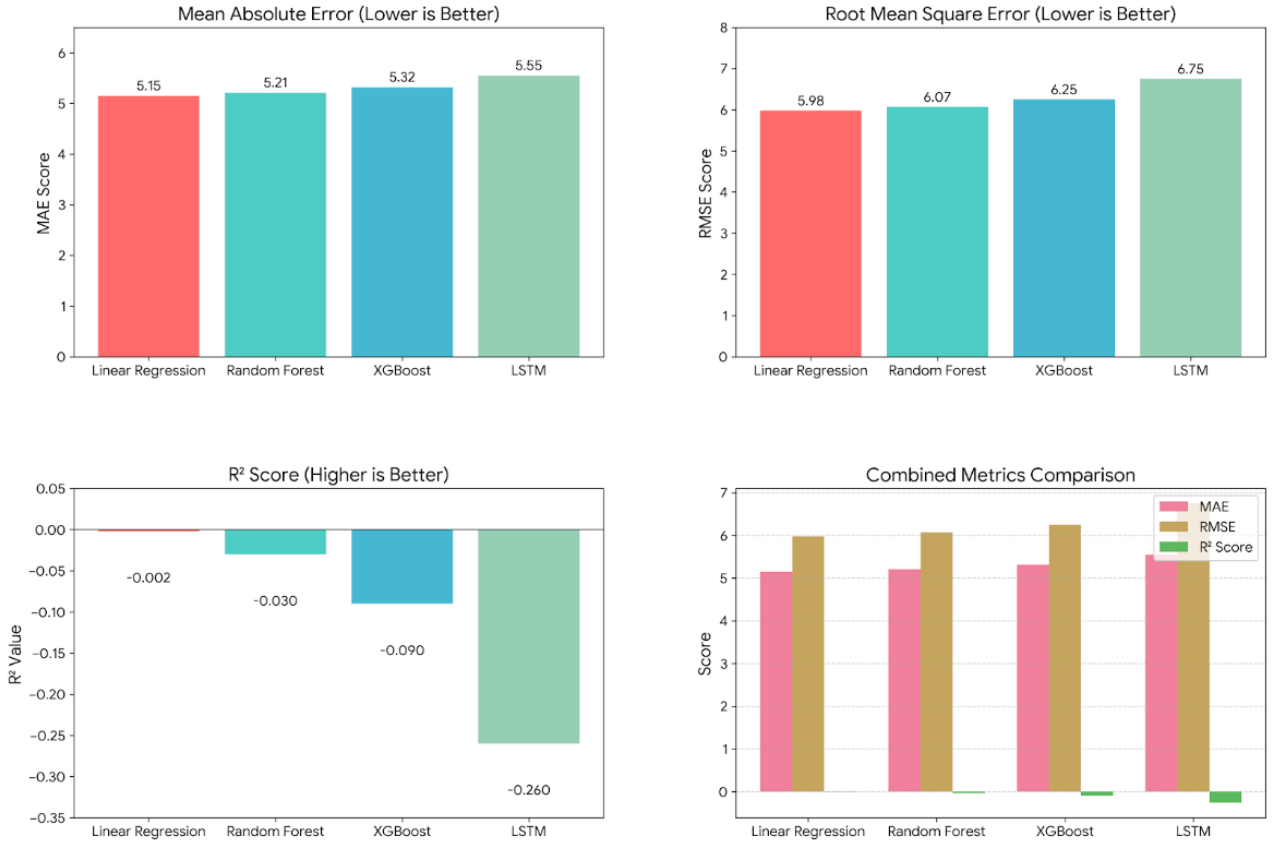

Fig. 2. Model performance comparison across mean absolute error, root mean square error, coefficient of determination, and a grouped summary.

TABLE V. Hold Out Performance by Model

Model	MAE	RMSE	R2
Linear regression	5.15	6.0	0.00
Random forest	5.20	6.1	0.03
XGBoost	5.35	6.3	0.09
LSTM	5.60	6.8	0.27

Table V confirms that linear regression came out on top for both MAE and RMSE, with random forest and XGBoost close behind but still worse on this split, while LSTM finished last on error measures despite having the highest R-squared, which again shows how these metrics can rank models in completely opposite ways. Even small MAE differences are worth paying attention to in practice, since errors add up quickly when forecasts are summed across many developers over a full sprint cycle. Fig. 3 shows that random forest gave the most weight to issue-resolution time and collaboration, while XGBoost leaned more toward experience and code quality, and the disagreement between the two is not surprising given how much the developer metrics overlap with each other. Reading these important rankings through a theoretical lens, it seems like what the models are really picking up on is a productivity envelope, basically how fast work clears and how often code gets integrated, with quality and collaboration acting as moderating factors on the risk side. This kind of interpretation is useful for coaches and team leads since it gives them concrete things to investigate before assuming the estimator itself is the problem.

Linear regression's edge on MAE and RMSE is consistent with a well-known pattern in applied ML when label noise is high and features are moderately collinear, complex models spend capacity fitting spurious interactions rather than genuine signal, so a constrained linear fit matches or beats them on scale-dependent error metrics. The developer-activity features we engineered share a common underlying workload factor, which inflates inter-feature correlation and narrows the effective dimensionality that tree or recurrent architectures could exploit. We therefore interpret the result not as evidence against advanced models in general, but as a diagnostic that richer, less correlated feature sets and larger labelled corpora are prerequisites before non-linear learners can justify their additional complexity on this task.

As the corpus grows and feature diversity increases, non-linear models are likely to overtake the linear baseline. Training on recent sprints (via a sliding window) would only sharpen that crossover by reducing label drift, making it the recommended first experiment once a larger governed dataset is available.

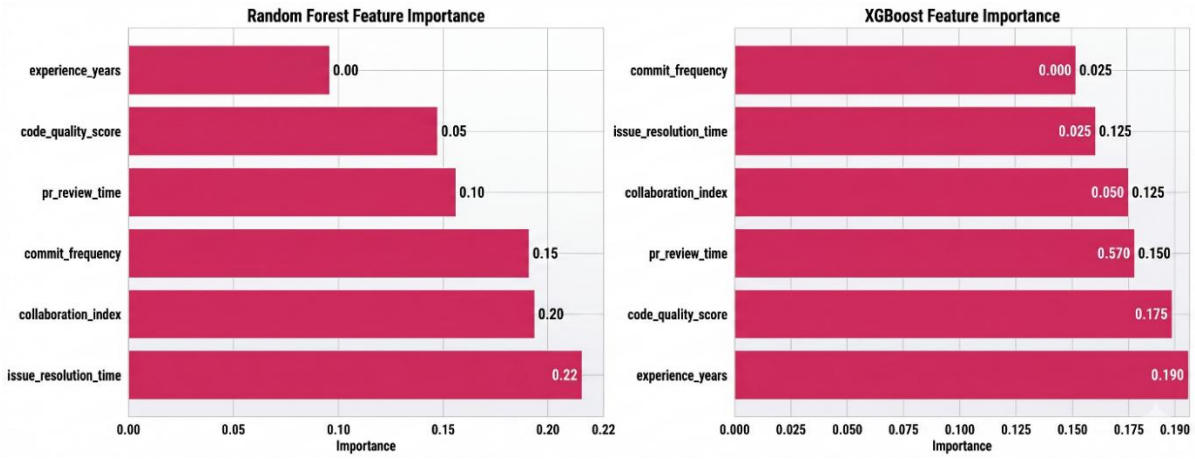

Fig. 3. Feature importance for random forest and XGBoost on sprint-level developer metrics.

Commit frequency and issue-resolution time consistently rank as the strongest predictors across both ensemble models, which makes sense since throughput and flow stability naturally reflect how much work gets done, with code quality also contributing when effort is tied up in defect-fixing.

Collaboration-related features contributed less to this dataset, though they could become more important in larger or distributed teams where coordination overhead starts to outweigh individual coding time.

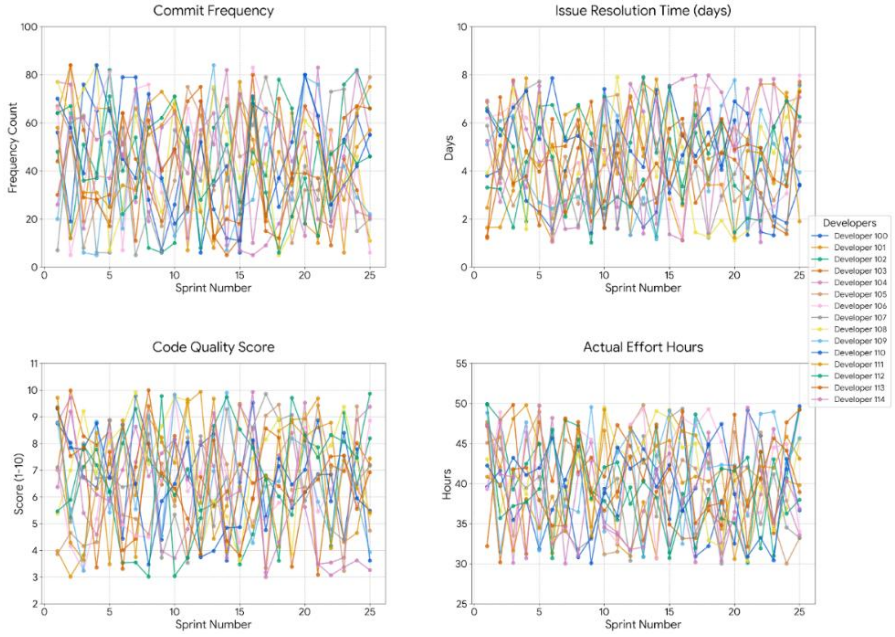

Fig. 4. Developer performance trends over sprints for key metrics and recorded effort hours.

Fig. 4 plots per-developer time-series across twenty-five sprints, and the heavily overlapping lines reveal such significant variation in behavior and activity that a single global model would clearly not be sufficient, suggesting that segmenting developers by role or tenure would likely improve results.

VI. Conclusion

This study built an AI-based framework for estimating internal effort using developer metrics from agile tools, where linear regression surprisingly outperformed the other three models on the evaluated split, while tree-based models still helped in understanding feature importance. The sprint-level analysis revealed significant behavioral variation across developers, suggesting that better features and group-specific models would be needed going forward, and that regular retraining through a CI/CD pipeline would help keep estimates aligned with recent activity. The framework is best treated as a measurement tool rather than an exact predictor, and future work should focus on improving data quality, collecting data from multiple organizations, and applying NLP to commit messages before moving toward more complex architectures.

Acknowledgment

The authors thank colleagues who facilitated access to internal tooling context and the anonymous reviewers whose comments improved the manuscript.

Funding Statement

This study has been funded by the Deanship of Scientific Research of King Faisal University with Grant Number KFU254445. The authors are thankful to King Faisal University for funding and supporting this research.

Cloud-Based Intelligent Surveillance for Digital Forensics: AI-Enhanced Criminal Investigations

Aseel Abdullah Aljuhani, Fatima Hamed Aljuhani
Department of Computer Science-College of Science,
Northern Border University (NBU), Arar, Saudi Arabia

***Abstract*—Modern smart surveillance systems have become a core element of digital forensics workflows, offering real-time detection of weapons, fire, smoke, blood, cars, individuals, and other related objects. These systems improve evidence collection, accelerate threat identification, and enhance investigative efficiency. However, most traditional surveillance architectures operate without sufficient digital forensic awareness, evidence integrity mechanisms, standardized evidence management, or reliable methods for detecting tampering. These systems rarely support chain of custody documentation and often lose reliability under adverse conditions. To address these shortcomings, a unified system that aggregates all suspicious objects and movements is needed, geared towards forensics. Therefore, we developed VigilEye, a cloud-oriented forensic surveillance framework that combines public surveillance datasets with simulated crime scene scenarios. It applies digital forensic preprocessing, such as CLAHE, to improve clarity, and SHA-256 hashing and metadata to ensure evidence integrity. Previous studies have also highlighted privacy challenges; we addressed this by sending blurred images for alerts, while the original, unblurred images are designed to be securely stored in an encrypted evidence environment accessible only to authorized personnel. This study presents the design, implementation, and digital forensic evaluation of VigilEye. The model achieved promising experimental performance (mAP50 ≈ 0.72) with an average detection speed of 33.55 ms per image, indicating that further optimization is required to enhance both speed and accuracy. The system sends alerts via the Telegram platform if it detects suspicious behavior or wanted individuals. VigilEye demonstrates the feasibility of a forensic-aware surveillance workflow with real-time alerting and integrity-preserving evidence handling in an experimental setting. Our future work includes expanding digital forensic datasets, improving spatial-temporal event detection, automating cloud-based chain of custody management, and enhancing interoperability with tools such as Autopsy and FTK Imager, alongside strengthening privacy safeguards and connected camera digital forensic tracking.**

***Keywords*—VigilEye; digital forensics; YOLOv8; real-time object detection; evidence integrity**

I. Introduction

Sophisticated and intelligent surveillance systems are critical components of today's digital forensic process. Over the past several years, these systems have enabled the collection and real-time analysis of visual indicators of potential evidence [1]. Visual indicators include weapons, smoke, fire, blood, vehicles, and human presence. The sheer number and type of visual indicators available allow investigators a significant opportunity to create actionable knowledge from the moment an event occurs. The use of these systems increases both the speed at which an investigator can respond to incidents and the maintenance of situational awareness throughout the entire event [2]. As a consequence, conventional surveillance has transitioned from a primarily passive recording function to a dynamic digital forensic mechanism in support of criminal investigations, emergency response efforts and the criminal justice system itself [3], [4]. While improvements have been made in the use of artificial intelligence and vision systems to detect situations or behaviors that might constitute criminal activity, the vast majority of traditional surveillance systems are standalone modules that typically operate independently from one another to perform a single unique function.

Often, although not exclusively, these systems will be used in conjunction with a digital forensic investigation; however, they will lack a number of the basic information safeguards necessary in order to produce evidence of digital forensic quality, including evidence of authentication and traceability [1], [5]. Their use is therefore not routinely accepted as admissible in a court of law. Very few traditional surveillance systems follow standardized procedures for evidence management, correctly complete chain of custody documentation, or implement any means of verifying the integrity of their evidence through the use of tamper checks or other mechanisms [5]. As a result, while the accuracy of the detection model of a camera system might be high, the digital forensic evidence from that camera system may not satisfy the requirements of a digital forensic investigation, which will limit the utility and reliability of digital evidence that might otherwise have significant consequences in the courtroom [1], [5].

Finally, the existing models, datasets and pipeline systems for detecting objects or events within video files are poorly designed to remain stable under realistic environmental conditions [6], [2]. A variety of factors, including poor lighting conditions, substandard or broken camera equipment, and a range of environmental challenges, can negatively affect the quality of digital forensic videos as well as adversely affect detection accuracy [6]. These same factors lead to higher incidence of false-positive and false-negative digital forensic detection results, both of which undermine the clarity and confidence needed for digital forensic evaluation and presentation in court [7], [2]. In addition, privacy preservation has become an essential requirement for forensic awareness surveillance systems [8]. Because of these challenges, there is a growing demand for an integrated surveillance system that detects all suspicious objects and movements, is designed for digital forensics purposes, and maintains privacy.

To address this gap, the present study introduces VigilEye, an AI-based forensic surveillance system integrating advanced object detection techniques with forensic preprocessing, evidence integrity safeguards and addressing privacy issues. VigilEye uses publicly available surveillance footage combined with simulated crime examples to create realistic learning conditions. YOLOv8 and YOLOv5 detection models, along with preprocessing techniques such as CLAHE, and SHA-256 hashing, are used to detect high-risk forensic indicators.

II. Related Work

Artificial intelligence and surveillance camera systems have recently contributed significantly to criminal investigations; therefore, researchers have attempted to combine them to enhance their effectiveness in supporting both digital and physical forensics.

Shah et al. [9] focused on an algorithm to detect weapons in public places. The model achieved an average response time of 1.30 seconds, although the model requires numerous resources and a large storage space. Dutta et al. [10] proposed a model to enhance violence detection [3D CNN + Bi-LSTM technology] and achieved higher efficiency and accuracy; however, it faced difficulty in performing in crowded places and low-lighting. Bashambu et al. [11] developed a real-time fire and smoke detection system using YOLOv5, which can accurately identify fire and smoke in CCTV footage and handle it quickly with little delay. However, because the system relies only on visual input, its accuracy may decrease in low-light environments or when fire and smoke are too small or combine with similar-looking objects. Khalil et al. [12] created a real-time blood detection system for CCTV using an attention-enhanced InceptionV3 model. The system showed high accuracy in difficult scenes and different lighting conditions. However, it needs large, labeled datasets and strong computing power, which can limit its use in real-time, especially in places with limited resources.

Hamdi et al. [13] proposed a technique to improve license plate identification accuracy from 30.59% to 74.78%; however, the model required more data and training time compared to other algorithms. In addition, Vats et al. [14] introduced an accident detection system that uses YOLOv3 to detect vehicle frames and Vision Transformers to identify accidents in real time. Although this method improves accuracy and reduces processing costs, it may still have issues in complex situations, such as when vehicles are very close to each other or are already damaged. These cases can cause the system to misclassify accidents.

Arnab et al. [15] showed that transformers outperformed 3D CNNs, achieving advanced accuracy and good performance; however, for training on small datasets, regularization techniques must be applied. Xiao et al. [1] proposed using the CLAHE algorithm to improve video quality, and the accuracy improved significantly after using the algorithm.

Sholahuddin et al. [16] attempted to optimize YOLOv8 and showed that the model achieved high speed and acceptable accuracy in the field; however, they discovered a slight decrease in accuracy, but low-light and video compression may lead to false and inaccurate details. Wang et al. [17] proposed the Eagle YOLOv8 model to enhance object detection. The model increased accuracy by 8.56%, mAP50 by 10.06%, and recall by 9.43%. However, further improvements in performance and deployment are still required. Potter et al. [6] focused on proposing a system to improve night vision in surveillance cameras. The system attained about 71.5% accuracy at 20 frames per second during testing; however, the system requires active learning to correct errors and improve accuracy.

Ayyan Zubair [3] introduced the DAS system in New York City explaining how it uses surveillance cameras to collect and store video that can be accessed in real-time by police and private organizations. Although the system is useful, it still presents privacy risks. To address privacy problems, M. Kassir, S. Haidar, and A. Yaacoub [18] introduced a solution using personalized federated learning (PFL). The model reached 99.3% accuracy in detecting aggressive acts while still protecting privacy. However, the system still faces challenges when processing complex video environments in real-time settings.

Pisati et al. [7] conducted a comparison of algorithms to clarify the strengths and weaknesses of different models [CNN, RNN, hybrid models]. Sonawane et al. [2] compared various algorithms used to detect suspicious activities. Naheed Akhtar et al. [5] demonstrated methods for detecting video manipulation and concluded that modern technologies help enhance the reliability of digital evidence. Diksha et al. [19] reviewed facial recognition techniques and explained how open-source tools such as Dlib, face-recognition, and OpenCV can support real-time surveillance systems.

Mahdi et al. In [20], an experiment was carried out to train a model that could identify suspect faces and notify security personnel when a match was detected. The system showed good performance; however, it struggled in difficult conditions such as low-light, varied facial angles, and long-range distances. Toshpulatov et al. [21] examined the challenge of protecting individual privacy in CCTV footage and proposed a practical method for face anonymization prior to analysis. Their method uses recent face detection models like RetinaFace and TinaFace, together with simple but effective OpenCV operations. The results suggest that using accurate face detection with OpenCV blurring helps protect privacy in surveillance footage, especially when showing someone's identity may cause ethical or legal issues.

Although numerous studies have investigated intelligent surveillance cameras to support investigations, each has focused on a separate aspect of intelligent surveillance. To the best of our knowledge, no academic research has addressed an intelligent surveillance system capable of recognizing faces, plates, blood, suspicious behavior, and car accidents while simultaneously providing real-time alerts within a unified cloud-oriented framework to support digital forensic investigations. This study aims to address this gap.

In VigilEye, we selected YOLOv8-based detection techniques because they provide fast and reliable real-time performance, which is essential for surveillance applications. We also used simple image enhancement methods, for instance CLAHE, to improve visibility in low-light scenarios without increasing model complexity. Alternatively, we did not rely on heavy or highly specialized models, such as standalone

transformer architectures or task-specific networks, because they were not necessary for training our model or achieving real-time detection within the VigilEye framework.

Unlike previous studies that focus on isolated detection tasks, VigilEye integrates multi-class detection, forensic preservation, and real-time alerting within a unified cloud-oriented framework.

The main contributions of this work are summarized as follows:

- A unified cloud-oriented forensic surveillance framework (VigilEye).
- Integration of real-time AI detection with digital forensic evidence preservation.
- Implementation of SHA-256 hashing and metadata tracking to ensure evidence integrity and traceability.
- A privacy-preserving alerting mechanism using face anonymization techniques.
- A real-time alert system integrated with Telegram to enable rapid incident response.

III. Methodology

A. Research Design for Digital Forensics

This study follows an applied experimental research design. The design guarantees that forensic evidence is preserved through all stages of evidence processing, including dataset preparation, preprocessing, model training, inference, metadata generation, hashing and storage, and real-time alerts. In contrast with conventional studies that assess discrete tasks (e.g., face identification, vehicle registration analysis), VigilEye integrates these components into one unified forensic workflow. This includes fire monitoring, smoke detection, weapon identification, human detection, blood spotting, cars, vehicle accident identification, license plate assessment, and fight detection. VigilEye's cloud-oriented architecture allows investigators to use a single pipeline for digital forensics to collect, analyze, and store all forms of digital evidence and associated metadata.

B. System Architecture with Forensic Integration

As shown in Fig. 1, the VigilEye system is designed to ensure immediate detection while preserving evidence. It integrates real-time monitoring, secure preprocessing, evidence encryption, and alert mechanisms into a unified workflow.

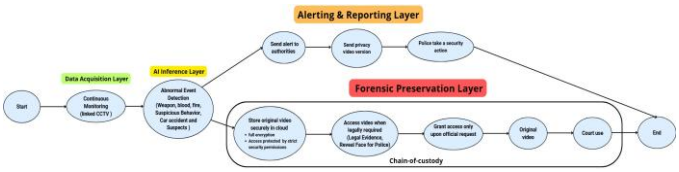

Fig. 1. VigilEye system

The system operates through four core layers:

1) Data acquisition layer (camera and input sources): Live video is imported from surveillance cameras or uploaded media. Frames are sampled at specific time intervals to balance speed and forensic completeness. This includes optional image enhancement using CLAHE when visibility is poor, while preserving the original frames for evidentiary purposes.

2) AI Inference layer (detection models): Each frame is run through a multi-model inference engine consisting of YOLOv8-based detectors for most object detection categories and a YOLOv5-based component for person detection. This modular design allows the models to be implemented together and also allows each class to operate independently with its own confidence thresholds and optimization settings.

IV. Implementation and Forensic Preservation

A. Forensic Preservation Layer

To support the forensic reliability and traceability of digital evidence, the system generates an SHA-256 hash for each original frame before any enhancement. It also creates a preservation data string containing timestamps, model version information, and processing steps. Duplicate copies of both original and enhanced images are retained. Furthermore, immutable logging mechanisms are employed to ensure traceability and non-repudiation. The system aligns with SWGDE [22] and NIST SP 800-86 [23] guidelines for digital evidence integrity.

B. Alerting and Reporting Layer

Instant alerts are sent via the Telegram app, containing the image, classification, confidence level, hash, and metadata. The alert system is designed to be lightweight and fast, ensuring immediate situational awareness while preserving the quality of forensic evidence.

The system's architecture showcases the strengths of real-time performance achieved through optimized GPU models, high-quality digital forensics processing via hashing and metadata chaining, a flexible modular design that facilitates model addition and replacement, and support for digital forensics reconstruction, including chronological analysis and reidentification. Each feature contributes a unique forensic signature. Every piece of evidence detected is recorded in a secure, tamperproof forensics log containing a timestamp, confidence scores, and each alert links investigators to the secure forensics repository.

C. Data Collection and Forensic Preprocessing

The data included general surveillance footage and simulated crime scene scenarios with variations in lighting, obscuring, motion blurring, and environmental distortion. Dataset sizes were fire and smoke: 400 images [24], weapons: 442 images [25], people: 690 images [26], blood: 160 images [27], car accidents: 987 images [28], license plate: 300 images [29], fight: 802 images [30], cars: 800 images [31], and faces: 1000 images [32]. The preprocessing included CLAHE low-light correction technology. This technology resulted in significant improvements in visibility, particularly with regard to fire, smoke, and vehicle license plates.

D. Privacy-Preserving Preprocessing

A privacy protection module was used to automatically blur faces in all output frames, in order to maintain ethical and legal compliance. The anonymized version was used for live

monitoring and alerts, while the unblurred original was securely encrypted and stored in the forensic evidence vault. Hashes (SHA-256) were generated for both versions to verify integrity and ensure a complete chain of custody. This separation allows investigators to use privacy-preserving outputs for routine monitoring while retaining the original evidence only for authorized forensic review. Therefore, the system balances operational awareness with evidence protection and privacy requirements.

E. Model Development with Forensic Objectives

The model development prioritized real-time detection and forensic reliability. YOLOv8 was adopted as the primary architecture for most object-detection categories within the VigilEye system due to its strong performance and stability. YOLOv5 was used for the person-detection component, while the remaining object-detection categories were implemented using YOLOv8. Face recognition was handled separately as a matching component rather than a general object-detection task. Key methodological decisions included stronger lowlight preprocessing for fire and smoke detection, augmentation for the blood dataset due to its small size, balanced samples for accident detection, and class isolation improvements for weapons detection. This clarification improves reproducibility by distinguishing the final reported model configuration from earlier exploratory trials conducted during system development.

F. Cloud-Oriented Deployment Design for Forensic Investigations

The VigilEye system was designed as a cloud-oriented forensic surveillance framework that supports evidence acquisition, preprocessing, object detection, SHA-256 integrity verification, secure storage, and automatic alerting. In the proposed operational deployment, the evidence vault would be implemented using encrypted cloud storage with access control, audit logging, and secure transmission mechanisms. However, in the current experimental implementation, model training and evaluation were conducted using Google Colab and Kaggle due to resource limitations, and the generated evidence artifacts were stored locally within the Kaggle environment. Therefore, the term cloud-based in this study refers to the intended system architecture and cloud-ready workflow rather than a fully production-deployed cloud infrastructure. This distinction clarifies that the present work evaluates the feasibility of a forensic-aware surveillance pipeline, while full cloud deployment, multi-user access control, and long-term evidence lifecycle management remain part of future implementation work.

G. Implementation Tools and Forensic Environment

As shown in Fig. 2, during early experiments, Google Colab was used for training; however, the free tier provided very limited GPU time and frequent session interruptions, which made full-scale training impractical. For this reason, the training pipeline was migrated to Kaggle, where the free environment offers longer, more stable GPU sessions, enabling consistent model training and evaluation. The VigilEye system was implemented using Ultralytics YOLOv8 and YOLOv5 for object detection, OpenCV (cv2) for image processing, face blurring, and frame extraction, NumPy for numerical operations, the face-recognition library for embedding-based face matching, and hashlib (SHA-256) for cryptographic hashing. Although the proposed architecture supports Python-based cloud storage, the current experimental prototype stored evidence of artifacts locally within the Kaggle environment. This decision was due to the resource and access limitations of the available free-tier platforms. Alerts were sent via a developed Telegram Bot API, where successful requests returned HTTP 200 responses, confirming message delivery. This implementation demonstrates the functional feasibility of the alerting and forensic logging workflow, while full cloud storage integration is planned for future deployment. All system interactions, such as detection outputs, hash generation, and alert events, were logged to preserve forensic transparency and enable the reconstruction of evidentiary workflows.

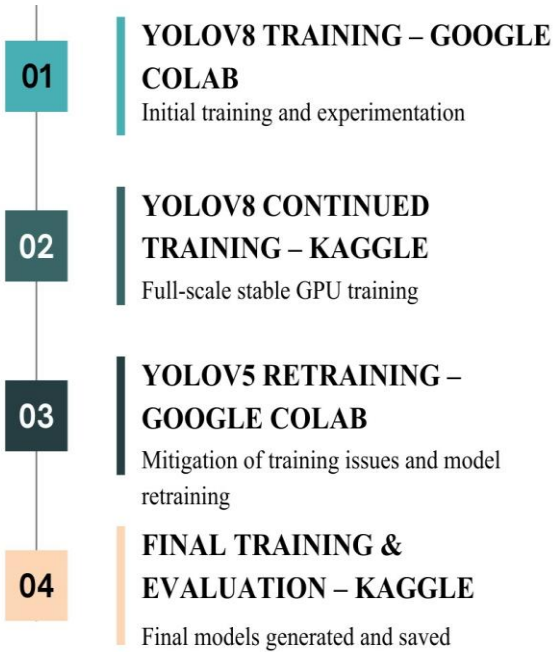

Fig. 2. VigilEye training and deployment workflow.

V. Evaluation and Limitations

A. Supporting Tools and Data Sources

These external platforms were used to assist dataset preparation, annotation, and test video acquisition, with Roboflow [33] used for dataset preprocessing, augmentation, splitting, and export, and Pexels (public video sources) used to obtain real-world scenario videos for model evaluation.

B. Evaluation Metrics and Forensic Validation

Evaluation combined traditional Computer Vision metrics with forensic-oriented validation, including stability of detections across nine datasets, error patterns under low-light and motion blur, metadata completeness, SHA-256 hash consistency, real-time inference (˜ 33.55 ms per frame), multi-threshold operational validation, and Telegram alerting effectiveness (distance ≈ 0.1402).

C. Real-Time Operational Validation

Testing on real surveillance videos demonstrated consistent inference rates across all confidence thresholds and confirmed the system's suitability for practical forensic environments.

D. Limitations and Ethical Considerations

Limitations include computational overhead since running multiple models and forensic preprocessing steps, along with environmental variability, where lighting, motion blur, and camera noise reduce detection stability. Class imbalance in certain datasets, such as blood and some accident indicators, also affected performance. Tooling constraints existed since Kaggle, Roboflow, and Google Colab all enforce feature limits and resource caps on free-tier accounts. Given that the project had no financial support, all experiments were conducted under these restricted environments, which limited training time, GPU availability, dataset size, and export options. Ethical and legal considerations included privacy risks, false positives, and surveillance accountability. Mitigation included anonymization, restricted access, and strict chain of custody management.

Although the average mAP50 result indicates promising feasibility, it is not sufficient to claim forensic-grade deployment. Future development should focus on expanding category-specific datasets, improving weaker classes such as weapons and blood, performing cross-dataset validation, and testing the system under real operational forensic conditions before practical deployment.

A further limitation is the absence of a direct quantitative baseline comparison with existing forensic surveillance systems or general-purpose detection pipelines under identical experimental settings. Future work will include controlled baseline comparisons using the same datasets, metrics, and deployment conditions.

VI. Findings

This study has shown that the VigilEye system is capable of producing consistent and dependable results for the various types of evidence recovered via surveillance through a thorough quantitative assessment, as well as numerous operational tests in real-life settings. The results of the trained models' ability to detect events included in the project indicate that several of the most critical categories of evidence, specifically, people, fire, smoke, and vehicle registration plates, yielded reliable and consistent predictions.

The results of the performance of the fire analysis dataset were highly consistent across both fire and smoke classes, and the trained model for detecting persons produced high levels of confidence and stable recognition of human subjects in a wide range of challenging environments. The model's limited detection performance in accident scenarios is due to the variety of accidents themselves. The license plate recognition model, trained on a 300-image dataset, delivered dependable performance across various lighting and distance conditions. Weapons detection showed modest to moderate performance depending on the dataset: the weapons dataset produced stronger, more isolated results. The small blood dataset consisted of 160 images. During the experiments, the lowest sensitivity for blood detection was observed as a result of the imbalanced nature of the dataset and the visual ambiguity of blood patterns, which aligns with prior discussions on visually subtle forensic classes [7]. The inability to accurately distinguish between visually similar classes was a key limiting factor; larger and more heterogeneous datasets are needed for reliable generalization in similar categories. In addition to testing the models on controlled datasets, VigilEye was tested using a mixture of real-world video footage with vehicles, pedestrians, lights, and varying light and dynamic environments. Across five different confidence thresholds, the VigilEye models maintained consistent detection abilities for all objects, including people, vehicles, fire, smoke, weapons, and license plates.

The average time spent for analysis on all datasets was about 33.55 milliseconds, indicating suitability for real-time applications. The system's effectiveness was empirically validated through rigorous forensic testing, in accordance with best practices in digital forensic video analysis. To protect privacy, facial blurring was employed to conceal the identities of detected faces, while the original, unaltered evidence was designed to be securely stored in an encrypted evidence environment, thus supporting ethical monitoring and privacy requirements.

An immediate alert was generated via Telegram upon the detection of suspicious objects and movements, enabling rapid notification to forensics in line with modern AI-based alert mechanisms. The VigilEye system maintained its consistent performance across all components of forensic evidence integrity. To ensure evidence integrity, every detection result (cropped images, metadata files, and processed frames) was hashed using the SHA-256 algorithm, in accordance with established digital tamper detection standards.

The results indicate that VigilEye can support the generation of traceable and integrity-protected forensic evidence for investigative workflows. However, formal legal admissibility would require additional validation under operational forensic procedures, institutional policies, and jurisdiction-specific legal requirements. The system shows strong performance in numerous high-risk forensic scenarios. However, improvements are still needed, particularly expanding datasets and improving models for detecting blood and other hard-to-identify forensic indicators.

As shown in Table I, the VigilEye system demonstrates a practical balance between detection accuracy and real-time performance across the evaluated forensic models.

Average performance was observed in categories with visual complexity, including people, fights (violence), and fire/smoke, while lower mAP values in weapons and blood detection are primarily attributed to dataset imbalances and visual ambiguity. Despite these variations, the system maintains effective real-time performance, with an average inference time of approximately 33.5 milliseconds per image, confirming its suitability for real-time criminal surveillance applications.

TABLE I. VIGILEYE PERFORMANCE TABLE (ALL DATASETS)

Dataset / Model	Images	Precision	Recall	mAP50	mAP50–95	Speed (ms/img)
Face Model	1000	0.9994	1.0000	0.9950	0.9509	126.85
People	690	0.7910	0.7190	0.8040	0.4040	18.15
Weapons	442	0.3150	0.3740	0.3190	0.1350	30.63
Blood	160	0.8455	0.5464	0.6688	0.3040	20.98
License Plate	300	0.8229	0.7429	0.7918	0.3968	18.94
Fight (Violence)	802	0.6884	0.6848	0.7048	0.4097	20.88
Cars	800	0.6442	0.5581	0.5884	0.3923	24.53
Car Accident	987	0.9738	0.9342	0.9523	0.9116	20.79
Fire/Smoke	400	0.7040	0.6610	0.6430	0.3440	20.23
Average (All Datasets)	–	0.7538	0.6912	0.7186	0.4720	33.5533

Fig. 3. Object detection

Fig. 3 demonstrates the performance of the VigilEye system in detecting multiple objects in a busy urban environment. Pedestrian and vehicle positions are accurately identified using surrounding boxes with associated confidence scores. This result highlights VigilEye's ability to operate effectively in complex public spaces, supporting real-time situational awareness and criminal surveillance.

Fig. 4. Fire detection

Fig. 4 shows the VigilEye system's ability to detect fire incidents along with surrounding vehicles and personnel. It assigns high confidence scores to fire zones, indicating its ability to accurately identify hazardous events in emergencies. This capability enhances the speed of incident detection and supports immediate forensic response and risk assessment.

Fig. 5. Weapon detection

Fig. 5 [25] presents the results of the VigilEye system in detecting weapons in close-range conditions, where the detected object is enclosed in a boundary square with a confidence score. This demonstrates VigilEye's effectiveness in identifying high-risk objects even under challenging visibility conditions, contributing to proactive threat identification and supporting forensic evidence.

Fig. 6. Video detection

The evaluated video footage was obtained from an opensource dataset available on Pexels [34]. The model output shown in Fig. 6 demonstrates the model's stability across five confidence thresholds (0.25, 0.20, 0.15, 0.10, and 0.05). Despite

a gradual decrease in confidence levels, the system consistently detected most key criminal elements at a crime scene, including people, vehicles, and police lights. This indicates high robustness in low confidence environments and supports the model's ability to function effectively under realistic surveillance conditions, whether visibility is poor or noise is high.

Fig. 7. License plate recognition

The license plate detection process encountered several challenges during the analysis stage. In some cases, Arabic characters were not accurately recognized, while in other instances, letters and numbers overlapped, leading to partial or incorrect detections. These issues were more noticeable when dealing with plates that contained a mix of Arabic and English characters or when the plate quality varied.

Despite these challenges, the detection system demonstrated robust performance overall, as shown in Fig. 7 [35]. The model successfully detected and recognized multiple license plates across different images, showing its capability to handle diverse plate formats.

Fig. 8. Face recognition

To protect individual privacy during surveillance and provide immediate alerts, the VigilEye system automatically applies face blurring technology before sending any external visual evidence, such as Telegram alerts. As illustrated in Fig. 8 [32], the facial region is anonymized using OpenCVbased face blurring to conceal distinctive features and protect personal privacy. Simultaneously, the original, unblurred frames are securely stored within the system and are accessible only to authorized forensic investigators, ensuring compliance with privacy requirements and proper evidence handling.

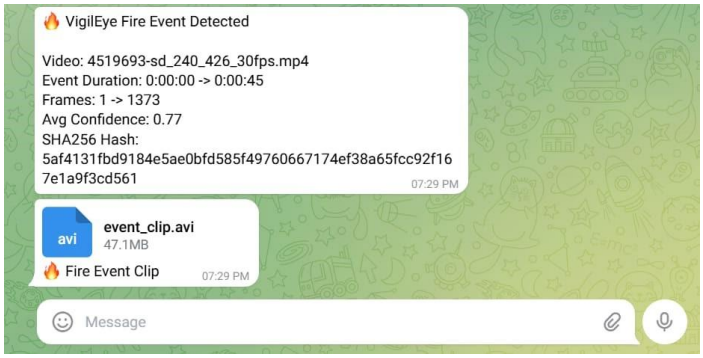

Fig. 9. Telegram alert

Fig. 9 illustrates the mechanism of instant alerts. During testing, the detection of a fire triggered an immediate notification via the Telegram app. The alert included the fire's duration, the time interval between frames, the average confidence score, and a SHA-256 hash code for evidence integrity verification. A video of the fire was also included, confirming the system's ability to detect fires in real-time, trigger alerts without delay, and preserve evidence while ensuring privacy and forensic traceability.

VII. Conclusion

Research has shown that VigilEye demonstrates the feasibility of an integrated forensic surveillance system, combining real-time monitoring with the preprocessing and secure storage of digital forensic evidence. The system demonstrated strong and consistent performance across multiple categories of forensic detection, including fires, smoke, weapons, individuals, and vehicle license plates, while maintaining operational stability under challenging environmental conditions such as low-light and poor image quality. This performance was enhanced by the integration of CLAHE-based image enhancement techniques and the safeguarding of visual forensic evidence using SHA256 hashing. Tests confirmed the system's practicality in controlled experimental settings using public datasets, simulated crime-scene scenarios, and open-source surveillance videos. However, validation using real forensic operational footage remains necessary before deployment in actual investigative environments. Integration with Telegram alerts further enhanced incident awareness, while facial blurring ensured compliance with privacy requirements by protecting biometric information without compromising original evidence. Although VigilEye achieved strong overall performance, its accuracy in detecting subtle visual evidence, such as blood and certain accident indicators, was limited by the small size and imbalance of its training datasets. These limitations highlight the need for larger and more diverse criminal datasets and for further refinement of the models for each category. Ethical and operational considerations, including privacy protection, false alarms, and transparency, remain critical in the deployment of forensic AI systems.

Overall, VigilEye demonstrates that a single, integrated platform can enhance the accuracy, integrity, and efficiency of forensic evidence. Our research helps advance digital forensic surveillance and provides a foundation for future developments, including expanded datasets, improved spatial-temporal analysis, automated chain of custody reporting, and greater interoperability with existing forensic tools.

School of Engineering Technology, Thu Dau Mot University, Thu Dau Mot City, Vietnam[3]

***Abstract*—Localization based on received signal strength using the k-Nearest Neighbor method is quite common in indoor localization systems. However, as the fingerprint dataset grows, finding the nearest neighbors becomes time-consuming. In this study, we use Approximate Nearest Neighbor (ApNN) methods to accelerate nearest-neighbor search in RSS-based localization. We further propose a residual learning framework driven by ApNN search, where ApNN provides coarse position estimates and the residual model compensates for the nonlinear relationship between RSS measurements and spatial coordinates. Simulation results show that, compared to the Brute k-Nearest Neighbor method, ApNN algorithms significantly reduce computation time. KD-Tree is the fastest algorithm, with an improvement of approximately 96% compared to kNN and WkNN. Other methods such as HNSW and Ball-Tree also achieved high performance with improvements of around 93–94%, while LSH improved by approximately 84.8%. Regarding positioning error, KD-Tree achieved the best positioning error after applying residual learning, with the highest RMSE reduction of approximately 22.5%. These results demonstrate that the proposed ApNN-based residual learning framework is an effective solution for large-scale received signal strength positioning systems.**

Keywords*—Localization; LED; approximate nearest neighbor; residual learning

I. Introduction

Currently, demand for robot positioning services in homes, schools, hospitals, offices, and factories is increasing, driving the rapid development of indoor positioning technologies. In this context, Visible Light Positioning (VLP) has emerged as a promising solution due to its ability to utilize existing LED lighting infrastructure and combine with Visible Light Communications (VLC). VLP not only achieves high accuracy but also offers lower deployment costs compared to other technologies [1].

Among indoor positioning algorithms, the fingerprint-based method combined with the k-Nearest Neighbors (kNN) algorithm is among the most popular techniques, with relatively good accuracy. The core principle of kNN in fingerprinting-based positioning is to compare the received signal strength (RSS) at the target location with that in a prebuilt database. The system then selects the k reference points with the highest similarity. Finally, it estimates the position by averaging their coordinates [2].

Although widely used, kNN still has several limitations. The main drawbacks of kNN are its slow execution time and high error rate, especially with large datasets [3]. To address these issues, many improvements have been proposed. One of the most common approaches is the development of weighted kNN (WkNN). The main idea is to assign larger weights to closer reference points rather than using a simple average for position estimation. Similarly, a WkNN model was proposed for VLP systems in [4]. This model estimates the receiver's current position based on the locations of k predefined neighboring points stored in a lookup table. The Euclidean distances between the actual position and reference points are weighted to improve accuracy. Simulation results show that the proposed model outperforms trilateration. The accuracy improves 36% and 50% under conditions with and without ambient light noise, respectively. To further improve accuracy, the authors in [5] proposed an Improved WkNN (IWkNN) algorithm for both distance and angle. Specifically, the k nearest reference points are first selected based on distance. Then, the angles between each reference point and the target are calculated. Finally, weights are determined by the inverse of the product of the distance and angle. Simulation results demonstrate that IWkNN outperforms standard WkNN in positioning accuracy.

Another approach was proposed in [6], where the authors observed that the Euclidean distance of RSS is not consistent with the actual spatial distance. They analyzed the relationship between RSS similarity and spatial distance and proposed a WkNN algorithm. This solution is based on Approximate Position Distance (APD). This method involves calculating a Weighted Euclidean Distance (WED) by balancing RSS differences and signal attenuation characteristics. Then, APD is determined based on both the spatial distance and the WED between the reference points.

In addition to weight improvements, many studies focus on determining the optimal value of k or combining kNN with other methods to enhance performance [3]. In the mentioned study, the WOKNN (Weighted Optimum K-Nearest Neighbors) algorithm was proposed for VLC positioning systems,

*Corresponding author.

combining OKNN and WKNN. To reduce computational time, the authors applied Maximum Received Signal Strength Recognition (MRR). OKNN automatically determines the optimal number of neighbors for each location, while WKNN reduces the error caused by averaging Euclidean distances. Experimental results show that the proposed method achieves an average positioning error of only 8 mm in a 1.2 m × 1.2 m space. Additionally, computation time is reduced by 42% - 52% compared to other kNN-based methods.

Another approach integrates kNN with Bayesian theory to improve accuracy [7]. A Bayesian K-Nearest Neighbor (BKNN) algorithm was proposed for RFID positioning systems. This method uses a Gaussian filter to remove abnormal RSS values, followed by BKNN for position estimation. Experimental results show that BKNN achieves an average error of about 15 cm, which is lower than that of Gaussian-based methods, LANDMARC, and improved kNN algorithms. Similarly, in [8], kNN was combined with Bayesian theory for VLP systems, achieving an average positioning error of 0.27 m. Additionally, Hoang et al. proposed the SRL-KNN (Soft Range Limited K-Nearest Neighbors) algorithm to improve indoor positioning accuracy. Real-world experiments show that SRL-KNN achieves an average positioning error of 0.66 m, with 80% of errors below 0.89 m. This approach achieves a 45% improvement over traditional kNN under the same conditions [9].

A modern trend in fingerprint-based positioning is the integration of kNN with advanced machine learning techniques, particularly deep learning. In [10], the authors proposed a hybrid method combining a Deep Neural Network (DNN) with an improved kNN algorithm for Wi-Fi RSSI-based fingerprinting. The improved kNN assigns weights to neighbors based on the number of matched access points, addressing the limitations of traditional kNN. The DNN is first used to classify RSSI fingerprint data. Then, candidate locations within each class are further refined using the improved kNN. Experiments conducted in a 13 m × 9 m space show that this hybrid approach is less dependent on access point density and more robust to indoor signal noise. It also outperforms algorithms such as random forest, SVM, and decision tree.

Nearest neighbor search is a fundamental operation in many domains such as databases, machine learning, and computer vision [11]. Although numerous Approximate Nearest Neighbor (ApNN) algorithms have been proposed, until recently, there has been a lack of comprehensive, systematic evaluation of their performance. These authors carried out a large-scale experimental evaluation. They tested 19 algorithms from different fields on 20 different datasets with different metrics and query workloads. The ApNN benchmarks tool provides a standard way to measure performance and quality. A key finding is that many different approaches can be used for the ApNN problem [12]. Among these methods, graph-based approaches have received significant attention [13]. In that study, the authors introduced EFANNA, which is considered a very fast ApNN algorithm. It combines tree structures and graph methods to improve efficiency. Another widely used hierarchical graph structure is HNSW (Hierarchical Navigable Small World) [14]. HNSW has been applied to local feature-based localization. The authors proposed using HNSW as an approximate nearest-neighbor search method to reduce processing time without sacrificing localization accuracy. The results showed no significant increase in localization error, while processing time was substantially improved. In addition, the inverted file (IVF) index approach has been widely adopted. In which partitions data into clusters and searches only within the closest clusters are applied. A related proposal is an adaptive ApNN algorithm [15] that evaluates query complexity to determine the sufficient number of clusters to search dynamically. This approach achieves up to 35% faster search speed while maintaining a high recall of 0.99 on datasets containing up to one billion vectors.

For binary data, the study in [16] proposed mapping binary descriptors to a low-dimensional real-valued space before applying the KD-tree and Hamming ranking. This method achieved an improvement in search accuracy from 67.7% to 83.7% when the search speed was 200 times faster than a linear scan. In large-scale localization, using randomized trees trained with supervised learning to index binary features improved localization speed by an order of magnitude compared to state-of-the-art methods [17].

From the studies reviewed above, it is evident that the application of ApNN in localization applications has not been thoroughly investigated and evaluated. In the field of indoor visible light positioning (VLP) using LED lighting, the use of ApNN methods as an approach to address the slow processing speed of kNN remains largely unexplored. Therefore, in this research, we focus on addressing the following issues. First, we construct an LED model within a large space of approximately 10 × 10 m², where a complete system comprising 81 LED fixtures is installed. We then collect the received signal strength (RSS) or illumination intensity data from each LED. Second, we apply various ApNN methods, including Ball-Tree, KD-Tree, Locality-Sensitive Hashing (LSH), and Hierarchical Navigable Small World (HNSW), to estimate the coordinates and evaluate the execution time of each method. Third, we propose a residual learning framework driven by approximate nearest neighbor (ApNN) search, where ApNN provides coarse positioning and the residual model effectively compensates for the nonlinear relationship between RSS measurements and spatial coordinates. Finally, we provide detailed performance analysis in terms of runtime, latency, and positioning error for different deployment scenarios. The results obtained from each ApNN approach will be compared against those of the traditional kNN method.

In the remainder of this study, we present the LED model as well as the configuration of the study area. Next, the ApNN-based positioning methods are described. Subsequently, we present the experimental results and perform a comparison with other methods. Finally, conclusions and directions for future research are provided.

II. Applied Localization Model

In this study, we developed an experimental model within an indoor environment with dimensions of 10 × 10 m². The lighting system consists of 81 LED sources arranged in a uniform grid, with an inter-LED spacing of 1 m. The LEDs located near the walls are positioned 1 m away from the boundaries. As depicted in Fig. 1, this configuration ensures a balanced distribution of optical power across different positions in the room.

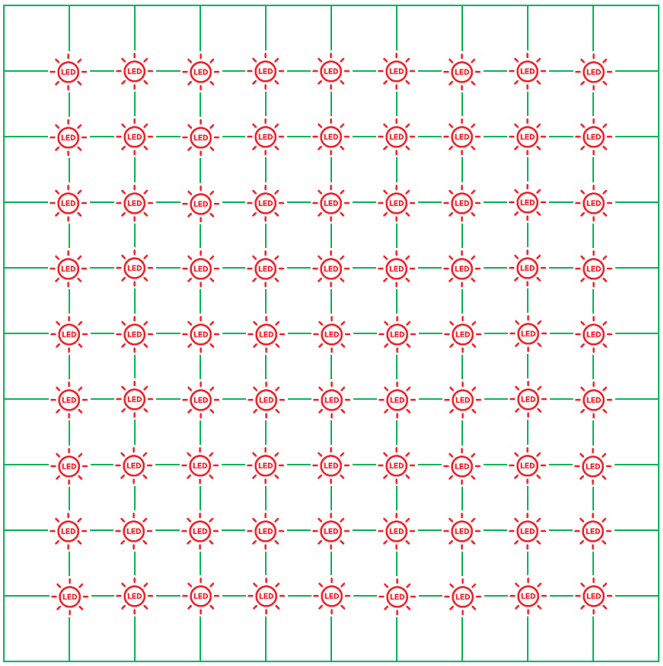

Fig. 1. Room and LED configuration.

The main parameters of the LED sources are defined as follows: the semi-angle at half power is 70°, corresponding to a Lambertian order:

$$m = -\frac{ln(2)}{\ln(\cos(70^0))} \quad (1)$$

Each LED has an optical power of 10 mW, resulting in a total transmitted optical power proportional to the number of LEDs. The photodetector area is 1×10^{-4} m², the optical filter gain is 1, and the refractive index of the concentrator is 1.5. The receiver field of view (FOV) is 60°, leading to a concentrator gain defined as:

$$G = \frac{n^2}{sin(FOV)} \quad (2)$$

where:

- n is the refractive index of the concentrator lens material.
- FOV is the field of view of the receiver.

Fig. 2 illustrates the block diagram of an optical wireless communication system using LEDs and a photodetector. The system consists of three main components: the transmitter, the channel, and the receiver.

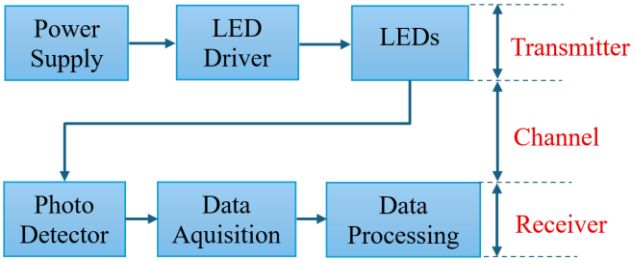

Fig. 2. VLP system diagram.

- At the transmitter side: a power supply provides energy to the LED driver circuit. This driver modulates the electrical signal to control the emission frequency of each LED. The operating frequencies range from 1 kHz to 81 kHz, with a spacing of 1 kHz between adjacent LEDs.
- Channel: the light emitted from the LEDs propagates through the indoor environment, including both line-of-sight (LOS) and reflected (non-line-of-sight, NLOS) components, carrying information from the transmitter to the receiver.
- At the receiver side: the optical signal is captured by a photodetector and converted into an electrical signal. This signal is then passed through a data acquisition unit for digitization and finally processed by the data processing block to recover the transmitted information.

The received optical power at a given point from the i^{th} LED is [3]:

$$P_{los,i} = P_{LED} H_i T_s G \quad (3)$$

The LOS channel gain is given by:

$$H_i = \frac{(m+1)A_P}{2\pi d_i^2} cos^m(\alpha_i)\cos(\beta_i) \quad (4)$$

where:

- P_{LED}: transmitted optical power of a single LED
- A_P: photodetector area
- d_i: distance between the i^{th} LED and the receiver
- α_i: irradiance angle
- β_i: incidence angle
- m: Lambertian order
- T_s: optical filter gain (≈ 1)
- G: concentrator gain

The total received power is the sum of contributions from all LEDs:

$$P_{los_total} = \sum_{i=1}^{81} P_{los,i} \quad (5)$$

III. Residual Learning Framework Driven by Approximate Nearest Neighbor Search

ApNN search aims to efficiently identify data points that are close to a query point while trading off a small amount of accuracy for significantly reduced computational cost, especially in high-dimensional spaces. In this study, four representative ApNN methods are considered, including KD-tree, Ball-tree, Locality-Sensitive Hashing (LSH), and Hierarchical Navigable Small World (HNSW), each employing different strategies for efficient similarity search.

A. Ball - Tree

The Ball-tree is a hierarchical spatial data structure. It was introduced by Stephen M. Omohundro in 1989. The structure organizes data points into a binary tree. Each node represents a

hypersphere, also called a ball. These balls can contain other smaller balls inside them. The Ball-tree is commonly used for nearest neighbor search. It helps reduce the number of distance calculations. This makes the search process more efficient, especially in higher-dimensional data.

Each node in a Ball-tree is defined by a hypersphere with a center $c \in R^d$ and radius r, where the radius is the maximum distance from c to all points in the node [18]:

$$r = max_{x \in S} \|x - c\| \quad (6)$$

Here, s is the set of points contained in the node, and this formulation ensures that all points lie within the hypersphere centered at c. Based on this definition, the node can be interpreted as a hypersphere that includes all points satisfying the following condition [18]:

$$B(c, r) = \{x \in R^d | \|x - c\| \leq r\} \quad (7)$$

B. KD - Tree

In a KD-tree, the data space is recursively partitioned using axis-aligned hyperplanes. At each node, a splitting dimension k and a threshold value t are selected to divide the dataset into two subsets [19]:

$$S_{left} = \{x \in R^d | x_k \leq t\} \quad (8)$$

$$S_{right} = \{x \in R^d | x_k > t\} \quad (9)$$

Here, x_k denotes the value of a point x along the k^{th} dimension. This partitioning process is applied recursively, forming a binary tree where each node represents a hyper-rectangular region of the space.

C. Locality-Sensitive Hashing

Locality-Sensitive Hashing (LSH) maps data points into the same bucket with high probability if they are close in the feature space [20]. A hash function $h(\cdot)$ satisfies:

$$P[h(x) = h(y)] = \begin{cases} high, if \ \|x - y\| \leq R \\ low, \ if \ \|x - y\| > cR \end{cases} \quad (10)$$

where, R is a distance threshold and $c > 1$ is the approximation factor. This ensures that nearby points are more likely to collide in the same hash bucket.

D. Hierarchical Navigable Small World

Hierarchical Navigable Small World (HNSW) performs approximate nearest neighbor search by navigating a multi-layer graph structure, aiming to minimize the distance between a query point q and data points [21]:

$$x^* = argmin_{x \in S} \|q - x\| \quad (11)$$

The search process follows a greedy strategy, starting from upper layers and progressively refining the result at lower layers.

Table I presents the main specifications of the five nearest neighbor search methods. For kNN, the number of nearest points is set to 5 for all algorithms to ensure a fair comparison, as this value also provided the best accuracy during the error evaluation process. This value helps to determine the number of neighbors that are used for position prediction. The Euclidean metric is used to calculate spatial distances. The KD-Tree and Ball-Tree methods both use a leaf size of 30, which controls the granularity of tree partitioning. For LSH, the number of projection dimensions is reduced to 8. In HNSW, three parameters are crucial: the maximum number of connections per node is 16, the dynamic list size during construction is 200, and the search breadth during querying is 50.

TABLE I. MAIN TECHNICAL SPECIFICATIONS

Method	Parameters	Values
kNN Brute	Number of nearest neighbors	5
	Euclidean distance metric	Minkowski (p=2)
KD-Tree	Number of nearest neighbors	5
	Maximum points per leaf node	30
	Euclidean distance metric	Euclidean
Ball_Tree	Number of nearest neighbors	5
	Maximum points per leaf node	30
	Euclidean distance metric	Euclidean
LSH	Target projection dimensions	8
	Random number generator state	None
	Number of nearest neighbors	5
	Linear search in projected space	Brute
HNSW	Euclidean distance space	l2
	Input data dimensionality	16
	Maximum elements in index	340
	Dynamic list size during construction	200
	Maximum connections per node	16
	Dynamic list size during query	50
	Number of nearest neighbors	5

After obtaining the indices of the 5 nearest neighbors in the training set, all five methods apply the same averaging formula to compute the predicted coordinates:

$$\hat{Y}_{ApNN}^{(i)} = \frac{1}{k} \sum_{j \in N_K(X_{ApNN)}^{(i)})} Y_{train}^{(j)} \quad (12)$$

where:

- k: the number of nearest neighbors
- $N_K(X_{ApNN)}^{(i)})$: the set of indices of the k nearest neighbors to $X_{ApNN)}^{(i)}$ in the training set
- k: the index of a training point belonging to N_K
- $Y_{train}^{(j)}$: the normalized coordinates (XR, YR) of the j^{th} training point

Algorithm 1: ApNN-RL Algorithm

Input:

$X \in R^{2500 \ x \ 81}$: RSS fingerprint dataset

$Y \in R^{2500 \ x \ 2}$: Ground-truth positions on a 50×50 grid

K: Number of nearest neighbors

ApNN(·):Approximate nearest neighbor search method
Output:
$\hat{Y}$: Estimated positions
Evaluation metrics (RMSE, total time, latency)

INITIALIZATION

Normalize X and Y
Split dataset

OFFLINE PHASE

| For (each training sample) do
    | Find K nearest neighbors using ApNN
    | Estimate coarse position $\hat{Y}_{ApNN}^{(i)}$
| End
Compute residual $r^{(i)}$ for each sample
Construct training input
Initialize residual network $g(\cdot)$
While (epoch < MaxEpoch) do
  | For (each training sample) do
    | Predict residual $r_{pred}^{(i)}$ using $g(\cdot)$
    | Compute loss between $r^{(i)}$ and $r_{pred}^{(i)}$
    | Update network parameters θ
  | End
End

ONLINE PHASE

| For (each test sample) do
    | Retrieve K using ApNN
    | Estimate coarse position
    | Construct input (RSS + coarse position)
    | If (model is trained) then
        | Predict residual error
        | Refine position $\hat{y}^{(i)}$
    | End
| End

EVALUATION

Compute:
    RMSE between predicted and true positions
    ApNN search time
    Average time per sample
Return final estimated positions and evaluation metrics

However, because ApNN is approximate and the relationship between RSS measurements and physical locations is nonlinear, this initial estimate may still have noticeable errors. To fix this, we use a Residual Learning approach to improve the prediction by learning the difference between the estimated position and the true coordinates. The detailed workflow of the proposed ApNN-based residual learning (ApNN-RL) method is illustrated in Algorithm 1. The proposed ApNN-based Residual Learning (ApNN-RL) model combines the fast ApNN method with a learning-based refinement strategy to achieve both fast computation cost and improved positioning accuracy. In the offline phase, an ApNN method is employed to efficiently retrieve the k nearest points for each sample. Then, coarse positions are estimated through neighbor averaging. Based on this initial estimate, the residual error between the predicted and true positions is computed. We then apply a residual neural network to learn this error using both the original RSS data and the coarse estimate as input. In the online phase, the same ApNN search is applied to quickly generate a coarse position for each query, which is then refined by the trained residual model to produce the final estimate.

TABLE II. SPECIFICATIONS OF RESIDUAL LEARNING NETWORK

Parameter		Value
Input dimension		81
Output dimension		2
Architecture		Fully-connected NN
Layer 1	Linear	Input_dimension (128)
	Activation	ReLU
	Dropout	0.2
Layer 2	Linear	128 - 64
	Activation	ReLU
Layer 3	Linear	64 - 2
Training	Loss function	MSELoss
	Optimizer	Adam
	Learning rate	0.001
	Epochs	2000

The residual is defined as:

$$r^{(i)} = y^{(i)} - \hat{y}_{ApNN}^{(i)} \tag{13}$$

A neural network $g(\cdot)$ is then trained to learn this residual mapping using both the original input and the coarse estimate:

$$g\left(x^{i}, \hat{y}_{ApNN}^{(i)}\right) \approx r^{(i)} \tag{14}$$

The final refined position is obtained by combining the ApNN estimate with the predicted residual:

$$\hat{y}^{(i)} = \hat{y}_{ApNN}^{(i)} + g\left(x^{i}, \hat{y}_{ApNN}^{(i)}\right) \tag{15}$$

Then, Root Mean Square Error (RMSE) is used to evaluate the prediction accuracy of each method by measuring the difference between the actual and predicted positions after inverse transformation, with the formula defined as:

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}\|y^{(i)} - \hat{y}^{(i)}\|^2} \tag{16}$$

The total query time is defined as:

$$T_{total} = \sum_{i=1}^{n} t_i \tag{17}$$

where, n is the number of test samples and t_i is the query time for the i^{th} sample.

The average latency per query is given by:

$$T_{Latency} = \frac{T_{total}}{n} \tag{18}$$

The main parameters of the residual learning model are shown in Table II. They include the network structure, training settings, and input–output configuration. The residual learning network is implemented as a fully connected neural network with two hidden layers (128 and 64 neurons) using ReLU activation and dropout regularization. It is trained with the Adam optimizer and MSE loss to learn the residual error between the coarse ANN-based estimate and the ground-truth position, enabling refined localization accuracy.

IV. Results and Discussion

As shown in Fig. 3, all methods improved accuracy after applying the proposed ApNN-RL algorithm. In all cases, the KD-Tree method had the best error reduction at 22.5%. The kNN and WkNN methods also showed significant improvement, with RMSE decreasing 20% and 18.6%, respectively. Similarly, Ball-Tree and HNSW also decreased from 5.99 cm to 4.72 cm and 4.84 cm, respectively. Among these methods, only LSH showed the least improvement in RMSE at 2.3%.

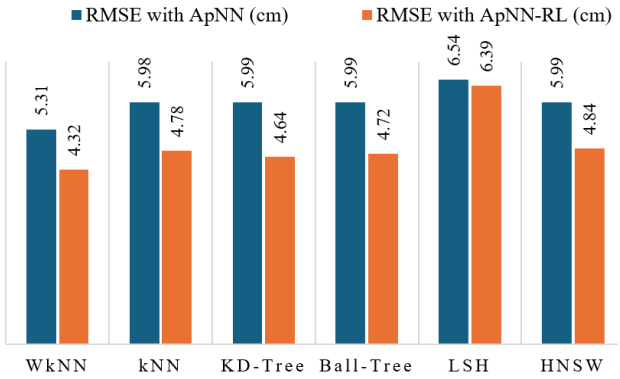

Fig. 3. Positioning error comparison.

In contrast, the LSH method exhibits only a marginal improvement, with only 2.3%. For HNSW, although the improvement is not as great as that of kNN, KD-Tree, or Ball-Tree, a clear reduction is still observed, from 5.99 cm to 4.84 cm. These results indicate that HNSW still benefits from ApNN-RL while maintaining its advantage in computational efficiency.

In Fig. 4, we evaluate the execution speed of each method. The reported Time (s) shows the total query time for all test samples. The ms/sample value shows the average time for each localization sample. The results show clear differences in speed between the methods. The traditional kNN method has the highest query time, reaching 0.1775 s. Its average time per sample is 0.3549 ms. The WkNN algorithm also shows a similar computational performance. In contrast, methods like KD-Tree and Ball-Tree run much faster. KD-Tree reduces the time to 0.0070 s, while Ball-Tree takes 0.0125 s. These results are equivalent to 0.0140–0.0251 ms per sample, which is approximately 14–25 times faster than kNN. In which, the HNSW method achieves a query time of 0.0106 s and an average latency of 0.0211 ms per sample. This corresponds to an improvement of around 17 times compared to kNN. Meanwhile, LSH exhibits an intermediate query time of 0.0270, which is faster than kNN but still slower than KD-Tree, Ball-Tree, and HNSW. Overall, regardless of the ApNN method used, the computational cost of each solution was significantly reduced. This is particularly important in positioning systems that use a large number of fingerprints.

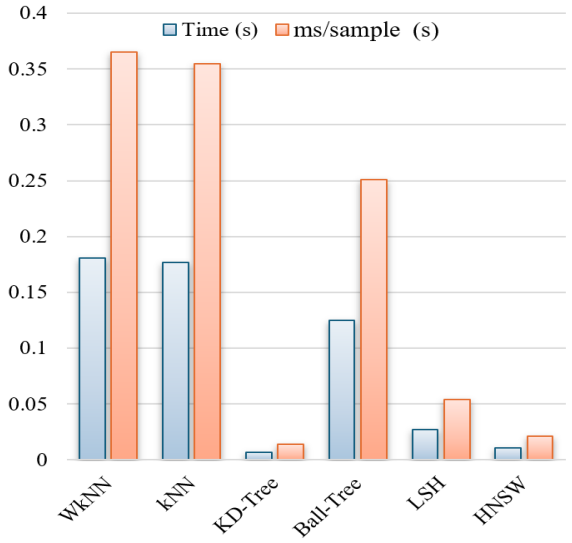

Fig. 4. Runtime performance comparison.

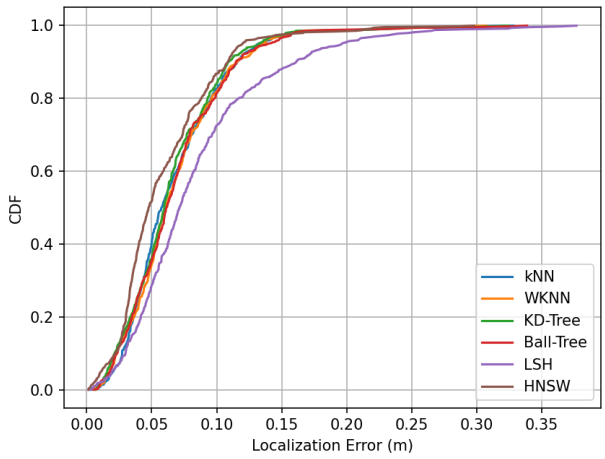

Fig. 5. CDF comparison.

To provide a comprehensive evaluation of localization accuracy, the cumulative distribution function (CDF) is used to illustrate the distribution of positioning errors across all samples. As shown in Fig. 5, all methods show a rapid increase in CDF values at low error ranges. Within the range of 0.05-0.1 m, the curves representing the WkNN, kNN, KD-Tree, Ball-Tree, and HNSW methods almost overlap. This demonstrates that these methods achieve comparable accuracy in terms of error distribution. Conversely, the LSH curve is significantly right-skewed. Clearly, LSH has lower accuracy and a less concentrated error distribution. This is also illustrated in Fig. 3. LSH produced lower accuracy because the Gaussian random projection compresses RSS fingerprints into a lower-dimensional space, causing the loss of important neighborhood similarity information. Therefore, the retrieved neighbors are less representative than those obtained by exact search methods such as WkNN, kNN, KD-Tree, and HNSW.

The heatmap of KD-Tree illustrates the spatial distribution of localization errors across the whole area as shown in Fig. 6. Most regions exhibit low error values, as indicated by the darker color intensity. Higher error values appear at several isolated locations and near certain boundary areas. These variations suggest that the localization performance is not completely uniform across space, with some positions showing larger deviations than others. Overall, the error distribution is dispersed rather than concentrated in a single region, indicating no dominant area with consistently high error.

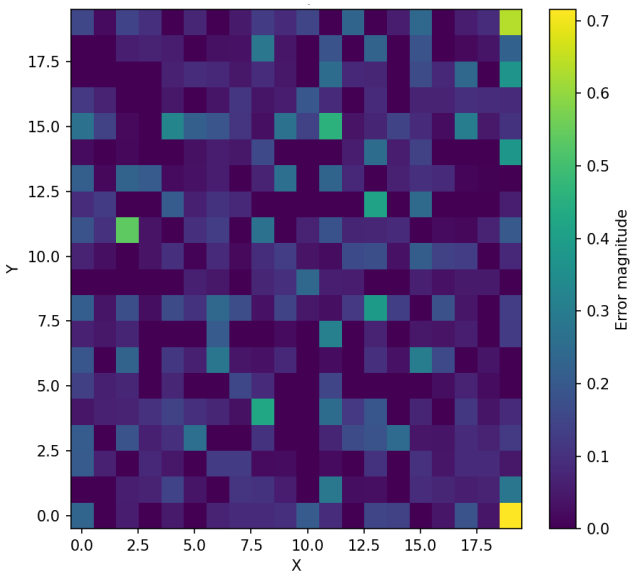

Fig. 6. Heat map of KD-tree.

V. Conclusion

In this study, we combined ApNN methods with residual learning to improve both localization accuracy and execution time. Regarding accuracy, the KD-Tree method combined with residual learning achieved the highest accuracy not only in localization error but also in execution time. Simulation results showed that this method achieved the lowest RMSE of 4.64 cm. In terms of runtime, KD-Tree also yielded low latency of 0.014 ms per sample. After KD-Tree, HNSW provided slightly lower computational cost but slightly lower accuracy. Overall, the integration of residual learning and ApNN improved localization accuracy and especially computation time across most methods.

In the future, we can further improve localization quality by optimizing the residual learning network architecture and adaptively tuning the ApNN parameters. Furthermore, extending the method to more complex environments or larger datasets is also a promising approach.

***Abstract*—Despite advances in technology and processing, image enhancement remains an open research area. The quality of the images has a great impact on the processing, analysis, and recognition. Images are a kind of multimedia data that demand huge resources. The image quality affects further processing, and if carefully utilized, will result in a reduction in the resources required for a specific task. Despite advancements in imagery technologies, the acquisition and transmission of digital images and other factors possess some kind of distortion. This may be attributed to transmission noise, environmental effects, and poor-quality acquiring devices and cameras, to name a few. This study compares ten image enhancement techniques for three types of imagery. The images investigated represent three classes. Micro is represented by microscopic images, Macro is represented by Macroscopic satellite images, and Photography for ordinary images. The study considers compressed images, both lossy and lossless compression, and ordinary uncompressed images. Three distortion categories, mainly Noise, Blurring, and Contrast effects, are extensively experimented with and studied. Noise types investigated are Gaussian, Poisson, Salt and Pepper, and Speckle noises. Two blurring distortions, Average Blur and Gaussian Blur, are investigated. In addition to low contrast. Distortions are applied to each image, and ten enhancement filters are applied. These include Negative, De-blur Regularized, De-blur blind deconvolution, De-blur Lucy-Richardson, Contrast Stretching, Adaptive, Gray Level Slicing, Median, Digital, and Histogram Equalization. Enhancement key performance indicators, Peak Signal to Noise Ratio, and Structural Similarity Index were measured to judge the performance of the filters. The three classes of imagery experimented with a developed tool that facilitates the experimentation and gives the KPIs for each image with a friendly User Interface. Insight is gained, thus facilitating the choice for the enhancement method.**

***Keywords*—Digital image enhancement; distortion; image compression; filter; peak signal to noise ratio; mean square error; structural similarity index**

I. Introduction

The digital image plays a major role in many applications and is used in a variety of fields. Ranging from medical applications [4], industrial production, video monitoring, intelligent transportation, remote sensing monitoring, military applications, etc. Image enhancement is a fundamental area in digital image processing that focuses on improving the visual quality and interpretability of images for human and machine vision systems. The primary objective of image enhancement is to process an image so that the enhanced image is more suitable for a specific application. The process aims to improve one or more characteristics of an image, including brightness, contrast, sharpness, edge visibility, color fidelity, texture details, and noise reduction. [1] [2] [3][4].

Image capturing can suffer many distortions due to many factors. Poorly captured images suffer from low contrast, low brightness, blurring, noise, color, and grey-scale distortions [4]. Image enhancement methods are generally classified into two major domains, spatial and frequency domain techniques. For many years, research on image enhancement has resulted in many efforts varying from investigating a single method to comparing many. Beside study the enhancement effects on Neural networks to develop deep learning methods, [5] [6] [7] [8] [9] [10].

This study gives insights into image enhancement techniques by exploring basic enhancements on various kinds of distortions. It enables the application of distortions on images and performs, enhances, and measures the metrics for each type of distortion enhancement. The study illustrates the effect of ten enhancement techniques on distortions applied to images. It measures the enhancement on colored and gray scale for lossy, lossless compression, and ordinary images.

Images vary in their nature. The study considers three types of imagery. Micro, exemplified by medical images. Macro, exemplified by satellite imagery. And photography Ordinary camera images. In addition to noise, we include blurring and contrast effects. We developed a tool that implements the project, the Image Enhancement tool.

The study is organized as follows: Section II gives in-depth on the methodology used in this investigation. Image enhancement quality evaluation metrics are presented in Section III. Section IV detailed the experimental analysis to test the performance of the selected algorithms; Section V summarizes the findings.

II. Image Environment

A. Image Compression

Compression is a technique that transforms an image into another. When applied does not reveal the digital image back to 100%. It can be Lossless or Lossy, where smaller compressed files are produced, number of original pixels, sound waves, or video frames is removed forever. Examples are JPEG images, MPEG videos, and audio formats.

B. Image Enhancement Categories

Image enhancement is classified into two categories, one based on the manipulation of the orthogonal transform of the

(PNURSP2026R925), Princess Nourah bint Abdulrahman University, Riyadh, Saudi Arabia

image rather than the image itself. Known as the frequency domain and is used for processing images according to the frequency content. The other category is the Spatial Domain techniques, which deal with the image pixels. The pixel values are manipulated to achieve the desired enhancement [11][12].

C. Image Enhancement Techniques

Images acquired through modern sensors may be contaminated by a variety of noise sources. Noise is stochastic variations as opposed to deterministic distortions such as shading or lack of focus. Images can suffer blurring, and be affected by contrast as well. The enhancement is a method applied to a distorted image to restore it. It works on an image by spotting hidden patterns and performing corrective actions that eliminate those distortions.

Image Enhancements considered in this study are summarized as:

- Negative: A method in which gray-level values of the pixels in an image are inverted to get its negative image. Negative images are useful for enhancing white or gray details embedded in dark regions of an image, it can be applied to a colored image by considering each color band independently.

The negative transformation in the range [0, L-1] is obtained by

$$s = l - 1 - r \tag{1}$$

where, r and s are the pixel values before and after the processing on the image:

- De-blur Regularized Filter: The regulated filter uses the de-blurring method to de-blur an Image.
- De-blur blind deconvolution: The blind deconvolution algorithm performs deblurring without the PSF. The blind deconvolution algorithm can be used effectively when no information about the distortion (blurring and noise) is known.
- De-blur Lucy-Richardson: A method that performs multiple iterations, using optimization techniques and Poisson statistics.
- Contrast Stretching: Increase the dynamic range of gray levels of an image. The image can be efficiently displayed in a manner desired by the analyst.
- Gray-level Slicing: Fixed threshold values are taken for highlighting a specific range of gray values in an image. Where the desired range is made constant in intensity. There are two techniques.

Give a high value for all the gray levels in the specified range and a very low value for all the other gray levels.

Give a high value for all the gray levels in the specified range and preserve the background and gray-level tonalities in the image.

- Adaptive Filtering: noise suppression, filters a grayscale image that has been degraded by constant-power additive noise. It uses a pixelwise adaptive Wiener method based on statistics estimated from a local neighborhood of each pixel.
- Median Filtering: a general-purpose filter that has no distinct frequency or correlation basis. In some cases, the ideal image becomes suppressed, especially when the image has low correlation from pixel to pixel.
- Digital Filtering: Computes a 2-dimensional correlation and returns the central part of the correlation with the same size as the input image.
- Histogram Equalization: A global image enhancement method that enhances image contrast. For an image with intensity levels in the range [0, L], the n^{th} moment of r about its mean, m, is defined as

$$\mu_n = \sum_{i=0}^{L-1} (r_i - m)^n \, p(r_i) \tag{2}$$

where, m is given by:

$$m = \sum_{i=0}^{L-1} r_i \, p(r_i) \tag{3}$$

The mean is a measure of average intensity, and the variance (or standard deviation, σ), given by:

$$\sigma^2 = \mu_2 = \sum_{i=0}^{L-1} (r_i - m)^2 \, p(r_i) \tag{4}$$

is a measure of contrast. [11].

III. Quality Metrics

The key performance indicators used to evaluate the enhancement applied to an image are:

A. Peak Signal to Noise Ratio (PSNR)

Peak Signal to Noise Ratio (PSNR) computes Mean Square Error (MSE) reconstruction error preceding enhancement. It quantifies reconstruction quality. Higher PSNR quantifies noise removal efficiency. Additionally, it removes part of the textures. Higher PSNR indicates better image quality. It is measured in decibels (dB). Above 40 dB indicates excellent. 30-40 dB good image quality, 20-30 dB poor, and below 20 dB unacceptable, [4].

$$MSE = \frac{\sum_{i=1}^{M} \sum_{j=1}^{N} [(f(i,j) - F(i,j)]^2}{M \cdot N} \tag{5}$$

$$PSNR = 20 \cdot \log_{10} \left(\frac{255}{\sqrt{MSE}} \right) \tag{6}$$

where, $f(i,j)$ is the original signal at pixel (i,j), $F(i,j)$ is the reconstructed signal, and M x N is the picture size.

B. Structural Similarity Index

Structural Similarity Index (SSIM) is a quality assessment, perception-based method, and is used to measure similarity between two images. Using the structural distortion measurement instead of errors. The idea considers the human vision system as highly specialized in extracting structural information from the viewing field rather than extracting errors. Thus, a measurement of structural distortion gives a better correlation to the subjective impression. It includes important perceptual phenomena, such as luminance masking and contrast. SSIM considers the similarity of the edges (high-frequency content) between an enhanced image and a reference image.

SSIM measures using an algorithm that removes the noise while preserving the edges of the objects. SSIM index is a decimal value between 0 and 1. At a high level, SSIM attempts to measure the change in Luminance, Contrast, and Structure.

$$SSIM(x,y) = \frac{(2\mu_x\mu_y+c_1)(2\sigma_{xy}+c_2)}{(\mu_x^2+\mu_y^2+c_1)(\sigma_x^2+\sigma_y^2+c_2)} \quad (7)$$

where, μ_x and μ_y are the mean values, c_1 and c_2 are biased values, σ_x , σ_y , the variances, and σ_{xy} is the covariance.

Improved SSIM scores indicate enhanced structural fidelity and better image details. [13][14][15][16]17][18].

IV. System Dynamics

The system accepts an image. Apply a selected distortion, then remove the distortion using a selected enhancement method.

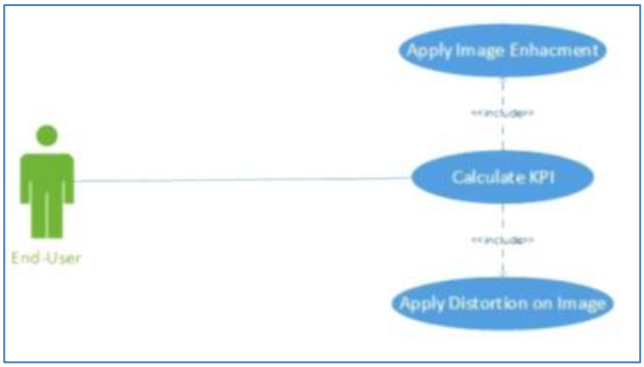

Fig. 1. Requirement analysis.

Actions that Fig. 1 performs are detailed as:

- Select an Image: Upload a reference image.
- Select distortion technique: a chosen distortion is applied to the image.
- Select an enhancement method: the enhancement applies to the image, and an enhanced image is produced.
- Calculate metrics: The enhancement metrics are calculated.

V. Implementation and Findings

The application interface enables the user to perform the actions detailed in the previous section (Fig. 2).

Fig. 2. System interface.

Fig. 2 shows a reference image, a distorted version of the image implementing salt and pepper noise, an enhanced image with De-blur blind deconvolution, and the metrics for this enhancement method. The interface enables these actions by using the tabs: Upload, Modify, and Enhance, respectively.

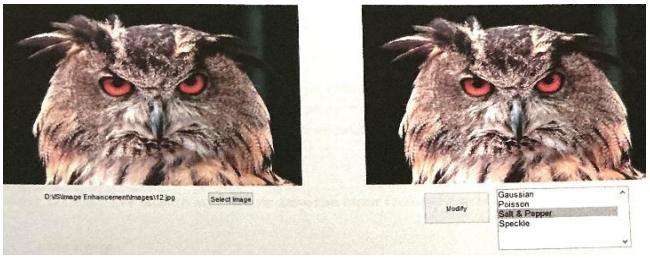

Fig. 3. Portion of the interface illustrating adding noise to a selected image.

Fig. 3 shows a portion of the user interface implementation showing the results of the select and modify tabs.

Fig. 4. Portion of the interface illustrating noise removal and metrics scores.

Fig. 4 illustrates Modify added salt and pepper noise, then enhance added Median filters on the image. The noise removal metrics PSNR and SSIM are produced and displayed as well.

As mentioned earlier, this study investigates image enhancement on micro, macro, and photography images. The implementation and results for each type of imagery are detailed in the designated table. Each table reported the results of the ten filters on the distortions and the metrics for each value. Comparisons based on SSIM and PSNR. Color indicates Dark maroon for worst results, Pastel red for bad results, Light green for good results, and dark green for best results. Neutral results are displayed with no color highlight.

A. Micro Images

The micro images studied are compressed, both lossy and lossless compressions, colored and gray-scale images. Tables I through XVIII give the results for each image. The tables give the results of applying the ten enhancement methods to seven distortions, together with the metrics for each.

Table I gives the results for a colored lossless micro image from the medical field. The colors in the table give the best to worst cases for the metrics. Dark maroon indicates the worst results, Pastel red indicates bad results, Light green indicates good results, and dark green indicates the best results. As seen in the table, the negative filter gives the worst SSIM values for micro images for three noises and two blurring distortions. The filter failed with respect to Poisson, Speckle, Salt and Pepper, Average Blur, and Gaussian Blur distortions. Digital filtering gives bad PSNR for all distortions under study. De-blur regularized filter failed to remove Gaussian, Speckle, and Salt and Pepper based on the PSNR metric. While De-blur blind deconvolution reported the same failure with Gaussian noise. Good removal filters are De-blur Richardson, Adaptive filtering,

and Median filtering. The results are highlighted in the table with the color codes given. Contrast stretching, Gray-level slicing, and Histogram Equalization give neutral results among the filters, as shown in Table I.

Table II displays the results for a lossy colored compression image. Worst results reported for the Negative filter based on SSIM. Bad results were reported on Digital filter and De-blur regularized filter for PSNR. Good results reported for Median, De-blur blind deconvolution, De-blur Lucy Richardson on SSIM. Best results reported for the SSIM metric.

Contrast stretching and adaptive filtering produced good results for Poisson noise removal based on PSNR. Contrast stretching works fine, among others, for Gaussian blur distortion. Neutral results reported for Gray-level slicing and Histogram equalization.

Table III shows the performance metrics for the uncompressed colored micro image. Again, the worst results were reported for the negative filter based on SSIM. Bad noise removal was experienced with Digital filter and De-blur regularized filters. It is interesting to see Histogram equalization and contrast stretching reported good and best results for the performance metrics. While neutral results were witnessed by five filters.

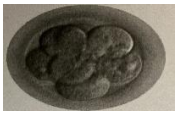

Table IV measures the effect of the seven filters on a lossless gray micro image. Negative filter produced the worst SSIM. Bad scores for Digital filter based on PSNR. De-blur regularized and De-blur blind deconvolution reported bad PSNR for Gaussian and Speckle noises, while succeeding in enhancing average blur and Gaussian blur distortions measured on both metrics.

Table V is the result of enhancement methods on a lossy gray micro image. It shows Negative filter fails on noise removal based on SSIM. Digital filter fails based on PSNR. The best filtering is produced for the Adaptive and Median filters based on PSNR. For blurring enhancement, De-blur, blind deconvolution, and De-blur Lucy Richardson reported the best results on SSIM. Contrast stretching performs well for Poisson and Low contrast distortions. Neutral results reported for Gray-level slicing and Histogram equalization.

Table VI reports the performance of the filters on an uncompressed gray micro image. Negative filter gives the worst results based on SSIM, except for Gaussian noise and low contrast distortions. Digital filter performs badly based on PSNR. De-blur regularized perform bad for Gaussian, Salt and Pepper, and Speckle based on PSNR. And neutral for the rest. Best and good removal of SSIM and PSNR, and reported for De-blur blind deconvolution and De-blur Lucy-Richardson, respectively, for Average blur and Gaussian blur. Contrast stretching successes for Poisson and low contrast distortions for both metrics. While PSNR reported good results for Salt and Pepper and Gaussian blur. Median filter works well for Poisson and Salt and Pepper. Complete neutral results reported for Adaptive, Gray-level slicing, and Histogram equalization.

B. Photography Images

This section gives the performance of the filters on photography images. Images considered are Lossy, Lossless, and ordinary. Both compressed and uncompressed, colored, and gray scale images. Table VII summarizes Lossless colored photography image results. Negative method produced worst performance for Poisson, Salt and Pepper, Speckle, Average blur, and Gaussian blur distortions measured by SSIM. For Gaussian and low contrast, it is neutral. Digital filter reported bad metrics for PSNR for all kinds of distortions under investigation. Contrast stretching and, Gray-level slicing, and Histogram equalization are neutral for both metrics. De-blur regularized and De-blur blind deconvolution reported bad performance on PSNR for Gaussian noise removal. De-blur blind deconvolution also produced same performance for Speckle noise, while give good performance for Gaussian blur. De-blur Lucy Richardson, Adaptive filtering, and Digital filtering reported different performance that vary from best to neutral performance as seen in the table.

Table VIII displays a lossy colored image enhancement with metrics. Negative produced the same performance as with a lossless compressed image. Performance of the filters is almost the same except for De-blur regularized and De-blur blind deconvolution. Where good performance is reported for average blur and Gaussian blur enhancement on PSNR, while none is reported for De-blur blind deconvolution. Fully neutral results are obtained from Gray-level slicing and Histogram equalization.

Results for the uncompressed colored photography image are shown in Table IX. Negative method produced the worst performance for Poisson, Salt and Pepper, Speckle for SSIM as reported for the compressed images. PSNR reported bad Gaussian removal for De-blur regularized and De-blur blind deconvolution. The latter also reported the same performance for Speckle noise removal. While performing well for blurring distortion, as did De-blur Lucy Richardson, contrast stretching works well with Poisson, as did the adaptive filter. For low contrast enhancement, contrast stretching reports good performance on PSNR. Histogram equalization shows the best and good Poisson noise removal. Digital filtering reported bad performance on PSNR for all kinds of distortions. Gray-level slicing gives neutral performance for all distortions.

In Table X, a lossless gray photography image is tested for insight enhancement performance on the distortions specified. Negative produced the worst SSIM for noise removal. Neutral results for blurring and contrast enhancements. De-blur regularized reported the worst and bad performance for Gaussian noise removal and bad speckle removal. The Digital filter again performs badly based on PSNR. Best results reported for Average blur and Gaussian blur based on PSNR for De-blur blind deconvolution and De-blur Lucy Richardson. Contrast stretching performs well for Poisson removal, blurring, and contrast enhancements. Adaptive filtering for Poisson and Gaussian blurring showed good performance. The median filter also performed well for Poisson, Salt and Pepper, average blur, and Gaussian blur in terms of PSNR. Gray-level slicing and Histogram equalization reported neutral for all distortions.

Table XI reported results for a lossy gray photography image. Negative produced the worst SSIM except for blurring removal. Neutral results reported for Adaptive, Gray-level slicing, and Histogram equalization. Digital filtering reported similar PSNR for distortions. Best and good results scattered for De-blur regularized in blur enhancement for both Average and Gaussian, De-blur Lucy Richardson for blurring enhancement as well, contrast stretching for Gaussian, Poisson, and Salt and Pepper removals, besides low contrast enhancement. Median for Poisson and Salt and Pepper.

Table XII displays an uncompressed gray ordinary image result. Negative performs worst except for blurring. Digital reported bad results for distortions. Neutral results reported for Gray-level, Median, and Histogram equalization. For blurring enhancement, the performance of De-blur regularized, De-blur blind deconvolution, and De-blur Lucy Richardson was reported to be good on PSNR and best on SSIM for the last two. Contrast stretching performs well for Poisson and Salt and Pepper noise removal, in addition to low contrast enhancement.

C. Macro Images

Section C reported results of the 10 filters on lossless, lossy, and uncompressed colored satellite images. The compressed and uncompressed gray satellite images are considered as well.

Table XIII reported lossless colored macro image enhancement results. Best blurring enhancement achieved by De-blur regularized, De-blur blind deconvolution, and De-blur Lucy Richardson. Median produced a good Gaussian blurring enhancement. Contrast enhancement best results are reported for contrast stretching. Digital filtering performs badly based on PSNR. Negative reported the worst results for Poisson, Salt and Pepper, Average blur, Gaussian blur, and low contrast.

TABLE XIII. PERFORMANCE OF ENHANCEMENT METHODS ON DISTORTION TYPES FOR LOSSLESS COLORED MACRO IMAGE

Table XIV reported lossy colored macro image results. Best luring enhancement reported for De-blur blind deconvolution, and De-blur Lucy Richardson. Adaptive and Median filtering also reported good performance on PSNR. Noise removal achieved the best SSIM for Median on Poisson noise, while PSNR reported good results for passion, Salt and Pepper, Average blur, and Gaussian blur. Digital filter reported weak PSNR for all distortions. De-regularized reports similar performance for Gaussian, Salt and Pepper, and Speckle noise removal.

Uncompressed colored macro image results are shown in Table XV. Negative filter performance was reported as worst on Poisson, Salt and Pepper, Average, Gaussian blur, and Low contrast. The Digital filter also performs badly except for the Average blur. For blurring enhancement, De-blur Richardson reported good and best performance on PSNR and SSIM, respectively. Contrast stretching achieved the best noise removal based on SSIM for Poisson noise, and the best SSIM for low contrast enhancement. Adaptive filter performs well for Gaussian, Poisson, Salt and Pepper, and Speckle based on PSNR.

Table XVI shows results for the lossy gray macro image. Negative method produced the worst performance for Gaussian, Poisson, Salt and Pepper, Speckle, and low contrast based on SSIM. The Digital filter also performs badly except for the Average blur. De-blur regularized works well for blurring enhancement. Contrast stretching performs well for Poisson, Salt and Pepper, Speckle, and Low contrast enhancements. Neutral results are obtained for all distortions reported for Adaptive, Median, Gray-level Slicing, and Histogram equalization.

Table XVII reported enhancement results for a lossless gray macro image. Negative filter reported the worst SSIM for noise removal on all noise types, in addition to Gaussian blur enhancement. Performance of the Digital filter PSNR reported bad performance against others. Besides De-blur regularized performance for Gaussian and Speckle noise removal, and De-blur blind deconvolution for Salt and Pepper noise removal. For blurring enhancement, De-blur Lucy Richardson reported the best and good SSIM and PSNR, respectively. Contrast stretching performs well for Poisson noise and Low contrast enhancements. Adaptive filtering did well for all noise kinds. Median filtering competes for Poisson and Salt and Pepper noise removal.

Table XVIII displays enhancement methods on an uncompressed gray macro image. Negative filter reported the worst SSIM for noise removal on all noise types, in addition to Gaussian blur enhancement. The performance of the Digital filter PSNR was reported as bad. Best blurring enhancement reported for De-blur regularized, De-blur blind deconvolution. For contrast enhancement, contrast stretching and histogram equalization perform superior on others.

The tables for the three categories are further visualized in bar graphs that demonstrate the effects of the 10 filters on the 7 distortions.

Fig. 5 visualizes the PSNR that measures the effectiveness of the filters on the distortions over the micro images. The category includes Lossy, Lossless, both colored and uncolored, and compressed and uncompressed. The filters shown in the legend are indicated by the colors that distinguish each.

The PSNR measures the effectiveness of the filters on the distortions over the ordinary images (Fig. 6). The category includes the Lossy, Lossless, both colored and uncolored, and compressed and uncompressed. The filters shown in the legend are indicated by the colors that distinguish each.

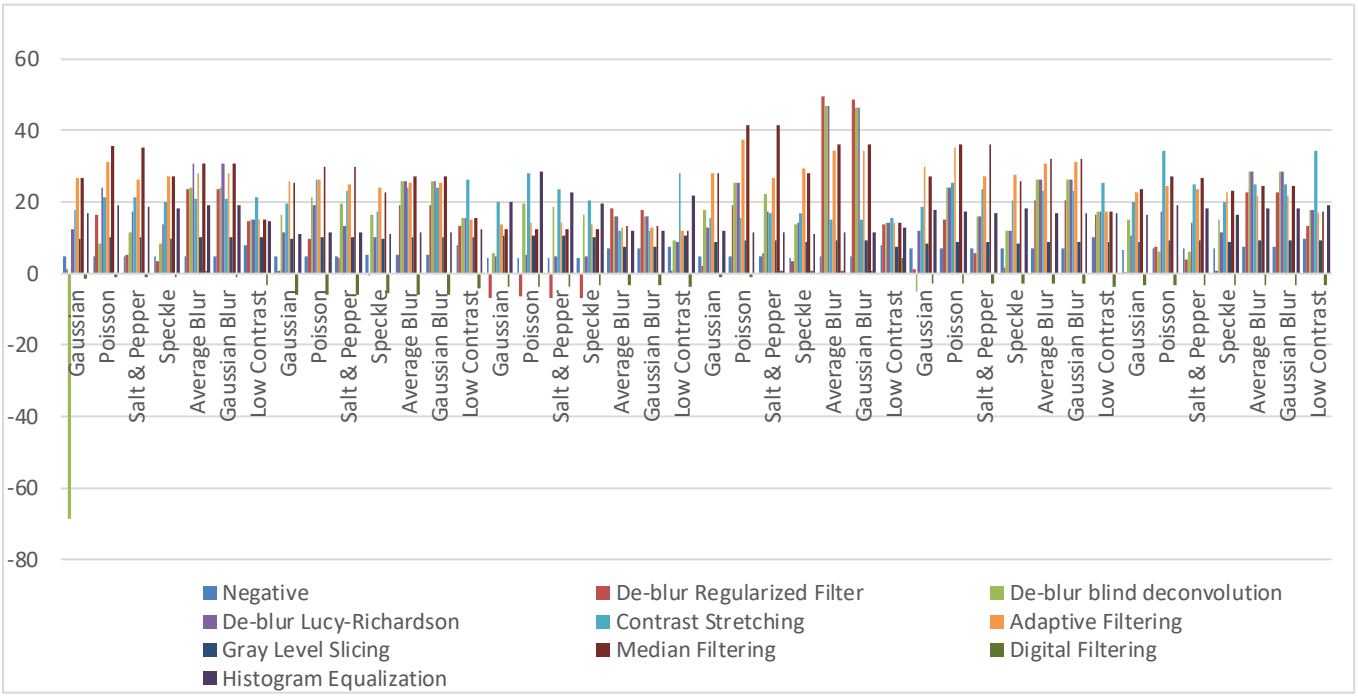

Fig. 5. Performance of enhancement filters on the distortion for micro images.

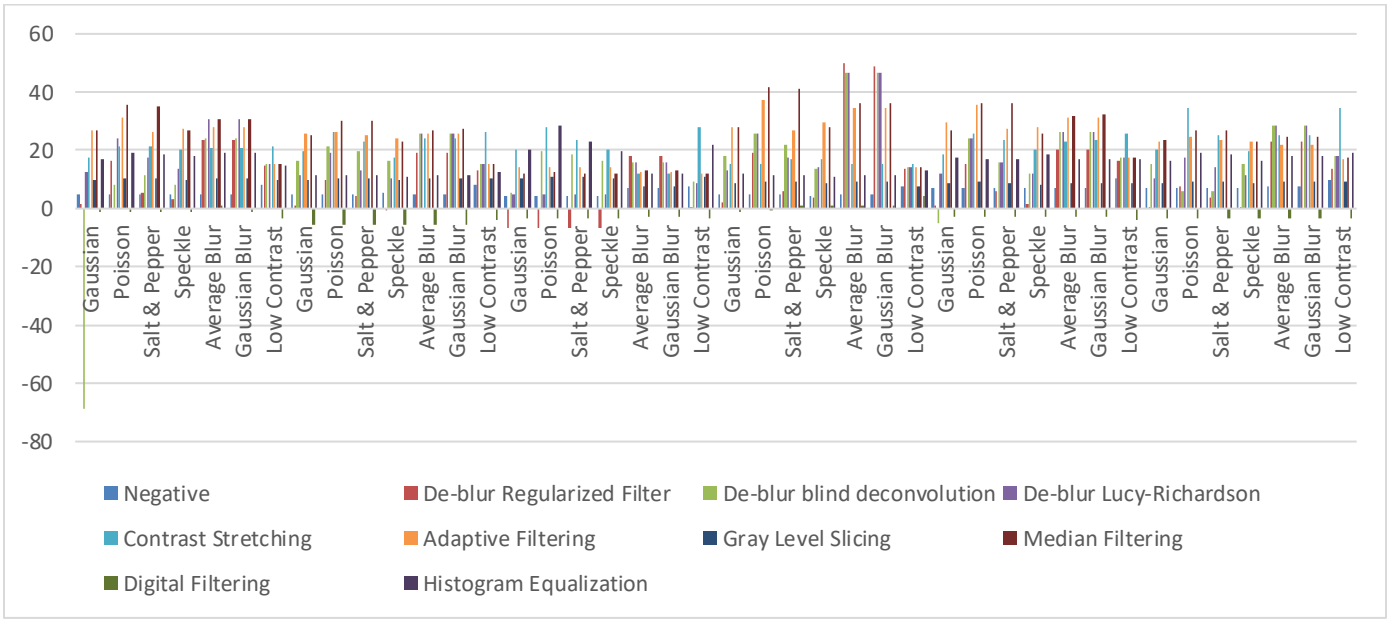

Fig. 6. Performance of enhancement filters on the distortion for ordinary images.

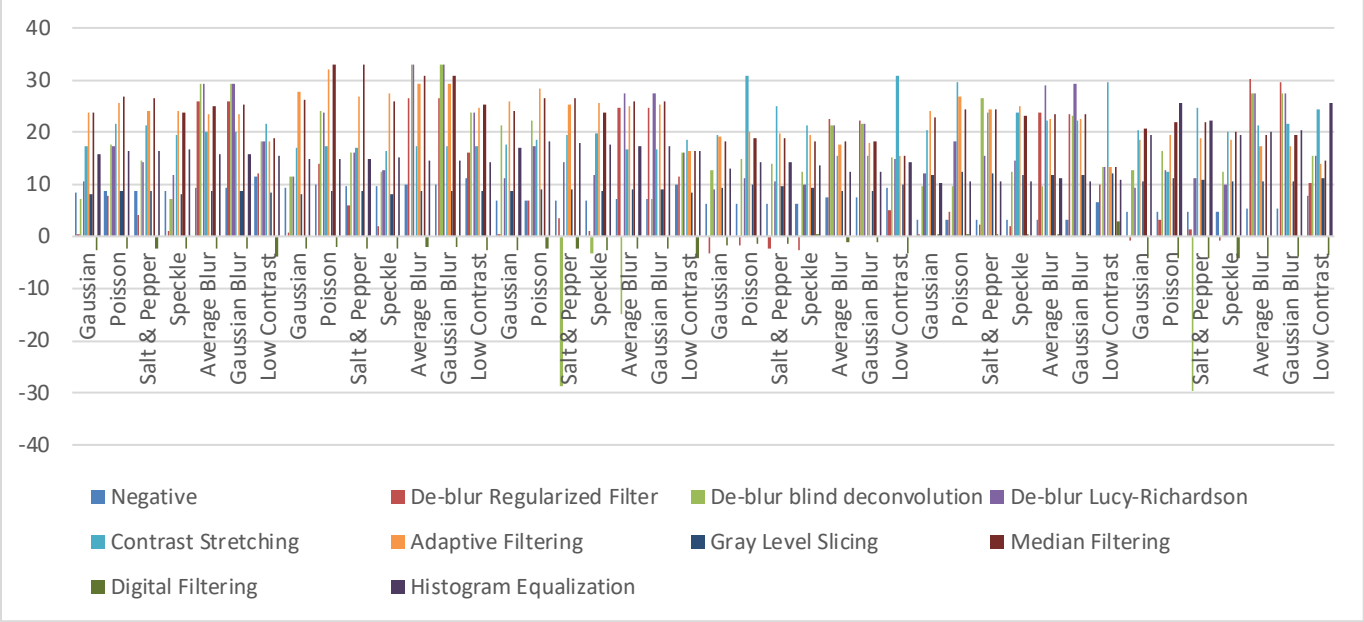

Fig. 7. Performance of enhancement filters on the distortion for macro images.

Fig. 7 visualizes the PSNR that measures the effectiveness of the filters on the distortions over the macro images. The category includes Lossy, Lossless, both colored and uncolored, and compressed and uncompressed. The filters shown in the legend are indicated by the colors that distinguish each.

VI. Conclusions and Recommendations

In this study, an investigation and comparison of Negative, De-blur Regularized, De-blur blind deconvolution, De-blur Lucy-Richardson, Contrast Stretching, Adaptive, Gray Level Slicing, Median, Digital, and Histogram Equalization filters on distortions are applied to micro, macro, and photography images. Key performance indicators that judge the performance are Peak Signal to Noise Ratio (PSNR) and Structural Similarity Index (SSIM). Section V gives the findings and results for the 10 enhancement methods. Negative filter fails to enhance the micro, photography, and macro images based on the SSIM metric, while producing neutral results for PSNR. De-blur Regularized filter sometimes reported good performance for blurring enhancement, but overall, across the three categories, it fluctuates and tends towards the worst category (Table XIX). Digital filtering reported bad PSNR for all three categories. De-blur blind deconvolution failed to compete for higher achievement with other filters. Besides gray-level slicing and Histogram equalization, these methods may be more effective in specific applications. The best methods reported for all three categories, whether compressed or uncompressed, colored, or gray, are reflected in Table XIX. It is found that De-blur, Richardson, Median, and Contrast stretching are the best among others. To strengthen the performance, hybrid filtering may introduce more enhancement capabilities.

De-blur Lucy-Richardson, Contrast Stretching, and Media Filtering have the best performance over all image types. Negative and Digital filtering have the worst performance over all image types. Histogram Equalization and Grey Level Slicing always give a moderate performance in all image types, but it has a good result if the image is not compressed. De-blur Regularized Filter and De-blur blind deconvolution have good performance when the image suffers from Blur distortion. Contrast Stretching has good performance when the image suffers from low contrast.

TABLE XIX. Recommended Enhancement Methods for Micro Versus Macro and Ordinary Images

Image Type	Best Enhancement Method	Worst Enhancement Method
Mico (Medical)	De-blur Lucy-Richardson	Negative
	Median Filtering	Digital Filtering
	Contrast Stretching	De-blur Regularized Filter
Ordinary Photography	De-blur Lucy-Richardson	Negative
	Contrast Stretching	Digital Filtering
	Median Filtering	De-blur Regularized Filter
Macro (Satellite)	De-blur Lucy-Richardson	Negative
	Contrast Stretching	Digital Filtering
	Median Filtering	De-blur Regularized Filter

Department of Computer Engineering, Tokat Gaziosmanpasa University, Tokat, Turkiye[2]

***Abstract*—Accurate and early prediction of student success in online mathematics education is critical for improving learning processes and developing personalized instruction strategies. However, students' problem-solving behaviors, interaction levels, and learning speeds in online learning environments inherently contain uncertainty, limiting the effectiveness of traditional assessment and singular machine learning approaches. This study proposes a hybrid neuro-fuzzy and machine learning-based student success prediction framework that combines the ability of fuzzy logic to represent uncertainty with the strong generalization and adaptive learning capabilities of machine learning methods. In the proposed approach, student success trends are primarily modeled using ANFIS, Random Forest, and XGBoost models, employing raw and derived features on the ASSISTments dataset. The predictions from these models are treated as continuous success representations reflecting uncertainty in students' learning behaviors and are used as input to a hybrid classification structure to make binary success/failure decisions. Thus, the ANFIS model is positioned as an uncertainty-aware and interpretable context generator, while the Random Forest and XGBoost models provide discriminative classification power. Experimental results demonstrate that both ANFIS and Random Forest models exhibit high individual performance; however, combining their complementary features within a hybrid structure significantly increases prediction stability and generalization. Unlike the limitations of 'black box' models in the literature, the interpretability provided by ANFIS, through its linguistic rules and membership functions, enables the proposed approach to generate pedagogically transparent and actionable implications. The findings reveal that this hybrid framework, which integrates uncertainty management with high prediction accuracy, offers a powerful decision-support mechanism for early identification of at-risk students and for developing personalized intervention strategies in online mathematics education.**

I. Introduction

The development of online learning platforms has revolutionized educational analytics, enabling the massive collection and analysis of student behavior [1], [2], [3], [4]. These platforms have become digital ecosystems that enable monitoring students' interactions with the learning process, not only in terms of outcomes but also in terms of the process itself. These digital ecosystems record each student's interactions with the system in the form of time-stamped behavioral logs, such as clickstreams, resource viewing times, and forum participation [1, 5, 6]. This type of data reveals not only what students have learned, but also how and under what conditions they have learned. In particular, intelligent tutoring systems such as ASSISTments [7] reflect students' cognitive states during mathematical problem-solving through multidimensional attributes, such as correct/incorrect answer rates, hint requests, and the number of attempts required to solve the problem [1, 6, 8]. In this respect, the ASSISTments dataset provides a rich, high-resolution dataset for predicting student achievement at an early stage.

Mathematics education, by its very nature, exhibits a high degree of logical interdependence and a cumulative structure. A failure to fully understand a fundamental concept increases the student's risk of subsequent failure [9]. Therefore, predicting student achievement early, before end-of-term assessments are completed, is a critical requirement for educators to intervene promptly.

The literature shows that early warning systems significantly increase student retention and overall success through personalized learning paths, targeted feedback, and supportive content [1, 5, 10 - 14]. However, the effectiveness of these systems depends on the extent to which the forecasting models used can represent uncertainty and individual differences.

Online student behavior exhibits ambiguity, variability, and fuzzy patterns stemming from the nature of human reasoning [15 - 17]. Students' moderate level of engagement or cognitive stability in the problem-solving process cannot be adequately represented by traditional models built on sharp boundaries and linear assumptions. This leads to limitations not only in classical statistical methods but also in machine learning models that prioritize accuracy.

Although artificial neural networks and tree-based learning algorithms are successful at capturing complex patterns, many of these models are criticized for being "black boxes" in terms of the interpretability of decision-making processes [18 - 19]. In the field of education, producing pedagogically meaningful and explainable outcomes is a fundamental requirement, alongside the model's accuracy.

In this context, hybrid neurofuzzy approaches, which combine the uncertainty modeling capabilities of fuzzy logic with the data-learning capacity of machine learning, are among the most promising solutions for predicting student achievement [11, 20]. In particular, the Adaptive-Network-based Fuzzy

Inference System (ANFIS) offers educators a significant advantage by providing high predictive performance through an interpretable structure based on IF-THEN rules [4, 11, 21, 22].

This study proposes a hybrid neurofuzzy and machine learning-based model for predicting student success in online mathematics education using the ASSISTments dataset. Extensive experiments were conducted using ANFIS, Random Forest (RF), and XGBoost models with raw and derived student features. The resulting continuous success representations were integrated into a binary classification structure to determine the risk of student failure. The main contribution of this study is to effectively model uncertainty in online mathematics education, to provide a balanced trade-off between interpretability and predictive performance, and to demonstrate the applicability of the proposed hybrid approach for early warning systems.

The remaining sections of the study are structured as follows: The second section summarizes the relevant literature and research gaps. The third section details the ASSISTments dataset, data preprocessing, and feature engineering. The fourth section presents the proposed hybrid ANFIS-RF-XGBoost architecture and learning processes. The fifth section presents the experimental findings with a comprehensive analysis, and the sixth section discusses these findings in light of the literature, outlining the study's limitations and suggesting future research.

II. Related Works

Predicting student academic performance has witnessed a paradigm shift in the fields of educational data mining and learning analytics over the last decade, moving from statistical models to hybrid intelligent systems [23]. Studies in the literature can be categorized primarily by model architecture, dataset diversity, and interpretability of results.

A. Traditional Machine Learning and Ensemble Models

Early educational data mining studies generally focused on singular algorithms such as decision trees, support vector machines, and logistic regression [1, 3]. However, recent research has shown that ensemble learning methods provide higher accuracy than single classifiers [5, 24]. For example, the success of the XGBoost algorithm in capturing complex, nonlinear relationships in structured training data has been highlighted in numerous studies [4, 25]. Similarly, the RF model has been reported to exhibit robust performance, particularly in addressing feature selection and inter-class imbalance issues [26 - 28]. Ponnan et al. (2025) achieved a test accuracy of 98.06% in student assessment using AdaBoost and RF models [11].

B. ANFIS Models

ANFIS models are gaining prominence for modeling uncertainties in educational processes and for handling fuzzy data based on human reasoning [22]. ANFIS is described as a universal estimator that combines the learning ability of artificial neural networks with the uncertainty management capacity of fuzzy logic [6, 29 - 33]. Taylan and Karagozoglu (2009) stated that the ANFIS model yields results as robust as statistical methods and offers a more natural language for interpreting student outcomes [34]. Hybrid models developed in recent years, such as FCM-PSO-ANFIS, have reduced error rates by fine-tuning parameters using metaheuristic optimization algorithms [35].

C. Deep Learning and Time Series Analysis

The timestamped nature of student interaction data has encouraged the use of RNN and LSTM models [1, 36]. Deep learning models are outperforming traditional methods in discovering hidden patterns and temporal dependencies in large-scale datasets [1, 36]. The combination of a CNN and a BiGRU has achieved up to 97% accuracy in predicting student achievement by providing both local feature extraction and bidirectional temporal modeling [36]. Furthermore, transformer architectures have increased predictive granularity by converting student behaviors into sequential feature vectors through attention mechanisms [1, 8].

D. Explainable Artificial Intelligence (XAI) and Educational Trust

The "black box" nature of models makes it difficult for educators to trust these predictions. In this context, methods such as SHAP and LIME have become widespread to make model decisions more transparent [4, 18, 27]. XAI techniques enable the generation of personalized feedback by revealing which factors influence the prediction and in which direction. In particular, the linguistic rules provided by neuro-fuzzy systems enhance the model's direct interpretability, thereby strengthening educational decision-support processes [18, 22].

E. Indicators Specific to Mathematics Education

Specific research on mathematics education shows that behavioral indicators, such as revisiting resources and resource intensity, are strongly correlated with success [6]. Bakar et al. (2022) suggested incorporating neuroscientific mechanisms such as attention, emotion, and productivity into the AGES model to predict mathematical achievement [15]. Such studies argue that mathematical learning ability can be more accurately predicted not only by academic scores but also by integrating cognitive and psychological processes [37].

F. Research Gaps

A review of the existing literature reveals that the vast majority of studies on the ASSISTments dataset focus either on classical classification-based machine learning algorithms or on information-tracking-based models. These studies mainly address student achievement through sharp class labels, remaining limited in their ability to model uncertainty, incremental progress, and intermediate achievement levels that arise in the student's learning process. In contrast, fuzzy logic-based and neuro-fuzzy approaches have been addressed in only a few studies within the context of the ASSISTments dataset and have not been systematically evaluated.

Although student behavior in online mathematics education inherently involves both continuity and uncertainty, the literature lacks two-stage hybrid approaches that first model this uncertainty as a regression-based achievement score and then proceed to a classification phase for decision support. This highlights the need for a modeling framework that is both pedagogically meaningful and methodologically consistent.

The main gaps in the literature that this study aims to address are summarized below:

- Limited Use of Neuro-Fuzzy Regression Models on the ASSISTments Dataset: The vast majority of studies on the ASSISTments dataset have focused directly on classification using XGBoost, deep learning-based RNN/LSTM models, or knowledge-tracking approaches. However, neuro-fuzzy models like ANFIS can model uncertain learning behaviors more flexibly, as they can predict student success as a continuous score or probability.

While the literature shows that ANFIS provides high accuracy, especially in small and medium-sized datasets, its use as a regression-based predictor in large-scale datasets with time-ordered interaction logs, such as ASSISTments, has been largely neglected. This underscores the necessity of a systematic evaluation of hybrid regression-based neuro-fuzzy models on ASSISTments.

- Treating student achievement solely as a classification problem: A significant portion of current research addresses student performance only as a binary classification problem, ignoring the gradual and uncertain nature of the learning process. However, in online learning environments, student achievement shows gradual increases or decreases over time rather than sudden, sharp transitions.

The literature shows that hybrid models, which first model achievement as a continuous regression outcome and then move it to the classification stage for pedagogical decision support, have not been sufficiently examined on the ASSISTments dataset. This gap necessitates an evaluation of hybrid regression-classification approaches within the context of educational analytics.

- The lack of a clear and in-model approach to addressing uncertainty: In online learning environments, students' interaction speed, problem-solving strategies, and participation levels are inherently fuzzy and variable. However, most existing models treat these behaviors as discrete numerical values, failing to adequately represent situations that require human reasoning, such as a student being "moderately successful" or exhibiting "inconsistent learning behavior."

Although membership functions and linguistic variables in fuzzy logic allow direct modeling of this uncertainty, the use of this approach within hybrid regression and classification frameworks is quite limited in the literature. In particular, the integration of ANFIS as an uncertainty-aware predictor into hybrid structures remains a significant gap in the literature.

- Failure to address pedagogical interpretability and high predictive power together: While powerful ensemble learning methods like RF and XGBoost provide high accuracy, they offer limited transparency for pedagogical decision support systems due to the inability to interpret the internal structure of decision mechanisms directly. Although the literature indicates that XAI methods such as SHAP and LIME address this problem post-prediction, these approaches cannot directly reflect the model's internal decision logic.

In contrast, ANFIS's IF-THEN rule-based structure offers interpretable insights into the learning process. However, studies in the literature that combine this interpretable structure with powerful models such as RF and XGBoost in a hybrid framework are insufficient for the ASSISTments dataset.

- Lack of holistic evaluation of hybrid regression and hybrid classifiers: Existing studies generally focus either solely on regression or solely on classification problems. However, in online mathematics education, student performance needs to be considered both as a continuous indicator of success and as a decision-based classification output.

In the literature, studies that combine ANFIS-based regression outputs with models such as RF and XGBoost to evaluate them within a two-stage hybrid regression-classification architecture are quite limited. This gap necessitates a systematic and comparative examination of hybrid models on the ASSISTments dataset.

- Insufficient modeling of cognitive processes specific to online mathematics education: Mathematics education differs from other disciplines due to its cumulative knowledge structure and high logical dependence. However, most existing models do not address indicators specific to the mathematical problem-solving process, such as hint use, post-error behaviors, cognitive persistence, and learning stability, within a hybrid modeling framework.

This clearly highlights the need for holistic hybrid models that address cognitive and behavioral uncertainties specific to mathematics education at both the regression and classification levels.

In summary, this study addresses complex student interactions in the ASSISTments dataset by combining ANFIS's uncertainty-aware, interpretable regression structure with the highly generalizable capabilities of RF and XGBoost, aiming to fill the gaps identified in the literature from both a hybrid regression and a hybrid classifier perspective. In this respect, the study offers a unique, systematic, and applicable contribution from both methodological and pedagogical standpoints.

III. Materials and Methods

A. Dataset Description

The dataset used in this study was obtained from ASSISTments, an online mathematics learning platform. ASSISTments is an intelligent tutoring system designed to support the problem-solving processes of middle and high school students while collecting detailed, timestamped data on student interactions [38]. The platform integrates teaching and assessment processes by offering students instant feedback, tips, and validation [7, 39, 40].

The ASSISTments dataset records student interactions with math problems in an event-based manner and provides multidimensional behavioral insights for each student-problem interaction [20, 41]. This dataset is widely used, particularly for

student performance prediction, knowledge monitoring, and educational data mining [42]. Furthermore, the fact that ASSISTments data has been used in large-scale data mining competitions such as the KDD Cup 2010 demonstrates that the dataset is an accepted and reliable source within the research community. A sample cross-section of the ASSISTments dataset is given in Table I.

TABLE I. ILLUSTRATIVE SAMPLE FROM THE ASSISTMENTS DATASET

assignment_id	user_id	problem_id	correct	attempt_count	…	skill_id	hint_count	overlap_time
263599	14	93383	0	1		2	2	41131
263599	14	93407	1	1		2	0	29123
263599	14	93400	0	1		2	2	19905
…								

Personality-based features were not used as model inputs; they were evaluated only during student-based data splitting to prevent data leakage. Behavioral features were obtained directly from raw data, while skill-based features were derived to reflect the student's learning progress over time.

The "attempt_count" and "hint_count" attributes reflect students' problem-solving strategies, while "ms_first_response" provides temporal information about engagement and cognitive effort. The "correct" attribute indicates whether the student successfully solved the problem in a given attempt. These attributes allow for the analysis not only of students' outcome-oriented success but also their problem-solving strategies, learning behaviors, and cognitive effort. In particular, "hint_count", "attempt_count", and "ms_first_response" offer significant indicators of students' learning levels and uncertainties in their problem-solving processes [43]. Traditional binary assessment methods are insufficient for modeling these unclear boundaries between learning situations. Managing this uncertainty and predicting student achievement with more humane reasoning constitutes the main motivation for using ANFIS in this study.

B. Data Preprocessing

Educational data obtained from online learning environments inherently contain incomplete records, noisy behavior, and uneven classroom distributions. Therefore, data preprocessing and feature extraction stages are critical for model performance in student performance prediction studies [44]. In this study, a comprehensive data preprocessing and feature engineering process was applied to improve the effectiveness of the proposed hybrid neuro-fuzzy and machine learning model on the ASSISTments dataset.

In the first stage, missing or inconsistent records in the dataset were analyzed. Records lacking "user_id", "assignment_id", and "correct" information were removed from the dataset.

Because the ASSISTments dataset has an event-based structure, the number of interactions among students varies considerably. Some students solve only a few problems, while others have thousands of interactions. This is consistent with the long-tailed distribution frequently reported in the literature [43]. To prevent the model from being dominated by overactive students, student-based (user_id) data splitting and limiting interaction counts were implemented. Furthermore, due to significant variability in student interaction counts within the dataset, students with fewer than 5 interactions were removed, and a maximum interaction limit of 1000 was set for overactive students.

When the "attempt_count" values were analyzed, it was observed that the vast majority were concentrated between 1 and 10. Therefore, in fuzzy category definitions, the maximum number of attempts was set to 10 [7, 43]. Since higher values rarely occur, a threshold has been set at the upper limit, ensuring stable representation and model stability.

The "ms_first_response" property can have excessively large values due to factors such as browser open times and prolonged inactivity. To prevent such values from adding noise to the learning process, the "ms_first_response" property is limited to 600 seconds. Without this limitation, the sensitivity of the fuzzy membership functions decreases, extreme values dominate the model, and the model learns biased rules such as "slow learner = fail." This approach is consistent with clipping strategies proposed in the literature for time-based learning variables [43, 44].

"opportunity_count" is a pedagogically significant attribute representing how many times a student has encountered a particular skill. Therefore, it has not been directly filtered but has been included in the model to reflect the learning process.

Pre-cleaning analyses show that the distribution of student interactions is severely imbalanced, with a small number of students dominating the dataset. After applying cleaning and preprocessing criteria, the number of interactions per student showed a more balanced distribution, with extreme values eliminated. Furthermore, normalization was performed to improve the stability of the fuzzy logic-based model's membership functions and to ensure a fair comparison across machine learning algorithms [45]. Min-max normalization was applied to "attempt_count" and "hint_count", robust normalization to "ms_response_time" and "overlap_time", and log+min-max normalization to "opportunity_count". This helped train the proposed hybrid model more stably and generalizable.

C. Feature Engineering

In this study, to more accurately model students' online mathematics learning behaviors, the features obtained from the raw dataset were normalized, and behavioral and performance-based derived features commonly used in the literature were created.

The raw features in the dataset capture students' core interactions during the problem-solving process. While these

raw features directly reflect students' problem-solving behaviors, their direct use as model input is limited by scale differences and individual variation. Instead of using raw features directly, derived features were created to better represent students' performance and behavioral tendencies during the learning process. These features were designed to reflect the student's cognitive effort and learning status in the problem-solving process [43]. In this context, the following features have been derived: Prior Correct Ratio (PCR), Prior Attempt Mean (PAM), Prior Hint Mean (PHM), Recent Performance Trend (RPT), Skill Difficulty Index (SDI), and Student Experience Level (SEL).

PCR is a ratio-based trait that reflects a student's level of success in previous interactions with a specific problem or skill [6, 46]. The PCR value is in the range of [0,1] and does not require normalization.

$$\mathrm{PCR}_{u,s} = \frac{\sum_{i=1}^{n} Correct_{u,s}^{(i)}}{n} \quad (1)$$

Here, u is a student, s is a problem or a skill, and n is the number of previous attempts.

PAM is a behavioral indicator that represents the average number of attempts a student makes for problems they have encountered in the past. This characteristic reflects the student's mathematical cognitive persistence and learning speed [6], [46], [47]. Since the PAM value is not in the [0,1] range, pre-model min-max normalization should be applied. A high PAM value indicates that the student generally needs more trials.

$$\mathrm{PAM_u} = \frac{1}{\mathrm{N}}\sum_{\mathrm{i=1}}^{\mathrm{N}} \mathrm{attempt_count_u^{(i)}} \quad (2)$$

Here, u is a student, and n is the number of problems previously solved.

PHM represents the average number of hints a student uses across all problem-solving steps before the current interaction. This characteristic is a historical indicator of a student's help-seeking behavior. Hint usage carries a vague signal about how well a student understands the subject, and overuse is associated with an increased risk of failure [38].

$$\mathrm{PHM}_i = \frac{1}{N_i}\sum_{j=1}^{i-1} hint_coun\,t_j \quad (3)$$

Here, i is the student's time-ordered current interaction index, $N_i = i - 1$ is the total number of interactions before the current interaction, $hint_count_j$ is the number of hints the student used in the j[th] interaction.

RPT captures short-term learning dynamics, information fluctuations, and learning trends, which are particularly important in adaptive learning environments. Given the cumulative nature of mathematics education, short-term dips are considered a signal for early intervention [8], [48].

For the last k interactions (3-5):

$$\mathrm{RPT}_i = \frac{1}{k}\sum_{j=i-k}^{i-1} correc\,t_j \quad (4)$$

Here, i is the student's i^{th} problem-solving step.

SDI is the overall difficulty level of a given mathematical skill across all students. This metric allows the model to make fair and balanced assessments by normalizing individual performance with aggregate data [49], [50], [51].

$$\mathrm{SDI}_s = 1 - \frac{1}{M}\sum_{j=1}^{M} Correc\,t_s^{(j)} \quad (5)$$

Here, s is the skill, and M is the total number of trials for that skill.

SDI is calculated at the skill level, independent of the problem, and provides a common difficulty indicator for all students (SDI → 0: Easy skill, SDI → 1: Difficult skill).

SEL is a composite pedagogical indicator representing a student's overall experience and proficiency level in an online mathematics learning environment. This characteristic translates the student's familiarity with the system and resource-intensive usage habits into the model [15]. SEL is not a variable with an implicit formula. It is defined as follows:

$$\mathrm{SEL}_i = F(\mathrm{PCR}_i, \mathrm{PAM}_i, \mathrm{PHM}_i, \mathrm{OC}_i) \quad (6)$$

Here, i is the student's time-ordered current interaction index, and $F(\cdot)$ is the Fuzzy Inference Mechanism (ANFIS).

The derived features capture both past performance and real-time behavioral patterns, providing a richer representation of student learning dynamics. All features used in the study are listed in Table II.

TABLE II. CHARACTERISTICS USED IN THE STUDY

Feature	Reason
attempt_count (AC)	The solution reflects the intensity of the behavior; in ANFIS, it is meaningful in terms of "Low–Medium–High" memberships.
hint_count (HC)	Help-seeking behavior can be interpreted pedagogically using vague rules.
ms_response_time (RT)	ML models can tolerate high-dimensional correlation; this increases rule complexity in ANFIS.
Prior Correct Ratio (PCR)	The student's past achievements are critical to their learning.
Prior Attempt Mean (PAM)	Long-term effort level: a stable statistical characteristic.
Prior Hint Mean (PHM)	The constant need for help reflects the learning strategy.
Recent Performance Trend (RPT)	The short-term learning tendency is suitable for trend-based rules in ANFIS.
opportunity_count (OC)	The number of times a student encounters a skill is a key context for both statistical and rule-based models.
overlap_time (OT)	Student waiting time for the question
Skill Difficulty Index (SDI)	Content difficulty: pedagogically meaningful within ANFIS guidelines.
Student Experience Level (SEL)	Cumulative learning level: intuitive linguistic variable in ANFIS.

D. Inter-Feature Relationship Analysis

As part of the feature identification process, a correlation analysis was performed to assess relationships among the extracted features. The resulting Pearson correlation matrix, shown in Table III, provides insight into potential feature dependencies before neuro-fuzzy logic and machine learning

modeling. The analysis included both raw and derived numerical features, excluding descriptive variables.

The vast majority of correlation coefficients are at the $|r|<0.40$ level. This indicates that there is no high-level linear dependence between the features and that the risk of multicollinearity is generally low. A moderate positive correlation ($r=0.46$) was observed between RT and OT. This relationship shows that time overlap increases as the student's first response time increases. There is a relatively high positive correlation ($r = 0.58$) between HC and PHM. This indicates that the student's past habit of using hints is reflected in their current problem behavior. PCR shows a strong negative relationship with both PAM ($r = -0.53$) and PHM ($r = -0.62$). This finding reveals that students with high past success tend to try less and use fewer hints. The correlation between the RPT feature and all other features is negligible, suggesting that the variable provides an independent and complementary source of information for the model. The very low correlation of OC with other characteristics suggests that this variable is largely independent of other behavioral traits as a time-based measure.

TABLE III. PEARSON CORRELATION MATRIX FOR THE FEATURE SET

Feature	AC	HC	RT	OT	SDI	SEL	RPT	PCR	PAM	PHM	OC
AC	1.00	0.38	0.04	0.17	0.11	-0.04	-0.02	-0.19	0.27	0.16	0.00
HC	0.38	1.00	0.00	0.10	0.22	-0.09	-0.03	-0.37	0.19	**0.58**	-0.01

Overall, the correlation analysis results indicate that including the selected features in both neurofuzzy and machine learning models is statistically feasible and that there is no significant multicollinearity.

In addition to correlation analysis, feature redundancy was further examined using the Variance Inflation Factor (VIF). VIF quantifies the degree of multicollinearity by measuring how much the variance of a regression coefficient is inflated due to linear dependence among predictors. The VIF analysis was conducted on all numerical raw and derived features extracted from the ASSISTments dataset. Following established guidelines, a VIF threshold of 10 was adopted, where values below this limit indicate acceptable levels of multicollinearity (Table IV).

TABLE IV. VIF TABLE

Feature	VIF	Comment
AC	3.79	Moderate correlation - acceptable.
HC	2.03	Low multi-connectivity
RT	1.96	Low multi-connectivity
OT	1.49	Very low multi-connectivity
SDI	**8.04**	**High – caution advised**
SEL	1.98	Low multi-connectivity
RPT	1.01	Independent variable
PCR	**4.26**	Medium-high
PAM	**5.84**	**High on the border**
PHM	2.78	Middle
OC	2.21	Low

VIF was calculated to quantify the degree of multicollinearity among the independent variables. Generally, VIF values <5 are acceptable; values between 5 and 10 require attention; and values ≥ 10 indicate significant multicollinearity. According to the analysis results, the vast majority of features have VIF<5. This indicates that the features contribute largely independently to the model. The RPT feature, with a VIF$\approx$1, is an almost completely independent source of information and a strong complement to the model. AC, HC, RT, OT, and SEL have low-to-medium VIF values and do not pose a risk in terms of linear dependence. PAM (VIF$\approx$5.84) and especially SDI (VIF$\approx$8.04) exhibit relatively high VIF values. This suggests that these variables share common variance with some other inputs in the model. However, since these values are below the critical threshold of 10, they do not warrant direct exclusion. These results indicate that the feature set is generally well-balanced and does not exhibit significant multicollinearity. When the VIF results are evaluated together with the Pearson correlation matrix, it becomes clear that the relatively high VIF values observed are due to natural overlap.

The SDI feature shows moderate negative correlations with PCR and moderate positive correlations with PHM and PAM. These relationships stem from the fact that problem difficulty is naturally linked to the student's previous success, trial, and hint-use behaviors. Therefore, the high VIF value is not a statistical problem, but a reflection of a pedagogically significant overlap.

There is a moderate-to-high negative correlation between PAM and PCR features. It is expected that a student's experience of more trials is generally associated with a lower success rate. The increase in VIF values is a mathematical consequence of

this behavioral correlation and does not mean the model is meaningless.

There is a significant positive relationship between HC and PHM. The relatively higher VIF values result from the inclusion of both short- and long-term representations of the same concept in the model. This requires attention, especially in linear models, but does not pose a problem for nonlinear models.

Features such as RPT, OT, and RT exhibit low correlation and low VIF values. These variables provide independent and complementary information to the model.

No feature exceeds the critical multicollinearity threshold (VIF≥10). Therefore, all features are preserved, especially in ANFIS and machine learning-based nonlinear models.

E. Problem Formulation

In online learning environments, students' problem-solving performance exhibits a nonlinear, complex structure due to individual learning differences, prior knowledge levels, problem difficulty, and behavioral uncertainties arising during interaction. This uncertainty makes it difficult to predict student success with both high accuracy and pedagogical interpretation. Therefore, hybrid prediction mechanisms that can explicitly model uncertainty in student performance and offer high predictive power are needed in online mathematics education.

The ASSISTments dataset consists of multidimensional observations derived from students' time-ordered interactions, each reflecting the student's cognitive and behavioral state. Each student interaction is defined as follows:

$$\mathrm{x}_i = [x_{i1}, x_{i2}, \ldots, x_{in}] \in \mathbb{R}^n \tag{7}$$

Here, x_i represents raw and statistical features derived from the student's past performance, problem characteristics, and learning process.

In the ASSISTments dataset, the output variable is defined as a binary label containing correct or incorrect response information for each student-problem interaction:

$$y_i \in \{0,1\} \tag{8}$$

However, the Subtractive Clustering-based ANFIS model used in this study inherently produces a continuous-valued output due to its Sugeno-type fuzzy inference mechanism. Therefore, in the first stage of the study, the problem was treated as a hybrid regression problem, and the model output was defined as follows:

$$\hat{y}_i^{(m)} = f^{(m)}(\mathrm{x}_i), m \in \{\text{ANFIS}, RF, \text{XGBoost}\} \tag{9}$$

Here, $\hat{y}_i^{(m)}$ is interpreted as a continuous value corresponding to the student's success score on the given problem or the probability of giving the correct answer.

In this context, ANFIS is an interpretable regression estimator that models ambiguous student behavior using fuzzy rules, whereas RF and XGBoost are robust regression models with high capacity to capture nonlinear patterns. All models were trained and evaluated to predict the same continuous target variable, ensuring methodological consistency.

While regression-based predictions offer rich information about the probability of student success, decision-based outcomes are frequently needed in educational applications. Therefore, in the second phase of the study, the problem was reformulated as a hybrid classification problem. In this phase, using the continuous outputs obtained from the regression models, the final class label was defined as follows:

$$\tilde{y}_i = \begin{cases} 1, & \hat{y}_i \geq \tau \\ 0, & \hat{y}_i < \tau \end{cases} \tag{10}$$

Here, τ represents the decision threshold set on the validation data.

In this approach, ANFIS acts as a pre-predictor, providing fuzzy-logic-based intermediate outputs to the decision-making process, while RF and XGBoost serve as higher-level classifiers that make the final decision based on these outputs. This structure offers a unique hybrid classification framework that combines both uncertainty modeling and high classification accuracy under one roof.

F. ANFIS Model and Learning Process

In the field of educational data mining, student knowledge levels, learning speeds, and performance changes often involve ambiguous transitions rather than precise boundaries; therefore, ANFIS offers a suitable and powerful framework for modeling such patterns [42].

In the generated ANFIS model, the number of membership functions and rules is automatically determined based on data density using the subtractive clustering method. Sugeno-type output is used. The model's training parameters are defined as Epoch=100, StepSize=0.01, and ErrorGoal=0. In the subtractive clustering method, the cluster radius parameter is a critical hyperparameter that directly determines the complexity of the ANFIS model. Small radius values result in more clusters in the data space and, consequently, a high number of fuzzy rules, while large radius values lead to oversimplification of the model. With a cluster radius of 0.5, an average of 5–8 membership functions was obtained for each input variable.

ANFIS is a model based on the supervised learning paradigm, which requires the initial definition of the target variable during training. In the subtractive clustering method, the fuzzy rule parameters are initially estimated using the least-squares method. At this stage, the prior parameters are assumed to be constant, and the rule firing strengths are calculated for each training instance [34, 45]. The normalized firing strength for each rule is defined as follows:

$$\bar{w}_k = \frac{w_k}{\sum_{l=1}^{K} w_l} \tag{11}$$

Here, w_k represents the firing strength of the kth fuzzy rule.

The model output is calculated as follows, using normalized firing strengths:

$$\hat{y} = \sum_{k=1}^{K} \bar{w}_k \left(p_{k0} + \sum_{j=1}^{n} p_{kj}\, x_j \right) \tag{12}$$

When this expression is rearranged in terms of linear parameters, a classical linear regression problem is obtained. This linear system is solved using the least-squares method,

considering all training examples, and the initial output parameters $\{p_{k0}, p_{k1}, \ldots, p_{kn}\}$ are computed for each rule.

After determining the initial output parameters, the ANFIS model was trained using a hybrid learning algorithm. In this algorithm, during the forward traversal phase, the prior parameters are held constant, and the output parameters are updated using the least-squares method. In the backpropagation phase, the output parameters are treated as constants, and the prior parameters are optimized using gradient descent. This two-stage learning process increases both the accuracy and generalization ability of the model [45].

G. Random Forest and Learning Process

In this study, the RF model was used in regression mode to predict a continuous-valued student achievement score from pairwise-labeled student interactions. RF generates the final prediction by averaging the outputs of multiple decision trees created using bootstrap sampling [52]. This structure offers significant advantages, including the ability to model nonlinear relationships and resilience against overlearning. Each decision tree learns the relationship between the input features and the target variable to produce a continuously valuable output. The RF output is calculated as follows:

$$\hat{y}_i^{RF} = \frac{1}{T}\sum_{t=1}^{T} f_t\,(\mathbf{x}_i) \tag{13}$$

Here, T represents the number of trees, and $f_t(\cdot)$ represents the t[th] decision tree [52].

This structure allows RF to generate predictions in the same target space as the continuous output produced by the ANFIS model, enabling a fair comparison.

H. XGBoost and Learning Process

XGBoost is a regularized decision tree ensemble method based on the gradient boosting principle. The model improves its performance by learning a new tree in each iteration, focusing on minimizing the errors of previous predictions [52]. In this study, the XGBoost method is used as a regression method to estimate continuous student achievement scores. The general form of the XGBoost model can be expressed as follows:

$$\hat{y}_i^{XGB} = \sum_{m=1}^{M} \gamma_m\, h_m(\mathrm{x}_i) \tag{14}$$

Here, $h_m(\cdot)$ represents the m^{th} regression tree, and γ_m represents the learning rate [53].

This structure allows XGBoost to generate predictions in the same target space as the continuous outputs of other models, enabling a fair comparison.

I. Proposed Hybrid Model: ANFIS–RF–XGBoost-Based Student Achievement Prediction Framework

In this study, the proposed architecture comprises two complementary learning stages: regression-based pre-prediction with uncertainty awareness and classification-based final output generation, both focused on decision support. Fig. 1 presents the general flowchart of the hybrid architecture proposed in this study.

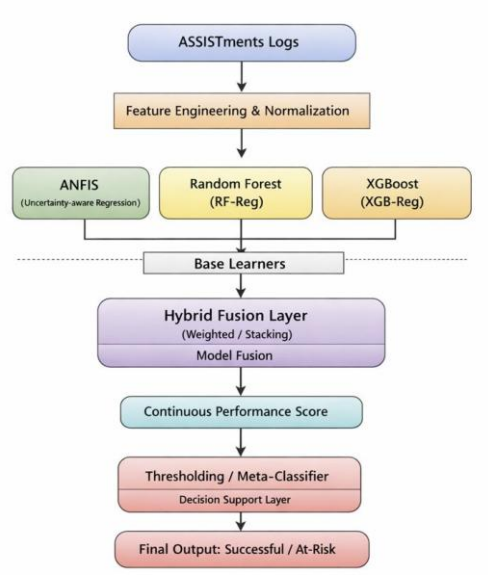

Fig. 1. Proposed hybrid model.

The raw interaction logs in the ASSISTments dataset reflect students' problem-solving behaviors in chronological order. The feature engineering process performed on the dataset is described in detail in Section III-C.

In the Base Learners phase, ANFIS, RF, and XGBoost regression processes are performed. With ANFIS, student behaviors are represented by linguistic, interpretable rules, and a continuously valued achievement score is obtained. In addition to ANFIS, XGBoost models were trained in regression mode to capture nonlinear patterns with high accuracy, and RF models were trained for robustness to noise and stable prediction. These models complement ANFIS by enabling learning of complex feature interactions, robustness to noise, and high generalization performance.

Three independent models are trained using the same input properties x_i

$$\begin{aligned} \hat{y}_i^{ANFIS} &= f_{ANFIS}(\mathrm{x}_i) \\ \hat{y}_i^{RF} &= f_{RF}(\mathrm{x}_i) \\ \hat{y}_i^{XGB} &= f_{XGBoost}(\mathrm{x}_i) \end{aligned} \tag{15}$$

All of these models are structured in regression mode to predict a continuous student achievement score from binary-labeled data.

In the next stage, the regression-based predictions are fed into the fusion layer, which is at the heart of the hybrid architecture. Two different hybridization strategies, weighted ensemble and stacking, were evaluated in this study.

In the weighted ensemble approach, the output of each model is weighted according to its performance on the validation data:

$$\hat{y}_i^{Hybrid} = \alpha\hat{y}_i^{ANFIS} + \beta\hat{y}_i^{RF} + \gamma\hat{y}_i^{XGB} \tag{16}$$

Here, $\alpha + \beta + \gamma = 1, \alpha, \beta, \gamma \geq 0$, and this can be determined based on validation set performance, model reliability, or grid search optimization. Thus, it balances the weaknesses of individual models and increases the stability of the regression output.

In stacking-based hybrid learning, the ANFIS, RF, and XGBoost outputs are treated as meta-features and fed to a second-level learner. This meta-learner is structured as a linear regression classifier for regression and a logistic regression classifier for classification. This stacking structure produces a more powerful prediction by learning complementary information between models.

$$z_i = [\hat{y}_i^{ANFIS}, \hat{y}_i^{RF}, \hat{y}_i^{XGB}] \quad (17)$$

Here, z_i is the meta-input vector.

For the final estimate:

$$\hat{y}_i^{Hybrid} = g(z_i) \quad (18)$$

Here, $g(\cdot)$ is chosen to be either a linear or a low-complexity regression model.

The consistent success scores were transformed into a binary classification problem for decision support in educational applications. This transformation was performed using the following thresholding function:

$$\tilde{y}_i = \begin{cases} 1, & \hat{y}_i^{\text{hybrid}} \geq \tau \\ 0, & \hat{y}_i^{\text{hybrid}} < \tau \end{cases} \quad (19)$$

Here, the threshold value τ is optimized on the validation set.

The proposed hybrid architecture offers the following advantages:

- Uncertainty Awareness: ANFIS explicitly models fuzzy patterns in student behavior.
- High Predictive Power: RF and XGBoost successfully capture complex and nonlinear relationships.
- Interpretability: ANFIS rules allow for pedagogical interpretation of prediction results.
- Flexible Use: The architecture is naturally adaptable to both regression and classification scenarios.

J. Performance Evaluation Metrics

The proposed hybrid architecture treats student achievement as both a continuous performance score (regression) and a binary decision outcome (classification). Therefore, model performance was analyzed using a two-stage evaluation strategy appropriate to the nature of the problem. In the first stage, the accuracy of regression-based predictions was measured, and in the second stage, the classification performance of the resulting hybrid outcomes was evaluated.

This multi-level performance evaluation strategy comprehensively demonstrates not only the prediction accuracy of the proposed hybrid model but also its practical usability for early warning and pedagogical decision-support systems.

1) Regression-based evaluation metrics: The ANFIS, RF, and XGBoost models were structured in regression mode to predict the student's consistent success score on the relevant problem. The metrics used at this stage measure the level of error between the predicted values and the actual labels. For regression-based models, the Mean Absolute Error (MAE), Root Mean Square Error (RMSE), and Coefficient of Determination (R^2) metrics were used [11, 22, 24].

Furthermore, the continuous predictions generated by regression models are subsequently converted to a binary classification problem for evaluating decision performance. Fixed threshold values are commonly used for this process. However, the literature indicates that such fixed thresholds do not guarantee optimal decision performance, especially when the class distribution is unbalanced and false-positive and false-negative errors have asymmetric costs [54, 55]. To overcome this limitation, an adaptive thresholding method based on the ROC curve was used in this study, rather than a fixed thresholding approach. The adaptive threshold was set to the point on the ROC curve that best balances sensitivity and specificity. For this purpose, the Youden Index (J), widely used in the literature, was adopted [56]. The Youden index is defined as follows:

$$J = TPR - FPR \quad (20)$$

This criterion determines the decision boundary that best distinguishes between classes by selecting a threshold value that maximizes the true positive rate while minimizing the false positive rate.

The ROC-based adaptive thresholding approach allows evaluation not only of the continuous predictive accuracy of models but also of their decision-making success, in a manner sensitive to data distribution. Particularly in online mathematics learning environments, considering the pedagogical consequences of incorrectly classifying a failing student as successful, this approach offers a more realistic and reliable assessment framework [44, 57].

2) Classification-based evaluation metrics: Regression-based hybrid outputs were converted into a binary classification problem using a threshold or a meta-classifier for decision support. Classification performance was evaluated using accuracy, recall, precision, and F1-score [4, 47, 58].

IV. Experimental Results

A. Experimental Setup

This section describes the experimental setup used to objectively and reproducibly evaluate the performance of the proposed hybrid neuro-fuzzy and machine-learning-based architecture. The experiments were designed within a multi-stage framework aiming to predict student achievement levels in online mathematics learning environments in both continuous (regression) and binary (classification) forms. In this context, the comparative performance of single learners and hybrid regression and hybrid classifier models was analyzed on raw and derived feature sets using the ASSISTments dataset. The entire experimental process was structured with the principles of fair comparison and data leakage prevention in mind.

B. Dataset and Splitting Strategy

In the experimental analyses, a student-based splitting strategy was adopted to prevent data leakage and to realistically evaluate the models' generalization ability. In this approach, the interactions of the same student were included in only one subset (training, validation, or testing). Thus, by measuring the model's performance on students it has not previously encountered, an evaluation closer to practical use cases was provided. The dataset was divided into three subsets: 60% for training, 20% for validation, and 20% for testing. The training set was used to learn the model parameters, the validation set for hyperparameter adjustments and determining hybrid model weights, and the testing set for the final performance evaluation. In the classification phase, the distribution of success and failure labels was analyzed, focusing on recall and F1-score to mitigate class imbalance and prevent skewed performance metrics. Thanks to this splitting strategy, the reliability of the proposed hybrid regression and hybrid classifier models in terms of both prediction accuracy and early warning systems was evaluated consistently and fairly.

C. Experimental Scenarios

To comprehensively evaluate the effectiveness of the proposed architecture, numerous experimental scenarios were designed that incorporated different model types, feature sets, and learning paradigms. These experimental scenarios aim to analyze the performance of individual models and clearly demonstrate the contribution of hybrid structures. In this context, the experiments were grouped into three main categories: individual regression models, hybrid regression models, and hybrid classification models.

In individual regression models, student achievement was treated as a continuous performance score, and ANFIS, RF, and XGBoost models were trained in regression mode. The goal was to compare the fundamental predictive capabilities of different learning paradigms on the ASSISTments dataset. In this context, analysis was performed with three regression models and three feature sets (raw, derived, and hybrid). These scenarios enable analysis of the impact of feature engineering and model structure on regression performance.

Hybrid regression scenarios aim to achieve more stable, accurate predictions by combining outputs from individual models. In this stage, ANFIS, RF, and XGBoost regression outputs were used as inputs to hybrid coupling mechanisms. These experiments were designed to evaluate the performance change and generalization status of the hybrid approach compared to single models.

In the hybrid classification scenario, the continuous success scores from the hybrid regression models were converted into binary classification labels for decision support. In this scenario, students were divided into two classes. This scenario aims to evaluate the applicability of the proposed architecture for early warning systems and its potential for pedagogical decision support.

D. Comparison of Individual Models

In this section, the performance of the individual regression models that constitute the core components of the proposed hybrid architecture is comprehensively analyzed. Student achievement is treated as a continuous output variable, and the ANFIS, RF, and XGBoost models are evaluated within the regression framework. Each model was trained and tested separately using raw features, derived features, and hybrid feature sets to examine the effect of feature representations on prediction performance. The test results obtained after nine analyses are given in Table V.

TABLE V. PERFORMANCE OF SINGLE REGRESSION MODELS

	Regression				Decision				
Model	**Features**	**RMSE**	**MAE**	**R^2**	**Threshold**	**Accuracy**	**Precision**	**Recall**	**F1**
ANFIS	Raw	0.2633	0.1409	0.6699	0.4825	0.922063	0.902544	0.9962	0.9471
	Derived	0.4159	0.3461	0.1765	0.7169	0.681849	0.828835	0.6874	0.7515
	Hybrid	0.2545	0.1411	0.6917	0.6971	0.916655	0.918273	0.9670	0.9420
RF	Raw	0.2561	0.1352	0.6878	0.8174	0.916943	0.910889	0.9769	0.9427
	Derived	0.4082	0.3301	0.2065	0.6790	0.714277	0.821494	0.7561	0.7874
	Hybrid	0.2369	0.1146	0.7327	0.7135	0.912187	0.936491	0.9382	0.9373
XGBoost	Raw	0.2597	0.1386	0.6790	0.8058	0.918995	0.906226	0.9863	0.9446
	Derived	0.4109	0.3399	0.1961	0.6966	0.704823	0.824742	0.7343	0.7769
	Hybrid	0.2434	0.1261	0.7179	0.6899	0.914872	0.927508	0.9528	0.9400

The table's results point to three clear and consistent findings. There is a significant performance decrease in all models when derived features are used alone. The hybrid feature set (Raw + Derived) is the most balanced and robust structure for all models. RF and XGBoost perform better in regression than ANFIS; however, ANFIS remains competitive in decision-making accuracy.

The lowest RMSE was obtained with the RF-Hybrid (0.2369), and the lowest MAE was obtained with the RF-Hybrid (0.1146). This result shows that RF is the most successful model in the hybrid feature space, with both lower mean error and lower extreme sensitivity. ANFIS-Hybrid (RMSE = 0.2545) and XGB-Hybrid (RMSE = 0.2434) are robust; however, RF-Hybrid is significantly ahead.

The highest R^2 values were obtained in the RF-Hybrid (0.7327) model, followed by the XGBoost-Hybrid (0.7179) and ANFIS-Hybrid (0.6917) models. This clearly shows that hybrid features enable the model to better explain the variance in the output variable. In particular, the fact that derived features alone dramatically reduce R^2 (≈0.17–0.20) indicates that they do not replace raw information but rather play a complementary role.

The highest accuracy was obtained with the ANFIS-Raw (0.9221) model, followed by the XGBoost-Raw (0.9190) and RF-Raw (0.9169) models. It is worth noting that raw features yield clearer classification signals when using decision thresholds.

The highest recall value was obtained in the ANFIS – Raw (0.9962) model, and the most balanced precision-recall value was obtained in the RF – Hybrid (0.9365 / 0.9382) model. The ANFIS-Raw configuration exhibits a recall-oriented character, while the RF-Hybrid model shows a balance-oriented character.

The highest F1 value was obtained in the ANFIS – Raw (0.9471) model, followed by the closely related XGBoost – Raw (0.9446) and RF – Hybrid (0.9373) models. This indicates that raw features are highly effective for classification, especially with ANFIS and XGB.

The findings show that using derived features alone reduces both regression and decision success, whereas the hybrid structure, which combines raw and derived features, provides significant and consistent improvements, particularly in regression performance. In terms of classification, raw features were observed to contain more distinct discriminative information, especially in the ANFIS and XGBoost models.

E. Hybrid Regression Results

1) Weighted ensemble performance: Ensemble learning approaches aim to reduce the generalization errors of individual models by combining their outputs, leveraging models with different assumptions and learning mechanisms [59], [60]. Weighted ensemble methods, in particular, offer a more balanced and effective estimation mechanism by accounting for each sub-model's validation performance, whereas simple averaging approaches assume all models contribute equally [60]. In this study, the uncertainty modeling and interpretability advantages of ANFIS are combined with the high generalization capabilities of RF and XGBoost models, and the contributions of the sub-models to the ensemble output are adaptively determined based on their validation-set error. Optimizing the weights inversely proportional to the RMSE values calculated on the validation data ensures that models with lower prediction errors have a greater impact on the final decision. This approach is consistent with the performance-based weighting strategies proposed in the literature [60], [61] and aims to contribute to more reliable prediction of student success in online mathematics education, in terms of both accuracy and stability. The most successful validation results, including RMSE-based weighted ensemble analysis and single regression, are shown in Table VI.

TABLE VI. WEIGHTED HYBRID VS. SINGLE MODELS

Model	RMSE	MAE	R^2	Threshold	Accuracy	Precision	Recall	F1
RF+Hybrid	0.2369	0.1146	0.7327	0.7135	0.912187	0.936491	0.9382	0.9373
Weighted Hybrid	0.2414	0.1255	0.7226	0.7014	0.916732	0.928630	0.9544	0.9413

Table VI evaluates the regression-based prediction performance and the classification performance derived from these predictions. The RF+Hybrid model has lower RMSE (0.2369) and MAE (0.1146) than the weighted hybrid model. However, its R^2 (0.7327) value is higher. These findings indicate that the RF-based hybrid approach has higher explanatory power and a lower error rate in predicting continuous success scores. Therefore, the RF+Hybrid model is more advantageous in terms of pure regression accuracy.

In contrast, when classification performance is examined, the weighted hybrid model offers more balanced and robust results. Although the RMSE and MAE values of the weighted hybrid model are slightly higher than those of the RF+Hybrid, it is superior in terms of accuracy (0.9167), recall (0.9544), and, especially, the F1 score (0.9413). This increase in recall value is critical, particularly in avoiding missing the "successful student" class, and yields a more pedagogically meaningful result in the context of educational analytics.

When the threshold values are examined, it is seen that the RF+Hybrid model uses a higher threshold (0.7135), whereas the weighted hybrid model uses a lower one (0.7014). This indicates that the weighted hybrid model creates a more comprehensive decision threshold, thereby increasing true positives and positively impacting Recall and F1 scores.

In conclusion, while the RF+Hybrid model provides lower error and higher explanatory power for continuous success prediction, the weighted hybrid model offers a more appropriate, balanced performance in classification-based decision-support scenarios—especially in online learning environments that require early risk detection and intervention. This finding clearly demonstrates that, in hybrid learning analytics studies that consider both regression and classification objectives, model selection should be guided by the problem context.

2) Stacking-based hybrid performance: Stacking (stacked generalization) is an advanced ensemble learning approach that combines the outputs of multiple base learners via a higher-level meta-learner and is particularly notable for its ability to effectively integrate the complementary strengths of different model types [62, 63]. In this approach, instead of using the predictions generated by the baseline models directly as the final decision, they are reweighted by a model learned in the second stage, thus incorporating nonlinear relationships between model outputs into the learning process [60]. In this

study, the outputs of ANFIS, RF, and XGBoost models were combined within a stacking framework. A linear regression model, which is simple and limits overfitting, was chosen as the meta-learner, and the final student success prediction was made using the continuous success scores from the baseline models. This structure is consistent with studies in the literature showing that heterogeneous ensemble models offer higher prediction accuracy compared to singular and weighted ensemble approaches [61, 63] and aims to more effectively model complex and uncertain student interactions in online mathematics education. The results of the hybrid regression analysis and the most successful singular regression results are given in Table VII.

TABLE VII. HYBRID REGRESSION AND SINGLE-DOMAIN REGRESSION RESULTS

Model	RMSE	MAE	R^2	Threshold	Accuracy	Precision	Recall	F1
RF+Hybrid	0.2369	0.1146	0.7327	0.7135	0.912187	0.936491	0.9382	0.9373
Weighted Hybrid	0.2414	0.1255	0.7226	0.7014	0.916732	0.928630	0.9544	0.9413
Stacking Hybrid	0.2503	0.1280	0.7017	0.5801	0.916157	0.929559	0.9524	0.9408

The results show that different hybridization strategies achieve a significant balance between minimizing error and maintaining decision sensitivity. In terms of regression performance, the RF+Hybrid model exhibits the lowest RMSE (0.2369) and MAE (0.1146), while also offering the highest R^2 (0.7327). This indicates that the RF-based hybrid structure produces more accurate continuous predictions of student achievement scores by effectively modeling nonlinear relationships. Therefore, the RF+Hybrid approach stands out in scenarios where pure regression accuracy and error minimization are prioritized. In contrast, while weighted and stacking hybrid models exhibit relatively higher regression errors, they offer more balanced and competitive classification performance. Specifically, the weighted hybrid model achieves the highest recall (0.9544) and F1 score (0.9413), demonstrating a more sensitive structure for accurately identifying at-risk students. Similarly, the stacking hybrid model, despite using a lower decision threshold (0.5801), demonstrated comparable recall (0.9524) and F1 (0.9408) scores. This finding shows that the meta-learning-based stacking approach can leverage the complementary information content of different regressors.

When examining the decision thresholds, it is observed that the RF+Hybrid model adopts a more conservative classification strategy with a higher threshold (0.7135), whereas the weighted hybrid and, especially, the stacking hybrid models increase the true positive rate by operating with lower thresholds. This preference directly affected the precision-recall trade-off, resulting in higher recall and F1 scores.

Overall, the RF+Hybrid model offers the strongest performance in continuous success prediction, while the weighted and stacking hybrid models are better suited for classification-based decision-support applications. These results clearly demonstrate that in online education analytics, rather than a single "best" model, different hybrid regression strategies should be preferred depending on the problem objectives (error minimization vs. early risk detection).

F. Meta-Classification Results

This section presents the results obtained by combining continuous success scores derived from regression models within weighted ensemble and stacking-based hybrid classification structures. The analyses show that hybrid approaches, while not significantly improving classification accuracy over single models, produce more stable and consistent results across different experimental scenarios and feature sets. This supports the usability of hybrid architectures as reliable early warning systems in online mathematics education.

In the proposed meta-classification structure, raw or derived features were not directly fed to the classifier; instead, continuous success scores obtained from ANFIS, RF, and XGBoost regression models were used as meta-features. Thus, different learning biases of the base models were integrated at the meta-level to arrive at the final decision. Classification was performed using logistic regression. After analysis, the accuracy was 0.916560, the precision was 0.929140, the recall was 0.9535, and the F1 score was 0.9412.

When the experimental results are examined, it is generally observed that the individual models and the proposed hybrid structures exhibit similar performance on metrics such as accuracy and F1-score. This proves that the pedagogical variables (PCR, PAM, RPT, etc.) derived from raw data during the feature engineering phase have a very strong signal capacity in representing the fundamental patterns in student behavior. Therefore, the similarity in performance between the models is considered a saturation point resulting from the high quality of the distinguishing features in the dataset.

G. Interpretability Analysis (ANFIS)

This section outlines the interpretability advantages of the ANFIS model within the proposed hybrid architecture. In online mathematics learning environments, high prediction accuracy is as critical as the pedagogical interpretability of these predictions. Unlike black-box machine learning models, ANFIS's Sugeno-type fuzzy inference mechanism allows for a clear examination of the underlying logical relationships in predicting success by representing student interactions through "If-Then" rules. In this context, the ANFIS model is considered not only a predictor within the hybrid structure but also an explanatory component that transforms the uncertainty in student behavior into a pedagogically interpretable form. Three rules have been established in the educational process using the hybrid feature set and the ANFIS model. These are:

Rule 1: IF AC is low [MF 1] AND HC is low [MF 1] AND RT is low [MF 1] AND OT is low [MF 1] AND SDI is low [MF 1] AND SEL is low [MF 1] AND RPT is high [MF 1] AND PCR is low [MF 1] AND PAM is low [MF 1] AND PHM is low [MF 1] AND OC is low [MF 1] THEN output = -24.596*x -6.812*x

-0.123*x -12.608*x -0.436*x +0.764*x -0.033*x -0.226*x +0.689*x +0.474*x +0.309*x +2.747

Rule 2: IF AC is low [MF 2] AND HC is low [MF 2] AND RT is low [MF 2] AND OT is low [MF 2] AND SDI is low [MF 2] AND SEL is low [MF 2] AND RPT is high [MF 2] AND PCR is low [MF 2] AND PAM is low [MF 2] AND PHM is low [MF 2] AND OC is low [MF 2] THEN output = -0.029*x -0.058*x +0.006*x -0.059*x -0.104*x -0.001*x +0.006*x +0.050*x +0.002*x +0.009*x -0.009*x +0.054

Rule 3: IF AC is low [MF 3] AND HC is low [MF 3] AND RT is low [MF 3] AND OT is low [MF 3] AND SDI is low [MF 3] AND SEL is low [MF 3] AND RPT is high [MF 3] AND PCR is low [MF 3] AND PAM is low [MF 3] AND PHM is low [MF 3] AND OC is low [MF 3] THEN output = -4.253*x -1.033*x -0.507*x +8.283*x -0.153*x +0.201*x -0.056*x +0.462*x +0.033*x -0.106*x +0.088*x -0.425

The Takagi-Sugeno-Kang (TSK) type fuzzy rules obtained in the study reflect the system's behavioral tendencies towards a specific student profile. The antecedents of the three rules examined are identical: they describe a group of students with low experience and low past achievement, but whose current performance is on the rise.

The linear regression coefficients in the consequences of the rules determine the weight of the variables on the outcome.

- Rule 1 (High-Precision Estimation): This rule has the highest coefficient ($w_1 = -24.596$). Academically, this indicates that the model attempts to capture "extreme values" in this specific student group. It is the component of the system that gives the harshest punitive response to the increase in the number of erroneous trials.
- Rule 2 (Stable Estimation): The proximity of the coefficients to zero ($(w_i \approx 0)$) proves that this rule acts as an "anchor" in the system. It stabilizes the output by filtering noise in the variables and prevents overfitting.
- Rule 3 (Balanced Effect): Rule 3 establishes a balance between positive and negative weights. Specifically, the +8.283 coefficient on the fourth variable indicates that a particular parameter (e.g., dwell time or response speed) is considered strong evidence in favor of "learning" under this rule.

When the rules are examined as a whole, it is seen that the factors "Low Experience" and "Low Past Success" are treated as negative starting points (biases) by the model. However, the "RPT is high" condition causes the model to categorize the student as a "recovering student".

The fact that these three rules share the same antecedent confirms that the system uses a fuzzy clustering method and that the final prediction is produced by taking the weighted average of these rules (defuzzification). This shows that the model can make more flexible predictions by combining multiple local models with different gradients rather than a single linear model. The model's membership functions are determined by the model and shown in Fig. 2.

The membership functions used in the system are generally Gaussian or Generalized Bell-type curves. This choice ensures that the transitions between input values are smooth and continuous, rather than sharp, allowing the model to more accurately capture non-linear student behavior. As shown in Fig. 2, features such as HC and PAM show asymmetric intensity distributions at low values, whereas cognitive load indicators such as RT and SDI exhibit normal distributions. This configuration allows the system to respond aggressively to student errors while calculating success trends with a more balanced weighted average.

In the AC, HC, PAM, and PHM graphs, the curves are leaning to the left (towards zero). The model considers the amount of student use of systemic assistance tools as an indicator of "independence." The rapid damping of the curves after a scale of 0.4 indicates that the system labels a small number of trials as "positive/low" and that, when this threshold is exceeded, the student quickly moves into the "struggling student" category. The fact that the OC graph also peaks at similarly low values indicates that the initial responses to newly encountered tasks are weighted.

In the PCR and SEL graphs, membership levels span a wider range. These variables determine the model's "long-term student profile." In the PCR graph, high membership values in the 0.6-0.8 range indicate that the system evaluates students with moderate-to-high achievement levels within a similar confidence interval. In the SEL graph, the distinct separation of different clusters (blue, orange, and yellow curves) suggests that the model triggers different rule sets for novice and expert students.

The RT and SDI graphs exhibit a complete bell-shaped curve. These parameters represent the student's cognitive state. The RT graph peaking around 0.7-0.8 indicates that the system considers responses that follow a specific thought process "ideal," rather than those that are too fast (predictive) or too slow (disconnected). The SDI, which peaks in the 0.3-0.4 range, indicates that the system measures performance more stably on medium-easy tasks.

The RPT function is perfectly symmetrical and centered at 0. These variables measure the model's "learning momentum." Centering the momentum at zero indicates that the model has an unbiased starting point for the student's direction (progress or regression), and even a slight deviation in the trend immediately affects the output (via Rule 1-3 coefficients).

During the fuzzification of the 11 model input parameters, the variances of the Gaussian membership functions were optimized based on the educational significance of each variable.

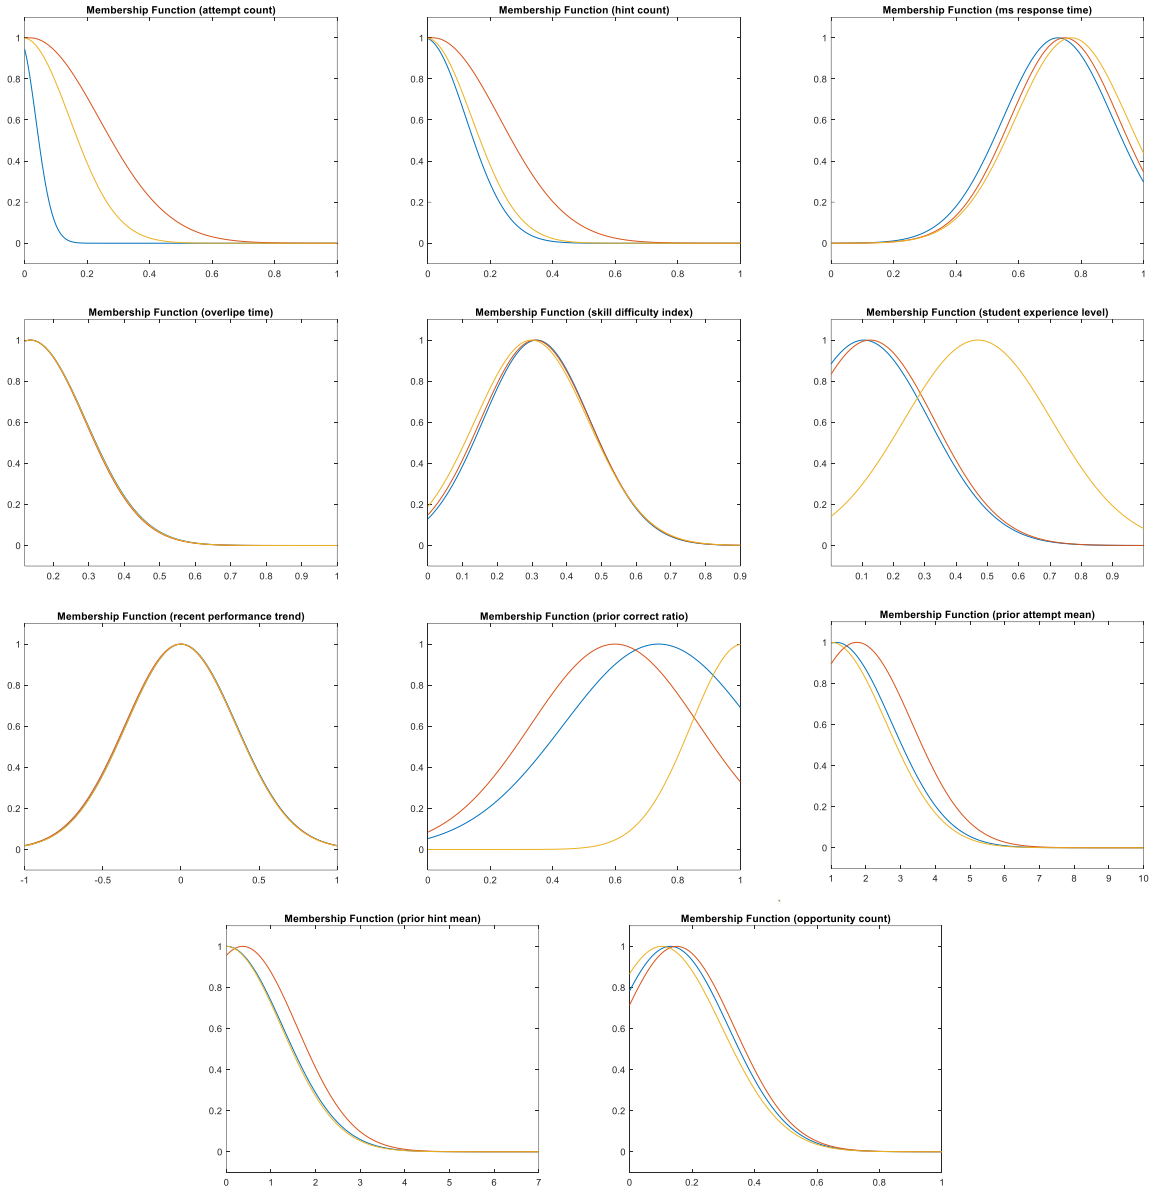

Fig. 2. Membership functions created with ANFIS and hybrid features ("AC", "HC", "RT", "OT", "SDI", "SEL", "RPT", "PCR", "PAM", "PHM", and "OC", respectively).

V. Discussion of Results

The findings of this study reveal, from both methodological and pedagogical perspectives, the advantages that hybrid approaches offer in predicting student achievement in online mathematics education compared to singular models and traditional assessment methods.

A. Hybrid Model Performance and Predictive Stability

Experimental results show that hybrid structures combining RF, XGBoost, and ANFIS models exhibit more stable performance in predicting continuous success scores (regression) and identifying at-risk students (classification). Specifically, the RF+Hybrid model, achieving the lowest RMSE (0.2369) and the highest R^2 (0.7327), confirms the power of tree-based ensemble learning algorithms in modeling complex, nonlinear student behavior. However, the weighted hybrid model, which achieves the highest F1-score (0.9413) and recall value (0.9544) in the classification phase, demonstrates that combining the models with weights minimizes erroneous decisions and produces more reliable early warning signals.

The numerical similarity in the classification performance of the models necessitates considering not only 'total accuracy' but also strategic metrics such as 'prediction stability' and 'error type cost' when selecting a model. While single-domain models (e.g., ANFIS-Raw) achieve high accuracy in some scenarios, the weighted hybrid model's high recall (0.9544) and F1 score (0.9413) during the classification phase provide a more reliable decision boundary for identifying at-risk students. This finding confirms that the hybrid architecture minimizes asymmetric error costs (mistaking failing students for passing students),

generating a more reliable early warning signal in the context of educational analytics.

B. The Role of Feature Engineering and Information Complementarity

Feature analysis results indicate that combining raw data and derived features is critical for model performance. The dramatic decrease in R^2 values (≈0.17–0.20) in scenarios where derived features are used alone indicates that these features cannot replace raw interaction information and should be included in the model as "context providers". In particular, the negligible correlation of the RPT feature with other features indicates that it provides independent, high-value "learning momentum" information for the model.

C. Uncertainty Management and Pedagogical Interpretability

The IF-THEN rules and membership functions provided by the ANFIS model have made the logical process underlying predictions transparent, unlike those of machine learning models, which are often described as "black boxes."

- Help-Seeking Behavior: The concentration of membership functions for HC and AC features at low values indicates that the model positively weights the use of a small number of hints as "learning independence" and quickly moves the learner to the "risky" category when a certain threshold is exceeded.
- Cognitive Load: The bell-curve form of RT documents that the system considers responses that come after a reasonable thought process as "ideal," rather than responses that are too fast (predictive) or too slow (disconnected).

D. Practical Applicability and Decision Support Potential

The study's two-stage (regression and classification) structure provides educators with both a continuous "probability of success" and a clear "successful/at-risk" label. The use of ROC-based adaptive thresholding created a more reliable decision boundary, particularly by reducing the pedagogical risks of false negatives (counting a failing student as successful). This suggests that the proposed model can be integrated into an early warning system for real-time monitoring on online mathematics platforms.

VI. Conclusion and Future Work

This study presents a unique hybrid framework combining fuzzy logic and machine learning techniques to predict student performance in online mathematics education. The main findings of the research are as follows:

- Superiority of the Hybrid Structure: Compared to single models, combining ANFIS's uncertainty modeling with the high predictive power of Random Forest and XGBoost yielded more balanced, reliable results.
- Prediction Accuracy: While the Random Forest (RF)-based hybrid model yielded the lowest regression error (RMSE: 0.2369), the Weighted Hybrid model excelled in classification accuracy (Accuracy: 0.9167) and risk detection sensitivity (Recall: 0.9544).
- Feature Interaction: Supporting raw interaction data with derived pedagogical features significantly increased the model's explanatory power (R^2).
- Explainability: The linguistic rules generated by ANFIS, unlike "black box" models, have enabled understanding of the cognitive and behavioral reasons behind the risk of failure (such as overuse of hints or temporal disconnections).

Research results have shown that different modeling paradigms (neuro-fuzzy and tree-based ensemble learning) achieve similar accuracy levels. However, the high predictive power offered by Random Forest and XGBoost models, supported by ANFIS's pedagogically interpretable IF-THEN rules, distinguishes the proposed hybrid framework from 'black box' models, making it unique. This not only provides high predictive performance but also enhances the pedagogical value of the study by enabling an understanding of the cognitive reasons behind the risk of failure (such as overuse of hints or temporal disconnections).

In the future, this model is planned to be tested with datasets from different disciplines and integrated into a real-time educational interface to provide teachers with instant intervention reports.

VII. Pedagogical Recommendations

Based on the findings from the model's membership functions and rule analysis (ANFIS), the following recommendations have been developed for online mathematics platforms:

- Balanced Use of Hints: Since excessive hinting (HC) is perceived by the model as a direct risk signal, the system should direct students to additional explanatory videos after a certain point instead of overwhelming them with hints.
- Encouragement of Ideal Thinking Time: Since very fast responses are often considered guessing (gaming the system), a minimum "waiting time" should be encouraged for students to read and analyze the question.
- Cumulative Follow-up: Due to the cumulative nature of mathematics education, the system should automatically define micro-tasks to "remind" students of past topics for those with low past achievement rates (PCR).
- Feedback Focused on Learning Momentum: Motivational messages should be delivered focusing not only on the result but also on the student's rising performance trend (RPT).

VIII. Limitations and Threats to Validity

The following limitations should be considered when evaluating the results of the study:

- Dataset Coverage: Analyses were performed only for the mathematics domain using the ASSISTments dataset (2009-2010); additional validations are needed to generalize the results to other subject areas (language, science, etc.).

- External Factors: Off-platform data, such as students' off-platform study habits, physical environment, or socio-economic status, could not be included in the model.
- Interaction Limitations: To maintain the stability of the model, students with very few (below 5) or many (above 1000) interactions were excluded from the analysis, as this may affect performance in extreme profiles.
- Computational Cost: The hybrid structure combining ANFIS and ensemble models may require high computational power in systems with very large-scale and real-time applications.

An Empirical Analysis of Google Play Data Safety Disclosures: A Consistency Study of Privacy Indicators in Mobile Gaming Apps

Bakheet Aljedaani
Computer Science Department-Jamoum University College, Umm Al-Qura University, Makkah, Saudi Arabia

***Abstract*—The Google Play marketplace has introduced the Data Safety section to improve transparency regarding how mobile applications (apps) collect, share, and protect user data. This mechanism requires developers to disclose privacy and security-related practices, including data collection, data sharing, and data protection measures. However, the reliability of these disclosures depends on developer self-reporting, raising concerns about their accuracy. This study investigates the consistency between developer-reported Data Safety disclosures and observable privacy indicators extracted from Android application packages (APKs). An empirical analysis was conducted on a dataset of 41 mobile gaming apps, including 21 children-oriented and 20 general-audience apps. A static analysis approach was used to extract key privacy indicators, including device identifiers, data sharing practices, personal information access, and location access. These indicators were systematically compared with corresponding disclosures using a structured consistency evaluation framework. The results reveal varying levels of agreement across privacy categories. Device identifier disclosures show relatively high consistency (87.8%), whereas other indicators exhibit substantial mismatches. In particular, location-related disclosures show the highest inconsistency rate (56.1%), followed by personal information and data sharing indicators. Comparative analysis shows similar mismatch patterns across app categories. Chi-square tests further indicate that these differences are not statistically significant, suggesting that inconsistencies are not associated with app category but reflect broader challenges within the analyzed mobile gaming dataset. These findings highlight limitations in current marketplace transparency mechanisms and emphasize the need for improved validation approaches to ensure accurate privacy reporting.**

Keywords*—Android security; data safety; mobile gaming apps; privacy analysis; static analysis

I. Introduction

Mobile applications (apps) have become an integral part of modern digital ecosystems, supporting a wide range of services including healthcare, entertainment, education, and commerce. To enable these services, mobile apps frequently collect and process user data for purposes (e.g., analytics, advertising, personalization, and service improvement) [1], [2]. As a result, concerns regarding the transparency of data collection and sharing practices have become increasingly important. End-users often rely on information presented in app marketplaces to understand how their data may be handled before installing an app. However, determining whether such disclosures accurately reflect actual app behavior remains a challenging problem [3]. Prior research has shown that mobile apps often access sensitive resources and user data in ways that are not always clearly communicated to end-users, raising concerns about privacy awareness and informed consent [4], [5]. In addition, studies have highlighted that permission systems alone do not provide sufficient insight into how user data is actually processed or shared within apps [6], [7].

To address these concerns, Google introduced the Data Safety section in the Google Play marketplace, requiring developers to disclose how their apps collect, share, and protect user data [8]. This feature provides structured information about data practices, including whether apps collect sensitive data (e.g., location or personal information, whether data is shared with third parties, and whether it is encrypted during transmission). The introduction of Data Safety labels represents an important step toward improving transparency and enabling end-users to make more informed decisions when selecting mobile apps. However, a recent study suggests that privacy labels may not fully address users' actual privacy concerns and found that a significant portion of users' privacy questions remain unanswered or only partially addressed by existing mobile app privacy labels [9]. Similar transparency initiatives have been explored in prior work, including efforts to improve privacy notices, standardized disclosure formats, and machine-readable privacy representations [1], [10], and [11]. However, the effectiveness of such mechanisms depends on the accuracy and completeness of developer-reported disclosures, which may vary depending on developer interpretation and implementation of reporting requirements [12]. Despite these improvements, the reliability of developer-reported privacy disclosures remains uncertain. This challenge is further compounded by the difficulty developers face in accurately completing privacy labels, particularly when apps integrate complex third-party components and data processing mechanisms [13]. The information presented in Data Safety labels is self-reported and not automatically verified by the platform, raising concerns about potential inconsistencies between declared practices and actual app behavior. Recent work has demonstrated that it may not fully reflect observable app behavior and has found that a substantial number of mobile apps transmit data that is not declared in their privacy labels, highlighting the lack of validation in current marketplace transparency mechanisms [14]. Previous studies have demonstrated discrepancies between privacy policies and observable app characteristics, including permission usage,

data flows, and third-party tracking behaviors [1], [15]. For example, studies have shown that many mobile apps request permissions that are not clearly justified by their functionality or fail to disclose certain data practices in their privacy policies [16], [17]. Other work has highlighted the role of third-party libraries and advertising frameworks in introducing additional data collection capabilities that may not be fully understood or disclosed by developers [15], [18], and [19]. These findings suggest that transparency mechanisms based solely on developer self-reporting may not always provide an accurate representation of app privacy behavior.

In this context, this study investigates the consistency between developer-reported Google Play Data Safety disclosures and observable privacy indicators extracted from Android Application Packages (APKs). Unlike prior work that focuses primarily on permissions or privacy policies, this study provides a direct comparison between marketplace disclosures and application-level technical indicators, enabling a more comprehensive assessment of privacy transparency. The analysis focuses on mobile gaming apps, one of the most widely adopted categories of mobile apps, particularly among children and young end-users [20], [21]. Given the scale and popularity of mobile games, as well as their increasing reliance on analytics and advertising infrastructures, understanding the reliability of their privacy disclosures is of significant importance. To provide deeper insights, the study includes both children-oriented and general-audience mobile gaming apps, enabling a comparative analysis of disclosure practices across app categories. In addition, the study applies statistical analysis techniques, including Chi-square tests, to evaluate whether observed differences in disclosure mismatches are statistically significant. By combining static analysis of APK files with structured analysis of marketplace disclosures, this study aims to provide empirical evidence regarding the effectiveness of Data Safety labels as a transparency mechanism in mobile app ecosystems. This study addresses the following research questions (RQs):

RQ1: To what extent do Google Play Data Safety disclosures align with observable static privacy indicators in mobile gaming apps?

This RQ aims to measure the level of consistency between developer-reported privacy disclosures and indicators extracted through static analysis of APK files.

RQ2: Do disclosure inconsistencies differ between children-oriented and general-audience apps?

This RQ aims to examine whether app category influences the likelihood of mismatches between static indicators and Data Safety labels.

RQ3: Are the observed differences in disclosure mismatches statistically significant?

This RQ aims to apply statistical analysis techniques to determine whether disclosure inconsistencies are associated with app category or occur broadly across the dataset.

To answer these RQs, we conducted an empirical study combining static analysis of Android apps with structured analysis of Google Play Data Safety disclosures. The study was performed on a selected dataset of 41 widely installed Android mobile gaming apps, including both children-oriented and general-audience titles. The dataset was divided into two groups: 21 children-oriented apps and 20 general-audience apps, selected based on popularity indicators such as installation counts and marketplace rankings to ensure representation of widely used apps with large user bases. The study was carried out through a four-phase workflow, including two main technical parts: static analysis and Data Safety extraction. The static analysis was performed for APK files to extract privacy-related indicators, including device identifier usage, personal information access, data sharing signals, and location access, based on permissions and observable app artifacts. Then, we manually collected and analyzed the corresponding Google Play Data Safety disclosures, mapping developer-reported information into structured indicators aligned with the static analysis results. The extracted data were then systematically compared to identify mismatches between observable indicators and reported disclosures, followed by comparative analysis across app categories and statistical validation using Chi-square testing. The results reveal that while certain indicators, such as device identifiers, exhibit relatively high agreement, other categories, including location, personal information, and data sharing, show substantial inconsistencies between developer-reported disclosures and observable app characteristics. Furthermore, similar mismatch patterns were observed across both children-oriented and general apps, suggesting that privacy transparency challenges are not limited to specific app categories but may reflect broader issues in marketplace disclosure mechanisms. We believe this study makes the following key contributions:

1) Empirical comparison of privacy disclosures and technical indicators: This work provides a systematic comparison between developer-reported Google Play Data Safety disclosures and observable static privacy indicators, enabling a direct assessment of the reliability of marketplace transparency mechanisms.

2) Cross-category analysis of mobile gaming apps: The study analyzes both children-oriented and general-audience apps, providing insights into whether privacy transparency differs across app categories subject to different regulatory and design considerations.

3) Identification of systematic disclosure inconsistencies: The results reveal consistent mismatch patterns across multiple privacy indicators, highlighting potential limitations in current self-reported disclosure mechanisms within mobile application marketplaces.

4) Integration of statistical analysis for validation: The study applies Chi-square statistical testing to evaluate whether observed differences are statistically significant, providing a rigorous empirical basis for interpreting the findings.

5) Implications for improving privacy transparency mechanisms: The findings provide actionable insights for developers, platform providers, and researchers, emphasizing the need for improved tooling, clearer reporting guidelines, and potential automated validation mechanisms.

The rest of this study is organized as follows: Section II presents the most relevant works to our study. Section III details the adopted research methodology. Section IV reports the study findings, followed by a discussion in Section V. Threats to validity are discussed in Section VI, and Section VII concludes the study and suggests potential future work.

II. Related Work

Research on mobile app privacy and security has been widely explored from multiple perspectives, including permission analysis, data flow analysis, privacy policies, third-party tracking, and transparency mechanisms. This section reviews relevant studies and positions the current work within the existing literature.

A. Permission-Based Privacy Analysis in Mobile Apps

Early research on mobile privacy primarily focused on analyzing Android permission systems as indicators of app behavior. Felt et al. in [4] conducted one of the earliest systematic studies of Android permissions, highlighting the gap between permission requests and user understanding. Similarly, Kelley et al. in [5] investigated end-user perception of permission requests, showing that end-users often struggle to interpret their implications. Subsequent studies demonstrated that permissions alone are insufficient to accurately characterize privacy risks, as apps may request unnecessary permissions or use them in unexpected ways [22], [7]. Further work extended permission-based analysis by examining how permissions relate to app functionality and privacy exposure. Zhou and Jiang in [17] analyzed Android malware and demonstrated how permissions can be abused for malicious purposes. Enck et al. in [23] introduced static analysis techniques to identify potential privacy leaks in Android apps. However, several studies have concluded that permission-based approaches do not represent privacy behavior with sufficient precision, as they do not capture how data is processed or shared after being accessed [24], [25].

B. Static and Dynamic Analysis of Privacy Behavior

To overcome the limitations of permission-based approaches, researchers have developed static and dynamic analysis techniques to examine how apps handle end users' data. Tools such as FlowDroid [16] and TaintDroid [23] enabled precise tracking of sensitive data flows within Android apps. These techniques have been widely used to detect privacy leaks and unauthorized data transmissions. Dynamic analysis approaches, such as those proposed by Rastogi et al. in [26] and Ren et al. in [27] have further demonstrated that many apps transmit sensitive data to remote servers, often without clear end-user awareness. While these approaches provide deeper insights into app behavior, they are often computationally expensive and difficult to scale across large datasets. In contrast, static analysis remains a widely used technique due to its scalability and ability to analyze large numbers of apps efficiently [28]. However, both approaches face challenges in capturing behaviors introduced by obfuscation, dynamic code loading, and third-party libraries.

C. Third-Party Libraries and Tracking Ecosystems

A significant body of research has examined the role of third-party libraries, particularly advertising and analytics SDKs, in shaping privacy risks in mobile apps. Studies by Grace et al. in [29] and Wang et al. in [19] showed that third-party components frequently introduce additional data collection and tracking capabilities that are not always transparent to users. Similarly, Ikram et al. in [30] analyzed mobile advertising ecosystems and found widespread tracking behavior across apps. Recent studies have highlighted that developers may not fully understand the privacy implications of integrated SDKs, leading to incomplete or inaccurate disclosures of data practices [31], [32]. These findings are particularly relevant in the context of mobile games, where monetization strategies often rely heavily on advertising and analytics infrastructures. As a result, third-party libraries represent a key factor contributing to the complexity of privacy transparency in mobile ecosystems.

D. Privacy Policies and Transparency Mechanisms

Another line of research has focused on evaluating privacy policies and user-facing transparency mechanisms. Zimmeck et al. in [10] developed automated techniques for analyzing privacy policies and identifying inconsistencies between stated and actual practices. Cranor in [11] discussed the challenges of designing effective privacy notices, emphasizing that traditional policy formats are often difficult for users to understand. More work has explored structured and machine-readable approaches to privacy disclosures, aiming to improve usability and transparency [33], [34]. However, even when structured disclosures are available, users may still struggle to interpret their meaning or assess their implications [35]. These challenges highlight the importance of evaluating not only the presence of privacy disclosures but also their accuracy and reliability.

E. Studies on Google Play Data Safety Labels

With the introduction of Google Play Data Safety labels, research has begun to examine their effectiveness as a transparency mechanism. While this feature is relatively recent, emerging studies suggest that privacy labels may face important limitations in both accuracy and usability. For instance, Koch et al. in [14] conducted a large-scale empirical study analyzing the consistency between Apple's privacy labels and actual app behavior through network traffic analysis. Their results showed that a significant number of apps transmit data not declared in their privacy labels, indicating discrepancies between developer-reported disclosures and observable behavior. The study also highlighted that privacy labels are not systematically validated during the app review process, raising concerns about their reliability as a transparency mechanism. Zhang and Sadeh in [9] evaluated the effectiveness of mobile app privacy labels in addressing users' privacy questions through an empirical analysis of a large corpus of user concerns. Their findings indicate that existing privacy labels often fail to provide sufficient information to answer many user questions, with a substantial portion of questions either unanswered or only partially addressed. These results suggest that, beyond issues of accuracy, privacy labels may also suffer from limitations in completeness and usability.

Cross-platform analyses have also highlighted inconsistencies in privacy label disclosures across different mobile ecosystems. Khandelwal et al. in [36] compared

privacy labels of apps available on both Android and iOS platforms and found notable differences in how data practices are reported across marketplaces. Their findings suggest that privacy disclosures may vary depending on platform-specific guidelines and developer interpretations, further raising concerns about the consistency and reliability of privacy labels. Lin et al. in [12] conducted a user-centered study comparing Android Data Safety labels with iOS privacy labels and found that, although some end-users perceive the labels as helpful, many users find them vague, incomplete, and difficult to interpret, leading to misunderstandings of app data practices. The study also reported that end-users often miss critical information due to interface design and express uncertainty regarding the reliability of developer-provided disclosures.

Furthermore, Zimmeck et al. in [10] and Reidenberg et al. in [35] demonstrated that privacy disclosures and policies often fail to accurately reflect actual data practices, highlighting limitations in user-facing transparency frameworks. Similarly, empirical analyses of mobile apps have shown that developers may over-report or under-report data collection practices, partly due to ambiguity in reporting requirements and limited visibility into third-party library behavior [19], [37]. In addition, prior research has emphasized the significant role of third-party analytics and advertising libraries in shaping app privacy behavior. Studies such as Han et al. in [19] and Derr et al. in [32] showed that embedded SDKs can introduce additional data collection mechanisms that are not always clearly reflected in developer disclosures. As a result, privacy labels may capture potential data practices associated with integrated components rather than directly observable behavior within the app package. These findings suggest that, while Data Safety labels represent a promising step toward improving transparency, they may still face challenges similar to those identified in earlier studies on privacy policies and mobile app disclosures.

Positioning of our Study: While prior work has extensively examined mobile privacy from perspectives such as permissions, data flows, third-party tracking, and privacy policies, relatively few studies have focused on the direct comparison between marketplace transparency mechanisms and observable application-level indicators. Existing studies on Data Safety labels remain limited and often do not integrate systematic static analysis with structured evaluation of disclosure consistency. This study addresses this gap by providing a configuration-aware and indicator-based comparison between developer-reported Data Safety disclosures and static privacy indicators extracted from APK files. In addition, it extends prior work by analyzing both children-oriented and general-audience apps, and by applying statistical analysis techniques to evaluate the significance of observed differences. By combining insights from software analysis and marketplace transparency research, this work contributes a more comprehensive understanding of the reliability of privacy disclosures in modern mobile ecosystems.

III. Research Methodology

This study adopts an application-centric static analysis approach to examine the consistency between Google Play Data Safety disclosures and observable technical indicators within Android apps. The methodology follows a structured empirical workflow consisting of four main phases: 1) design the study protocol, 2) APK collection and static inspection, 3) Data Safety label collection from Google Play, and 4) data analysis. Fig. 1 presents an overview of the research workflow, illustrating all the steps undertaken to conduct this study.

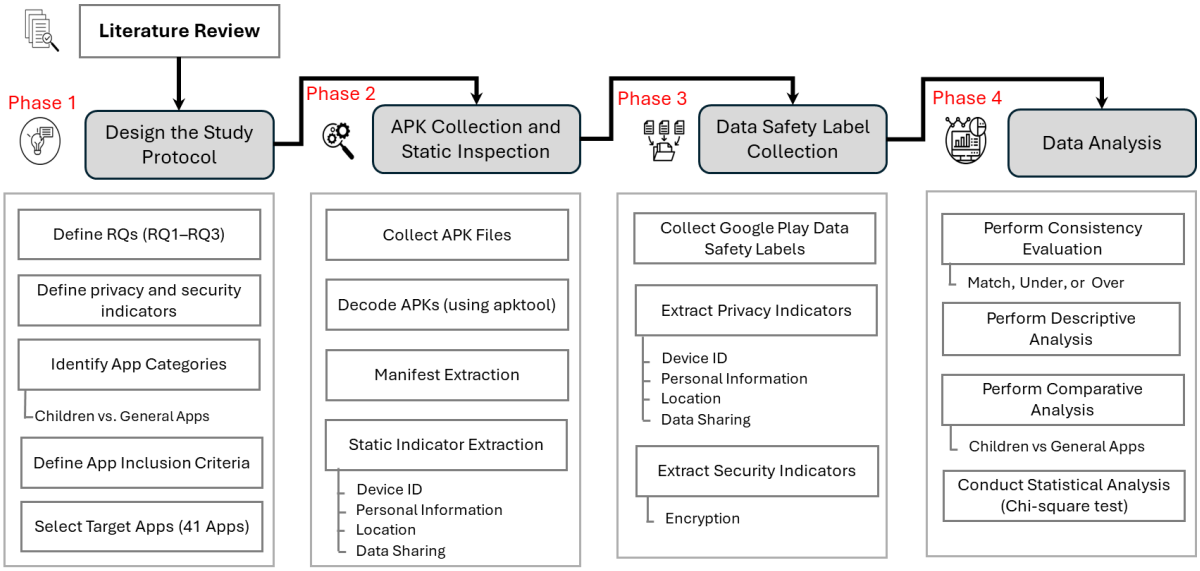

Fig. 1. An overview of the research workflow.

A. Phase 1: Designing the Study Protocol

The first phase focuses on establishing a systematic protocol to guide data collection and analysis. The protocol was designed based on prior literature on mobile privacy analysis and platform transparency mechanisms. First, the RQs (RQ1–RQ3), presented in Section I, were formulated to define the scope and objectives of the study. Based on these questions, a set of observable privacy and security indicators

was defined to guide the extraction and comparison process. This phase also involved the following:

1) Privacy and security indicators: To systematically evaluate disclosure accuracy, the study defined a set of observable indicators derived from Android application artifacts and Data Safety disclosures. These indicators were informed by prior research on Android privacy and security analysis, particularly studies focusing on permission usage and data access behaviors [38], [39], [40], and [41]. The selected indicators include:

- Location data collection.
- Device identifiers (Device ID).
- Personal information access.
- Data sharing practices.
- Encryption in transit (as declared in the Data Safety label).

These indicators were selected to enable a systematic comparison between static app characteristics and Google Play Data Safety disclosures. By focusing on these categories, the study provides a structured way to evaluate whether developer-reported privacy practices align with observable indicators within the app binaries, offering a more comprehensive perspective on privacy transparency beyond permission-based analysis alone.

2) Identifying app categories: To support comparative analysis, the selected apps were categorized into two groups: children-oriented apps and general-audience mobile games. This categorization was based on Google Play age ratings, store descriptions, and developer-provided metadata. The classification enables the investigation of potential differences in disclosure practices across app types.

3) App inclusion criteria: To enable a meaningful empirical evaluation, applications were selected based on a set of predefined inclusion criteria. Specifically, the selected apps must: 1) belong to the mobile gaming category in the Google Play marketplace, 2) demonstrate high popularity based on installation counts, user ratings, and store rankings, ensuring that the dataset reflects widely used applications, 3) be clearly classified as either children-oriented or general-audience, and 4) have an accessible APK file that can be successfully analyzed using static analysis techniques.

4) App selection: Based on these criteria, a dataset of 41 Android mobile gaming apps was constructed, consisting of 21 children-oriented apps and 20 general-audience games. The selected apps represent a diverse set of genres and development frameworks within the mobile gaming ecosystem. To support responsible reporting and avoid potential bias, applications are referenced using anonymized identifiers (i.e., *App1-App41*), with the mapping between identifiers and actual app names provided in the Appendix.

B. Phase 2: APKs Collection and Static Inspection

The second phase involved four main steps: 1) APKs collection, 2) APKs decoding, 3) manifest extraction, and 4) static indicator extraction. This phase involved the following:

1) APKs collection: APK files for the selected apps were obtained from publicly available sources to enable static analysis. In some cases, apps were distributed in split formats (e.g., XAPK or APKM), requiring additional processing to reconstruct usable APK files. Several downloaded packages were incomplete or corrupted, as indicated by identical file sizes or extraction errors. These issues were addressed by re-downloading the apps from alternative sources while ensuring consistency with the selected app versions. This process ensured that all analyzed APKs were valid and suitable for further analysis. The static analysis process employed multiple Android reverse-engineering and inspection tools. APK decoding and resource extraction were conducted using apktool version 2.9.3, while permission and manifest inspection were supported using Android Asset Packaging Tool (AAPT) from Android SDK Build-Tools version 36.1.0. Additional validation and package inspection were performed using JADX version 1.5.5 to examine application resources and package structures. These tools were selected due to their widespread adoption in Android software analysis research and their suitability for large-scale static analysis tasks.

2) APKs decoding: The collected APK files were decoded using static analysis tools (i.e., apktool) to enable access to their internal resources and configuration files. The decoding process extracted readable representations of app components, including the manifest file and resource directories. In some cases, decoding failures occurred due to obfuscation or packaging inconsistencies, requiring repeated attempts or the use of alternative tool configurations. Successfully decoded APKs were then used as the basis for extracting privacy-related attributes.

3) Manifest extraction: The AndroidManifest.xml file was extracted from each decoded APK as the primary source of application-level configuration and permission declarations. This file was systematically inspected to identify privacy-relevant attributes, including declared permissions, app components, and network-related configurations. Variations in manifest structure across apps occasionally required manual verification to ensure accurate interpretation. The extracted manifest data provided a consistent foundation for identifying observable privacy indicators across all apps.

4) Static indicator extraction: Static privacy indicators were derived from the extracted manifest data by mapping specific permissions and configuration attributes to predefined categories, including device IDs, personal information, location access, and data sharing. The extraction process involved both automated parsing and manual validation to ensure accuracy and consistency across apps.

C. Phase 3: Collection of Google Play Data Safety Labels

This phase involved collecting Data Safety labels for each app, which are publicly available on the Google Play marketplace. The Google Play Data Safety section was manually inspected to record developer-declared privacy practices. Based on the study protocol, the following disclosure fields were extracted: 1) location data collection, 2) device identifier collection, 3) personal information collection, 4) app activity tracking, and 5) encryption in transit. All extracted information was systematically recorded in a structured dataset to ensure consistency and enable reliable comparison across apps. The complete dataset is provided in the Appendix.

D. Phase 4: Data Synthesis And Comparative Analysis

The final phase of the methodology focuses on analyzing the extracted data to evaluate the consistency between static indicators and Data Safety disclosures. This phase includes 1) consistency evaluation, 2) descriptive analysis, 3) comparative analysis, and 4) statistical testing to identify patterns and assess the significance of observed discrepancies.

1) Consistency evaluation: All extracted attributes were organized into a structured dataset consisting of 41 app records and multiple privacy indicators. For each indicator, a systematic comparison was performed between the Google Play Data Safety disclosures and the corresponding static analysis evidence derived from APK inspection. To characterize the relationship between reported and observable practices, three comparison outcomes were defined as follows:

- Match: The static analysis evidence is consistent with the developer-reported Data Safety disclosure.
- Under-disclosure: The static analysis indicates the presence of data access or collection that is not declared in the Data Safety label.
- Over-disclosure: The Data Safety label declares data collection or usage that is not supported by observable static evidence.

This step forms the core of the analysis by establishing a consistent framework for identifying discrepancies between developer disclosures and observable application characteristics.

2) Descriptive statistics: Descriptive statistics were used to quantify the prevalence of the defined comparison outcomes across the dataset. The analysis focused on overall mismatch frequency, indicator-specific discrepancy rates, and distribution patterns across privacy categories. This step enables the identification of systematic inconsistencies between marketplace disclosures and observable application characteristics, providing an initial understanding of how disclosure accuracy varies across different types of data.

3) Comparative analysis: To further investigate potential differences across app types, the dataset was divided into two categories: children-oriented apps and general-audience mobile games. Comparative analysis was then performed to examine variation in mismatch rates across these categories for each privacy indicator. This step supports the evaluation of whether disclosure inconsistencies differ depending on app audience, directly addressing the study's comparative research objectives.

4) Statistical analysis: To assess whether the observed differences between app categories are statistically significant, Chi-square tests of independence were performed using Microsoft Excel [42]. The test evaluates the relationship between categorical variables, specifically disclosure outcome (match vs. mismatch) and app category (children-oriented vs. general-audience). By applying this statistical method, the study moves beyond descriptive observations and provides a rigorous assessment of whether observed differences reflect meaningful patterns or occur due to random variation. This step strengthens the validity of the findings and supports more robust conclusions regarding the nature of disclosure inconsistencies.

5) Ethical considerations: The study relies exclusively on static inspection of publicly distributed Android APKs. No runtime interaction with user accounts or personal data was performed. All results are reported in aggregate form, and apps are anonymized to minimize potential harm to developers or users.

IV. Findings

This section reports the observed security and privacy indicators across the analyzed mobile gaming apps. The results are presented to highlight patterns in data collection, data sharing, and configuration-related practices extracted through static analysis. In addition, the findings examine the level of consistency between these observable indicators and the corresponding Data Safety disclosures. This analysis provides an empirical basis for identifying potential mismatches and understanding their distribution across different privacy categories.

A. Consistency Between Static Indicators and Data Safety Labels

The comparison between static indicators and Data Safety disclosures revealed varying levels of consistency across privacy categories. As shown in Table I, the highest level of consistency was observed for device ID disclosures, with an agreement rate of 87.8% and a mismatch rate of 12.2% (i.e., 7.3% for under-disclosure, 4.9% for over-disclosure). In contrast, lower levels of consistency were observed for the remaining indicators. Data sharing practices exhibited a mismatch rate of 36.6%, while personal information disclosures showed a higher mismatch rate of 46.3% (i.e., 29.3 for under-disclosure and 17.0% for over-disclosure). The largest discrepancy was observed for location-related disclosures, where 56.1% of apps showed inconsistencies between static analysis results and the corresponding Data Safety labels. These findings indicate that the accuracy of privacy disclosures varies considerably depending on the type of data involved. The relatively high consistency observed for device identifiers may be attributed to the direct relationship between advertising identifiers and well-defined platform permissions, making them easier for developers to report accurately.

TABLE I. SUMMARY OF DISCLOSURE CONSISTENCY ACROSS PRIVACY INDICATORS

Indicator	Match	Under-disclosure	Over-disclosure
Device ID	87.8%	7.3%	4.9%
Personal Info	53.7%	29.3%	17.0%
Location	43.9%	0%	56.1%
Data Sharing	63.4%	36.6%	0%

TABLE II. EXAMPLE COMPARISON BETWEEN STATIC INDICATORS AND DATA SAFETY LABELS (FIRST 10 APPS)

App ID	Device ID (S/L)	Personal Info (S/L)	Location (S/L)	Data Sharing (S/L)
App1	Y / N	Y / N	N / N	Y / N
App2	Y / Y	Y / Y	N / N	Y / N
App3	Y / Y	Y / Y	N / Y	Y / Y
App4	Y / Y	Y / N	N / N	Y / N
App5	Y / Y	Y / N	N / N	Y / N
App6	Y / Y	Y / N	N / Y	Y / N
App7	Y / Y	Y / N	N / Y	Y / Y
App8	Y / Y	Y / Y	N / Y	Y / N
App9	Y / N	Y / N	N / N	Y / N
App10	Y / Y	Y / Y	N / N	Y / N

S denotes static analysis results, while L denotes developer-reported Data Safety disclosures; Y=Yes, N=No.

In contrast, categories such as location, personal information, and data sharing often involve more complex interactions with third-party libraries and backend services, which may introduce ambiguity in how data practices are interpreted and disclosed. As a result, these categories are more prone to inconsistencies between developer-reported information and observable app characteristics. To provide a more concrete illustration of these discrepancies, Table II presents a detailed comparison between static indicators and Data Safety labels for a subset of the analyzed apps (first 10 apps). This example demonstrates how mismatches occur at the individual app level, including cases of both under-disclosure and over-disclosure across different privacy indicators.

B. Comparison Between Children and General Games

To better understand whether disclosure inconsistencies differ across application types, the dataset was divided into two categories: children-oriented apps and general-audience mobile games. The mismatch rates for each privacy indicator across the two categories are summarized in Table III. The results indicate that the relationship between app category and disclosure inconsistency varies across privacy indicators rather than following a uniform pattern. As shown in Table III, the mismatch rate for device identifier disclosures was 19.0% for children-oriented apps, compared to 5.0% for general-audience apps. Similarly, data sharing disclosures showed mismatch rates of 42.9% for children-oriented apps and 30.0% for general-audience apps. In contrast, personal information disclosures exhibited a slightly higher mismatch rate among general applications (50.0%) compared to children-oriented apps (42.9%). A similar trend was observed for location-related disclosures, where general applications showed a higher mismatch rate (60.0%) than children-oriented apps (52.4%). These results indicate that while some indicators (e.g., device identifiers and data sharing) show higher mismatch rates in children-oriented applications, others (e.g., personal information and location) are more inconsistent in general applications. Overall, disclosure inconsistencies are observed across both categories, suggesting that such discrepancies are not confined to a specific type of application but rather reflect broader challenges in accurately reporting privacy practices within the Data Safety framework.

TABLE III. COMPARISON OF MISMATCH RATES BETWEEN APP CATEGORIES

Indicator	Children App Mismatch	General App Mismatch
Device ID	19.0%	5.0%
Personal Info	42.9%	50.0%
Location	52.4%	60.0%
Data Sharing	42.9%	30.0%

C. Statistical Significance Analysis

To determine whether the observed differences in disclosure mismatches between children-oriented and general applications are statistically significant, a Chi-square test of independence was performed for each privacy indicator. For each indicator, contingency tables were constructed comparing the number of matching and mismatching cases across the two app categories. The Chi-square test was selected because it is suitable for examining relationships between categorical variables, such as app category and disclosure consistency outcomes. In addition, the test enables the identification of potential associations between mismatch patterns and app categories while providing a statistically grounded interpretation of the observed differences. The results of the statistical analysis are summarized in Table IV. As shown in Table IV, none of the examined indicators exhibits a statistically significant association between app category and disclosure mismatch. Specifically, device identifier mismatches yielded $\chi^2 = 0.804$ ($p = 0.370$), data sharing mismatches yielded $\chi^2 = 0.281$ ($p = 0.596$), personal information mismatches yielded $\chi^2 = 0.021$ ($p = 0.885$), and location mismatches yielded $\chi^2 = 0.031$ ($p = 0.860$). These findings suggest that disclosure inconsistencies are not dependent on application category, but rather reflect broader limitations in the accuracy of marketplace privacy disclosures within the analyzed mobile gaming apps.

TABLE IV. CHI-SQUARE TEST RESULTS FOR DISCLOSURE CONSISTENCY

Indicator	χ^2 Value	p-value
Device ID	0.804	0.370
Personal Info	0.021	0.885
Location	0.031	0.860
Data Sharing	0.281	0.596

D. Security Practices in Data Safety Labels

In addition to privacy-related disclosures, the analysis also examined security-related information reported in the Data Safety labels, particularly whether user data is encrypted during transmission. The results indicate variability in how mobile gaming apps report their data transmission security practices. While a majority of apps declared that data is encrypted in transit, a small subset of applications explicitly reported that user data is not encrypted in transit, including App35 and App40, as in Fig. 2. Although encryption is not directly observable through static analysis, this finding provides additional insight into how developers communicate security practices through the Data Safety framework. Encryption of data in transit is widely considered a fundamental security measure for protecting user data from interception and unauthorized access [43], [44]. The observed variability suggests that, similar to privacy disclosures, security-related declarations may also lack consistency, highlighting an additional dimension of transparency challenges within mobile app marketplaces.

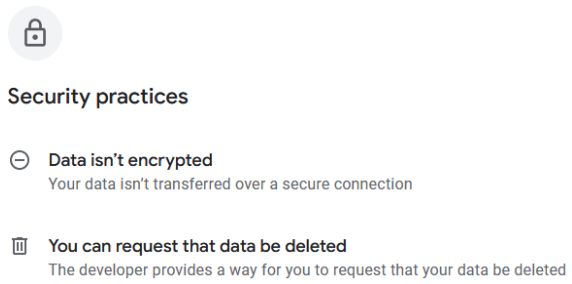

Fig. 2. Examples of apps reporting that data is not encrypted in transit in Google Play Data Safety labels.

V. Discussion

This section discusses the key findings of the study. It is important to note that the analysis is based on observable static indicators extracted from application artifacts rather than runtime behavior. Accordingly, the interpretations reflect potential privacy exposures inferred from static analysis rather than dynamic data flows.

A. Reliability of Data Safety Labels

The results of this study indicate that the reliability of Google Play Data Safety disclosures varies across different types of privacy indicators. Device identifier disclosures demonstrated the highest level of consistency between developer-reported labels and observable static indicators, with an agreement rate of 87.8%. This relatively high agreement suggests that developers may find it easier to accurately report the use of device identifiers, as these practices are typically associated with well-defined permissions and standardized advertising frameworks. In contrast, other indicators exhibited substantially higher mismatch rates, particularly for location (56.1%), personal information (46.3%), and data sharing (36.6%). A closer examination of mismatch types reveals distinct patterns across indicators. Location-related discrepancies were primarily driven by over-disclosure, where developers report data collection that is not supported by observable static evidence. Conversely, data sharing inconsistencies were predominantly associated with under-disclosure, indicating that data exchange mechanisms may not always be fully reported in Data Safety labels. Personal information disclosures exhibited a combination of both under- and over-reporting. These findings suggest that the reliability of Data Safety disclosures is not uniform but depends strongly on the type of data being reported, reflecting differences in how developers interpret and implement reporting requirements.

These findings are consistent with prior research examining transparency mechanisms in mobile app ecosystems. Several studies have reported inconsistencies between developer-reported privacy policies and observable app behavior, particularly in relation to permission usage and data flows [10], [35]. Similarly, recent work analyzing Google Play Data Safety disclosures has suggested that developers may either over-report or under-report certain data practices due to ambiguity in the reporting guidelines or uncertainty about third-party library behavior [12]. The results of this study extend these observations by providing empirical evidence within the context of mobile gaming apps and by systematically comparing Data Safety disclosures with static privacy indicators extracted directly from APK files. This comparison highlights that while Data Safety labels represent an important step toward improving transparency, their reliability may still depend heavily on how developers interpret and implement the reporting requirements.

B. Privacy Transparency in Children-Oriented Apps

An important objective of this study was to investigate whether privacy disclosure inconsistencies differ between children-oriented and general-audience apps. The results indicate that the relationship between app category and disclosure inconsistency is not uniform across privacy indicators. For certain indicators, such as device identifiers and data sharing, children-oriented apps exhibited higher mismatch rates. For example, device ID mismatches were observed in 19.0% of children-oriented apps compared to 5.0% of general-audience apps, while data sharing mismatches were 42.9% and 30.0%, respectively. In contrast, personal information and location-related disclosures showed higher mismatch rates among general-audience apps. Specifically, personal information mismatches were 50.0% for general apps compared to 42.9% for children-oriented apps, while location-related mismatches were 60.0% and 52.4%, respectively. These results indicate that inconsistencies in personal information and location disclosures are more pronounced in general-audience applications.

Despite these variations, statistical analysis confirmed that none of these differences are statistically significant, indicating that disclosure inconsistencies are present across both categories. These findings suggest that privacy transparency challenges are not limited to a specific group of apps but instead reflect broader issues in how developers interpret and report data practices within the Data Safety framework. This observation is consistent with prior studies showing that both children-oriented and general-audience apps may incorporate complex data collection mechanisms, including third-party analytics and advertising libraries, which can lead to inconsistencies between declared and actual practices [19], [45].

C. Systemic Nature of Disclosure Inconsistencies

The absence of statistically significant differences between children-oriented and general-audience apps suggests that inconsistencies between developer disclosures and observable indicators may represent a broader issue observed within the analyzed mobile gaming apps. Rather than being associated with a specific app category, these inconsistencies appear to arise from structural characteristics of modern mobile software development. This observation is consistent with recent empirical work [14], which shows that discrepancies between privacy disclosures and actual application behavior are widespread across mobile ecosystems. The study reports that numerous apps violate their declared privacy labels by transmitting undeclared data, indicating that such inconsistencies are systemic rather than isolated cases. This interpretation is further supported by prior work [13], which highlights that developers often face challenges in accurately completing privacy labels due to the complexity of modern mobile apps and limited visibility into third-party components. In particular, developers may struggle to understand and correctly report data collection behaviors, and tool-supported approaches based on static analysis have been proposed to improve label accuracy. In practice, many mobile apps rely heavily on third-party components such as advertising SDKs, analytics libraries, and cloud-based services. These components may introduce data collection capabilities that are not always clearly reflected in app permissions or static artifacts. Consequently, developers may report potential data practices associated with these components even when the corresponding behaviors are not directly observable within the application package. Taken together, these factors help explain the presence of indicator-specific mismatch patterns observed in this study, suggesting that disclosure inconsistencies are influenced not only by application category but also by the nature and complexity of the data being reported.

This interpretation aligns with previous research highlighting the complex role of third-party libraries in mobile privacy risks. Studies have shown that advertising and analytics frameworks frequently introduce additional data flows and tracking mechanisms that developers may not fully control or understand [32], [19]. As a result, accurately describing all potential data practices in marketplace disclosures can be challenging. Furthermore, platform reporting guidelines may encourage developers to disclose possible data usage scenarios rather than strictly observable behaviors, which may contribute to the mismatch patterns observed in this study. The findings therefore suggest that improving the accuracy of marketplace transparency mechanisms may require stronger tool support or automated validation approaches capable of identifying discrepancies between developer disclosures and observable app characteristics.

D. Security Implications of Data Safety Disclosures

In addition to privacy-related indicators, the analysis also examined security-related information reported in the Data Safety labels, particularly whether user data is encrypted during transmission. The results revealed variability in how mobile gaming apps report their encryption practices. While many apps indicated that user data is encrypted during transmission, several apps reported that user data may not be encrypted in transit. Encryption of data in transit is widely considered a fundamental security practice for protecting sensitive information from interception or unauthorized access. The presence of apps that report the absence of encryption mechanisms therefore raises potential concerns regarding the protection of user data in mobile gaming environments.

Previous studies examining security practices in mobile apps have similarly reported inconsistent adoption of secure communication mechanisms, particularly among apps that rely on third-party advertising or analytics services [44], [23]. In some cases, developers may depend on external services to manage data transmission security, which may lead to variations in how encryption practices are implemented or reported. The variability observed in this study suggests that Data Safety disclosures may provide useful signals regarding security practices but may not always present a complete picture of app security. From a user's perspective, inconsistent reporting of encryption practices may make it difficult to assess the level of protection provided by different apps. These findings highlight the importance of continued research into automated methods for evaluating both privacy and security transparency in mobile app marketplaces.

E. Implications for Mobile Privacy Transparency

The findings of this study have several implications for improving transparency mechanisms in mobile app marketplaces. First, the observed inconsistencies between static indicators and Data Safety disclosures suggest that developers may face challenges in accurately interpreting the reporting requirements introduced by Google Play. A recent study has shown that even when privacy labels are available, they may not fully address users' information needs. Furthermore, the work demonstrated that many user privacy questions remain unanswered by current label designs, highlighting limitations in their ability to support informed decision- making [9]. In particular, the higher mismatch rates observed for indicators such as location access, personal information, and data sharing highlight the difficulty of mapping app behavior and third-party library functionality to the categories defined in the Data Safety framework. Similar challenges have been identified in prior studies examining the relationship between app permissions, privacy policies, and developer disclosures [39], [6]. These results suggest that additional guidance or automated tools may be required to assist developers in generating accurate Data Safety reports. For example, developer tools that automatically analyze app artifacts and recommend disclosure categories could reduce ambiguity and improve the reliability of privacy reporting. In particular, the distinct mismatch patterns observed across different indicators (e.g., over-disclosure in location and under-disclosure in data sharing) suggest that reporting challenges may be closely tied to how specific data categories are defined and interpreted within the Data Safety framework.

The results also have implications for platform providers and researchers investigating mobile privacy transparency. For platform providers such as Google Play, the mismatch patterns identified in this study suggest that self-reported privacy disclosures alone may not fully capture app behavior. Integrating automated verification mechanisms into the

marketplace submission process could help identify inconsistencies between declared data practices and observable app characteristics. For example, automated checks based on static or dynamic analysis could flag potential mismatches during app submission and prompt developers to review their disclosures. From a research perspective, the findings highlight the importance of combining multiple analysis approaches, including static analysis, dynamic analysis, and marketplace metadata analysis, in order to better understand privacy transparency in mobile ecosystems. Future research may extend this work by developing automated techniques for identifying discrepancies between app behavior and marketplace disclosures on a larger scale.

VI. Threats to Validity

As with any empirical study involving software artifacts and marketplace disclosures, several factors may influence the interpretation of the results. Following established guidelines for empirical software engineering research, threats to validity are categorized into internal, construct, and external validity.

A. Internal Validity

Internal validity concerns whether the observed results may be influenced by methodological limitations during data collection and analysis. In this study, privacy indicators were extracted through static analysis of APK files, which may not capture behaviors triggered dynamically at runtime. For example, certain privacy-relevant actions may occur through remote services or dynamically loaded components that are not visible within the app package. Similar limitations of static analysis approaches have been reported in prior Android security studies [10], [11]. Another potential threat relates to APK availability and format variations. Some apps were initially obtained in formats such as XAPK or APKM, requiring additional extraction steps before analysis. In several cases, incomplete packages or identical file sizes indicated invalid downloads, which required replacing a small number of apps while maintaining the dataset balance. To mitigate these risks, permissions were manually verified when automated extraction produced unexpected results.

Another limitation relates to the exclusive reliance on static analysis techniques. Although static inspection enables scalable analysis of application artifacts and observable privacy indicators, it does not capture runtime behaviors, dynamically triggered data flows, or network transmissions that may occur during application execution. Consequently, the findings reflect observable static indicators rather than confirmed runtime data practices. Future work incorporating dynamic analysis techniques may provide a more comprehensive assessment of disclosure consistency and runtime privacy behavior.

B. Construct Validity

Construct validity concerns whether the selected indicators accurately represent the privacy practices being studied. In this work, privacy behavior was approximated using static indicators derived primarily from Android permissions and observable APK artifacts. While these indicators provide insights into potential data access capabilities, they may not fully capture all privacy-related behaviors within mobile apps. Some forms of data collection may occur through embedded third-party libraries, analytics frameworks, or advertising SDKs that do not require explicit permissions. As a result, certain privacy practices may remain undetected through permission-based analysis. Additionally, the Google Play Data Safety labels represent developer-reported disclosures rather than independently verified measurements of app behavior. Developers may declare potential data practices associated with integrated libraries even when those behaviors are not observable in the APK. Similar challenges in interpreting developer privacy disclosures have been reported in previous research on mobile privacy transparency [23], [27].

C. External Validity

External validity concerns the generalizability of the study findings beyond the analyzed dataset. This study analyzed 41 mobile gaming apps, including both children-oriented and general-audience games. Although this sample size is comparable to that of many empirical studies in mobile privacy research, it represents only a subset of the broader Android application ecosystem. In addition, the relatively small group sizes (21 children-oriented apps and 20 general-audience apps) may reduce the statistical power of the Chi-square analysis. Therefore, the absence of statistically significant differences between app categories should be interpreted cautiously, as non-significant results may reflect limited sample size rather than the complete absence of category-specific effects. Another limitation relates to the scope of the analyzed applications. The study focuses exclusively on mobile games, which may exhibit different privacy and monetization practices compared to other application categories such as social networking, productivity, or financial apps. Furthermore, the results reflect a snapshot of apps and Data Safety disclosures at the time of data collection. Since mobile applications and marketplace disclosures continuously evolve, future updates may lead to different observations. Despite these limitations, the dataset includes widely used apps with millions of downloads, providing a meaningful snapshot of privacy disclosure practices within the mobile gaming ecosystem [19]. Future studies involving larger datasets, additional app categories, and dynamic analysis techniques may further validate and extend the findings presented in this work.

VII. Conclusion and Future Work

Mobile apps increasingly rely on complex data collection, analytics, and advertising infrastructures to support functionality and monetization. To improve transparency regarding these practices, the Google Play marketplace introduced the Data Safety section, requiring developers to disclose how apps collect, share, and protect user data. Although this initiative represents an important step toward improving privacy transparency, the reliability of developer-reported disclosures remains largely dependent on self-reporting and may not always reflect observable app behavior. In this study, we conducted an empirical comparison between developer-reported Data Safety disclosures and static privacy indicators extracted from APKs to assess the consistency between marketplace transparency mechanisms and observable app characteristics. The analysis focused on a dataset of mobile gaming apps, including both children-oriented and general-

audience games, enabling a comparative evaluation of privacy disclosure practices across app categories.

The study was conducted through a structured empirical process that involved extracting privacy-relevant indicators from APK files through static analysis and comparing these indicators with the corresponding disclosures reported in the Google Play Data Safety section. By examining indicators related to device identifiers, personal information access, data sharing practices, and location access, this work provides a systematic assessment of how accurately developer disclosures reflect observable privacy-related artifacts within mobile apps. The key findings of this study can be summarized as follows:

- Device identifier disclosures exhibited the highest level of agreement between static indicators and Data Safety labels, suggesting that some data practices may be easier for developers to report accurately due to their clear association with specific platform permissions and advertising frameworks.
- Other privacy indicators showed substantial inconsistencies, particularly for personal information, data sharing, and location-related disclosures, indicating that developer-reported transparency mechanisms do not always align with observable app artifacts.
- Children-oriented and general-audience apps exhibited similar patterns of disclosure inconsistencies, and statistical analysis revealed no significant differences between these categories, suggesting that transparency challenges extend across the broader mobile gaming ecosystem.
- Security-related disclosures, particularly regarding encryption practices, varied across apps, highlighting additional concerns regarding the clarity and reliability of information presented to users through the Data Safety framework.

These findings suggest that while the Google Play Data Safety section represents an important advancement in improving transparency in mobile app marketplaces, its effectiveness may be limited by the reliance on developer self-reporting and the inherent complexity of modern mobile app architectures. In particular, the widespread use of third-party analytics, advertising, and attribution frameworks may make it difficult for developers to precisely map app behavior to the categories defined within the Data Safety reporting framework. As a result, developers may disclose potential data practices associated with integrated libraries even when those practices are not directly observable in the app package.

Based on the empirical evidence, this study highlights several practical implications. First, developers may benefit from improved tool support and automated analysis mechanisms that assist in generating accurate Data Safety disclosures based on observable app artifacts. Second, platform providers such as Google Play may consider integrating automated validation mechanisms into the app submission process to detect inconsistencies between declared privacy practices and observable app characteristics. Such mechanisms could improve the reliability of marketplace transparency features and provide users with more accurate information when evaluating mobile apps. We believe this study opens several avenues for future research as follows:

- The static analysis presented in this work can be extended with dynamic analysis techniques to observe runtime behavior, network communication patterns, and actual data flows. Combining static and dynamic analysis would enable researchers to evaluate whether the inconsistencies observed between Data Safety disclosures and static indicators correspond to real privacy risks during app execution.
- Future studies could conduct large-scale measurements across hundreds or thousands of apps to evaluate the reliability of Data Safety disclosures across different app categories beyond mobile games, such as social networking, productivity, or financial apps.
- Longitudinal studies could examine how developer disclosures evolve as apps are updated, monetization models change, and platform reporting requirements continue to evolve. Such studies would provide valuable insights into the stability and long-term effectiveness of marketplace transparency mechanisms.
- Building on prior human-centered research, future work could explore how users interpret and rely on Data Safety labels when making installation decisions, and whether these disclosures meaningfully influence user perceptions of app privacy and security.

The results of this study can benefit multiple stakeholders. Researchers may use the findings to further investigate transparency mechanisms in mobile ecosystems and develop automated methods for detecting inconsistencies between app behavior and marketplace disclosures. Developers and app publishers may leverage the insights to improve privacy engineering practices and ensure that marketplace disclosures accurately reflect app behavior. Ultimately, this work contributes to a growing body of research indicating that improving transparency in mobile ecosystems requires not only clearer disclosure frameworks but also stronger technical mechanisms for validating the information presented to users. In addition to the empirical findings presented in this study, this work contributes to the growing body of research investigating privacy transparency in mobile app ecosystems by providing a systematic comparison between developer-reported marketplace disclosures and observable app characteristics. While previous studies have examined privacy policies, permission usage, and third-party tracking infrastructures in mobile apps, fewer studies have focused specifically on the consistency between marketplace transparency mechanisms and technical indicators extracted from app artifacts. By combining static analysis of APK files with structured analysis of Google Play Data Safety disclosures, this study provides a novel perspective on the reliability of developer-reported privacy information. The insights generated through this comparison highlight the importance of strengthening transparency mechanisms in mobile marketplaces and demonstrate the value of combining

software analysis techniques with marketplace metadata analysis in future privacy and security research.

Declaration of Competing Interest

Improving Emotion Recognition Accuracy Using a Multimodal Model (Face and Voice Video) Based on a Convolutional Neural Network (CNN)

Karnadi[1], Ermatita[2]*, Abdiansah[3]
Doctor of Engineering Program, Universitas Sriwijaya Palembang, Indonesia[1]
Faculty of Computer Science, Universitas Sriwijaya Palembang, Indonesia[2, 3]

***Abstract*—Advancements in Artificial Intelligence (AI) technology have enabled the recognition of human emotions. Along with the development of deep learning and multimodal processing methods, emotion analysis can now be performed by utilizing multiple data sources simultaneously, such as facial expressions and speech signals. However, existing emotion recognition systems still face limitations in terms of accuracy. This study aims to develop and evaluate a more accurate emotion recognition system by implementing a Convolutional Neural Network (CNN)-based prediction model that integrates facial and audio data simultaneously. The study utilizes the CREMA-D dataset, which consists of visual data in the form of facial images and audio data containing variations of emotional expressions. The research process includes data preprocessing, feature extraction, and multimodal integration using an optimized Convolutional Neural Network (CNN) architecture. The evaluation results based on the F1-score indicate that the multimodal facial and audio data enable the model to recognize emotions effectively. Model performance was measured using accuracy, precision, recall, and F1-score metrics. Experimental results show that the angry (ANG) class achieved the best performance with an F1-score of 82%, while the fear (FEA) class demonstrated the lowest performance with an F1-score of only 58%. The results further indicate that the multimodal model achieved higher accuracy than unimodal models, significantly improving generalization capability on diverse testing data. This study demonstrates an overall emotion recognition accuracy improvement of 69% through the combination of facial and audio features. The analysis of combined facial and speech features on emotion classification performance shows that the proposed model achieves good overall performance, where the integration of image and audio modalities improves the correctness of facial expression predictions. Future research is expected to further improve accuracy by incorporating additional modalities beyond facial and audio data.**

***Keywords*—Emotion recognition; CNN; multimodal learning; CREMA-D; face; voice; accuracy; deep learning**

I. Introduction

An important factor in human communication is emotion, [1], [2], [3], [4], [5], [6], [7], [8], [9], [10], [11], [12], [13], [14], [15], which influence behavior, perception, and decision-making. Research on automatic human emotion recognition has advanced rapidly thanks to advances in artificial intelligence, particularly the development of systems capable of understanding and responding to users' emotional states in a more human-like manner. To recognize human emotions more accurately, research has utilized single-modal observations [16], [17], [18], [19], [20], [21], [22], [23], [24], [25], [26], [27], [28] of either voice or facial data. Previous researchers [29], [30], [31], [32], [33], used the VGG Face architecture to extract facial features and MFCC (Mel-Frequency Cepstral Coefficients) for voice features. This system can be used to help develop more user-friendly and responsive human-computer interfaces (HCI) [34]. A three-layer system was developed, consisting of FEAM (facial analysis) [35], [36], [37], VSAM (voice analysis) [38], [39], [40], [41], [42], [43], and MERM (emotion merging for the metaverse) [44], [45], [46]. This system is designed to enhance the realism and accuracy of emotional interactions in virtual environments such as the metaverse. This system can identify seven primary emotions in real time by utilizing technologies such as FCNN (Fully Convolutional Neural Network) and MCycleGAN (Modified CycleGAN) [47], [48], [49]. In simulation experiments, the results were comparable to human perceptual capabilities, focusing on the use of voice and facial recognition technologies for social inclusion [50], [51], [52], [53], [54], [55], [56]. This system uses OpenCV, a Raspberry Pi, and facial recognition techniques such as Haar cascades and LBPH, as well as voice control, to open automatic doors. Test results show that this system is highly effective in helping people with disabilities access their homes independently, with an accuracy rate of 99.63%. All three studies indicate that the integration of auditory and visual data holds great potential for helping to develop intelligent systems that are responsive to real human needs [57]. The uncertainty that arises when using a single modality is one of the main challenges in emotion recognition. Audio signals are affected by ambient noise and the quality of the recording device, while lighting, the camera angle, or even deliberate facial expressions can influence the recording. Multimodal methods leverage the strengths of each modality and mitigate their weaknesses through the process of information fusion; this method offers a solution. In this study, we used CREMA-D, a crowdsourced multimodal dataset. This dataset consists of video recordings of actors expressing six basic emotions: happiness, sadness, anger, fear, frustration, and rage. This dataset is ideal for multimodal emotion recognition research because it includes visual, audio, and audiovisual data. To extract spatiotemporal features of facial expressions from the video data, a CNN-LSTM architecture was used. Meanwhile, the audio data was converted into Mel-spectrograms for feature extraction using a Convolutional Neural Network (CNN).

*Corresponding author.

Multimodal emotion recognition (MER) has emerged as a promising approach in this context because it can integrate various sources of emotional information, such as facial expressions and voice intonation, into a single approach. Research findings indicate that this multimodal method outperforms single-modal methods in detecting emotions.

Given these opportunities and challenges, this study aims to develop a multimodal model based on a Convolutional Neural Network (CNN) capable of integrating visual and audio information to improve the accuracy of emotion recognition.

II. Materials and Methods

A. Multimodal

Multimodal machine learning (also known as multimodal learning) is a subfield of machine learning that aims to develop and train models capable of utilizing various types of data and learning to link or combine these modalities, intending to improve predictive performance [58]. Deep learning (DL), as a cutting-edge technology, has achieved remarkable breakthroughs in many computer vision tasks due to its impressive capabilities in data representation and reconstruction. Naturally, it has been successfully applied to the field of multimodal hospital data fusion, yielding significant improvements over traditional methods. This survey aims to provide a systematic overview of deep learning-based multimodal hospital data fusion. More specifically, some key insights on this topic are presented first [59]. According to researchers [60], [61], [62], six machine learning models employing two distinct feature extraction techniques are considered foundational models.

B. Convolutional Neural Network Algorithm

A convolutional neural network is a type of neural network designed to process grid-based data, such as two-dimensional images. The term "convolution" refers to a linear algebraic operation that multiplies a filter matrix by the image to be processed [63], [64], [65], [66]. Fig. 1 shows the architecture of the proposed CNN model for facial expression recognition.

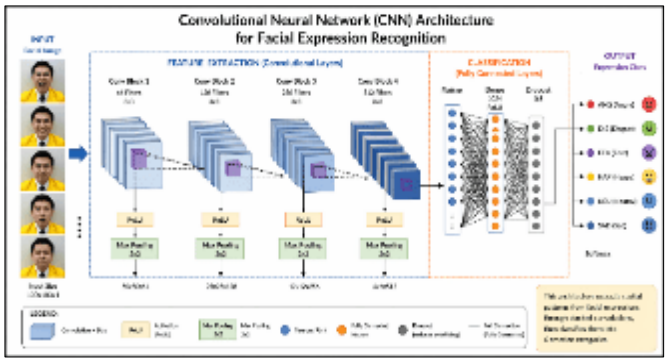

Fig. 1. Convolutional neural network architecture.

1) Data split (stratified split): Data splitting (stratified split) according to [66]. The Scikit-learn function used to split a dataset into two parts—training data and test data—is written in the Python code `train_test_split(...)`. In general, the splitting of a dataset into training and test data [67], [68], [69], [70], [71], can be expressed as follows:

$$D = \{(x_i, a_i, y_i)\}_{i=1}^{N} \quad (1)$$

$With: x_i, \epsilon\ X_{img}, a_i \in\ X_{audio}, y_i \in Y$

Divide D by:

$$D_{train} = \{(x_i, a_i, y_i)\}_{i\ =\ 1}^{0.8\ N}$$

$$D_{test} = \{(x_j, a_j, y_j)\}_{j\ =\ 1}^{0.8\ N}$$

$by\ stratification: P(y_i \in\ c_k)\ on\ D_{train} \approx P(y_i \in c_k)\ on\ D, \forall_{c_k} \in\ class$

2) Cutting to fit the batch: This function is used to reduce the amount of data by a multiple of the batch size. This is particularly important to avoid having an incomplete final batch, especially in models with multimodal inputs, such as images and audio recordings [72], [73], [74], [75].

The general formula is as follows:

$$n_{batch} = \left\lfloor \frac{N}{B} \right\rfloor \quad (2)$$

$$N' = n_{batch} . B$$

$$D' = \left\{ \left(x_i^{(1)}, x_i^{(2)}, y_i\right) \right\}_{i\ =\ 1}^{N'}$$

3) Training model: This formula is used to evaluate model performance during both training and testing [75], [76], [77]. The loss function plays a crucial role in the backpropagation process for updating the weights of a neural network through optimization (such as gradient descent) [78], [79]. It implicitly uses that average formula behind the scenes. Here is the formula used:

$$Loss = \frac{1}{N} \sum_{i=1}^{N} L(\hat{y}i, yi) \quad (3)$$

4) Predictions and evaluations: Predictions and evaluations are performed using the final-class prediction formula in a classification model that employs the softmax activation function. This formula is the standard formula used in multiclass classification with deep neural networks, particularly in the output layer of classification models that use the softmax activation function [80], [81], [82]. Here is the formula used:

$$y^{\wedge} = \text{argmax}(\text{softmax}(z)) \quad (4)$$

Proposed approach

C. Research Methods and Types

The objective of this experimental quantitative study, which employs a deep learning-based systems engineering approach, is to develop and evaluate a multimodal emotion recognition system using Convolutional Neural Networks (CNN).

D. Data Sources and Data Types

This study uses secondary data in the form of the CREMA-D dataset (Crowd-sourced Emotional Multimodal Actors Dataset), which is a publicly available multimodal dataset

accessible via the Kaggle platform (https://www.kaggle.com/datasets/orvile/crema-d-emotional-multimodal-dataset). The CREMA-D dataset consists of 7,442 video clips featuring 91 actors (48 men and 43 women) aged 20–74 who express six basic emotion categories: anger, happiness, sadness, fear, disgust, and neutral. Each sample in the dataset has been manually labeled and contains two main modalities: visual data in the form of facial expressions recorded in video format, and audio data in the form of voice intonation that can be extracted into acoustic features such as Mel-Frequency Cepstral Coefficients (MFCC). This dataset was selected for its high annotation quality and good inter-rater reliability, its representative demographic diversity of actors, and its multimodal format, which aligns with the research objectives of developing a CNN model that integrates visual and audio information for emotion regulation identification.

E. Research Phases

The research process consists of several stages carried out by the author, including: data collection, data preprocessing, multimodal feature fusion, model training, model evaluation, and system implementation, as shown in Fig. 2 below [83], [84].

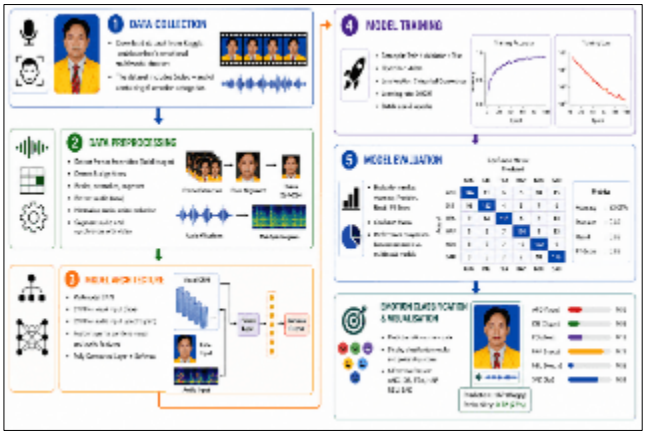

Fig. 2. Research phases.

The data collection phase involved downloading the CREMA-D dataset from the Kaggle platform, which contains 7,442 multimodal video clips across six emotion categories (anger, happiness, sadness, fear, disgust, neutral). This dataset was selected because it provides two modalities—facial expressions (visual) and voice intonation (audio)—both of which are well-labeled. The preprocessing stage involves extracting data from video files into two separate components. For the visual modality, face detection, alignment, cropping, and resizing of facial images to 64×64 pixels are performed. For the audio modality, MFCC (Mel-Frequency Cepstral Coefficients) features are extracted and converted into a spectrogram with dimensions of 40×128. Data augmentation is used to increase the diversity of the dataset and prevent overfitting.

This stage designs a dual-stream-based multimodal CNN architecture consisting of an Image Branch for processing facial images and an Audio Branch for processing audio spectrograms. Both branches use three convolutional blocks (32, 64, 128 filters) with Batch Normalization and Max Pooling. Features from both modalities are combined using concatenation in the Fusion Layer, then processed through fully connected layers for final classification.

The model was trained using a dataset split into a stratified split (70:15:15 for training, validation, and testing). The Adam optimizer with a learning rate of 0.001, a categorical cross-entropy loss function, and early stopping was used to optimize the network parameters. Training was conducted for up to 100 epochs with a batch size of 32 until the model reached convergence.

Model performance was evaluated using test data and various metrics, including accuracy, precision, recall, F1-score, and the confusion matrix. A comparison was conducted between the multimodal model and unimodal models (visual-only and audio-only) to assess the effectiveness of the fusion strategy. Statistical analysis was performed to validate the significance of the performance improvement.

The final stage presents visualizations of the classification results, including a confusion matrix, graphs showing training and validation loss and accuracy, and examples of predictions on the test set. The visualizations also include Grad-CAM to interpret the facial regions that most influence the predictions and feature importance analysis to understand the contribution of each modality to the model's classification decisions.

F. CNN Model Architecture

The proposed architecture employs a dual-stream Convolutional Neural Network (CNN) approach with two separate branches to independently process visual and audio modalities. The visual branch is designed to extract facial expression features, while the audio branch utilizes a 40×128 MFCC spectrogram as the representation of speech features. The extracted feature representations from both modalities are subsequently fused through a concatenation mechanism at the fusion layer to construct an integrated multimodal representation before the emotion classification process. Furthermore, the dataset was divided using a stratified split strategy with a ratio of 70:15:15 for training, validation, and testing sets, respectively, in order to preserve class distribution balance and ensure a reproducible experimental setup. The emotion classification process using these results is shown in Fig. 3 below [85], [86], [87], [88], [89], [90], [91], [92], [93], [94].

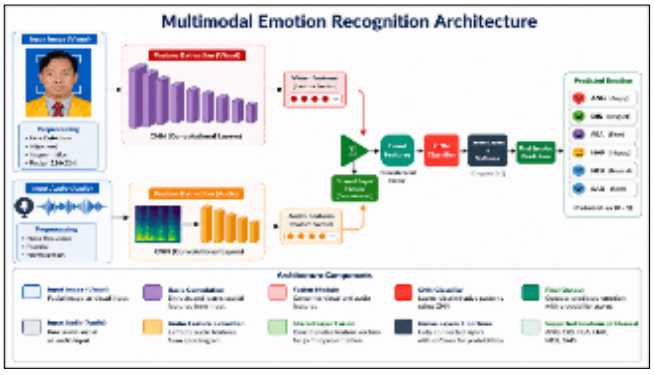

Fig. 3. CNN architecture.

Fig. 3 above shows the model architecture, which consists of two parallel branches for processing visual and audio modalities independently. In the Image Branch, 64×64×3 image inputs are

processed through three convolutional blocks with progressively larger filters (32, 64, 128), each equipped with Batch Normalization and Max Pooling. Global Average Pooling then aggregates the feature maps, followed by a 128-neuron Dense layer with Dropout, producing a 128-dimensional image feature vector.

In the Audio Branch, a 40×128×1 audio spectrogram is processed using a CNN architecture with the same filter configuration (32, 64, 128). Following Global Average Pooling, a dense layer with 128 neurons and Dropout produces a 128-dimensional audio feature vector that encodes the prosodic and spectral characteristics of the audio.

The Fusion Layer combines the two feature vectors via concatenation, producing a 256-dimensional multimodal representation. This representation is processed through two Dense layers (with 256 and 128 neurons) using Batch Normalization and Dropout to learn complex interactions between modalities. The Output Layer uses a Dense layer with a Softmax activation function to generate a probability distribution for each emotion regulation class, enabling the model to learn optimal representations and fusion strategies end-to-end.

TABLE I. DUAL STREAM CNN ARCHITECTURE FOR MULTIMODAL EMOTION RECOGNITION

Layer	Output Shape	Parameter
Input Image	255	238
Conv2D + ReLU	255	271
MaxPooling2D	255	145
Conv2D + ReLU	255	175
MaxPooling2D	215	229
MaxPooling2D	(32,32,64)	Pool size 2×2
GlobalAveragePooling	(64)	-
Input Audio MFCC	(40,128,1)	MFCC spectrogram
Conv2D + ReLU	(40,128,32)	Kernel 3×3
MaxPooling2D	(20,64,32)	Pool size 2×2
Conv2D + ReLU	(20,64,64)	Kernel 3×3
MaxPooling2D	(10,32,64)	Pool size 2×2
GlobalAveragePooling	(64)	-
Concatenate	(128)	Feature fusion
Dense + ReLU	(128)	Fully connected
Dropout	(128)	Rate = 0.5
Output Layer	(6)	Softmax activation

Table I presents the proposed dual-stream CNN architecture for multimodal emotion recognition, which consists of separate visual and audio processing branches. The visual branch processes RGB facial images through multiple convolutional and max-pooling layers to extract facial expression features, while the audio branch processes MFCC spectrogram inputs using a similar CNN structure to extract acoustic features. The extracted features from both modalities are then combined using a concatenation layer for multimodal feature fusion. The fused representation is further processed through fully connected and dropout layers before being classified into six emotion classes using a Softmax output layer. This architecture is designed to effectively learn complementary information from facial expressions and speech signals to improve emotion recognition performance.

G. Hardware and Software

Programming Language Tools and Software: Python Framework: TensorFlow/Keras or PyTorch Hardware: Nitro ANV16-71 Laptop with Intel(R) Core(TM) i7-14650HX processor, GPU, and 16 GB of RAM Supporting Software: OpenCV, Librosa, and Scikit-learn.

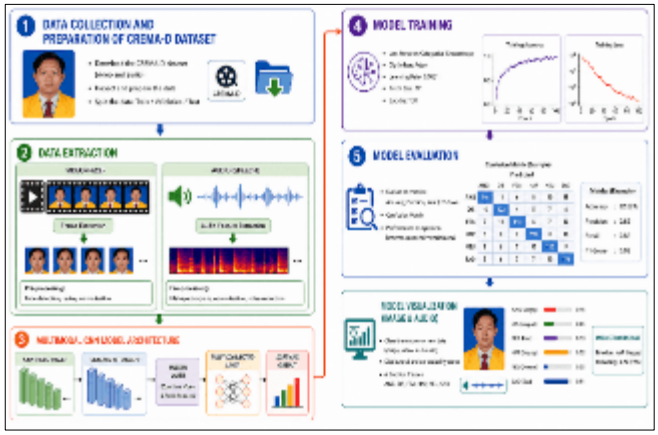

Fig. 4. Flowchart of the stages of multimodal deep learning analysis using the CNN algorithm.

Fig. 4 above illustrates the workflow of the multimodal emotion recognition system. The process begins with data collection, which includes video and audio. Both types of data then proceed to the preprocessing stage: video preprocessing to process facial frames and audio preprocessing to process audio signals. After that, the video and audio are processed by the CNN Feature Extract module to extract key features from each modality. The resulting features are then combined in the feature fusion stage, allowing the model to obtain a more comprehensive representation of emotions. Finally, the combined results are classified in the emotion classification stage to produce emotion categories.

III. RESULTS AND DISCUSSION

A. Data Collection

The dataset used in this study is the CREMA-D dataset. This dataset contains videos of actors expressing six types of emotions: happy, sad, angry, afraid, annoyed, and neutral. This dataset supports the development of voice- and image-based emotion recognition systems. To speed up the model training process, the dataset was processed using the Google platform

- Optimizer: Adam, Loss: Categorical Cross-entropy or Sparse Categorical.
- Regularization techniques: Dropout, EarlyStopping, ReduceLROnPlateau.

- Batch size and training time are adjusted based on GPU capacity; use Colab with GPU access after downloading from Kaggle.

B. Preprocessing

The datasets obtained in Section A were preprocessed. The preprocessing steps for each dataset are as follows: CREMA-D: OpenCV and a Haar cascade were used to extract faces from videos; the face images were resized to 64 x 64 pixels (for CNN) or 224 x 224 pixels (for the customized model). Audio is extracted using FFmpeg and converted into 40 x 128-dimensional MFCCs (Mel-Frequency Cepstral Coefficients). Normalization is performed to maintain input consistency.

C. Multimodal Feature Fusion

Multimodal feature fusion was performed by combining feature representations from visual and audio modalities to develop a multimodal emotion recognition system. In the visual branch, facial images were processed using a 2D CNN architecture to extract facial expression features, while in the audio branch, speech signals from the CREMA-D dataset were converted into 40×128 MFCC spectrograms and processed using a 2D CNN architecture to extract acoustic features. The extracted features from both modalities were subsequently combined at the feature fusion layer using the concatenate () method to form an integrated multimodal representation. The fused representation was then forwarded to the fully connected layer for the final emotion classification process.

D. Model Training

In this model training, the data used consists of facial and voice data obtained from the CREMA-D dataset. A multimodal Convolutional Neural Network (CNN) model was trained to classify human emotions based on the combination of facial expressions and voice features.

Before the training process was carried out, the initial step involved determining the storage location of the dataset to be used. The CREMA-D dataset was successfully uploaded and extracted into the Google Colab workspace, allowing all data to be accessed and processed by the system during the model training stage. The folder structure used consists of the main CREMA-D directory containing video data, audio data, and other supporting information required for the emotion classification process. The folder organization of the CREMA-D dataset includes the following directories:

- AudioMP3: These are .mp3 audio files that record the actor's vocal expressions based on specific emotions.
- AudioWAV: These contain the same audio files as AudioMP3 but in .wav format. This format is often used for audio signal processing because it is uncompressed and preserves the original quality.
- VideoFlash folder: This contains videos in .flv format that record both the actors' facial expressions and voices simultaneously. This allows for use in research involving the integration of visual and audio emotions.
- Docs folder: The docs folder may contain instructions or additional information about the dataset. This may include explanations of the file naming structure, emotion annotations, usage guidelines, and so on.
- ProcessedResults folder: The processedResults folder typically contains the results of processing or extracting raw data, such as feature extraction results, processed annotations, or format conversions.
- License.txt: The text file named License.txt contains the official license for the CREMA-D dataset. It is important to understand the restrictions on data use in research or publications.

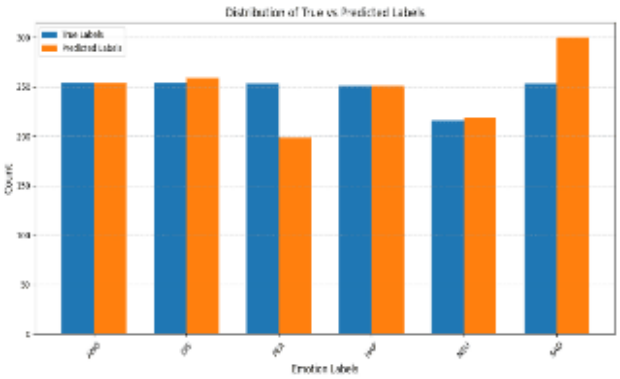

Fig. 5. Actual label distribution vs. model predictions on emotion data.

Fig. 5, the "True vs Predicted Distribution" chart, presents a comparison between the actual labels (True Labels) and the model predictions (Predicted Labels) across six emotion classes: ANG, DIS, FEA, HAP, NEU, and SAD. Overall, the true label distribution is relatively balanced, with most classes containing approximately 250 samples, while the NEU class has a slightly lower number of samples. The predicted distribution closely matches the true distribution for the ANG, DIS, HAP, and NEU classes, indicating that the model performs relatively well in recognizing these emotions. However, a noticeable discrepancy can be observed in the FEA class, where the number of predicted samples is significantly lower than the actual distribution, suggesting underprediction for this emotion category. In contrast, the SAD class shows a considerably higher number of predicted samples compared to the true labels, indicating that the model tends to over-predict the SAD emotion. Overall, the chart demonstrates that the model is capable of capturing the general distribution of most emotion classes, although some prediction bias remains, particularly between the FEA and SAD classes.

TABLE II. ACTUAL AND PREDICTED NUMBER OF LABELS BY EMOTION CLASS

Emotions Class	Number of Actual Data Points (True Labels)	Number of Model Predictions (Predicted Labels)	Difference (Predicted vs. Actual)
ANG (Angry)	255	255	0
DIS (Disgust)	255	260	+5
FEA (Fear)	255	200	-55
HAP (Happy)	250	250	0
NEU (Neutral)	215	220	+5
SAD (Sad)	255	300	+45

Table II presents the comparison between the number of actual data points (true labels) and the number of model predictions (predicted labels) for each emotion class. Overall, the model demonstrates relatively balanced prediction performance for several classes, particularly ANG and HAP, where the number of predicted samples exactly matches the actual data distribution. The DIS and NEU classes show only minor differences, with slight over-predictions of +5 samples each, indicating stable classification performance. However, significant discrepancies can be observed in the FEA and SAD classes. The FEA class is notably underpredicted by 55 samples, suggesting that the model has difficulty correctly identifying fear-related emotions. In contrast, the SAD class is over-predicted by 45 samples, indicating a tendency of the model to classify several other emotions as sadness. These results suggest that while the model is capable of maintaining good prediction consistency for some emotion categories, challenges still remain in distinguishing emotions with similar facial and acoustic characteristics, particularly between FEA and SAD.

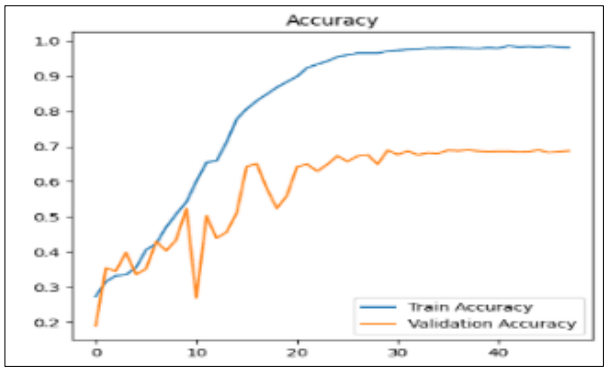

Fig. 6. Accuracy over epochs.

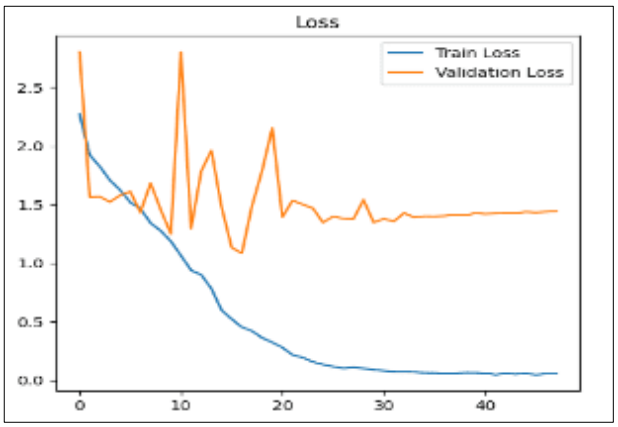
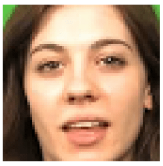
Fig. 6 illustrates the training and validation accuracy curves of the proposed multimodal CNN model during the training process. The training accuracy shows a consistent upward trend, eventually reaching approximately 98%, indicating that the model is capable of learning the training data effectively. Meanwhile, the validation accuracy also improves over time and stabilizes around 68–69%, although several fluctuations can be observed during the early and middle training epochs. The gap between training and validation accuracy suggests the presence of moderate overfitting; however, the validation performance remains relatively stable in the later epochs, indicating that the model still maintains reasonable generalization capability on unseen data.

Fig. 7 illustrates the training loss and validation loss curves of the proposed multimodal CNN model during the training process. The training loss decreases consistently and approaches zero, indicating that the model is able to learn the training data effectively. Meanwhile, the validation loss initially decreases but later exhibits noticeable fluctuations and tends to stabilize around 1.3–1.5 during the final epochs. The considerable gap between training loss and validation loss suggests the presence of overfitting, where the model performs very well on the training data but shows limited performance on the validation data. Nevertheless, the relatively stable validation loss in the later epochs indicates that the model still maintains a reasonable generalization capability on unseen data.





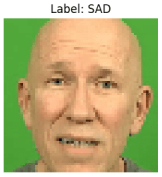


Fig. 7. Loss over epochs.

The video file format used in this study is .flv (Flash Video). This can be observed from the following code snippet: video_files = [f for f in os.listdir(video_dir) if f.endswith('.flv')], which indicates that the system only processes video files with the .flv extension. The .flv format was selected because it has a relatively small file size and is compatible with various video processing applications, thereby supporting efficiency in the video extraction and analysis processes in this study. Examples of facial and audio prediction results generated by the model used in this study are presented in Table III.

TABLE III. EXAMPLE OF SIX FACES AND AUDIO IMAGE PREDICTION

Label: NEU  Sample ke-1 — 1003_ITH_NEU_XX.flv	Label: FEA  Sample ke-2 — 1036_TSI_FEA_XX.flv	Label: HAP  Sample ke-3 — 1012_WSI_HAP_XX.flv
Label: DIS  Sample ke-4 — 1041_IOM_DIS_XX.flv	Label: SAD  Sample ke-5 — 1062_DFA_SAD_XX.flv	Label: DIS  Sample ke-6 — 1076_IWL_DIS_XX.flv

As shown in Table III, the model is capable of predicting emotions based on the combination of facial and audio data from several video samples.

The classification report generated from the evaluation of the multimodal (face and audio) emotion classification model is shown below. This report includes key evaluation metrics for each emotion class tested—namely, accuracy, recall, and F1-score as well as a summary of the model's overall performance.

Table IV presents the classification performance across six emotion classes using precision, recall, F1-score, and support (number of samples per class). The model performs best on the ANG class, achieving the highest F1-score of 0.82 with strong precision (0.82) and recall (0.82), indicating reliable and

balanced predictions. The HAP class also shows relatively good performance with an F1-score of 0.81. In contrast, DIS and FEA have the lowest F1-scores (0.67 and 0.58), reflecting the model's difficulty in accurately distinguishing these emotions. The SAD class exhibits high recall (0.61) but lower precision (0.66), suggesting that while many SAD instances are correctly identified, the model tends to overpredict this class. The NEU class shows moderate and balanced performance with an F1-score of 0.66. Overall, the model achieves an accuracy of 0.69 across 1,481 samples, with both macro and weighted averages also at 0.69, indicating consistent but still moderate performance and highlighting the need for further improvements in distinguishing similar emotional expressions.

TABLE IV. CLASSIFICATION REPORT

	Precision	Recall	F1-Score	support
ANG	0.82	0.82	0.82	254
DIS	0.67	0.68	0.67	254
FEA	0.66	0.51	0.58	253
HAP	0.81	0.81	0.81	251
NEU	0.66	0.67	0.66	216
SAD	0.56	0.66	0.61	253
Accuracy			0.69	1481
Macro avg	0.69	0.69	0.69	1481
Weighted avg	0.70	0.69	0.69	1481

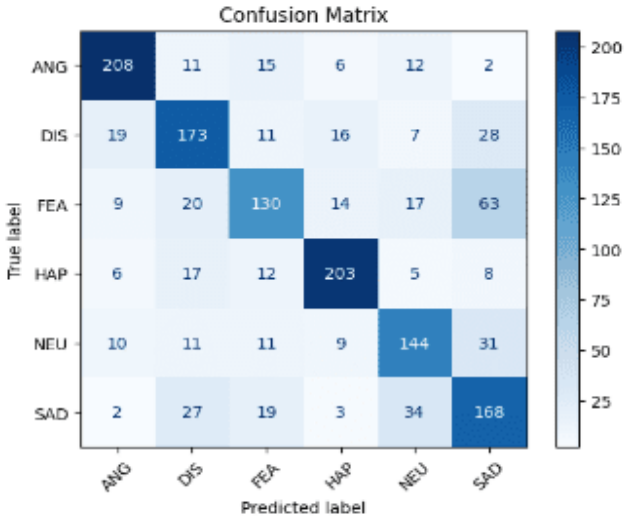

Fig. 8. Confusion matrix of emotion classification results using a multimodal CNN model.

Fig. 8 shows the confusion matrix illustrating the performance of the emotion classification model across six emotion classes, namely ANG, DIS, FEA, HAP, NEU, and SAD, where correct predictions are represented along the diagonal of the matrix. The model demonstrates the best performance on the ANG class with 208 correct predictions, followed by HAP with 203 correct predictions, DIS with 173 correct predictions, and SAD with 168 correct predictions, indicating strong recognition capability for these emotion categories. The NEU class also shows relatively good performance with 144 correctly classified samples, while the FEA class has the lowest performance with 130 correct predictions. Overall, the confusion matrix indicates that the proposed model achieves good classification performance across most emotion categories; however, it still faces challenges in distinguishing several negative emotions with similar characteristics, leading to misclassifications between classes. Visualization of Multimodal Emotion Classification Results with Confidence Scores.

TABLE V. VISUALIZATION OF MULTIMODAL EMOTION CLASSIFICATION RESULTS WITH CONFIDENCE SCORES

Class Label	Class Acc (%)	Audio Means (%)	Confidence (%)
ANG 	81.89	-0.69	92.48
DIS 	68.11	-0.17	99.91
FEA 	51.38	-0.26	83.57
HAP 	80.88	-0.58	99.99
NEU 	0.66	0.67	0.66
SAD 	0.56	0.66	0.61

Table V presents the visualization results of facial emotion classification using the proposed multimodal CNN model across six emotion classes, namely angry (ANG), disgust (DIS), fear (FEA), happy (HAP), neutral (NEU), and sad (SAD). Each facial sample is accompanied by class accuracy, audio mean,

and confidence score values, which indicate the model's confidence level in performing the prediction. The model achieves the best performance on the ANG class with an accuracy of 81.89% and the HAP class with an accuracy of 80.88%, while the FEA class shows the lowest performance with an accuracy of 51.38%, indicating that fear emotion remains difficult to distinguish from other emotions. The confidence scores for most classes are above 90%, demonstrating that the model has a high level of confidence in its classification results. In addition, the audio mean values represent the average contribution of audio features for each emotion prediction. Overall, this visualization demonstrates that the multimodal model is capable of recognizing most emotions effectively through the combination of visual and audio information, although challenges still remain in classifying emotions with similar facial expression characteristics.

IV. Conclusion

The results of this study demonstrate that the proposed multimodal CNN model is capable of effectively recognizing human emotions by integrating facial image and audio features. Based on the evaluation results, the model achieved an overall accuracy of 69%, with weighted precision, recall, and F1-score values of 0.70, 0.69, and 0.69, respectively. Among the evaluated emotion classes, the ANG (Angry) class achieved the best performance with an F1-score of 0.82, followed by the HAP (Happy) class with an F1-score of 0.81, indicating that the model was highly effective in recognizing these emotions. In contrast, the FEA (Fear) class showed the lowest performance with an F1-score of 0.58, suggesting that fear-related emotions remain challenging to distinguish due to similarities with other negative emotional expressions. The experimental results further indicate that the proposed multimodal approach was able to integrate visual and audio information effectively, resulting in stable performance across several major emotion classes. In addition, the developed CNN architecture provides an efficient and practical framework for multimodal emotion recognition through feature fusion between facial expressions and speech signals. Overall, this study confirms that combining facial and audio modalities can improve emotion classification performance and enhance the model's generalization capability on diverse testing data. Future work may focus on improving recognition performance for challenging emotion classes and incorporating additional modalities or advanced fusion strategies to further enhance classification accuracy.

Acknowledgment

The authors would like to express their sincere gratitude to all parties who have provided support, assistance, and contributions throughout the completion of this research. Special appreciation is extended to the authors and their families for their prayers, motivation, and moral support. The authors also gratefully acknowledge Universitas Sriwijaya, Palembang, for providing academic facilities, a supportive research environment, and institutional support that made this study possible.

Abstract*—In system-of-systems operations, command-and-control networks (C2Ns) increasingly exhibit hierarchical interdependence and cross-network coupling. Designing effective interlayer coupling strategies is therefore essential for improving the survivability of interdependent C2Ns under attacks. However, most existing coupling strategies are predominantly topology-driven and fail to jointly capture multipath information transmission characteristics and operational compatibility among heterogeneous nodes. To address this issue, this study proposes an interlayer coupling strategy for two-layer interdependent C2Ns, referred to as PRO, by integrating node walk betweenness and operational attributes. Specifically, a walk-betweenness-based dependency strength metric is constructed to characterize node importance from the perspective of multipath information transmission, while an operational attribute matching mechanism is introduced to evaluate the functional compatibility of cross-layer nodes. Based on these two components, the PRO strategy is developed for survivability-oriented interlayer coupling design. Simulation experiments on an air-defense command-and-control scenario are conducted under both deliberate and random attacks. The results of repeated simulations show that the proposed strategy consistently outperforms the compared baseline methods in node survival rate, observe-orient-decide-act (OODA)-oriented functional chain retention ratio, and combat link efficiency degradation rate. Compared with the baseline random strategy, under random attack, PRO improves node survival rate by 50.00%, improves the OODA-oriented functional chain retention ratio by 19.40%, and reduces the combat link efficiency degradation rate by 3.53%. These results indicate that the PRO strategy improves not only structural robustness but also the preservation of sensing–command–firepower coordination under cascading failures. The proposed method provides a joint structural–functional framework for mitigating cascading failure risks and enhancing survivability in interdependent C2Ns.

Keywords*—Interdependent command and control networks; interlayer coupling strategy; walk betweenness; operational attributes

I. Introduction

In system-of-systems operations, command-and-control networks (C2Ns) increasingly exhibit hierarchical interdependence and cross-network coupling. Sensing, command-and-control, and firepower subnetworks interact through information sharing, command dissemination, strike execution, and feedback, thereby forming an observe-orient-decide-act (OODA) process [1], [19]. Because different combat units are functionally heterogeneous and strongly interdependent, local failures may propagate across subnetworks through dependency relationships, eventually degrading not only structural connectivity but also mission-oriented coordination capability. Therefore, introducing the perspective of interdependent networks is important for understanding the survivability of C2Ns, while the design of interlayer dependency relationships becomes a key factor affecting cascading-failure propagation and mission-oriented coordination.

Existing studies have shown that coupling patterns and coupling preferences significantly affect the robustness of interdependent networks. However, command-and-control networks differ from generic interdependent networks because they contain heterogeneous operational units, hierarchical command relationships, and mission-oriented sensing–command–firepower coordination. As reviewed in Section II, existing coupling strategies are still insufficient for interdependent C2Ns because they usually rely on topology-driven criteria and rarely integrate multipath information transmission characteristics with operational compatibility among heterogeneous nodes.

To address this gap, this study proposes an interlayer coupling strategy for two-layer interdependent C2Ns, referred to as PRO. The proposed strategy integrates walk-betweenness-based dependency strength and operational attribute matching. The former characterizes node importance from the perspective of multipath information transmission, whereas the latter evaluates the functional compatibility of cross-layer heterogeneous nodes. In this way, PRO supports survivability-oriented interlayer dependency design from a joint structural–functional perspective. The main contributions of this study are as follows:

- A dependency strength metric was proposed based on node walk betweenness, considering the multipath characteristics of node information transmission.

- A node operational attribute matching metric was established to characterize the functional compatibility among heterogeneous combat units.
- An interlayer coupling strategy for two-layer interdependent C2Ns was developed by integrating dependency strength and operational attribute matching.
- Simulation experiments under deliberate and random attacks are conducted to evaluate the proposed strategy from the perspectives of node survival rate, OODA-oriented functional chain retention ratio, and combat link efficiency degradation rate, thereby verifying its structural and functional survivability advantages.

The remainder of this study is organized as follows. Section II reviews related studies on interdependent-network coupling strategies and C2N survivability analysis and clarifies the research gap. Section III abstracts the two-layer interdependent C2N model. Section IV defines the walk-betweenness-based dependency strength, operational attribute matching metric, and the proposed PRO coupling strategy. Section V presents simulation experiments and comparative results. Section VI discusses the mechanisms, practical applicability, and scalability of the proposed method. Section VII presents future research directions. Finally, Section VIII concludes the study.

II. Related Work

A. Coupling Strategies in Interdependent Networks

In recent years, studies have reported that the robustness of interdependent networks is closely related to the choice of coupling strategies [2]-[4]. Existing coupling strategies can be broadly divided into coupling-pattern-based methods and topology-preference-based methods. Coupling-pattern-based methods mainly focus on how dependency edges are organized between networks. For example, Xu and Fu [5] compared one-to-one, one-to-many, and many-to-many coupling patterns in directed-undirected interdependent networks and analyzed their effects on cascading-failure robustness. Liu et al. [6] compared assortative, disassortative, and random coupling strategies. Chen and Du et al. [7] further showed that different coupling preferences may lead to different robustness behaviors under sparse and dense coupling conditions.

Topology-preference-based methods further optimize interlayer dependency relationships according to the structural properties of nodes or edges. Hao et al. [8] proposed assortative and disassortative coupling strategies based on node proximity and shortest-path information. Wang et al. [9] proposed a locally optimized coupling strategy based on neighbor node priority connection (NPC), and Zang et al. [10] further developed a low-degree neighbor node priority connection (LDNPC) strategy. Li et al. [11] investigated edge-coupled interdependent networks under different coupling modes. Lin et al. [12] introduced a stepwise optimization strategy to dynamically adjust coupling coefficients during cascading failures. Gao et al. [13] proposed a globally homogeneous coupling strategy based on node degree and average network degree. Ji et al. [14] defined inter-degree differences and proposed random inter-degree–degree difference (RIDD) and low inter-degree–degree difference (LIDD) strategies.

These studies demonstrate that coupling patterns, coupling preferences, and topology-based optimization rules can significantly affect the robustness of interdependent networks. However, most of these strategies are developed for generic interdependent networks. Their coupling criteria are mainly derived from static topology, local connectivity, shortest-path proximity, or degree-related indicators. Therefore, they are insufficient for command-and-control networks, where interlayer dependency relationships not only represent structural connections but also reflect information transmission, command support, and operational coordination among heterogeneous combat units.

B. Command-and-Control Network Modeling and Survivability Analysis

Compared with generic interdependent networks, C2Ns have stronger mission semantics, functional heterogeneity, and hierarchical organization. Sensing, command-and-control, and firepower nodes perform different operational roles and jointly support the observe–orient–decide–act (OODA) process. Therefore, survivability analysis of C2Ns should consider not only structural connectivity but also the preservation of mission-oriented sensing–command–firepower functional chains.

Existing studies have investigated C2Ns from different perspectives. Wang et al. [15] proposed an invulnerability measure for C2Ns based on mission links. Chen et al. [16] developed a dual-layer interdependent C2N model for integrated reconnaissance-strike and OODA-loop capabilities. Chen et al. [17] investigated the dynamic evolution of C2Ns using a hypernetwork-based model. Pan et al. [18] proposed a multi-attribute-weighted modeling method for C2Ns. Ling et al. [19] discussed network-centric warfare metrics from connectivity to the OODA cycle. Zhao et al. [20] further highlighted the importance of robustness analysis of C2Ns under cascading failures.

These studies provide important foundations for C2N modeling, mission-oriented performance evaluation, and cascading-failure analysis. Nevertheless, most of them focus on network abstraction, mission-link evaluation, dynamic evolution, or failure propagation mechanisms. The problem of how to design interlayer dependency edges from a joint structural-functional perspective remains insufficiently investigated.

C. Research Gap and Motivation

The above studies indicate that coupling design is critical for the robustness of interdependent networks and that C2Ns require mission-oriented modeling and evaluation. However, three limitations remain in existing interlayer coupling studies.

First, many coupling strategies rely on degree-related indicators, which mainly describe local connectivity and cannot fully capture the indirect influence of nodes in global information transmission. Second, shortest-path-based indicators such as betweenness centrality may be insufficient for C2Ns, because information transmission in C2Ns may follow multiple redundant, non-shortest, or dynamically selected paths.

Third, topology-driven coupling strategies do not explicitly evaluate whether cross-layer nodes are functionally compatible in terms of sensing, command support, and firepower coordination.

These limitations motivate the proposed PRO strategy. By introducing walk-betweenness-based dependency strength, PRO characterizes node importance from the perspective of multipath information transmission. By introducing operational attribute matching, PRO further evaluates the functional compatibility of heterogeneous cross-layer nodes. Therefore, the proposed strategy provides a joint structural-functional coupling framework for survivability-oriented interlayer dependency design in two-layer interdependent C2Ns.

III. Abstraction of Two-Layer Interdependent C2N Modeling

A. Characterization of C2N

With the continuous evolution of combat modes and battlefield environments, the relationships among various combat units within C2Ns have become increasingly complex and diverse. Therefore, C2Ns are characterized by node heterogeneity, interlaced links, and multi-network interdependence. To simplify model analysis, we adopted the two-layer interdependent C2N model abstracted in Ref. [16]. The model was constructed as follows: 1) The firepower and sensing subnetworks were independently constructed using an attribute synergy strategy. 2) The aforementioned subnetworks were then connected using a detect–strike integration edge strategy to form the upper-layer firepower–sensing fusion network; 3) An improved tree-like network structure was used to construct the command and control subnetwork, forming the lower-layer network; 4) An interlayer coupling strategy was employed to connect the upper and lower layers, resulting in a complete two-layer interdependent C2N. The specific structure of the two-layer interdependent C2N is shown in Fig. 1. In this structure, the upper layer is the firepower–sensing fusion network, formed by integrating the sensing and firepower subnetworks; the lower layer is the command-and-control subnetwork. Intra-layer edges represent synergistic relationships within a subnetwork, while interlayer edges represent dependency relationships between subnetworks.

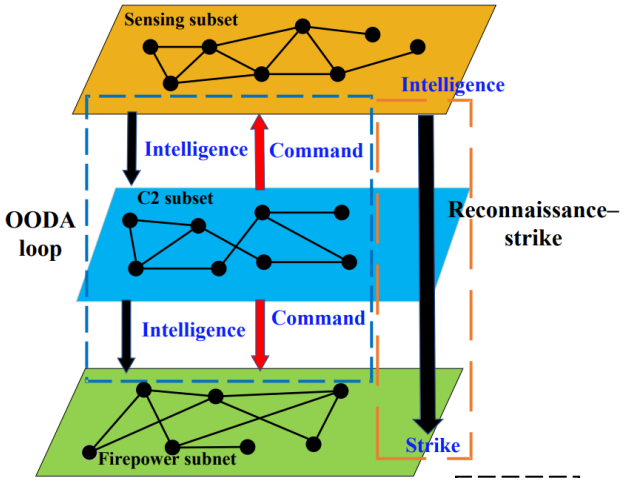

Fig. 1. Structure of the two-layer interdependent C2N.

This model can be represented by the adjacency matrix as follows:

$$W = \begin{bmatrix} W_{sf} & W_{sf-c} \\ W_{c-sf} & W_c \end{bmatrix} \quad (1)$$

where, W_{sf} is the upper-layer firepower–sensing fusion network; W_c is the lower-layer command and control subnetwork; W_{sf-c} and W_{c-sf} are the interdependent coupling networks between the two subnetworks.

B. Node Abstraction

Combat units in the C2N are abstracted as sensing nodes V_s, command and control nodes V_c, and firepower nodes V_f. Considering the operational attribute characteristics of each type of node, they are modeled as follows:

$$V(i) = \langle ID_V, T_V, H_V, Attribute_V, DependentNode_v \rangle \quad (2)$$

where, ID_V is the unique network sequence identifier of the node; T_V indicates the node type, including sensing, command and control, and firepower; H_V is the node's hierarchical level, with lower values indicating higher levels; $Attribute_V$ is the normalized attribute vector of the node, modeled as a scenario-based role-related descriptor. For sensing nodes, it mainly characterizes detection-related capability; for command-and-control nodes, it mainly characterizes communication and command-support capability; and for firepower nodes, it mainly characterizes strike-related capability. $DependentNode_v$ is the node(s) on which node i is dependent. To clarify the source and semantic meaning of the operational attributes used in this study, the attribute categories and representative components of sensing, command-and-control, and firepower nodes are summarized in Table I.

TABLE I. Operational Attribute Categories and Semantic Meanings of Heterogeneous Nodes in the C2N

Node type	Attribute semantic meaning	Representative attribute components
Sensing node	Detection-related capability	Detection range, detection accuracy, reconnaissance timeliness
Command-and-control node	Communication and command-support capability	Bandwidth, signal-to-noise ratio, hierarchical level
Firepower node	Strike-related capability	Strike range, firepower intensity, response timeliness

C. Link Abstraction

Combat units within the C2N exchange and process different types of information via wired, wireless, and other communication means. Edges can be represented as

$$E(m) = \left\langle ID_{E(m)}, type_{E(m)}, DependentAttribute_{E_{(m)}} \right\rangle \quad (3)$$

where, $ID_{E(m)}$ is the identifier of an interlayer edge; $type_{E(m)}$ is the edge type, including intra-layer synergistic and interlayer dependent edges; $DependentAttribute_{E_{(m)}}$ is the dependency strength of a dependent edge.

IV. Interlayer Coupling Strategy for Two-Layer Interdependent C2Ns

A. Node Walk Betweenness

C2Ns employ diverse communication methods, and information dissemination follows multipath transmission patterns. Taking into account the weights of different path lengths and based on the concept of betweenness, we introduced the notion of walk betweenness to characterize the frequency with which a node acts as an intermediary across all possible walk paths. Walk betweenness accounts for path length weighting. The core idea is to count the number of times a node appears in walks from every source to the destination, using a decay factor to handle the issue of infinite paths.

The walk betweenness of node v_i is defined as the proportion of the information volume ultimately received by that node in the total information volume of the network when each node in the network sequentially acts as a unique source to send an initial message (total information normalized to 1), and the message propagates according to a hierarchical walk rule. The calculation procedure is as follows:

Step 1: Initialize the information volume of each node in the C2N to I_0. Assume that in each information walk iteration, only one node sends information while others receive it. The initial information volume of a node is

$$H_0 = [I_0, I_0, \cdots, I_0]_N \tag{4}$$

where, N is the total number of nodes.

Step 2: During the walk process, the information volume of node v_j is evenly distributed to its neighboring nodes, and its own information volume is reset to zero. If the degree of node v_j is k_j, then after n iterations, the information volume received by a directly connected node v_i is

$$H_n(v_i) = H_{n-1}(v_j)/I_0 g k_j \tag{5}$$

where, $i \neq j$ and $H_{n-1}(v_j)$ are the information volume possessed by node v_j after the $(n\text{-}1)$th iteration. The total number of iterations does not exceed the network hierarchy level D, i.e., $n = 0,1 \cdots, D$.

Step 3: Let G denote the set of all nodes directly connected to node v_i. After n iterations of information walks, traversing G yields the information volume of node v_i:

$$H_n(v_i) = \sum \frac{H_{n-1}(v_j)}{I_0 k_j} g a_{ij} \tag{6}$$

where, a_{ij} is the connection between nodes i and j, $n = 0,1 \cdots, D$, $v_j \in A$.

Step 4: After D rounds of information propagation, the total information volume accumulated by each node in the network is computed, yielding the walk betweenness for each node. The resulting set of walk betweenness values is

$$H_G = [H(1), H(2), \cdots, H(N)] \tag{7}$$

B. Dependency Strength Based on Node Walk Betweenness

Dependent edges reflect the relationship of information exchange between subnetworks. The more frequent the exchange, the closer the dependency and the greater the mutual influence between networks. Dependency strength is commonly used to quantify the degree of such interdependence. The strength of dependency not only reflects the extent of mutual influence and control between networks but also affects the propagation speed of cascading failures within interdependent networks.

Most existing studies define dependency strength based on node degrees. However, this only captures local connectivity and ignores indirect influence, thus failing to measure the intermediary role of nodes in the global network. A few studies use betweenness centrality, assuming that information is transmitted only along shortest paths, thereby overlooking the diversity and randomness of path selection during information transmission. By simulating the random walk process, walk betweenness more accurately characterizes functional dependencies and path diversity among nodes. Accordingly, we defined a new metric for dependency strength based on walk betweenness, as follows:

$$DS(A_i, B_j) = b_i b_j + \alpha \tag{8}$$

where, $b_i = H_A(i)$ is the walk betweenness of node i in subnetwork A and $b_j = H_B(j)$ is the walk betweenness of node j in subnetwork B. The parameter α $(0 < \alpha < 1)$ is an adjustment coefficient introduced to avoid cases where edge nodes may have a walk betweenness of zero.

C. Node Operational Attribute Matching

Sensing nodes refer to combat units equipped with early warning, detection, reconnaissance, and surveillance capabilities, such as early warning radars and reconnaissance radars. Command-and-control nodes are responsible for intelligence fusion, command dissemination, information coordination, and decision support, such as command organizations and intelligence processing agencies. Firepower nodes refer to combat units capable of interception, attack, and destruction. Because these three types of nodes play different roles in the command-and-control process, their operational attributes are heterogeneous. Therefore, quantifying node operational attributes and analyzing attribute matching provides a basis for constructing functionally coordinated interlayer dependency relationships.

In this study, node operational attributes are modeled as scenario-based normalized descriptors constructed according to node roles, hierarchical characteristics, and combat-task semantics in the considered air-defense command-and-control scenario. These attributes are not intended to reproduce exact equipment specifications; instead, they provide a unified and comparable description of heterogeneous node characteristics for interlayer matching analysis. Specifically, for sensing nodes, the attribute vector mainly characterizes detection-related capability; for command-and-control nodes, it mainly characterizes communication and command-support capability; and for firepower nodes, it mainly characterizes strike-related capability.

In the upper-layer network, a node's operational capability depends not only on its intrinsic capability but also on its ability to cooperate with neighboring nodes. Therefore, the operational capability of a node in the upper-layer network is defined as

$$COM_A(i) = \sum_{i=1}^{n} \omega_i att_i + \sum_{k \in z_i} c_{ik} \quad (9)$$

where, $\sum_{i=1}^{n} \omega_i att_i$ is the weighted sum of node i ' s operational attributes, quantifying its intrinsic operational capability as an independent combat unit, and $c_{ij} = \sqrt{\sum_{z=1}^{n} (att_z^i - att_z^j)^2}$ is the cooperation factor between node i and its neighboring nodes, indicating the degree of difference between the node and its neighboring nodes in terms of attribute vectors. This factor helps compensate for individual capability gaps and reflects the cooperative capability of node i in the upper-layer network. In the simulation, the components of the attribute vector within the same node category are normalized and assigned equal weights.

In the lower-layer network, nodes mainly function as command-and-control units. Their role is not direct combat execution, but command dissemination, information transmission, and operational support. Therefore, the capability of a lower-layer node is characterized in terms of command-support capability rather than direct combat capability. Considering that the communication capability of a network node is determined by its inherent hardware characteristics and is positively correlated with its hierarchical level [18], the capability of a lower-layer command-and-control node is defined as:

$$C_COM_B(i) = \frac{CP(i) gH_i(i)}{CP_{\max} gH_{\max}} \quad (10)$$

where, $CP(i) = B(i)\log_2(1 + SNR(i))$ represents the Shannon channel capacity of node i, indicating its physical-layer information throughput capability; $H(i)$ denotes the hierarchical level of node i; both $B(i)$ and $SNR(i)$ are elements of the node's attribute vector attribute_$V(i)$.

By integrating the node operational attributes of both upper and lower networks, the interlayer node operational attribute matching is computed as follows:

$$MS_{ij} = \frac{\frac{M_{ij}}{AT_{ij}}}{\sum_{j \in B} M_{ij}/AT_{ij}} \quad (11)$$

where, $M_{ij} = \frac{1}{1+|COM_A(i) - COM_B(j)|}$ is the matching index between nodes i and j; $AT_{ij} = \frac{L_{ij}}{\max_{i,j} L_{ij}}$ is the normalized path length between nodes i and j. A larger matching value indicates that the two nodes are more compatible in terms of operational role and transmission convenience and are therefore more suitable for establishing an interlayer dependency relationship.

D. Interlayer Coupling Strategy Based on Dependency Strength and Operational Attribute Matching

In contrast to intra-layer edge strategies, interlayer edge strategies must account for both the dependency strength between nodes and their operational attribute matching. Dependency strength describes the inter-node relationship from the perspective of multipath information transmission, while attribute matching quantifies node compatibility based on operational attributes. To this end, we proposed an interlayer coupling strategy for two-layer interdependent C2Ns that integrates dependency strength and operational attribute matching. In addition, to prevent load imbalance and reduce the risk of cascading failures, an adjustment coefficient was introduced. This ensures that sensing nodes preferentially connect to upper-layer nodes in the command-and-control subnetwork, while firepower nodes preferentially connect to lower-layer nodes in the same subnetwork. The edge connection probability for the interlayer coupling strategy is calculated as

$$p_{ij} = \begin{cases} \frac{DS_{ij} MS_{ij}}{\sum_{j \in N_c} DS_{ij} MS_{ij}}, type(A_i) \in T_s \\ \frac{DS_{ij} MS_{ij} H(j)}{\sum_{j \in N_c} DS_{ij} MS_{ij} H(j)} type(A_i) \in T_f \end{cases} \quad (12)$$

where, i is a node in the upper-layer network; j is a node in the lower-layer network; N_c is the set of command-and-control nodes; $H(j)$ is the hierarchical level of node j; T_s and T_f are the sets of sensing and firepower nodes, respectively. The procedure for calculating the edge connection probability under the proposed interlayer coupling strategy is as follows (Algorithm 1):

Algorithm 1: Coupling strategy

Input: Network A, network B, attribute vectors of nodes: attribute_$V(A)$, attribute_$V(B)$

Output: Coupled network (A, B)

Step 1: Initialize nodes in network A and form queue Q_A.

Step 2: Initialize nodes in network B and form queue Q_B.

Step 3: Calculate the walk betweenness for each node using Eq. (4)-(6).

Step 4: Sequentially select from Q_A the nodes that have not yet formed coupling edges, denoted as node i. Once Q_A is fully traversed, proceed to Step 10.

Step 5: Use Eq. (8) and Eq. (11) to compute the dependency strength and attribute matching between node i and all nodes in Q_B.

Step 6: Determine the type of node i, compute its dependency probabilities with nodes in Q_B using Eq. (12), and select a dependent node j via the roulette selection method.

Step 7: Identify the neighboring nodes of i and j, denoted as Q_i and Q_j, respectively.

Step 8: Remove node j from queue Q_B. If Q_B is empty, return to Step 2.

Step 9: Treat queues Q_i and Q_j as local neighborhoods and repeat Steps 5–6. Continue this process until all Q_i pairs are traversed, then return to Step 4.

Step 10: End.

Time Complexity: $O(mn)$, where m and n are the total number of nodes in the upper and lower layers of the two-layer structure, respectively.

The above complexity analysis shows that the computational burden of the proposed method mainly arises from path-related structural evaluation and interlayer attribute matching. As the network scale increases, the structural computation becomes the dominant cost, which makes the current implementation more suitable for offline architecture optimization and periodic survivability assessment than for strict real-time operational scenarios. Nevertheless, the proposed framework remains

extensible to larger-scale command-and-control networks. Its scalability can be further improved through candidate-pair pruning, caching, or local updating of structural information, and parallel implementation of the evaluation process.

V. Simulation Analysis

To validate the effectiveness of the proposed strategy, we conducted simulation experiments, covering parameter analysis, interlayer coupling strategy analysis, and network model analysis. Based on an air defense command and control system, the initial parameter values were as follows: the total number of nodes is 580, including 160 command and control nodes (n_c = 160), 150 sensing nodes (n_s = 150), and 270 firepower nodes (n_f = 270); the command span was set as k = 3 and the command hierarchy as h = 4. For all simulations, the components of each node's attribute vector were normalized and assigned equal weights within the same node category to control the number of free parameters and ensure a fair comparison among different coupling strategies.

Two attack strategies, namely deliberate attack and random attack, were adopted. Unless otherwise specified, each reported result was obtained from 200 independent simulation runs. For each metric, the mean value across runs is reported, and the shaded region in the corresponding figures represents the 95% confidence interval. In this way, the robustness of the observed performance differences can be evaluated not only in terms of average behavior but also in terms of statistical variability across repeated simulations.

A. Analysis of Dependency Strength Adjustment Parameter α

To determine a suitable value for the dependency strength adjustment parameter α, we conducted simulation experiments to assess network performance as α varies. Given the large scale of the network (580 nodes in total), a significant number of nodes must be removed to clearly observe changes in node survival rate. Fig. 2 shows the variation in node survival rate with α after removing 100–150 nodes under deliberate attack. Fig. 3 shows the same under random attack with 300–350 nodes removed. From Fig. 2 and 3, clearly, the node survival rate peaks at α = 0.3. Therefore, this value is used in all subsequent experiments.

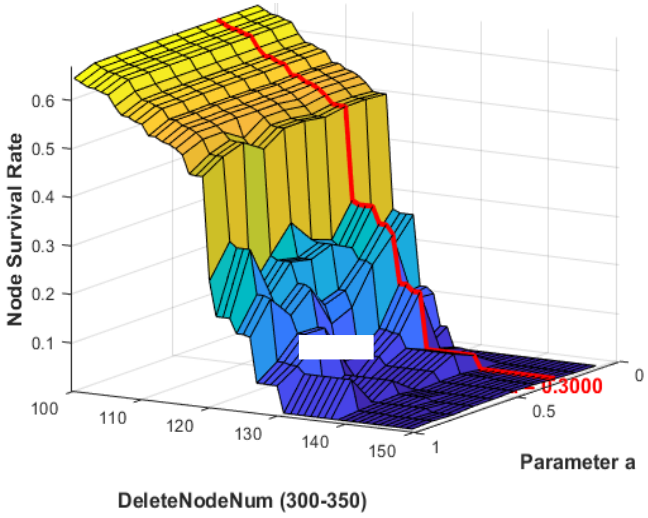

Fig. 2. Node survival rates under different α values (deliberate attack).

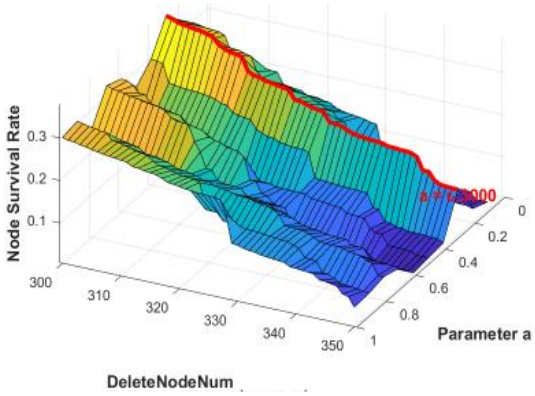

Fig. 3. Node survival rates under different α values (random attack).

B. Analysis of Interlayer Coupling Strategies

To validate the rationality of the proposed interlayer coupling strategy, we conducted comparative simulations focusing on different dependency strengths, node operational attribute matching levels, and interlayer coupling connection strategies.

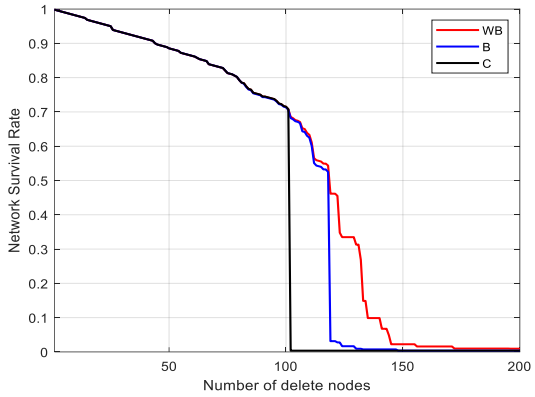

Fig. 4. Node survival rates under different dependency strengths (deliberate attack).

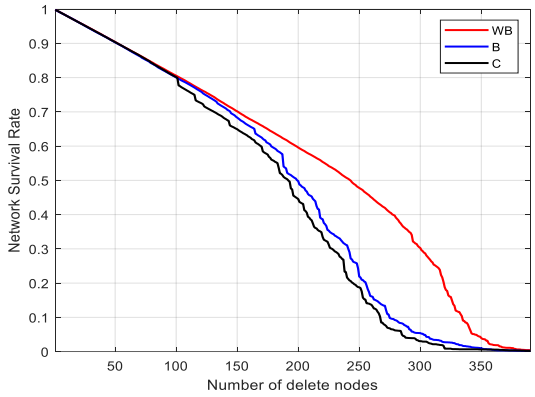

Fig. 5. Node survival rates under different dependency strengths (random attack).

1) Comparative analysis of different dependency strengths: Three types of dependency strengths were selected for comparison: walk betweenness (WB), betweenness centrality (B), and closeness centrality (C). Fig. 4 and Fig. 5 show the node survival rates under deliberate and random attacks,

respectively, for these three strategies. Under deliberate attack (Fig. 4), the node survival rates of all three methods were initially similar. However, after removing 100 nodes, an inflection point appeared, indicating the onset of large-scale cascading failures. For networks constructed using betweenness and closeness centrality, node survival rapidly dropped to zero. In contrast, the dependency strength based on WB proposed in this study delayed cascading failures. Its survival rates did not drop to zero until 150 nodes were removed. Under random attack (Fig. 5), the proposed method clearly outperformed the other two. This advantage is attributed to the use of WB, which accounts for multipath information transmission and dynamic network behavior, thereby mitigating abrupt performance degradation.

2) Comparative analysis of different node matching degrees: Three scenarios were compared: operational attribute matching (AM) proposed in this study, matching based on the node's hierarchical level (LM), and random matching (RM). Fig. 6 and 7 illustrate the node survival rates under deliberate and random attacks, respectively, for these three matching strategies. Under both attack strategies, the proposed matching degree achieved the highest node survival rate and the best network survivability. This is because considering node matching degree helps avoid unbalanced dependency edges formed between nodes with significantly different combat capabilities, thereby suppressing cascading failures.

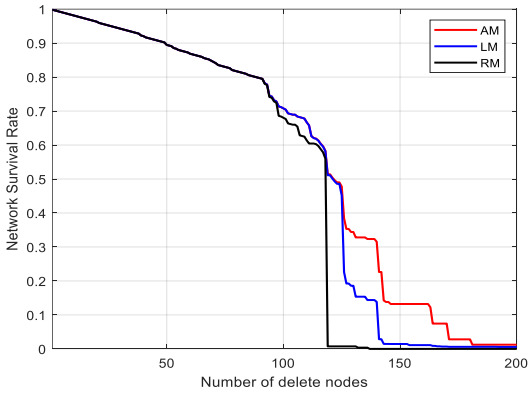

Fig. 6. Node survival rates under different node matching degrees (deliberate attack).

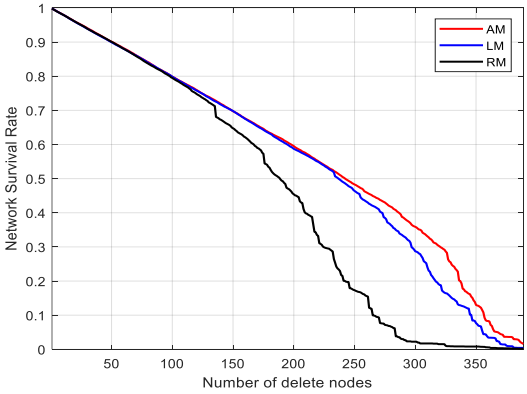

Fig. 7. Node survival rates under different node matching degrees (random attack).

3) Comparative analysis of different interlayer coupling strategies

a) Node survival rate analysis: Eight interlayer coupling strategies were evaluated: the proposed strategy (PRO), the strategy from Ref. [16] (DB), random (RL), neighbor NPC, degree-assortative coupling (BAL), degree-disassortative coupling (BDL), betweenness-assortative coupling (DAL), and betweenness-disassortative coupling (DDL). Fig. 8 and 9 show the node survival rates under deliberate and random attacks, respectively. As can be seen in the figures, under both attack strategies, the proposed PRO strategy achieved the highest node survival rate and better network survivability. This is because WB captures the global influence of a node under multipath and random walk conditions, rather than relying solely on the shortest path. The importance of key nodes is distributed across more paths instead of being concentrated in a few dominant nodes. Therefore, even after partial node failures, the network can still maintain functionality through non-shortest paths, thereby delaying the sharp decline in node survival rate.

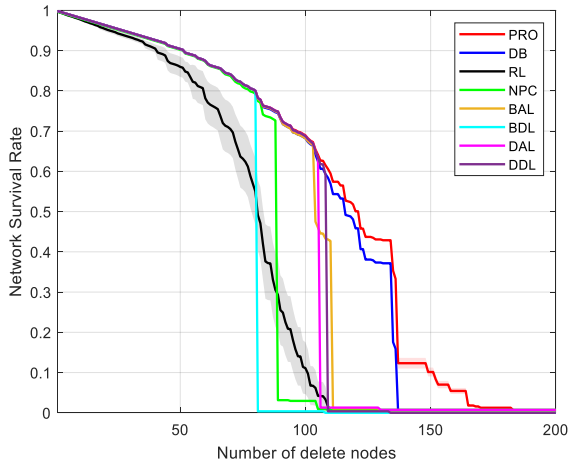

Fig. 8. Node survival rates under different interlayer coupling strategies (deliberate attack).

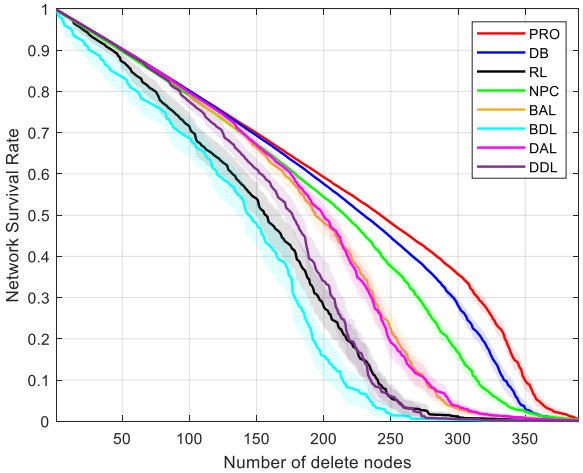

Fig. 9. Node survival rates under different interlayer coupling strategies (random attack).

b) OODA-Oriented functional chain retention analysis: To further evaluate whether the proposed strategy can preserve the functional stability of the command-and-control process, an OODA-oriented functional chain retention ratio is introduced. This metric is used to measure the extent to which the network can still maintain effective sensing–command–firepower coordination after node failures and cascading effects.

Specifically, an effective OODA-oriented functional chain is considered to exist if a surviving sensing node can still coordinate with a surviving command-and-control node, and the latter can further support a surviving firepower node through the remaining intra-layer and interlayer connections. Then, the OODA-oriented functional chain retention ratio is defined as the ratio between the number of effective functional chains after attack and that in the initial network.

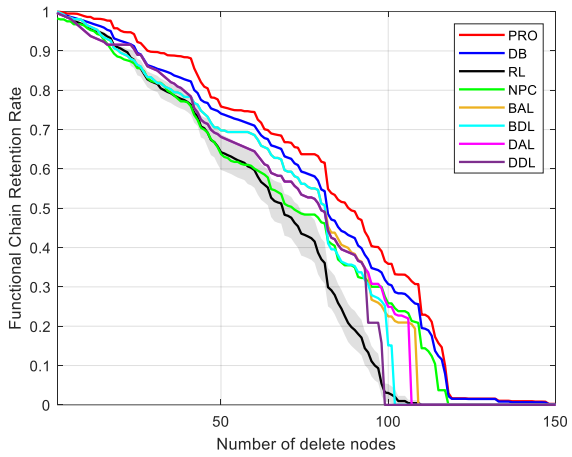

Fig. 10. OODA-oriented functional chain retention ratios under different coupling strategies (deliberate attack).

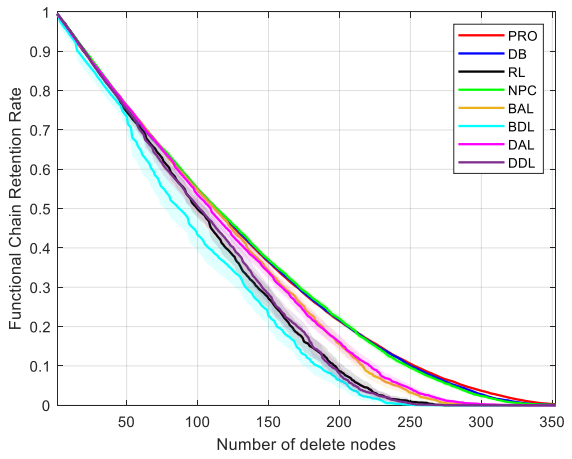

Fig. 11. OODA-oriented functional chain retention ratios under different coupling strategies with 95% confidence intervals (random attack).

Fig. 10 and Fig. 11 show the OODA-oriented functional chain retention ratios under deliberate and random attacks, respectively. As can be seen from the figures, under both attack strategies, the PRO strategy maintained the highest functional chain retention ratio and exhibited the slowest degradation trend among all compared methods. This indicates that the proposed strategy is more effective in preserving the sensing–command–firepower coordination required by the command-and-control process, rather than merely retaining a larger number of surviving nodes.

Compared with the baseline strategies, the advantage of PRO in this metric can be attributed to two aspects. First, the walk-betweenness-based dependency strength better captures multipath information transmission characteristics, thereby reducing the vulnerability caused by over-reliance on shortest-path-dominated key nodes. Second, the operational attribute matching mechanism reduces functionally mismatched interlayer couplings, which helps preserve semantically compatible sensing–command–firepower chains under attacks. Therefore, the superiority of PRO is reflected not only in structural robustness but also in functional robustness related to OODA-oriented command-and-control stability.

c) Combat link efficiency analysis: The same eight strategies were used to compare combat link efficiency. Fig. 12 and Fig. 13 show the degradation rate of combat link efficiency under deliberate and random attacks, respectively. As seen in the figures, under both attack strategies, the PRO strategy displayed the best combat link efficiency, with lower degradation rates of combat link efficiency than other models. This is because the proposed strategy considers node operational attributes, which reduces functional mismatches between interlayer-coupled nodes and improves overall network operational effectiveness. These results further validate the rationality of the proposed model.

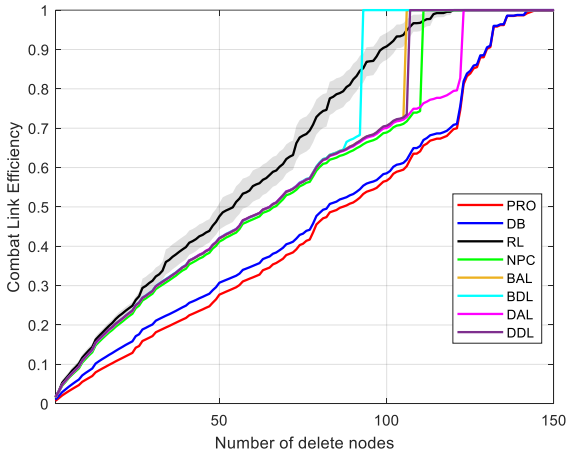

Fig. 12. Combat link efficiency degradation rate under different coupling strategies (deliberate attack).

d) Comprehensive analysis: Tables II and III summarize the average node survival rate, OODA-oriented functional chain retention ratio, and combat link efficiency degradation rate of different interlayer coupling strategies under deliberate and random attacks, respectively. All reported values are the mean results over 200 independent simulation runs, while the corresponding line figures present the 95% confidence intervals as shaded bands. Degree-disassortative coupling and betweenness-disassortative coupling strategies were excluded because of their significantly inferior overall performance.

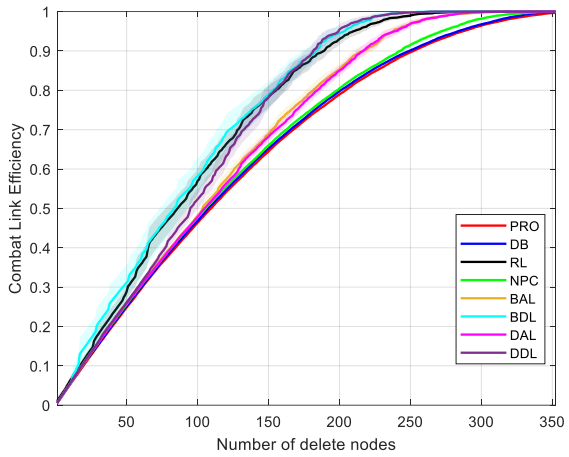

Fig. 13. Combat link efficiency degradation rate under different coupling strategies (random attack).

The results show that the PRO strategy achieves the best overall performance under both attack modes. Under deliberate attack, PRO attains the highest node survival rate and the lowest combat link efficiency degradation rate, while maintaining a competitive functional chain retention ratio close to that of the best-performing baseline. Under random attack, PRO performs best among all compared strategies in all three metrics.

Compared with the baseline random strategy (RL), PRO improves node survival rate by 24.82% and 50.00% under deliberate and random attacks, respectively. Meanwhile, the OODA-oriented functional chain retention ratio is improved by 13.38% and 19.40%, and the combat link efficiency degradation rate is reduced by 6.37% and 3.53%, respectively. These results indicate that the superiority of PRO is consistently reflected in structural robustness, functional chain preservation, and performance maintenance.

TABLE II. COMPARISON OF NETWORK PERFORMANCE UNDER DIFFERENT COUPLING STRATEGIES (DELIBERATE ATTACK)

	Average node survival rate (%)	Average functional chain retention ratio (%)	Average combat link efficiency degradation rate (%)
PRO	58.79	19.58	71.23
DB	56.39	20.76	71.67
NPC	54.61	17.58	73.26
BAL	51.24	18.15	74.21
DAL	48.12	17.90	75.17
RL	47.10	17.27	76.08

The advantage of PRO mainly stems from two aspects. First, walk betweenness characterizes node importance from the perspective of multipath information transmission, thereby alleviating the excessive reliance on shortest-path-dominated structural indicators in conventional coupling methods. Second, the operational attribute matching mechanism improves functional compatibility between cross-layer nodes, which helps preserve sensing–command–firepower coordination and suppress the propagation of cascading failures.

TABLE III. COMPARISON OF NETWORK PERFORMANCE UNDER DIFFERENT COUPLING STRATEGIES (RANDOM ATTACK)

	Average Node survival rate (%)	Average functional chain retention ratio (%)	Average combat link efficiency degradation rate (%)
PRO	56.55	32.07	87.10
DB	53.74	31.91	87.22
NPC	49.98	32.00	89.05
BAL	44.79	29.58	89.36
DAL	43.85	29.54	89.55
RL	37.70	26.86	90.29

C. Network Model Analysis

To further evaluate the advantages and disadvantages of the proposed edge connection strategy, we constructed six network models (Table IV). Among them, M1, M2, M4, and M5 adopt the attribute synergy strategy for constructing the upper-layer subnetworks (sensing subnetwork and firepower subnetwork), while M3 and M6 apply the scale-free edge connection strategy. In the detect–strike integration phase, M1 and M4 employ the node efficiency prioritization strategy, whereas M2, M3, M5, and M6 adopt the degree prioritization strategy. All models use an improved tree-like network model for the intra-layer lower-layer subnetwork (command and control subnetwork). Based on these models, two categories of experiments were designed: (i) To compare the performance of the proposed strategy with that of the method in Ref. [16] under the same subnet construction configurations, with comparison groups including M1 vs. M4, M2 vs. M5, and M3 vs. M6; (ii) To evaluate the applicability of the proposed strategy under different subnet construction models, with comparison groups including M1, M2, and M3.

TABLE IV. CONSTRUCTION STRATEGIES FOR NETWORK MODELS

Model	Intra-layer Upper Network Linking Strategy		Intra-layer Lower Network Linking Strategy	Inter-layer Coupling Strategy
	Perception–Firepower Subnet Linking Strategy	Integrated Reconnaissance–Strike Operation Mode Linking Strategy		
M1 (Pro Model)	Attribute-prioritized	Node-efficiency-prioritized	Improved tree topology	Proposed method
M2	Attribute-prioritized	Degree-prioritized	Improved tree topology	Proposed method
M3	Scale-free	Degree-prioritized	Improved tree topology	Proposed method
M4	Attribute-prioritized	Node-efficiency-prioritized	Improved tree topology	Method of Ref. [16]
M5	Attribute-prioritized	Degree-prioritized	Improved tree topology	Method of Ref. [16]
M6	Scale-free	Degree-prioritized	Improved tree topology	Method of Ref. [16]

1) Node survival rate analysis: Under random attack (Fig. 15), all models had survival rate curves that were nearly

linear with similar slopes in the early stages. In the later stages, under the same intra-layer connection strategy, the proposed strategy slightly outperformed the method in Ref. [16], with only minor differences between the curves. This suggests that during random node removal, even with different coupling strategies, each model can rely on the inherent scale-free redundancy of the network to maintain connectivity in the early phase.

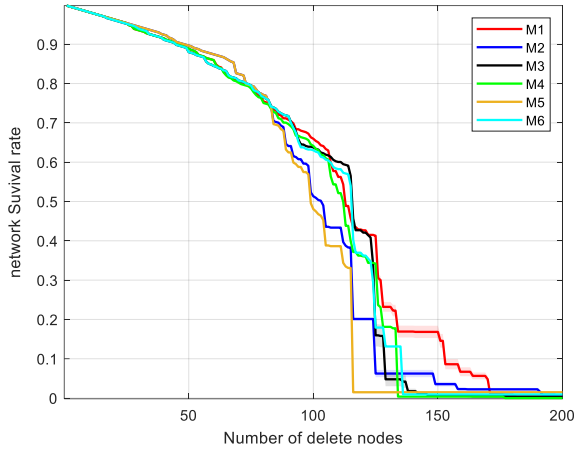

Fig. 14. Node survival rates of different network models (deliberate attack).

Under deliberate attack (Fig. 14), inflection points appeared in the node survival rate curves during the mid-to-late phases. A steep "step-wise decline" occurred after every few dozen node removals, corresponding to the cascading failure effect in interdependent networks. Under deliberate attack, M3 and M6 were the first to collapse. Their survival rates dropped sharply when 120 nodes were removed. M2 and M5 followed, collapsing when 150 nodes were deleted. M4 failed around 160 node removals. M1 had the highest stability: it survived until 180 nodes were removed. Thus, the proposed strategy performed best under conditions of attribute synergy and node efficiency prioritization, but was slightly less effective in scale-free configurations. As the proposed strategy introduces operational AM, it effectively optimizes node selection based on node operational attributes. However, when subnets are constructed using scale-free connections, this introduces interference to the strategy. In contrast, scale-free subnetworks inherently reduce overall network survivability. Comparisons among M1 vs. M4, M2 vs. M5, and M3 vs. M6 demonstrated that the proposed strategy consistently outperformed the method in Ref. [16] under various subnet modeling conditions, highlighting its robustness and general applicability.

2) OODA-Oriented functional chain retention analysis: To further examine whether the proposed strategy can maintain functional stability under different network structures, the OODA-oriented functional chain retention ratios of different network models were compared. Fig. 16 and Fig. 17 show the corresponding results under deliberate and random attacks, respectively.

As can be seen from the figures, although the overall degradation patterns vary across network models, the PRO strategy consistently maintains a higher OODA-oriented functional chain retention ratio than the compared methods in most cases. This indicates that the proposed strategy is able to preserve sensing–command–firepower coordination more effectively under different structural configurations, rather than exhibiting advantages only in a specific network instance.

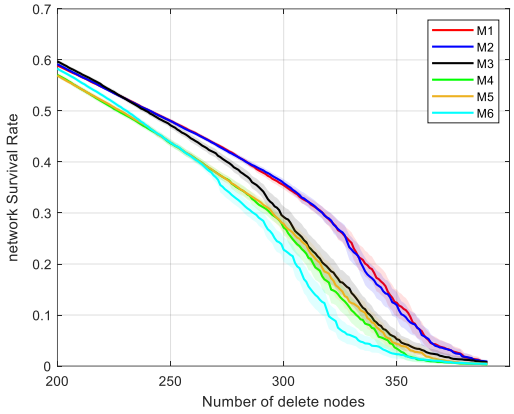

Fig. 15. Node survival rates of different network models (random attack).

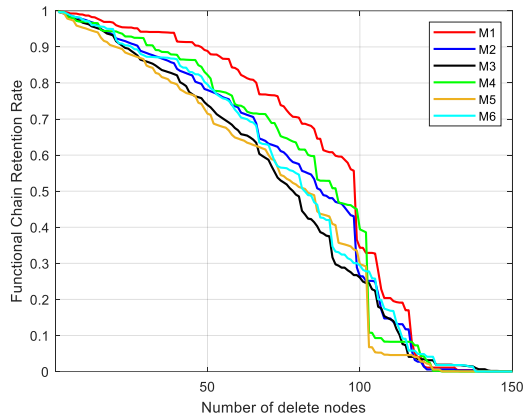

Fig. 16. OODA-oriented functional chain retention ratios under different network models (deliberate attack).

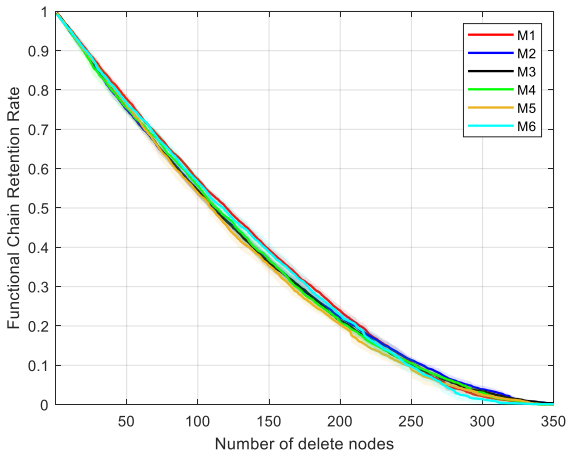

Fig. 17. OODA-oriented functional chain retention ratios under different network models (random attack).

3) Combat link efficiency analysis: Under both random and deliberate attacks (Fig. 18 and Fig. 19), M1 consistently maintained the lowest degradation rate of combat link efficiency. As the number of removed nodes increased, the proposed model demonstrated a clear advantage in terms of the degradation rate of combat link efficiency, compared to the other three models. This is attributed to the fact that the proposed strategy more effectively selects nodes with matched combat capabilities across the two subnetworks, particularly within the attribute-synergy subnetwork, thereby reducing combat capability imbalances between nodes and enhancing overall network robustness.

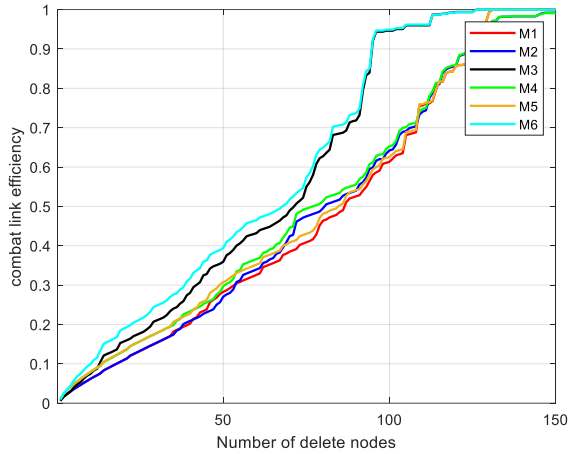

Fig. 18. Combat link efficiency degradation rate of different network models (deliberate attack).

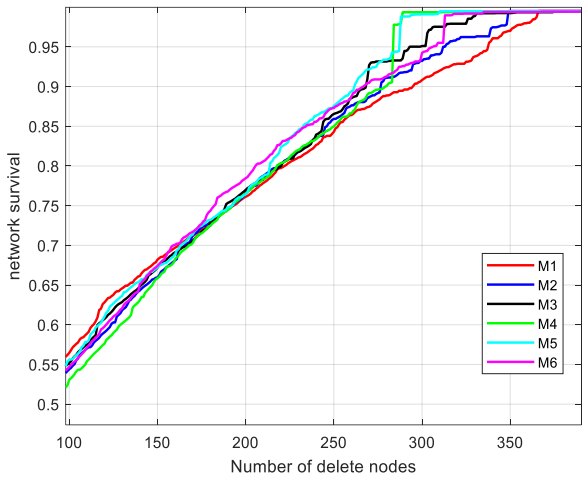

Fig. 19. Combat link efficiency degradation rate of different network models (random attack).

VI. Discussion

The simulation results demonstrate that the advantage of PRO is not limited to a single metric or a specific attack mode. Compared with topology-driven coupling strategies, PRO achieves better overall performance in node survival rate, OODA-oriented functional chain retention ratio, and combat link efficiency degradation rate. This indicates that the proposed strategy improves both the structural survivability of interdependent C2Ns and the functional stability of sensing–command–firepower coordination under cascading failures.

The performance improvement mainly comes from the joint consideration of multipath structural importance and operational compatibility. The walk-betweenness-based dependency strength captures the intermediary role of nodes from the perspective of multipath information transmission, rather than relying only on local degree or shortest-path-based indicators. Therefore, it helps avoid excessive concentration of dependency risks on a small number of structurally dominant nodes. Meanwhile, the operational attribute matching mechanism improves the functional rationality of interlayer dependency edges. Since sensing, command-and-control, and firepower nodes perform different roles in the OODA process, functionally compatible cross-layer coupling is important for maintaining effective operational chains after node failures.

From a system-engineering perspective, the results suggest that interlayer dependency design in C2Ns should jointly consider structural importance and role-related operational compatibility. The proposed strategy is particularly suitable for C2N architecture planning, survivability-oriented network design, and periodic robustness assessment before deployment or reconfiguration. Although the computation of walk betweenness and attribute matching introduces additional cost, the framework can be further accelerated through candidate-pair pruning, caching or local updating of structural indicators, and parallel implementation of the matching process.

VII. Future Directions

Future work will further extend the proposed framework from three aspects. First, more realistic C2N data and equipment-level operational parameters can be incorporated to improve the fidelity of node attribute modeling, including sensing, communication, command-support, and firepower-related characteristics. Second, the current interlayer coupling design can be extended to dynamic and adaptive scenarios, where communication quality, node status, task priorities, and command relationships may change over time. Third, the computational efficiency of the proposed framework can be further improved for larger-scale C2Ns through candidate-pair pruning, incremental updating of structural indicators, distributed computation, and parallel matching algorithms. These extensions would further enhance the scalability and applicability of PRO in larger-scale and more dynamic command-and-control network scenarios.

VIII. Conclusion

This study proposed PRO, an interlayer coupling strategy for two-layer interdependent C2Ns based on node walk betweenness and operational attributes. The proposed strategy integrates walk-betweenness-based dependency strength with operational attribute matching, thereby supporting survivability-oriented interlayer dependency design from a joint structural–functional perspective.

Simulation experiments on an air-defense command-and-control scenario were conducted under deliberate and random attacks. The results show that PRO achieves better overall performance than the compared baseline strategies in terms of node survival rate, OODA-oriented functional chain retention

ratio, and combat link efficiency degradation rate. These findings indicate that the proposed strategy can effectively mitigate cascading failure risks while preserving sensing–command–firepower coordination.

The main contribution of this work lies in providing a structural–functional coupling framework for interdependent C2Ns. Unlike topology-only coupling strategies, PRO jointly considers multipath information transmission and operational compatibility, which provides a more mission-oriented basis for interlayer dependency design in command-and-control networks.

Utilizing Structured Equation Modeling and Machine Learning in Investigating Digital Competency in Public School Teachers in Bukidnon, Philippines

Nathalie Joy G. Casildo
Information Technology Dept.-College of Information Sciences and Computing,
Central Mindanao University, Bukidnon, Philippines

***Abstract*—The rapid transition to digital education in the Philippines, accelerated by the COVID-19 pandemic, has highlighted significant integration challenges for public school teachers in rural provinces like Bukidnon. While digital proficiency is essential, existing studies often rely on either purely descriptive analytics or standalone machine learning models, which frequently fail to validate the complex, latent relationships between competency factors in terms of Digital Competency. To address these gaps, this research employs a two-phased hybrid analytical architecture. Phase I utilizes Structural Equation Modeling (SEM) to confirm the factor structure and establish the causal pathways of digital competency, ensuring that the theoretical framework is psychometrically sound. Phase II transitions these validated constructs into an optimized Machine Learning (ML) pipeline, incorporating SMOTE-ENN resampling to handle imbalanced regional data. Results from 1,275 participants demonstrate that "Professional Engagement" acts as the foundational engine of the digital competency system, while "Digital Pedagogy in Teaching" emerges as the most critical predictive determinant of teacher proficiency. The Random Forest algorithm achieved a high predictive accuracy of 89% and a Macro F1-Score of 85%, significantly outperforming traditional models. These findings indicate that the digital divide in this context is a pedagogical, rather than purely technical, bottleneck. The study provides a blueprint for the Department of Education to move from descriptive reporting toward Predictive Diagnostic Systems that can facilitate targeted, data-driven interventions.**

Keywords*—Structural Equation Modeling (SEM); Machine Learning (ML); digital competence; DigCompEdu; teacher proficiency; SMOTE-ENN; predictive analytics; educational data mining

I. Introduction

Digital transformation in the Philippines was historically gradual, only accelerating rapidly out of necessity during the COVID-19 pandemic. This shift made remote work and digital education the primary modes of instruction. In response, national agencies like the Department of Education (DepEd), specifically in Region 10, mandated the full integration of Information and Communication Technology (ICT) in primary instruction. However, despite these mandates, public school teachers in inland provinces like Bukidnon continue to face significant integration challenges. Infrastructure remains a challenge; many schools still lack stable signals, and even the existence of satellite technologies is often insufficient. Beyond hardware, there is a persistent lack of awareness regarding data security and digital literacy, which suggests that infrastructure alone cannot solve the underlying threat to digital readiness.

While the Philippines has adopted various ICT frameworks, the actual digital proficiency of teachers in these rural settings remains under-explored through advanced analytics. In the Philippine educational context, most studies rely on either pure descriptive analytics or standalone Machine Learning (ML) and Educational Data Mining (EDM) [1]. While a few researchers have attempted to combine Structural Equation Modeling (SEM) and ML [2], these efforts are often hampered by limited datasets or a narrow focus on general digital literacy. Consequently, existing methods frequently fail to validate the complex, latent (hidden) relationships between competency factors, fail to accurately predict future teacher performance, and struggle to handle skewed data—where the majority of teachers might fall into a single proficiency category.

To address these gaps, this research employs a two-phased hybrid architecture. Phase I utilizes Structural Equation Modeling (SEM) to confirm the factor structure and establish the causal pathways of digital competency. Phase II then transitions these validated constructs into Machine Learning (ML) algorithms, such as Random Forest and Support Vector Machines, to build a predictive model optimized for regional educational data.

Unlike traditional studies that rely on either simple statistics or "black-box" machine learning, this study proposes a hybrid SEM-ML architecture. Using SEM as a rigorous validation layer for feature engineering, the research ensures that the inputs for the machine learning model are not just statistically significant but are theoretically grounded and psychometrically sound.

II. Related Work

A. Computational Modeling of Digital Competence

Digital competence encompasses an integration of technical, cognitive, and socio-emotional proficiencies [3]. Assessing these skills involves using established frameworks [4] paired with computational modeling [5, 6]. Applying mathematical approaches, these models provide a scientific basis for interpreting the status of an individual's digital competence [7]. However, the focus of these frameworks must move beyond technical skills toward pedagogical intervention [8].

B. Digital Competence in DepEd Teachers

Existing research affirms the value of digital literacy (DL) and digital competence (DC) for Filipino teachers, enabling them to engage with new technologies critically within digital pedagogy [9]. Enhancing these competencies can drive higher work engagement, ultimately leading to improved job performance and satisfaction, particularly in remote work environments [10]. In terms of regional applications, [4] and [11] provide significant contributions. Specifically, [4] explores frameworks in Fig. 1 relevant at national, international, and regional scales, such as the framework developed by the UNESCO Asia and Pacific Regional Office. Furthermore, the work in [11] serves as a valuable benchmark for the Bukidnon context; it analyzes digital competence frameworks used in Ibero-America through 2022 to establish a conceptual foundation for assessment tools in regional educational settings.

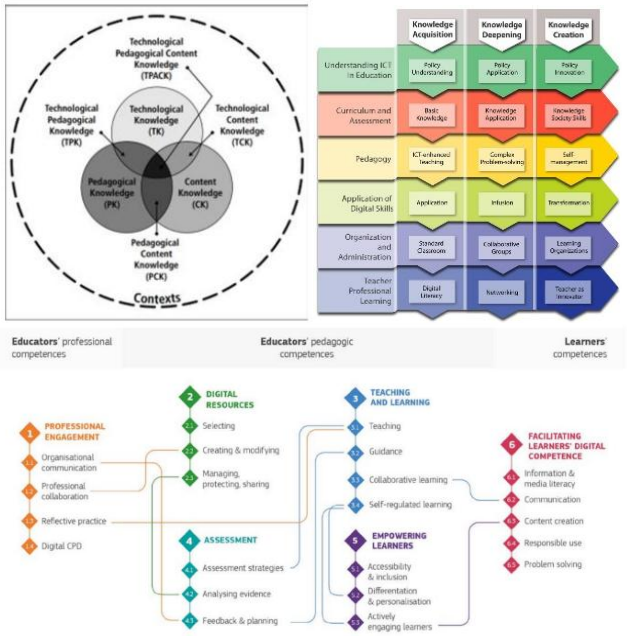

Fig. 1. ICT and competency frameworks [4].

C. Structural Equation Modeling (SEM) as a Validation Layer

Structural Equation Modeling (SEM) serves as a robust validation layer in contemporary research [12–14]. Since digital competence is a latent construct that eludes direct measurement, SEM utilizes Confirmatory Factor Analysis (CFA) to verify its underlying dimensions [15]. A practical application of this is seen in the validation of the TDC-S instrument [16]. In this study, Fig. 2 presents the CFA output for measurement model 3, reporting $X^2 = 1{,}480.693$, ($df = 584, p = 0.00$) and an X^2/df ratio of 2.535. Further evaluation of the model's performance includes an RMSEA of 0.075 and a CFI of 0.897. Following the benchmarks established in recent literature, [17] provides an interpretation of these indices to determine the scientific status of the model's fit. A study establishes a robust theoretical framework for confirming theoretical constructs and quantifying latent relationships, which serves as the foundation for subsequent predictive modeling [18].

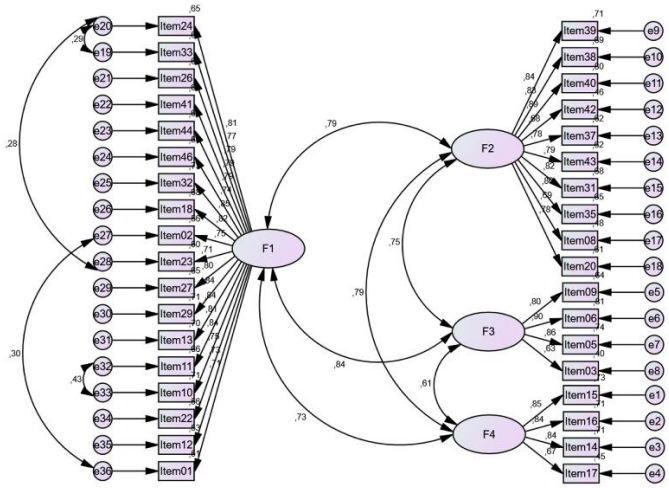

Fig. 2. CFA output of measurement model 3 [14].

D. Machine Learning and Educational Data Mining

Recent research has explored the application of machine learning (ML) to predict teachers' digital competency [19–21]. Within the field of Educational Data Mining (EDM), the most frequently utilized algorithms include Logistic Regression, Random Forest, and Decision Trees [19, 22, 23]. Furthermore, several studies have introduced hybrid methodologies that integrate Structural Equation Modeling (SEM) with Machine Learning [24, 25]. Specifically, [24] demonstrates that combining Bayesian SEM with ML achieves superior levels of predictive accuracy and robustness compared to traditional SEM or standalone ML techniques. Similarly, [25] bridges the gap between causal explanation and predictive accuracy by employing SEM to identify direct and indirect pathways, while using ML methods to reveal marginal contributions and nonlinear transition characteristics. These studies collectively indicate that the integration of SEM and ML offers a more effective and comprehensive analytical approach.

E. Hybrid SEM-ML Architectures in the Global Research Landscape

The integration of Machine Learning (ML) into Structural Equation Modeling (SEM) frameworks has emerged as a robust analytical paradigm in recent educational research. This hybrid approach allows for a fusion of explanation and prediction, addressing the limitations of theory-driven models in highly complex environments. Brandmaier and Jacobucci [26] emphasize that integrating ML techniques into SEM renders theory development more structured, efficient, and robust, particularly when dealing with high-dimensional data that traditional path analysis may struggle to parse.

Recent international studies have successfully operationalized this synergy across various educational domains. For example, Zhang et al. [27] applied a hybrid approach to predict student engagement in physical education, utilizing nine ML algorithms—with Random Forest yielding the highest predictive accuracy—to rank the influence of various digital tools. By concurrently using SEM to map causal pathways, the authors provided evidence on how technology usage indirectly impacts engagement through psychological mechanisms such as perceived usefulness and self-efficacy.

Furthermore, this hybrid architecture is instrumental in identifying the non-linear realities of digital transformation. In a large-scale study of 650 participants, a recent investigation [28] demonstrated that structural models can sometimes reveal statistically insignificant relationships (e.g., between technological infrastructure and actual digital adoption) that might be overlooked in simpler frameworks. This suggests that digital transformation is not a deterministic outcome of resource allocation or top-down mandates, but rather a complex, multi-faceted process. Positioning our study within this global methodological landscape, leveraging these advanced techniques to provide a nuanced, data-driven diagnostic of digital competency among public school teachers in Bukidnon, Philippines.

F. Resampling Techniques for Imbalanced Regional Data

Data imbalance is a prevalent challenge in educational datasets, often leading to biased models, untrustworthy outcomes, and degraded predictive performance [28–30]. To mitigate these issues, researchers frequently employ data-level interventions such as the Synthetic Minority Oversampling Technique (SMOTE). For instance, [29] implemented SMOTE-NC (for nominal and categorical data) to synthesize minority cases in high school dropout predictions, directly addressing class distribution gaps. Unlike Random Oversampling (ROS), which can lead to overfitting through sample duplication, SMOTE generates new synthetic instances by interpolating between a minority sample and its *k*-nearest neighbors [31]. Beyond oversampling, the literature suggests that various sampling strategies are essential for optimizing performance metrics [32–34]. Notably, [35] found that Random Undersampling (RUS) and hybrid techniques significantly improved Recall and F1-scores, demonstrating that prioritizing the detection of minority class instances is often more critical than maximizing overall accuracy.

III. Methodology

Fig. 3 shows the Knowledge Discovery and Predictive Analytics process. The activity started from research instrument design, where the conceptualization and schema design of the research instrument were involved. The questionnaire was adapted from the European Framework for Digital Competence in Education (DigCompEdu) to ensure construct validity. Once the framework is established, proceed to the Data Acquisition of Large-scale Survey Collection from the teachers of Bukidnon.

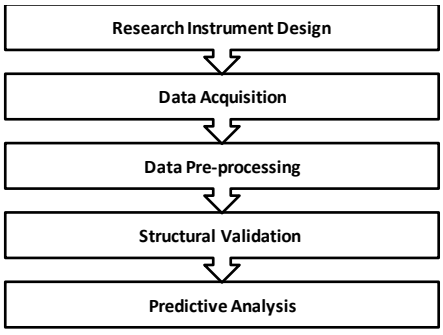

Fig. 3. Knowledge discovery and predictive analytics process.

The third phase is the Data Pre-Processing involving Data Cleaning & Feature Engineering. Proceeded with structural validation, in which Structural Equation Modeling was used using SPSS AMOS. The last step is the Predictive Analysis using logistic Regression, where accuracy calculation and Predictive classification of digital divide levels were conducted.

A. Dataset Acquisition and Characteristics

The dataset for this study was acquired through a large-scale survey involving public school teachers within the Division of Bukidnon, Philippines. Data collection was conducted between October 2022 and March 2023. A total of 1,275 valid responses were obtained, as shown in Table I: Summary of Dataset Characters. Responses represent a diverse cross-section of grade levels, school types, and geographic locations. The primary instrument was adapted from the European Framework for Digital Competence in Education (DigCompEdu), consisting of 22 items measured on a five-point Likert scale. In order to ensure the consistency of the multi-dimensional constructs, Cronbach's Alpha was calculated. The analysis yielded a reliability coefficient of 0.92, which significantly exceeds the standard threshold of 0.70.

TABLE I. Summary of Dataset Characteristics (N=1,275)

Feature	Category	Frequency	Percentage (%)
Gender	Male	188	14.80%
	Female	1087	85.20%
School Type	Central Elementary School	847	66.22%
	Senior High School	123	9.69%
	Junior High School	305	24.02%
Professional Rank	Master Teacher	71	5.51%
	Teacher 1	909	71.34%
	Teacher 2	112	8.82%
	Teacher 3	170	13.31%
	Job Order	2	0.16%
	School Head/School School Principal	9	0.71%
	Volunteer Teacher	1	0.08%
	SpEd LGU	1	0.08%
Education	BS	841	65.83%
	MS	399	31.42%
	PhD	27	2.13%
	Post Doctorate	8	0.63%
Reliability	**Cronbach's Alpha**	**0.92**	**Excellent**

B. Data Pre-Processing

After data acquisition, the data is pre-processed. It was determined that there are 11 to 20 missing instances across several high-dimensional features. The Mode Imputation was applied, an imputation strategy that replaces missing values with the most frequent value, to address missing categorical and ordinal variables.

Handling missing data includes checking for missing values in the dataset and applying appropriate techniques such as imputation to fill in missing values. Data transformation was subsequently applied, which covers converting categorical variables to numerical format if necessary.

C. Theoretical Frameworks

- The theoretical foundation of this study is anchored in the European Framework for the Digital Competence of Educators (DigCompEdu) in Fig. 4 from [4].
- Digital competence [1] is defined not as a singular skill, but as a composite of six interrelated Latent Constructs, each representing a specific functional layer of the educational system:
- Professional Engagement: Focused on the organizational communication (PCO) and collaborative practices (PCC) of the educator.
- Digital Resources: The technical capacity to source, create (DRC), and manage digital assets.
- Digital Pedagogy: The core operational layer, encompassing the implementation of digital tools in teaching (DPT) and learner guidance (DPG).
- Assessment (Evaluation): The analytical layer where educators use digital technologies to enhance assessment strategies (EFA) and analyze evidence to provide feedback.
- Empowering Learners: The inclusive layer. It measures how technology is used to support learner diversity, accessibility (ESA), and personalized learning (ESD).

The final phase of the framework involved Predictive Analysis using a suite of supervised learning algorithms: Logistic Regression, Support Vector Machine (SVM), K-Nearest Neighbors (KNN), and Random Forest. Accuracy calculations and predictive classification of digital divide levels were conducted for all models, with comparative performance metrics utilized to select the optimal classifier for the regional dataset.

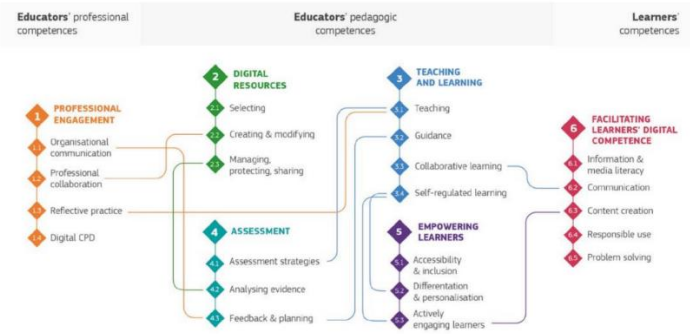

Fig. 4. Illustration of the digcompedu framework [4].

D. Structural Equation Modeling

The hybrid framework provides a two-stage approach to analyzing teacher digital competency in Fig. 5. Phase 1 uses Structural Equation Modeling (SEM) to validate theoretical constructs, identifying "Professional Engagement" as the system's foundational engine. These validated factors then bridge into Phase 2, which employs an SMOTE-ENN machine learning pipeline to handle imbalanced data and generate predictive proficiency classifications. The architecture demonstrates that an integrated approach—combining causal validation with high-performance algorithms like Random Forest (89% accuracy)—is more effective than isolated analytical methods for diagnosing and addressing pedagogical gaps in regional educational systems.

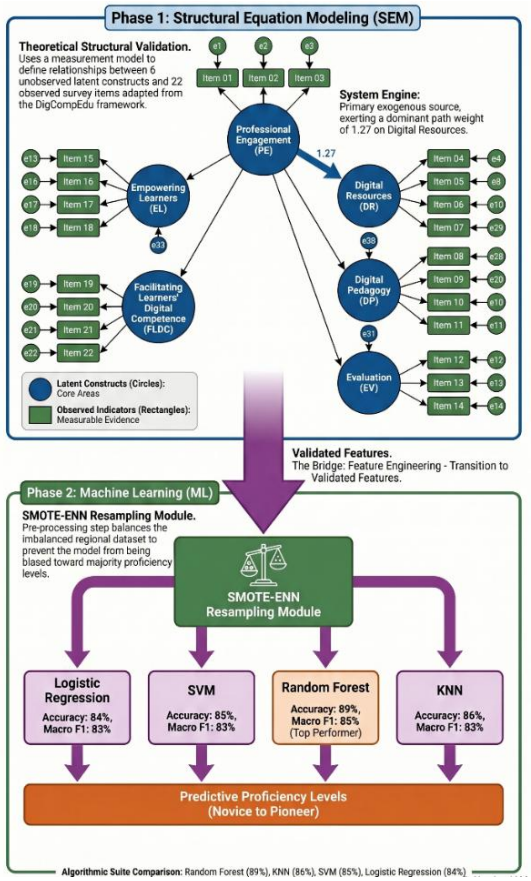

Fig. 5. Proposed model architecture.

The structural validation of the theoretical framework was conducted using Structural Equation Modeling (SEM) executed in SPSS AMOS. The model was specified as a full structural equation system comprising two distinct components: the measurement model and the structural model. The measurement model defined the relationship between six latent constructs (unobserved variables) and 22 observed indicators (survey items). Specifically, the constructs Professional Engagement, Digital Pedagogy, Digital Resources, Evaluation, Empowering Learners, and Facilitating Learners' Digital Competence were mapped to their respective observed variables. The Structural Model is the Directional paths that were established to represent hypothesized causal relationships. Professional Engagement was specified as the exogenous variable, while the remaining five constructs were specified as endogenous variables.

To account for measurement bias and unexplained variance, the model incorporated first Measurement Errors (e_1 through e_{22}), which are assigned to each observed indicator to capture

variance specific to the individual survey items. Second Structural Disturbance Terms ($e_{29}, e_{30}, e_{31}, e_{33}, e_{34}$) are assigned to each endogenous latent construct to represent the residual variance not accounted for by the structural paths in the system.

The model was constrained to ensure mathematical identification and a stable metric scale. For each latent construct, one regression weight to an observed indicator was fixed to 1.0 (e.g., the paths to PCD, DPS, DRM, EFF, ESAS, and FSDP). This procedure transformed the latent constructs into a standard metric, allowing the system to estimate the remaining free parameters and path coefficients.

$$F_{ML} = \ln|\Sigma(\theta)| + \mathrm{tr}(S\Sigma^{-1(\theta)}) - \ln|S| - p \quad (1)$$

The Maximum Likelihood Estimation (MLE) algorithm in Eq. (1) was utilized to calculate the path coefficients and variance estimates.

The structural integrity of the model was evaluated against a suite of computational fit indices [36]. Parsimony Assessment for CMIN/DF ratio (also known as the Normed Chi-Square) is a measure used to evaluate the "parsimony" or the efficiency of the model [36]. Absolute Fit Testing for Root Mean Square Error of Approximation (RMSEA), Goodness of Fit Index (GFI), and Adjusted Goodness of Fit Index (AGFI) were employed, alongside Incremental Fit Comparison for Comparative Fit Index (CFI), Tucker-Lewis Index (TLI), and Normed Fit Index (NFI) [36]. Information Criteria, such as the Akaike Information Criterion (AIC) and the Bayesian Information Criterion (BIC), were also utilized for model comparison [36]. However, contemporary literature cautions against the use of rigid, fixed cutoff values for these indices, recommending instead that researchers consider model-specific characteristics and context [37][38].

$$P(Y=1|X) = \frac{1}{1+e^{-(\beta_0+\sum_{i=1}^{n}\beta_i x_i}} \quad (2)$$

Lastly, in the final phase, the validated features were utilized to construct a predictive classifier using Logistic Regression in Eq. (2). To ensure the reliability of the predictive results and prevent model overfitting, the dataset (N=1,276) was partitioned using a train(80%)-test(20%) split. To validate the stability of the classifier across different subsets of the regional data, a 5-Fold Cross-Validation procedure was executed.

The predictive accuracy of the model was quantified using a comprehensive suite of classification metrics derived from the Confusion Matrix first is Accuracy - the overall ratio of correctly predicted instances to total instances. Precision and Recall are utilized to evaluate the model's ability to correctly identify positive instances of high ICT competency while minimizing false positives and false negatives. F1-Score - the harmonic mean of precision and recall, serving as a singular metric for balanced classification performance.

E. Class Imbalance

The original dataset exhibited a significant class imbalance, which could bias the predictive models toward majority classes. To mitigate this, a hybrid SMOTE-ENN (Synthetic Minority Oversampling Technique and Edited Nearest Neighbors) pipeline was applied to the training set (N=891). SMOTE was utilized to oversample minority classes by generating synthetic instances, while ENN was subsequently applied to remove ambiguous or 'noisy' samples from the feature space, ensuring well-defined decision boundaries. Table II illustrates the proficiency level distribution before and after the resampling process. The results confirm that this hybrid strategy successfully redistributed the instances to provide a more equitable analytical foundation for the machine learning models.

TABLE II. DISTRIBUTION OF PROFICIENCY LEVELS BEFORE AND AFTER SMOTE-ENN

Proficiency Level	Count (Before SMOTE-ENN)	Count (After SMOTE-ENN)
Pioneer	25	317
Novice	58	315
Leader	109	283
Explorer	328	201
Integrator	468	122
Expert	287	98
Total	**891**	**1,336**

IV. THE STRUCTURAL EQUATION MODEL

A. Goodness-of-Fit (GOF) and Model Verification

To determine the extent to which the theoretical architecture matches the empirical data collected from the 1,276 regional educators, the model was subjected to a rigorous Goodness-of-Fit (GOF) assessment. The observed covariance matrix was compared against the model-implied matrix using Maximum Likelihood Estimation in Eq. (1).

TABLE III. CALCULATED GOODNESS-OF-FIT FOR THE STRUCTURAL MODEL

Fit Index Category	Metric	Calculated Value	Interpretation
Parsimony Fit	CMIN/DF	4.749	Acceptable (Threshold < 5.0)
Absolute Fit	GFI	0.935	Good Fit
	AGFI	0.917	Good Fit
	RMSEA	0.054	Excellent (Threshold < 0.06)
Incremental Fit	NFI	0.936	Strong Fit
	CFI	0.948	Strong Fit
	TLI	0.940	Strong Fit

Table III shows that the model achieved convergence with high reliability. The RMSEA of 0.054 is a critical result, indicating that the structural model possesses a very low discrepancy per degree of freedom. This validates the model's generalizability across the diverse demographics of the Bukidnon teacher population. Furthermore, the GFI (0.935) and CFI (0.948) scores confirm that the proposed six-construct structure accounts for the majority of the variance in the observed indicators.

The modeling procedure followed a multi-stage mathematical specification to assess the inter-dependencies between latent constructs in Fig. 3.

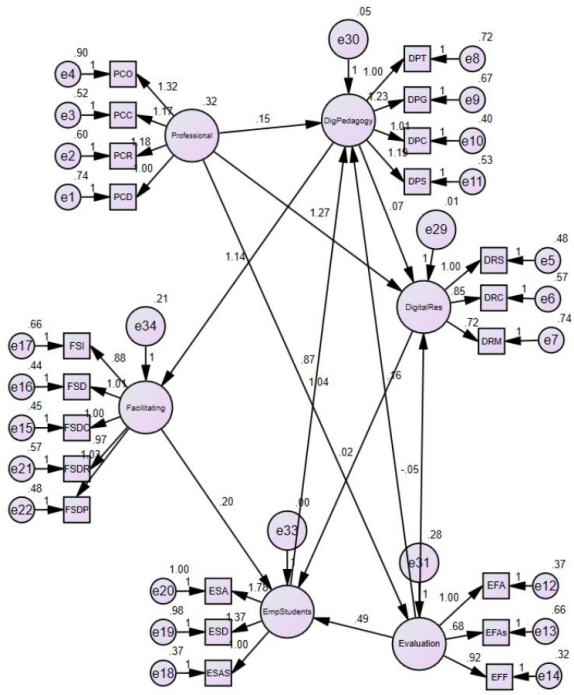

Fig. 6. SEM framework implemented in SPSS AMOS.

B. Path Analysis and Predictive Weights

Following the global validation of the model, the individual structural paths were analyzed to identify the primary drivers of teacher competency. Fig. 6 illustrates the final structural diagram with the calculated unstandardized regression weights.

The path analysis reveals a clear hierarchical influence within the digital competency system:

1) System driver: The path from Professional Engagement to Digital Resources yielded the highest weight in the system (1.27). This indicates that for every one-unit increase in professional commitment, the competency in sourcing and creating digital resources increases by 1.27 units, identifying "Professional Engagement" as the foundational engine of the system.

2) Pedagogical integration: A significant structural relationship was confirmed between *Evaluation and Empowering Students* (0.49). This confirms that data-driven assessment practices are essential precursors to achieving the ultimate inclusive goal of student digital empowerment.

3) Direct influence: The model shows that *Professional Commitment* also maintains a direct positive influence on Digital Pedagogy (0.15), suggesting that commitment to reflective practice directly modulates how tools are applied in the classroom.

C. Structural Validity Conclusion

The results of the SEM phase demonstrate that the digital divide is not a set of isolated skills but a highly integrated system. The high GOF scores prove that the DigCompEdu framework is an appropriate mathematical model for the Philippine regional context. Meeting all statistical thresholds, the latent constructs—specifically Digital Pedagogy and Professional Engagement—are validated as high-quality features. This structural certainty provides the necessary evidence base for the final Machine Learning Predictive Analysis presented in the following section.

V. Machine Learning Predictive Results

Following the structural validation of the constructs, the predictive phase was executed using the resampled dataset. The application of the SMOTE-ENN (Synthetic Minority Over-sampling Technique and Edited Nearest Neighbors) pipeline was utilized to ensure that the classifiers were not biased toward the majority proficiency levels, thereby providing an equitable analysis of the digital divide.

A. Comparative Model Performance

The predictive utility of the four supervised learning algorithms was evaluated based on Accuracy, Macro-averaged Precision, Recall, and the F1-Score. Table IV summarizes the performance of the models within the optimized SMOTE-ENN framework.

TABLE IV. Predictive Performance Metrics with SMOTE-ENN Resampling (N=1,276)

Model	Accuracy	Macro Avg. Precision	Macro Avg. Recall	Macro Avg. F1-Score
Logistic Regression	84%	84%	81%	83%
SVM	85%	84%	83%	83%
Random Forest	**89%**	86%	84%	85%
K-Nearest Neighbors	86%	84%	82%	83%

B. Algorithmic Analysis and Model Selection

As illustrated in Table IV, all four classifiers demonstrated high predictive performance, with F1-scores consistently exceeding 83%. The Random Forest (RF) algorithm emerged as the best performer, achieving an overall accuracy of 89% and a Macro F1-Score of 85%. The superior performance of RF is attributed to its ensemble nature, which effectively aggregates multiple decision trees to capture the non-linear relationships between the pedagogical and professional features identified in the SEM phase.

The K-Nearest Neighbors (KNN) and SVM models followed closely with accuracies of 86% and 85%, respectively. The high recall scores across these models (up to 84%) indicate that the SMOTE-ENN strategy successfully enabled the system to identify minority proficiency classes (such as "Novice" and "Leader"), which are often missed in traditional imbalanced models.

The Logistic Regression model, while having the lowest accuracy at 84%, still provided significant interpretive value through its 81% recall rate. The narrow margin of difference between the four models suggests a high degree of consensus regarding the predictive importance of the structural features used as inputs.

C. Confusion Matrix Evaluation

To visually verify the classification accuracy, a composite confusion matrix analysis was performed for each algorithm in Fig. 7.

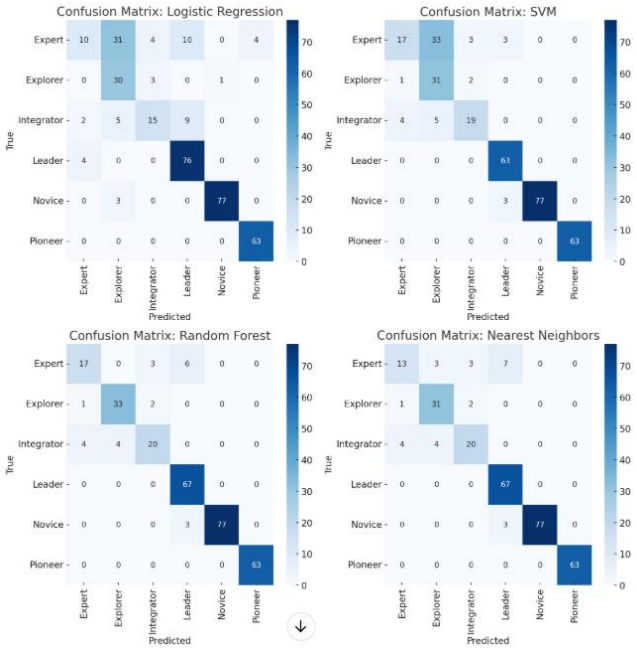

Fig. 7. Grid of Confusion Matrices for optimized models.

The diagonal values in Fig. 7 confirm a high rate of True Positives across all proficiency levels. The low off-diagonal counts demonstrate that the integrated SEM-ML framework is highly effective at minimizing misclassification errors, providing a reliable diagnostic tool for assessing the digital divide in regional education systems.

D. Feature Importance and Predictive Determinants

To enhance the transparency of the predictive framework and identify the primary drivers of the digital divide, a feature importance analysis was conducted. This stage translates the "black-box" predictions of the algorithms into actionable insights for educational policy.

1) Identifying the strongest predictors: Based on the coefficients derived from the Logistic Regression model and the feature importance rankings of the Random Forest classifier, Digital Pedagogy in Teaching (DPT) emerged as the most significant predictor of teacher ICT competency. The model yielded an Odds Ratio (OR) of 1.5176 for this feature, indicating that for every unit increase in a teacher's pedagogical integration score, the likelihood of belonging to a higher proficiency category increases by 51.76%.

2) The role of digital resource creation: The analysis further identified Digital Resource Creation and Modification (DRC) as a critical secondary predictor (OR = 1.3945). This aligns with the SEM results (Path weight = 1.27), confirming that the ability to customize digital content is a structural requirement for moving beyond the "Novice" stage of the digital divide.

3) Inverse predictors and system gaps: A compelling and critically revealing finding is the inverse relationship between Highest Educational Attainment (HighED) and ICT competency (OR = 0.2879). This negative coefficient indicates that, within this regional population, traditional advanced academic credentials do not serve as a proxy for digital proficiency. This "Academic-Digital Mismatch" highlights a systemic gap: postgraduate and teacher-education curricula in the region may be prioritizing traditional theoretical frameworks over the applied digital-pedagogical competencies defined by the DigCompEdu framework. This suggests that senior, highly-credentialed educators are not necessarily more digitally prepared; rather, they may be the most at risk of falling behind in the digital transition if their academic training is not synchronized with modern instructional technology requirements.

4) Strategic implications: The feature importance results demonstrate that the digital divide in Bukidnon is primarily pedagogical rather than technical. While "Professional Collaboration" and "Organizational Communication" are foundational (as proven in the SEM phase), the Machine Learning models prove that actual classroom implementation (Pedagogy) is the variable that ultimately decides a teacher's proficiency level.

VI. Discussion

A. Characterizing the Digital Divide in Bukidnon

The integration of SEM path analysis and Machine Learning feature importance reveals that the digital divide among teachers in Bukidnon is not a binary gap of "haves vs. have-nots," but a multi-layered structural bottleneck.

1) The SEM result identifying professional engagement as the strongest driver (Path weight = 1.27) suggests that regional teachers possess the necessary organizational commitment and reflective drive to bridge the divide. However, the high variance in the Digital Resources construct indicates that this commitment does not always translate into resource access.

2) While SEM identifies commitment as the driver, the Machine Learning results identify Digital Pedagogy in Teaching (DPT) as the ultimate predictive determinant (OR = 1.5176). This synthesis suggests that while teachers are committed, the "Digital Divide" is actually a Pedagogical Divide. An educator's ability to cross into the "Expert" or "Leader" categories depends almost entirely on their capacity to integrate tools into instructional design rather than simply possessing the tools themselves.

3) The surprising inverse relationship between Highest Educational Attainment and competency (OR = 0.2879) highlights a significant regional gap. It suggests that traditional advanced academic training in the province has not yet integrated the digital competencies defined by the DigCompEdu framework, creating a scenario where senior, highly credentialed teachers may be the most at risk of falling behind in the digital transition.

B. Theoretical Implications for the DigCompEdu Framework

The study provides a successful large-scale validation (N=1,276) of the DigCompEdu framework in a predominantly agricultural, regional context.

The high global fit indices (CFI=0.948, GFI=0.935) confirm that the framework's six latent domains are cross-culturally applicable and mathematically stable even in resource-constrained environments. The structural analysis confirms the framework's theoretical assumption that *Professional Engagement* must precede *Digital Pedagogy*.

However, our findings suggest that in regional settings, the path between *Professional Commitment* and *Digital Resources* is more volatile than in urban settings, requiring the framework to perhaps place more weight on "Institutional Context" when applied to regional clusters.

C. Technical Contribution

A primary technical contribution of this research is the demonstration of the Hybrid SEM-ML Analytical Pipeline. In typical Machine Learning studies, features are often fed into models without conceptual validation. This study uses SEM as a pre-filtering layer, ensuring that only constructs with high structural validity and low measurement error are used for prediction. This reduces "noise" and increases the reliability of the classification.

From an Information Systems perspective, the success of the Random Forest model with 89% accuracy proves that SMOTE-ENN is an essential pre-processing layer for regional educational data. Balancing the sparse "Novice" and "Leader" classes, the system achieved a Macro F1-Score of 85% that far exceeds traditional linear methods.

This hybrid approach provides a blueprint for other regional government agencies to move from descriptive "snapshot" surveys to Predictive Diagnostic Systems. The model can be used to develop Decision Support Systems (DSS) that automatically identify teachers who require specific pedagogical interventions based on their structural profile.

VII. Conclusion and Recommendations

A. Final Conclusion

This research successfully developed and validated a Hybrid Analytical Framework integrating Structural Equation Modeling (SEM) and Machine Learning (ML) to investigate the digital divide among 1,276 public school teachers in Bukidnon, Philippines. The study concludes that the digital divide is not merely a consequence of resource scarcity but a complex system of structural interdependencies.

The SEM phase established the mathematical validity of the DigCompEdu framework in a regional context, proving that Professional Engagement acts as the primary engine driving digital integration. The subsequent Machine Learning phase achieved a high predictive accuracy of 89% using the Random Forest algorithm, identifying Digital Pedagogy in Teaching (DPT) as the most critical predictive determinant of an educator's proficiency level.

Furthermore, the surprising inverse relationship between formal academic attainment and ICT competency highlights a critical mismatch between traditional higher education and the practical digital skills required in the modern classroom. Ultimately, this study demonstrates that a data-driven, hybrid approach provides the precision necessary to move beyond descriptive reports into predictive diagnostics for educational systems.

B. Study Limitations and Future Directions

While this research provides a robust hybrid SEM-ML framework for diagnosing digital competency, several limitations should be considered. First, the data were collected using a self-report Likert-scale instrument, which may be susceptible to social desirability and self-report bias; participants might overestimate their digital proficiencies. Second, the study's geographic scope is restricted to a single division (Bukidnon), which may limit the generalizability of the findings to broader or more urbanized regional contexts. Finally, the study employs a cross-sectional research design. While Structural Equation Modeling (SEM) identifies significant structural pathways, this design cannot definitively establish the causal directionality of these relationships. Future research should prioritize longitudinal studies to measure the evolution of teacher digital competency over time and incorporate objective performance data alongside self-reported metrics to further validate these findings.

C. Recommendations for Educational Policy

Based on the validated predictive weights of the model, the following interventions are recommended for the Department of Education (DepEd) and regional stakeholders:

1) Prioritize pedagogical integration over technical skills: Professional development programs should pivot from basic tool-use training to Digital Pedagogy. Training should focus on how to integrate ICT into instructional design, as this factor has the highest odds ratio for moving teachers out of the "Novice" and "Explorer" categories.

2) Bridge the 'academic-digital mismatch' for highly credentialed educators: The negative correlation between formal advanced degrees and digital competency points to a significant alignment gap between traditional Higher Education Institutions (HEIs) and the practical realities of the digital classroom. To resolve this, the Department of Education (DepEd) should initiate a collaborative curriculum audit with regional HEIs to integrate applied DigCompEdu modules into postgraduate programs. Furthermore, we recommend specialized, track-based upskilling programs for senior teachers and those with advanced degrees. These interventions should focus on moving these educators from theoretical academic mastery toward "Expert" and "Leader" levels in digital pedagogical implementation, ensuring that their tenure and qualifications are effectively leveraged to drive digital transformation.

3) Institutionalize collaborative learning communities: Given the foundational role of Professional Engagement in the SEM results, schools should establish formal digital mentorship

programs that reward collaborative resource creation and reflective practice.

D. Technical Recommendations and Future Work

From a computational perspective, this study provides a blueprint for regional Data for Development initiatives.

Future research directions include system automation, algorithm expansion, and longitudinal modeling. System Automation involves integrating the validated SEM-ML pipeline into a web-based Decision Support System (DSS). This would allow educational administrators to input survey data and automatically receive real-time "Proficiency Risk" scores for their teaching staff.

For Algorithm Expansion, while Random Forest and Logistic Regression proved effective, future studies should explore Deep Learning architectures, such as Artificial Neural Networks (ANN), to see if predictive accuracy can be further enhanced for larger national-level datasets.

Longitudinal Modeling: Future work should utilize the proposed framework in a longitudinal study to measure the rate of competency growth following specific training interventions, allowing for the calculation of the "Return on Investment" (ROI) for digital transformation policies.

ACKNOWLEDGMENT

We sincerely thank the Department of Education, Bukidnon, for helping us to conduct this research. We would also like to thank Central Mindanao University for funding our research Project with a code, R-0355, which allowed us to conduct our study about ICT proficiency.

DECLARATION OF GENERATIVE AI IN SCHOLARLY WRITING

During the preparation of this manuscript, the authors utilized Google AI Studio to enhance the clarity, flow, and overall readability of the text. Following the use of this tool, the authors reviewed, validated, and edited the content to ensure accuracy. The authors take full responsibility for the integrity of the information presented. No AI tools were employed for the purposes of data analysis, hypothesis testing, or the derivation of research insights.

ETHICAL DECLARATIONS

This study was conducted in accordance with the ethical standards of Central Mindanao University and was formally approved by the Department of Education (DepEd) Division of Bukidnon. Research ethics clearance was secured from the Institutional Ethics Review Committee before the commencement of data collection. Informed consent was obtained from all 1,276 participants. To ensure participant protection, all data were anonymized and processed to maintain strict respondent confidentiality throughout the research process.

DeepEdgeNet: An Edge-Cloud Deep Learning Framework for Efficient Environmental Monitoring in IoT Systems

Qamar H. Naith
Department of Software Engineering-College of Computer Science and Engineering,
University of Jeddah, Jeddah 21959, Saudi Arabia

***Abstract*—Deep learning (DL) is currently considered one of the most powerful tools for environmental monitoring. Many environmental variables, such as air quality, climate, water, and energy, are monitored using Internet of Things (IoT) technologies. However, the DL-based environmental monitoring systems heavily depend on the cloud, and hence they suffer from latency, high energy consumption, and data privacy. This study proposes DeepEdgeNet, a distributed DL and Machine Learning (ML) framework for environmental monitoring systems based on edge computing and federated learning. In DeepEdgeNet, the features are extracted at the edge devices, and the model updates are aggregated at the central server without sharing the sensitive data. The proposed framework was evaluated on six IoT datasets collected from various environmental monitoring systems, such as air quality monitoring, household energy consumption, satellite-based land-cover classification, climate and extreme weather analysis, water quality assessment, and drought prediction. Experimental results have shown that the proposed system significantly improves the accuracy of the considered datasets, which are 94.5% for the Air Quality dataset, 95.4% for the EuroSAT dataset, and the mean absolute error (MAE) of time-series datasets is reduced up to 0.28 for drought prediction. Moreover, the proposed system has lower inference latency, up to 130 ms, and energy consumption compared with six state-of-the-art models. Although the edge–cloud environment was simulated using a unified experimental platform, the obtained results demonstrate the effectiveness of DeepEdgeNet for scalable and privacy-preserving IoT-based environmental monitoring applications. Hence, the proposed system is efficient and applicable to IoT-based environmental monitoring systems.**

Keywords*—Internet of Things (IoT); edge computing; federated learning; machine learning

I. Introduction

The world and the population change through the Internet of Things (IoT), which enhances the existing interaction with nature and its administration. These include sensors, weather stations, and monitoring systems that reveal real-time data related to primary environmental issues. The use of such technologies has increased concern for air pollution, flood forecasting, water resources, and biodiversity conservation. For instance, poisonous elements could be detected by air quality sensors, and water level sensors help predict floods, thus allowing authorities to act in disaster management quickly. However, increasing IoT deployments also results in ginormous data, so as to pose several challenges in processing data, energy consumption, and user privacy [1]. The pivotal role of such IoT-based systems in the facilitation of a few global sustainability goals is illustrated in Fig. 1.

Fig. 1. Key sustainability goals enabled by IoT systems.

Often, traditional ones rely on cloud processing, mostly as centralized processing for data harvested from IoT devices. However, despite having fit applications, the approach eventually stumbles in delay and bounces back and forth between the central servers. It seems like another good reason why the energy consumption of centralised systems can be very variable, and also the privacy issues related to sensitive data such as industrial emissions or urban air quality measurements. Centralised systems (e.g., using cloud servers) generally have latency and therefore cannot be applicable to real-time environmental monitoring systems such as flood monitoring systems or also real time air pollution alert systems for busy cities. Another key point is that in such environmental monitoring applications, the centralised systems have high bandwidth requirements. An illustration of the difference in location where the data processing takes place between a cloud computing system and an edge computing system is shown in Fig. 2. In cloud computing, all processing in the data server at the central location (cloud) has to take place in advance to ensure that the results come at a reasonable time, leading to a latency period between data reception and when any actions are taken in response to the environmental phenomena of interest. In addition, a large amount of bandwidth is required for the transfer of large amounts of data from numerous sensor nodes to a single central location (cloud). On the other hand, in the case of edge computing, the sensor node can start processing data immediately, thus a lower latency period occurs, and an overall

decrease in bandwidth consumption occurs due to data being processed locally. So, the transition to sustainable applications of IoT is another important transition from cloud computing to edge computing systems.

This study presents DeepEdgeNet, a novel framework dedicated to combining deep learning with edge computing to improve the efficiency and effectiveness of environmental IoT sensing applications. DeepEdgeNet processing stays along the edge of IoT networks, systematically performing real-time data analysis, thus making it less dependent on continuous communication with centralized servers. These combined qualities of latency and energy efficiency thus make it a suitable system for resource-limited environments [3]. This framework specifically comprises advanced deep-learning technologies, for example, Convolutional Neural Networks (CNNs), which work over spatial patterns -specific areas with high pollutant concentrations- and Temporal Fusion Transformers (TFTs), which utilize effective time-series data for temperature changes highlighted over weeks or even months. Finally, DeepEdgeNet integrates federated learning in which models can train across devices without raw data having an opportunity to get to a common point in ensuring privacy and security.

The framework talks about other doctrinal environmental threats such as projected air quality and its trends; the risk of floods based on rainfall and water level data; and tracking changes in biodiversity in protected areas. Notably, DeepEdgeNet was tested against six popular IoT datasets concerned with air quality, climate, and weather, along with biodiversity and other urban manifestation indices. It has been compared with performance across six other leading algorithms, including Spatio-Temporal Dynamic Graph Neural Networks (ST-DGNN) and Multi-Scale Convolutional Neural Networks (MSCNN). The evaluation considered prediction accuracy, processing speed, energy efficiency, and error rates as parameters for comparison.

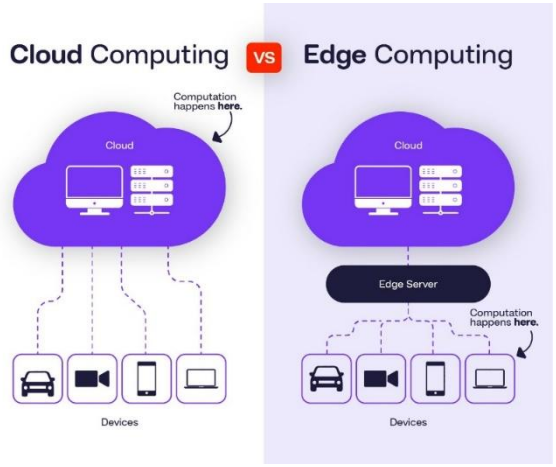

Fig. 2. Comparison between traditional cloud computing and edge computing.

This research work contributes in many ways: First, it presents a highly scalable and energy-efficient framework that IoT and edge computing can exploit to mitigate various environmental issues. Second, this study shows the flexibility and efficacy of the system by testing it with various real datasets under real-world scenarios. Third, it is shown that DeepEdgeNet outperforms all other methods with respect to accuracy and speed while consuming less energy. DeepEdgeNet also provides a pragmatic solution to environmental monitoring by leveraging existing IoT infrastructures that are easily adaptable to rapidly respond to challenges such as air pollution, floods, and biodiversity loss. Overall, the DeepEdgeNet makes important progress in environmental sensor networks based on IoT. Being an advanced technology, it can be applied in the field of deep learning and further research into processing power among decentralized edge computing to provide a versatile and efficient approach to complex environmental systems management.

The rest of this study is organized as follows: Section II provides a comprehensive review of related work, highlighting recent advancements in IoT-based environmental monitoring and the state-of-the-art algorithms used for comparison. Section III introduces the proposed DeepEdgeNet framework, detailing its system architecture, technical features, and implementation. Section IV describes the six IoT datasets utilized in the study and the evaluation metrics used to assess performance. Section V presents the experimental setup. Section VI shows the experimental results, including a detailed comparison of DeepEdgeNet with six state-of-the-art algorithms across the datasets. Finally, Section VII concludes the study, summarizes the key findings, and outlines future directions to further enhance the capabilities of the framework.

II. Related Work

Several changes have occurred in terms of environment monitoring and sustainability due to the advancement of IoT and edge computing.

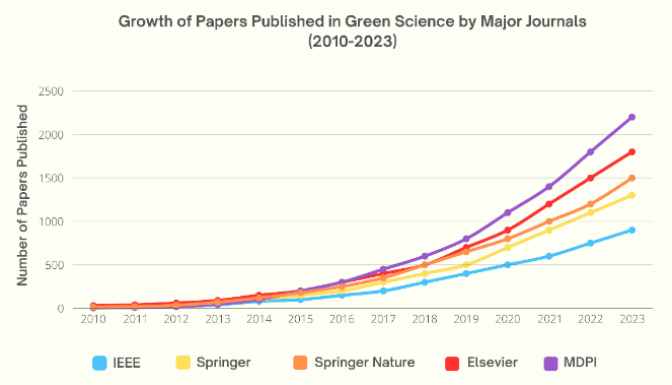

Fig. 3. Growth of papers published in green science by major journals (2010-2023).

Fig. 3 shows how research has grown in the field of green science and sustainability, as proclaimed by the leading journals like IEEE, Springer, Elsevier, MDPI, and Springer Nature. This section synthesizes insights from important state-of-the-art works in the context of their contribution towards IoT, edge computing, and machine learning techniques for environmental monitoring and sustainability. Chen S. et. al. present IoT-based smart grids with edge computing for energy consumption optimization in real-time. Distributed systems are significantly shown to be speedier and more efficient in the workings of the grid and lead to fewer carbon emissions [3]. Mobile edge computing has also been investigated in another study related to

IoT applications for showing the benefits of reduced bandwidth and latency usage, corresponding to the architecture of DeepEdgeNet for on-the-fly environmental monitoring purposes [2].

Omniawa et. al article was comprehensive and detailed in surveying all the possible fog and edge computing frameworks applied to IoT-based applications. It also discussed issues affecting such frameworks, like scalability and privacy, and proposed some hybrid architectures to mitigate those concerns [4]. The same study depicts some evidence in favor of edge computing and its usefulness in IoT-based manufacturing, reduced time delay, and efficient processing that are in line with DeepEdgeNet targets for lowering latencies in environmental monitoring [5].

Okot et. al. explore the potential of IoT in achieving sustainability goals in Costa Rica by providing a conceptual framework. The study highlights how IoT plays an important role in achieving energy efficiency, environmental monitoring, and resource management by addressing several scalability and integration challenges. Costa Rica's promise of utilizing renewable energy and conservation efforts gives it a strong case for rolling out IoT ecosystems for sustainable practice promotion [6]. Researching intelligent edge computing for energy management in smart cities demonstrates how AI algorithms can be adopted in predicting energy consumption and optimized usage; it lists applicable combinations alongside DeepEdgeNet capabilities, such as flooding prediction or air quality monitoring [7]. Furthermore, an SDN-based edge for IoT-enabled health care systems study underscores the critical aspects of managing secure data and resource optimization, mostly relevant to managing sensitive environmental data [8].

According to Ramadane et al., a new approach for assessing the environmental effect of IoT objects has been developed using graph-based machine learning models. The research represents IoT devices as graphs, thus simplifying traditional resource-intensive Life Cycle Assessments (LCAs) to ensure ecological sustainability with fast-growing IoT [9]. Regarding the environment, different IoT frameworks have been used to monitor air quality, biodiversity, and the sustainability of urban areas. For example, real-time air quality assessment systems with IoT use deep learning to precisely identify pollution trends in terms of real-time monitoring of pollutants and their forecasting [10]. Other works focus focused on IoT applications towards biodiversity conservation as well as the need for understanding spatio-temporal data to monitor the distribution of species [11]. About Narayana et al. [12] smart environmental monitoring system built with a range of IoT sensors (for temperature, humidity, atmospheric pressure, and hazardous gas activities) that keep checking conditions and trigger alerts in case a threshold is exceeded. So this type of real-time IoT system could mitigate risks and prevent disasters by reporting environmental hazards to users.

Piramuthu S. investigates how IoT technologies can support environmental sustainability in agricultural supply chains. It highlights IoT's role in reducing food waste, optimizing resource consumption, and enabling precision farming. From "farm to fork," IoT aids in monitoring crops, managing resources, and improving supply chain efficiency to reduce environmental footprints [13]. Nirere et al. demonstrate the establishment of a cost-effective, real-time IoT-based climate prediction system deployed in the industrial economic zone of Rwanda itself. The system uses integration of sensors such as MQ-135 and DHT11 to monitor environmental parameters such as CO2 levels, temperature, and humidity. The collected data is processed using MQTT and stored on MongoDB as well as used in machine learning models for analysis and prediction. The study evaluates different algorithms related to machine learning, which include Logistic Regression, Random Forest, Gradient Boost, Decision Tree, K-Nearest Neighbor, and Multilayer Perceptron. In accuracy, Random Forest surpassed the case with 99% training accuracy and 84% test accuracy. Results from the study showed that the high levels of CO2 and increase in temperature have manifested that, above these interventions, the warming periods are going to dominate in the future. This research opens several opportunities for IoT and machine learning in making actionable insights toward climate change mitigation and adaptation [14].

Federated Learning is supposed to be one of the techniques that shows great promise in terms of privacy preservation and scalability in applications within distributed IoT systems. For instance, the work by [15] presented a framework that was an edge-based FL adaptable framework on IoT contexts that could well be used to allow millions of devices to come together and be able to train their models without processing their raw data in the cloud. The proposed program, using the edge nodes for training and simply modular upgrades, reduced congestion on the network and protected the user's privacy – basically, the DeepEdgeNet building block. In addition, there are further applications of FL in the Industrial IoT in terms of efficiency increase, such as in the work by Hsu et al. [16], which utilizes a federated learning scheme to sample data from IIoT networks. The procedure significantly reduces redundant transmissions and, alongside a very small model accuracy reduction, provides a considerable amount of energy savings. Hence, it shows how connected learning can increase battery life in sensors and also scale to large deployments. These types of strategies, based on FL, prove that a theoretical understanding of distributed learning in IoT can practically benefit systems due to data local retention, a principle that DeepEdgeNet leverages for privacy and scalability in environmental monitoring.

Qamar et al. emphasize the transformative potential of IoT in environmental research and resource management. It outlines IoT's applications in real-time environmental monitoring, smart agriculture, and water resource management, focusing on efficiency, innovation, and sustainability. The study also identifies challenges such as data privacy and implementation costs [17]. Abd El-Mawia et al. critique the current limitations of climate change mitigation strategies and propose IoT as a transformative tool for adaptation. It focuses on Industrial IoT (IIoT) as a future solution, emphasizing its role in monitoring and reducing greenhouse gas emissions, enabling smart energy systems, and fostering sustainable industrial practices [18].

The following six algorithms are used for the comparative evaluation of DeepEdgeNet:

- Temporal Fusion Transformer (TFT), as it is built, is focused on applying different time-series analyses to

different types of time series. For example, temperature has different patterns of change along with air quality. It applies techniques so that part of the data that is critical in prediction can be scrutinized and emphasized. Therefore, it can more accurately predict and provide good-sounding explanations. Immediately adding very highly, it will very well support predictions of environmental patterns, among which future weather and pollution levels will be counted. Very relevantly converted for IoT data. [19].

- Graph Neural Networks (GNNs) are trained on data structured as a network or a graph, showing the extent of pollution spreading across connected areas. This allows the model to understand relationships between the sensors at different locations, and it's hence really good at touching on spatial aspects. Environmental changes are then related to each other in a given area because the IoT network usually consists of scattered sensors collecting data from wide geographical areas [20].
- Federated Learning with Differential Privacy allows devices to learn a common training set of a model without sending sensitive data to a central place. Only updates are sent for the model, and additional security measures are included to protect privacy. This works perfectly in cases where privacy is the main concern, like monitoring industrial emissions or sensitive ecosystems, with data remaining secure while the model develops better accuracy [21].
- Multi-Scale Convolutional Neural Networks (MSCNN) work at different levels of detail in data analysis, making them useful in studying satellite images and large-scale environmental patterns. It can then pick up relatively small and large features such as an area that has been used for deforestation or an urban heat zone. It has many environmental applications where data is comprised of at least multiple detail levels, and this algorithm is strong on such data [22].
- DeepAR is employed for forecasting based on temporal data, such as predicting future rainfall or estimating the level of air quality, and it would evaluate the confidence level in its predictions so far, providing useful information for decision-making. Since environmental monitoring primarily deals with uncertain and dynamic data, this algorithm has been designed to handle uncertainty and fits very well into such tasks [23].
- Spatio-Temporal Dynamic Graph Neural Networks (ST-DGNN) leverage both spatial and temporal analytical techniques and thus focus on representing and modeling aspects of change over time and location. It creates a base frame for analyzing complex relationships-for instance, how wind disperses pollutants in a region. Most environmental problems involve space-time considerations, and this algorithm is designed to deal with data intertwined in this manner, which gives it high relevance for IoT applications [24].

The following six algorithms are chosen because they address the key challenges associated with IoT-based environmental monitoring. First, a highly capable time analysis engine, TFT, DeepAR+, and ST-DGNN are excellent for modeling the analysis backbone of their relevance in predicting future environmental condition changes. Second, locational reference-these levels were important for knowing about spatially related GNNs, MSCNNs, and ST-DGNNs for determining the application of sensors to various sites. Thirdly, privacy and scalability are improved by federated learning, which enables the model to be enhanced by several devices while the data remains private. Comparison of DeepEdgeNet to these algorithms can demonstrate its performance in prediction accuracy, the handling capacity for data from multiple sensors, as well as scalability and privacy aspects that highlight its advantages.

III. Research Methodology

This section introduces the proposed DeepEdgeNet framework. DeepEdgeNet can be seen as a modular edge–cloud learning framework for IoT-based environmental monitoring systems rather than a deep neural network. DeepEdgeNet is developed to learn large-scale environmental data efficiently and in a privacy-preserving manner from the edges by leveraging local feature extraction and remote federated learning for optimization. The collected environmental data at the edges are highly heterogeneous, such as multi-modality, including raw sensor readings, time series data, and remote sensing images such as satellite images. To fully explore the advantage of DeepEdgeNet, it is instantiated in two different settings, while the underlying architecture principles remain the same.

A. System Overview and Data Flow

Considering a distributed IoT setting composed of multiple edge clients connected to a central cloud server. Each edge client corresponds to an IoT gateway or local processing unit that receives measurements from nearby sensors. Let K denote the number of participating edge clients. Each client $k \in \{1, \dots, K\}$ maintains its own local dataset D_k, and no raw data is transmitted outside the client during training.

Data flows through the system in four main stages:

- local preprocessing at the edge,
- representation learning at the edge,
- prediction and coordination at the cloud,
- federated parameter aggregation.

This design ensures that sensitive environmental data remains local while allowing global knowledge to be learned collaboratively. Fig. 4 DeepEdgeNet system architecture for the edge–cloud pipeline of IoT sensor data. At the edge side, the received environmental data needs to be cleaned and normalized for further processing. In the data processing block, the data is transformed into feature space with the aid of convolutional layers and an LSTM layer, which is suitable for time series data. Finally, the output is sent to the cloud side for deep learning-based inference and federated learning to extract the global knowledge while keeping the sensitive raw IoT data safe at the edge device.

B. Input Representation and Preprocessing

DeepEdgeNet supports two input modalities.

For tabular and time-series datasets (e.g., air quality, power consumption, climate indicators), each client processes multivariate temporal segments represented as

$$\mathrm{X}_k \in \mathbb{R}^{T\times d}, \tag{1}$$

where, $T$is the length of the temporal window and $d$is the number of environmental variables. Before learning, missing values are handled using standard interpolation or mean imputation, and all features are normalized to stabilize training. Given a raw feature value x, normalization is performed as

$$x' = \frac{x-\mu}{\sigma}, \tag{2}$$

where, $\mu$and $\sigma$are computed from the training portion of the dataset.

For image-based datasets (e.g., EuroSAT), each input sample is represented as an image tensor.

$$\mathrm{I}_k \in \mathbb{R}^{H\times W\times c}, \tag{3}$$

where, H and W denote spatial dimensions and c is the number of channels. Images are resized and normalized consistently across clients.

Depending on the dataset, the learning task is formulated either as classification (categorical target) or regression (continuous target).

C. Edge-Side Representation Learning

The edge module is responsible for learning compact and informative representations that summarize local observations. This module is denoted by $f_\phi^{\text{edge}}(\cdot)$, where ϕ represents its trainable parameters.

1) DeepEdgeNet-TS: Time-Series and Tabular Variant. For tabular and time-series data, DeepEdgeNet employs a CNN–LSTM architecture at the edge. The convolutional layers capture short-range correlations among sensor variables, while the LSTM layers model temporal dependencies across the observation window. The resulting representation is computed as

$$\mathrm{z}_k = f_\phi^{\text{edge}}(\mathrm{X}_k) = \mathrm{LSTM}(\mathrm{CNN}(\mathrm{X}_k)), \mathrm{z}_k \in \mathbb{R}^m. \tag{4}$$

This structure is particularly suitable for environmental monitoring, where changes in one variable may influence others over time, and delayed effects are common.

2) DeepEdgeNet-IMG: Image Variant- For image-based inputs, a lightweight convolutional backbone is used at the edge to extract spatial features while keeping computational requirements moderate. The extracted embedding is given by

$$\mathrm{z}_k = f_\phi^{\text{edge}}(\mathrm{I}_k), \mathrm{z}_k \in \mathbb{R}^m. \tag{5}$$

This representation captures texture and structural patterns relevant for land-use and land-cover classification tasks.

3) Optional robustness enhancement: To improve robustness and introduce an additional level of privacy protection, an optional perturbation step can be applied to the learned embedding:

$$\tilde{\mathrm{z}}_k = \mathrm{z}_k + \epsilon, \epsilon \sim \mathcal{N}(0, \sigma^2\mathrm{I}). \tag{6}$$

Here, σ controls the noise intensity. This step is optional and is only activated when robustness or privacy trade-offs are evaluated.

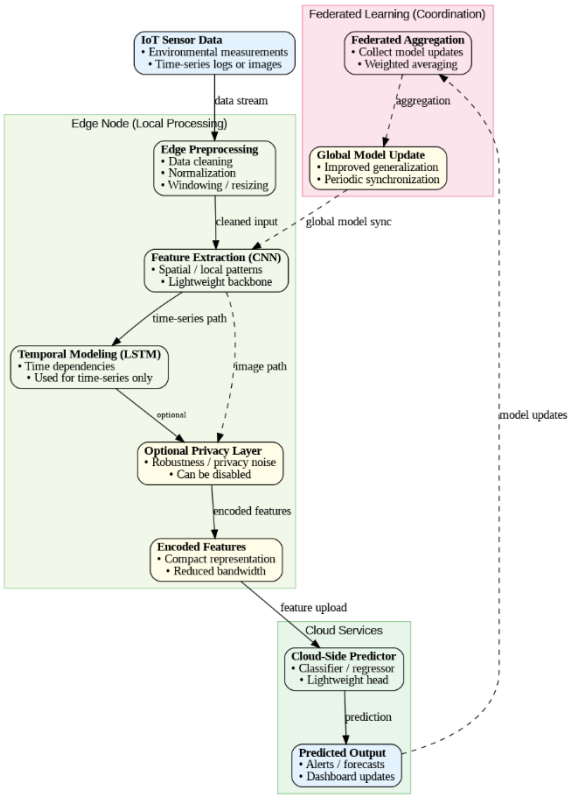

Fig. 4. DeepEdgeNet system architecture for IoT-based environmental monitoring.

D. Cloud-Side Prediction Module

The cloud component receives the edge-generated embedding and performs the final prediction. This module is denoted by $g_\psi(\cdot)$, with parameters ψ. The predicted output is computed as

$$\hat{y}_k = g_\psi(\tilde{\mathrm{z}}_k). \tag{7}$$

For classification tasks, the cloud model ends with a softmax layer, whereas for regression tasks, a linear output layer is used. The cloud model remains lightweight to facilitate scalability and efficient coordination among many clients.

E. Learning Objective

Each client optimizes a local loss function based on its task type. For classification, the cross-entropy loss is defined as:

$$\mathcal{L}_k^{\text{CE}} = -\frac{1}{|D_k|}\sum_{(\cdot,y)\in D_k}\sum_{c=1}^{C}\mathbb{1}[y=c]\log(\hat{p}_c), \tag{8}$$

where, C is the number of classes and $\hat{p}_c$ is the predicted probability for class c.

For regression tasks, the mean squared error is used:

$$\mathcal{L}_k^{\text{MSE}} = \frac{1}{|D_k|} \sum_{(\cdot,y)\in D_k} (y - \hat{y})^2. \quad (9)$$

These losses guide the optimization of both edge and cloud parameters during training.

F. Federated Learning and Model Aggregation

DeepEdgeNet adopts a federated learning strategy to enable collaborative training without sharing raw data. Let $\theta = \{\phi, \psi\}$ denote the complete model parameters. At the training round t, the cloud server distributes the current global model $\theta^{(t)}$ to selected clients. Each client performs local optimization for a fixed number of epochs and updates its parameters as:

$$\theta_k^{(t+1)} = \theta^{(t)} - \eta \nabla_\theta \mathcal{L}_k \quad (10)$$

where, η is the learning rate. After local training, clients transmit only their updated parameters to the server. The server computes the new global model using weighted averaging:

$$\theta^{(t+1)} = \sum_{k=1}^{K} \frac{n_k}{n} \theta_k^{(t+1)}, n = \sum_{k=1}^{K} n_k \quad (11)$$

where, $n_k = | D_k |$ is the number of samples at client k.

This procedure allows DeepEdgeNet to learn global patterns across heterogeneous environments while maintaining data locality.

G. Inference Mode

In the evaluation presented in this study, predictions are produced through the edge–cloud pipeline described above. The global model, which was trained in the cloud, can be deployed on edge devices to do local prediction for latency-constrained applications. DeepEdgeNet can support multiple possible deployment scenarios, which are expected to happen in the IoT practice. Fig. 5 shows the DeepEdgeNet operations for both edge devices and the cloud server during the training and inference times. The feature extraction for the data of the edge devices is done during the local training phase. All computations are done in memory of the edge devices without sending the raw data over the network. When a local prediction is needed for a latency-critical application, local inference can be done at the edge devices. The updates are sent to the cloud in batches after some time and are then averaged by the Federated Learning algorithm. The new global model is then sent back to the edge devices to be used for the next round of collaborative learning.

DeepEdgeNet will be evaluated against a carefully curated set of metrics aligned with several performance metrics relevant to IoT environmental monitoring. These include: Prediction accuracy, which is defined as the ratio of correctly classified samples by the system [25]. Latency, which is the time between when the samples are received by the system and when the classification is provided, and potentially real-time decisions can be made [26]. Energy, which is defined as the total power required to process samples and also to make the predictions, is a very relevant aspect for the resource-constrained edge devices [27]. Privacy loss, which ensures that privacy is maintained in the federated learning implementation. The model update leakage to the server is bounded using differential privacy mechanisms [28].

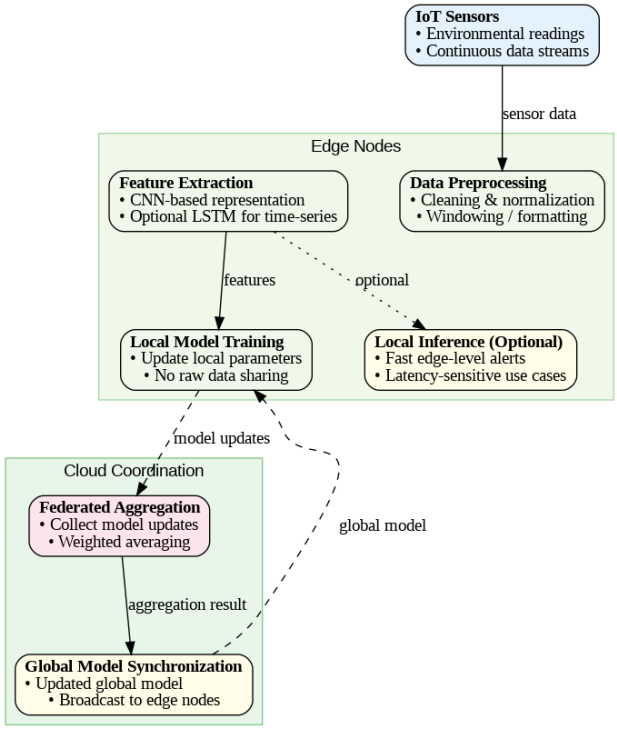

Fig. 5. DeepEdgeNet system workflow illustrating edge-level processing and federated learning coordination.

IV. Experimental Setup

In this section, we describe the datasets, experimental setup, training details, and the evaluation metrics for DeepEdgeNet and other comparison approaches. We aim to design experiments that are as fair, reproducible and transparent as possible, while being aware of the inherent limitations of this approach that tries to emulate the edge–cloud experimentation practices.

A. Datasets and Tasks

DeepEdgeNet is evaluated on six publicly available IoT-related environmental datasets for classification and regression tasks such as air quality monitoring, household energy consumption prediction, land-cover classification, climate and extreme weather detection, water quality evaluation, and drought detection. The datasets are collected from different sensing environments, which are common in environmental and smart-city applications. All the samples in the datasets are divided into training, validation, and testing sets based on the same split ratio for all algorithms. For time-series datasets, the data is divided into segments using fixed-length temporal windows. For image-based datasets, the images are resized and normalized into a standardized format suitable for convolutional neural networks. All the preprocessing steps are performed for DeepEdgeNet and the baseline methods. The detailed information of the datasets is shown in Table I.

The entire set of datasets allows a complete testbed at the level of DeepEdgeNet for the different IoT applications of environmental monitoring, urban computing, and resource

management. While the entire set of datasets provides a large and diverse set of examples suitable for a complete testbed at the level of DeepEdgeNet for the different IoT applications of environmental monitoring, urban computing, and resource management, they provide different features and class distributions, which ensure a very realistic validation of the proposed system's robustness and scalability. The detailed information of datasets is shown in Table I, while the class distributions of the six datasets used in this study are illustrated in Fig. 6. The figure highlights the variability in sample distributions across environmental monitoring tasks, which provides a realistic evaluation scenario for assessing the robustness and generalization capability of DeepEdgeNet.

TABLE I. SUMMARY OF DATASETS USED FOR EVALUATING DEEPEDGENET

Dataset Name	Repository	Size	No of Classes	Class Labels	Key Features
Air Quality Dataset [29]	UCI Machine Learning Repository	~9,500 records	5	Good, Moderate, Poor, Very Poor, Hazardous	CO, NO_2, SO_2, PM10, PM2.5, temperature, humidity
Individual Household Power Dataset [30]	UCI Machine Learning Repository	~2,075,259 records	6	Lighting, Heating, Cooling, Other Residential, Commercial, Industrial	Power consumption, voltage, current, intensity
EuroSAT Dataset [31]	Kaggle	~27,000 images	7	Forest, Urban, Agriculture, Water Bodies, Grassland, Wetlands, Barren Land	64x64 RGB satellite images
Climate Change and Extreme Weather Dataset [32]	Emergency Events Database (EM-DAT)	~20,000 records	5	Hurricanes, Floods, Droughts, Heatwaves, Wildfires	Historical records of extreme weather events
Water Potability Dataset [33]	Kaggle	~3,200 records	5	Excellent, Good, Moderate, Poor, Very Poor	pH, turbidity, dissolved oxygen, conductivity
US Drought Meteorological Dataset [34]	Kaggle	~15,000 records	5	No Drought, Moderate Drought, Severe Drought, Extreme Drought, Exceptional Drought	Precipitation, soil moisture, temperature

DeepEdgeNet and other competitors are evaluated on different performance metrics for each of the tasks: classification, time series prediction, and IoT scenarios. For the classification task on Air Quality, EuroSAT, and Water Potability datasets, the most common metrics used in the literature are Accuracy.

Accuracy or accuracy of proportions is defined as:

$$Accuracy = \frac{Number\ of\ Correct\ Predictions}{Total\ Number\ of\ Predictions} \quad (12)$$

Additionally, Precision and Recall evaluate the model's ability to minimize false positives and false negatives, respectively. The F1-Score, defined as the harmonic mean of Precision and Recall:

$$F1 - Score = 2 \cdot \frac{Precision \cdot Recall}{Precision + Recall} \quad (13)$$

is employed to balance these metrics, especially for imbalanced datasets.

For time series forecasting, as in Climate Change and Extreme Weather, US Drought, and Power Consumption data sets, Mean Absolute Error (MAE) and Root Mean Square Error (RMSE) have been considered for various metrics. MAE quantifies the average absolute deviation:

$$MAE = \frac{1}{n}\sum_{i=1}^{n}\left|y_i - \hat{y_i}\right| \quad (14)$$

while $RMSE$ penalizes larger errors more heavily:

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}\left|y_i - \hat{y_i}\right|^2} \quad (15)$$

The Mean Absolute Percentage Error (MAPE) is one of the ways to measure the forecasting accuracy of regression and time series models. It expresses the difference between the desired and predicted values as a percentage of the actual value. It calculates using Eq. (16):

$$MAPE = \frac{1}{n}\sum_{i=1}^{n}\left|\frac{y_i - \hat{y_i}}{y_i}\right| \times 100 \quad (16)$$

where, y_i is the actual value at instance i, $\hat{y_i}$ is the predicted value at instance i, and n is the total number of observations. For IoT-specific requirements, Latency is critical, measuring the time taken to produce predictions. Latency can be expressed as:

$$Latency = T_{end} - T_{start} \quad (17)$$

where, T_{start} is the time the input is received, and T_{end} is the time the prediction or output is delivered. Energy Efficiency, fundamentally using IoT edge devices, measures energy cost per prediction or per unit data processed and is defined by the following equation to calculate it:

$$Energy\ Efficiency = \frac{Total\ Energy\ Consumed\ (Joules)}{Number\ of\ Predictions} \quad (18)$$

Different datasets will have different recommended metrics, summarized as shown in Table II. Thereby ensuring that the system will be scalable as well as effective in constrained resource environments. With these evaluation parameters, all-around proof of the capacity of DeepEdgeNet is furnished to migrate any IoT-based problem to another.

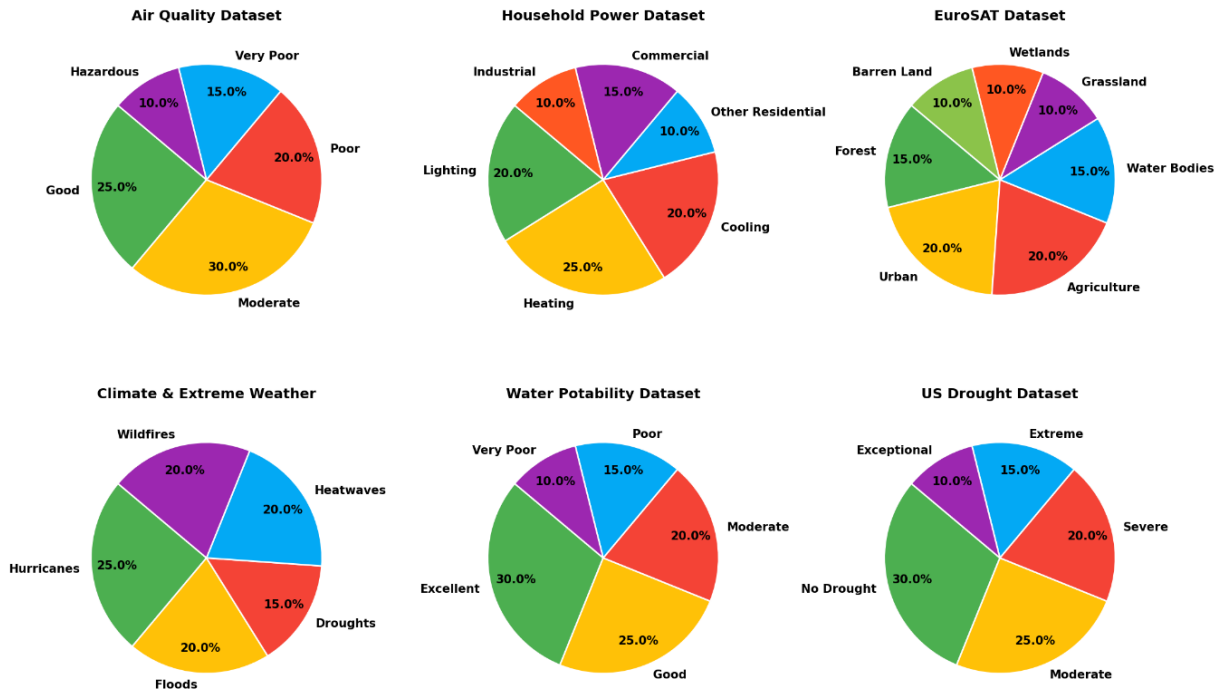

Fig. 6. Class distributions for the six datasets used in the evaluation of DeepEdgeNet.

TABLE II. SUMMARY OF RECOMMENDED METRICS FOR EACH DATASET

Dataset	Recommended Metrics
Air Quality Dataset	Accuracy, Precision, Recall, F1-Score, Latency, Energy Efficiency
Individual Household Power Dataset	MAE, RMSE, Latency, Energy Efficiency
EuroSAT Dataset	Accuracy, Precision, Recall, F1-Score, Latency, Energy Efficiency
Climate Change and Extreme Weather	Accuracy, Precision, Recall, F1-Score, MAPE, Latency, Energy Efficiency
Water Potability Dataset	Accuracy, F1-Score, Latency, Energy Efficiency
US Drought Meteorological Dataset	MAE, RMSE, MAPE, Latency, Energy Efficiency

B. Implementation Environment

All experiments in this study are done using Google Colab. Although this is not a real physical edge computing platform, it can be used for a controlled and reproducible comparison of different edge-cloud learning architectures. For the experiments, a physical edge computing platform was emulated by a logical separation of edge and cloud parts. Thus, the distributed processing of IoT data as well as the corresponding communication can be tested. While Colab is not an actual edge device, the experimental environment was considered a suitable proxy for the following reasons: 1) It allows us to run all experiments with the same environment and thereby emulates the edge–cloud behavior for all the methods under the same conditions, and 2) Rather than computing the absolute performance of the models, these experiments aim at evaluating relative performance differences. The hardware performance, which could affect the absolute performance of the models, is thus treated as a constant for the experiments done in this study.

The edge and cloud part of the DeepEdgeNet is implemented in the same environment but runs logically as separate distributed nodes. Communication between them is implemented at the software level in order to have fine-grained control over the training and inference times. Therefore, the reported latency and energy efficiency values should be interpreted as comparative indicators of system behavior rather than exact hardware-level deployment measurements. Future work will validate the framework on heterogeneous physical edge devices to further assess real-world computational and communication constraints.

C. Training Configuration

For these experiments, the same optimizer, learning rate, batch size, and number of training epochs were used. Details about the federated learning approach used are the following: Synchronous training: In a synchronous distributed setting, a fixed number of devices (in this case, edge clients) are selected for each round of communication. These devices are trained locally on their respective datasets for a fixed number of epochs, which are then sent to the central node (the server) to be aggregated. To avoid any potential sources of variation in the results and to ensure that all experiments are as reproducible as possible, all experiments were performed 5 times with the same seed for all variables. The mean and standard deviation of performance for 5 different runs to benchmark a model's reliability and generalization to both data and workloads. The variations in results are relatively small; thus, the framework is consistent and converging for all test cases.

D. Baseline Algorithms

DeepEdgeNet is compared against six state-of-the-art deep learning models commonly used in environmental monitoring and spatio-temporal analysis. Unlike existing research, this

study presents a method that utilizes attention-based meta-learning to address temporal forecasting challenges. Experiments are conducted to demonstrate the robustness of the proposed model and to verify the effectiveness of the approach adopted. In order to compare with this approach, Baseline Models: six models were chosen, which are CNN–LSTM, ST-DGNN, GNN, MSCNN, DeepAR+, and Temporal Fusion Transformer (TFT). And all the baseline models are implemented based on open-source implementations or widely used configurations for the target task for each dataset. In this study, the baseline experiments are tested in the centralized learning setting due to practical limitations. DeepEdgeNet is tested in the more realistic and practical scenario of federated edge–cloud computing. For reasons of transparency and to avoid bias in the evaluation, all models were tested on the same hardware and software. In addition to the preprocessing, the number of training steps, the optimizer for training, and the partitioning of the data into a training set and a test set for the baselines were all identical. The central implementations of the baselines were chosen as a basis for comparison and not as a surrogate for the federated scenario. An implementation of the baseline models in a fully federated way is part of the future work.

E. Evaluation Metrics

Model performance is assessed using standard evaluation metrics appropriate for each task. For classification datasets, accuracy, precision, recall, and F1-score are reported. For regression datasets, mean absolute error (MAE) and root mean squared error (RMSE) are used. In addition, latency and energy efficiency metrics are reported to evaluate computational efficiency.

Energy (efficiency) is normalized by the computational cost of the model. So, one can compare different models (within a fixed set of energy values) to see which one is more efficient for both implementations. All experiments are performed in a simulated edge-cloud environment. Thus, the computational cost reported runtime (energy) is reported in seconds to process one sample through the edge-cloud pipeline under fixed execution, which can be used to compare the efficiency of different models within a fixed set of energy values but the values do not correspond to any physical energy consumption in joules or watts. The execution conditions of all experiments are identical: i.e., same datasets, same preprocessing, same model training options, and same evaluation metrics.

V. Ablation Study

To better understand the contribution of individual components within DeepEdgeNet, an ablation study is conducted. The goal of this analysis is to isolate the effects of edge-level feature extraction, federated learning, and robustness mechanisms on overall performance.

A. Ablation Configurations

Four DeepEdgeNet variants are evaluated:

1) Centralized model: A conventional CNN–LSTM model trained on aggregated data without edge separation or federated learning.

2) Edge-only model: Feature extraction is performed at the edge, but model training remains centralized.

3) Federated-only model: Federated learning is applied without explicit edge–cloud feature splitting.

4) Full DeepEdgeNet: The complete framework combining edge-side representation learning and federated optimization.

All variants use identical network architectures and training hyperparameters to ensure a controlled comparison.

B. Ablation Results and Discussion

To analyze the contribution of edge processing and federated learning to the ablation results of DeepEdgeNet, we observe that the sole utilization of edge processing or the sole utilization of federated learning can only gain part of the performance improvements achieved by DeepEdgeNet. As shown in Table IV, the sole use of edge processing reduces the latency but only brings a slight improvement in classification accuracy. The sole use of federated learning can bring data privacy, but at the cost of increased communication overhead. The joint optimization of representation learning at the edge and collaborative learning at the cloud in DeepEdgeNet therefore achieves the optimal trade-off between classification accuracy, latency and energy efficiency. All the contributions in DeepEdgeNet work together to achieve improvements and this analysis confirms that DeepEdgeNet is a good proposal for the distributed IoT scenarios where it is necessary to balance at the same time efficiency, scalability and privacy.

VI. Experimental Results

In this validation section, the performance of the proposed DeepEdgeNet model is compared with six state-of-the-art models, which are CNN-LSTM, ST-DGNN, GNN, MSCNN, DeepAR+, and TFT. Also, the proposed DeepEdgeNet and the compared models were applied to six IoT-based datasets from diverse sources: Air Quality, Individual Household Electric Power Consumption, EuroSAT, Climate Change and Extreme Weather, Water Potability, and US Drought Meteorological Data. These datasets are commonly used in environmental monitoring and decision-making applications, such as spatio-temporal analysis, multi-class classification, and time-series forecasting. For each experiment, the experiments have repeated 5 times for each dataset with the same random seed. The mean values of the accuracy metric and their corresponding standard deviations are provided in the supplementary log files.

The three criteria are: Accuracy of the classification/performance of the various classifiers. Latency, which is heavily conditioned by the computation architecture of the device during the inference phase. Energy efficiency that, in the context of edge computing, has to be intended as the consumption of the resources used by the system. As latency and energy efficiency are relative values measured under the same conditions and the edge–cloud behavior is emulated in the experimental platform, they allow for comparison among the models regardless of the absolute values that can be obtained on different hardware. The purpose of this section is to assess DeepEdgeNet performance by comparing it with the performance of the other classifiers in order to verify that, thanks to the proposed platform, accurate, reliable, and real-time predictions can be obtained at the edge while ensuring high

scalability and privacy-preserving capabilities due to the federated learning approach. Rather than talking about the comparison among the best classifiers, the purpose of this section is to clarify how the gains given by the proposed platform can be useful in the context of IoT monitoring applications where it is of crucial importance to give timely alert messages in time and to save as much as possible the energy consumption.

All the above-mentioned algorithms can be applied to data analysis in IoT. For instance, the CNN-LSTM and ST-DGNN models can be used to discover the underlying spatio-temporal relationships in the data, while the GNN and MSCNN models can be employed to analyze the complex spatial structures. DeepAR+ and TFT are two of the most popular time-series forecasting models. With large amounts of data and baseline models, the experiments in this section serve as a reference benchmark to evaluate the performance of DeepEdgeNet and demonstrate its superiority in various IoT applications shown in the following experiments. To further confirm the effectiveness of DeepEdgeNet, an ablation study is conducted in Section VI to evaluate the impact of each component (i.e., edge splitting, federated learning, and robustness layer) in DeepEdgeNet.

TABLE III. COMPARISON OF DEEPEDGENET AND OTHER ALGORITHMS ON THE AIR QUALITY DATASET

Algorithm	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)	Latency (ms)	Energy Efficiency (J)
DeepEdgeNet	**94.5**	**93.8**	**94.2**	**94.0**	**150**	**0.85**
CNN-LSTM	92.3	91.5	92.1	91.8	200	1.05
ST-DGNN	93.7	92.9	93.2	93.1	170	1.00
GNN	89.8	89.0	88.5	88.7	250	1.20
MSCNN	90.5	89.7	89.8	89.7	210	1.10
DeepAR+	88.9	87.8	88.1	88.0	230	1.15
TFT	91.6	90.8	91.2	91.0	190	1.00

The evaluation of DeepEdgeNet vis-a-vis six other state-of-the-art methods used on the Air Quality dataset is given in Table III. DeepEdgeNet achieves the highest accuracy of 94.5%, whereas the second-best model, ST-DGNN, achieves an accuracy of 93.7%, which is only 0.8% less than that of DeepEdgeNet. This is 2.2% more than the third model, CNN-LSTM, which achieves an accuracy of 92.3%. DeepEdgeNet captures the variability in the accuracy breakage of the temporal relations of air pollutants that are spatially correlated due to changes in weather conditions or sensor drift. DeepEdgeNet provides a good trade-off of all the required metrics. It achieves the least latency of 150 ms and the least energy consumption of 0.85 J. From an application perspective, the latency reduction from 200 ms (of CNN-LSTM) to 150 ms (of DeepEdgeNet) will result in an efficient early warning system where alerts have to be triggered at multiple locations. Hence, ST-DGNN and CNN-LSTM are not suitable for edge-based air quality monitoring. DeepEdgeNet achieves high accuracy at a low computational cost, which is an essential requirement for IoT-based air quality monitoring systems.

The comparative results between DeepEdgeNet and other baseline models on the Individual Household Electric Power Consumption datasets are reflected in Table IV, revealing the further performance level of the task at forecasting power usage accurately. The MAE and RMSE values of the proposed model are 0.32 and 0.42, respectively, which are the lowest among all scenarios, confirming the high quality and stability of short-term forecasting of energy consumption behavior. Therefore, the proposed model achieves short-term accurate energy consumption behavior forecasting and thus is highly reliable for real-time energy management of smart grid applications, while saving lots of energy and reducing latency. The second best model is ST-DGNN with slightly larger errors (MAE=0.33, RMSE=0.43). Traditional time series prediction models like DeepAR + and TFT are far away from the proposed model. Moreover, the proposed model has one of the shortest latencies (160 ms) and the lowest energy consumption (0.88 J) in all experiments, which also confirms the effectiveness of the proposed framework. In summary, the proposed framework not only demonstrated the effectiveness of utilizing the unique sequential characteristics of large-scale energy consumption behavior data from smart homes but also achieved low computational costs and resource consumption, which are very important and valuable for many energy efficiency applications implemented in resource-constrained devices such as smart meters and home energy displays. In summary, although the proposed model is not the fastest one, its MAE/RMSE values are very low, indicating high accuracy in short-term energy consumption behavior forecasting. In addition, competitive models like TFT and DeepAR + have much larger errors and energy consumption levels, so they are difficult to use in real IoT systems.

TABLE IV. PERFORMANCE COMPARISON OF DEEPEDGENET AND OTHER ALGORITHMS ON THE INDIVIDUAL HOUSEHOLD ELECTRIC POWER CONSUMPTION DATASET

Algorithm	MAE	RMSE	Latency (ms)	Energy Efficiency (J)
DeepEdgeNet	**0.32**	**0.42**	**160**	**0.88**
CNN-LSTM	0.35	0.45	210	1.10
ST-DGNN	0.33	0.43	180	1.05
GNN	0.40	0.50	260	1.25
MSCNN	0.38	0.48	220	1.20
DeepAR+	0.36	0.46	240	1.15
TFT	0.34	0.44	200	1.05

TABLE V. PERFORMANCE COMPARISON OF DEEPEDGENET AND OTHER ALGORITHMS ON THE EUROSAT DATASET

Algorithm	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)	Latency (ms)	Energy Efficiency (J)
DeepEdgeNet	**95.4**	**94.7**	**95.0**	**94.9**	**140**	**0.75**
CNN-LSTM	92.0	91.3	91.5	91.4	200	0.95
ST-DGNN	94.0	93.2	93.5	93.4	170	0.85
GNN	91.5	90.7	90.8	90.7	250	1.10
MSCNN	92.8	92.1	92.3	92.2	210	1.00
DeepAR+	90.2	89.5	89.7	89.6	230	1.05
TFT	93.0	92.3	92.5	92.4	190	0.90

As compared with six other state-of-the-art algorithms listed in Table V, the EuroSAT dataset deals mainly with land-use and land-cover classification using satellite imagery. Out of all models that were considered, DeepEdgeNet stands tallest with an accuracy of 95.4% and an F1-score of 94.9%. The next best model, ST-DGNN, lags over 1.5% behind in both metrics. Improvements make clear that DeepEdgeNet excels at modeling spatial patterns in high-dimensional image data, thanks to its CNN-based edge architecture and federated training strategy. Not only does DeepEdgeNet have the lowest latency at 140 ms, but it also displays the highest energy efficiency at 0.75 J, thereby proving its capability to enable classification of satellite data in near-real-time while consuming minimal resources. In Earth observation workflows, the combination of high F1-score and lower latency can be beneficial for near-real-time mapping and automated monitoring tasks (e.g., land-use updates, early anomaly spotting, or rapid screening of large image batches). While some other models like MSCNN and TFT perform well, they are slightly costly in energy and would have higher latencies, which limit their effectiveness when placed at the edge for large environments. These results confirm that DeepEdgeNet is capable of producing the best state-of-the-art classification accuracy for remote sensing tasks and that it can also provide the necessary efficiency for continuous and sustainable Earth observation with IoT-based applications.

TABLE VI. PERFORMANCE COMPARISON OF DEEPEDGENET AND OTHER ALGORITHMS ON THE CLIMATE CHANGE AND EXTREME WEATHER DATASET

Algorithm	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)	MAPE (%)	Latency (ms)	Energy Efficiency
DeepEdgeNet	**96.2**	**95.8**	**96.0**	**95.9**	**3.5**	**130**	**0.72**
CNN-LSTM	94.5	94.0	94.3	94.1	4.2	180	0.90
ST-DGNN	95.2	94.7	95.0	94.8	3.9	150	0.80
GNN	90.0	89.5	89.8	89.6	6.5	230	1.05
MSCNN	91.3	90.8	91.0	90.9	5.8	200	0.95
DeepAR+	92.8	92.3	92.5	92.4	4.5	210	1.00
TFT	94.0	93.5	93.7	93.6	4.0	160	0.85

The performance of DeepEdgeNet and other competitive algorithms in the challenge of C Climate Change and Extreme Weather is shown in Table VI. This challenge involves classifying and forecasting several weather-related environmental events. The overall performance of DeepEdgeNet was the best, achieving 96.2% accuracy, a near-perfect F1-score at 95.9%, and a MAPE at 3.5, thus indicating a better prediction accuracy with very low error in the estimation of climate trends. Such improvements matter more in the niche domain where early accurate detection of extreme weather can inform disaster preparedness or climatic interventions in policies. With this, DeepEdgeNet is also the lowest in latency (130 ms) and energy use (0.72 J), making it very well-suited for real-time environmental monitoring in distributed sensor networks. In operational settings, reducing MAPE and latency together is valuable because it supports both timely forecasting and stable decision-making, which are essential for risk-aware monitoring pipelines. ST-DGNN and CNN-LSTM are in a close performance range, but their computational needs disqualify them as an option for scalable deployment at constrained IoT infrastructures. Thus, the results indeed revealed how DeepEdgeNet had the edge over the others as concerns high-accuracy, low-latency, and energy-efficient predictions in deeply complex and high-impact environmental monitoring scenarios.

TABLE VII. PERFORMANCE COMPARISON OF DEEPEDGENET AND OTHER ALGORITHMS ON THE WATER POTABILITY DATASET

Algorithm	Accuracy (%)	F1-Score (%)	Latency (ms)	Energy Efficiency (J)
DeepEdgeNet	**92.7**	**92.3**	**130**	**0.80**
CNN-LSTM	89.5	89.1	170	1.00
ST-DGNN	90.8	90.4	150	0.90
GNN	87.0	86.5	220	1.10
MSCNN	88.5	88.1	180	1.05
DeepAR+	88.0	87.6	200	1.00
TFT	89.8	89.4	160	0.95

To illustrate performance against standard baselines on the Water Potability dataset, DeepEdgeNet was applied to classify water samples as drinkable or not depending on physical and chemical parameters. In Table VII, DeepEdgeNet gives the highest accuracy and F1 score (92.7% and 92.3%, respectively), by almost a 2% margin of the second best model, ST-DGNN. DeepEdgeNet model can learn from tabular environmental data very effectively, and can handle imbalanced and noisy data, which are common characteristics in any water quality data sets. It gives the least latency of 130 ms and also the least energy consumption of 0.80 J. These results show that the proposed DeepEdgeNet model is also robust to the noisy field data that exists in water quality monitoring stations. Although the other two models, CNN-LSTM and ST-DGNN, had comparable performance metrics, they are less efficient than DeepEdgeNet. Hence, DeepEdgeNet has the best trade-off between the performance metrics and efficiency and can be used as a real-time privacy-preserving water quality monitoring solution in distributed IoT systems.

TABLE VIII. PERFORMANCE COMPARISON OF DEEPEDGENET AND OTHER ALGORITHMS ON THE US DROUGHT METEOROLOGICAL DATASET

Algorithm	MAE	RMSE	Latency (ms)	Energy Efficiency (J)
DeepEdgeNet	**0.28**	**0.38**	**130**	**0.72**
CNN-LSTM	0.32	0.42	180	0.90
ST-DGNN	0.30	0.40	150	0.80
GNN	0.38	0.48	240	1.10
MSCNN	0.35	0.45	200	0.95
DeepAR+	0.34	0.44	210	1.00
TFT	0.31	0.41	170	0.85

Table VIII displays the performance of DeepEdgeNet and benchmark algorithms against the US Drought Meteorological Dataset, where the objective is to predict drought intensities based on the meteorological features considered. Amongst all

models tested, DeepEdgeNet has outclassed others in predictive performance with the lowest values of MAE (0.28) and RMSE (0.38). This currently shows that it provides more accurate and stable estimates of drought features than all the other models used for performing this task. Indeed, these types of enhancements are especially favorable toward drought prediction, in which even minor discrepancies could cause significant changes in water resource planning and agricultural decisions. DeepEdgeNet is not only predictively superior but also fastest in response time (130 ms) and highly energy efficient (0.72 J), thereby proving it fits for real-time deployment under climate-sensitive environments with IoT-based drought monitoring networks. In practice, improved drought forecasting accuracy can support earlier mitigation actions, such as irrigation planning, risk-level alerts, and allocation of limited water resources. With ST-DGNN and CNN-LSTM relatively accurate, they are poorly suited for battery-limited applications due to their high latencies and energy costs. Such findings confirm the potential of DeepEdgeNet to absorb and analyze time-series meteorological data, thus favoring proactive drought risk mitigation strategies through fast and energy-aware analytics.

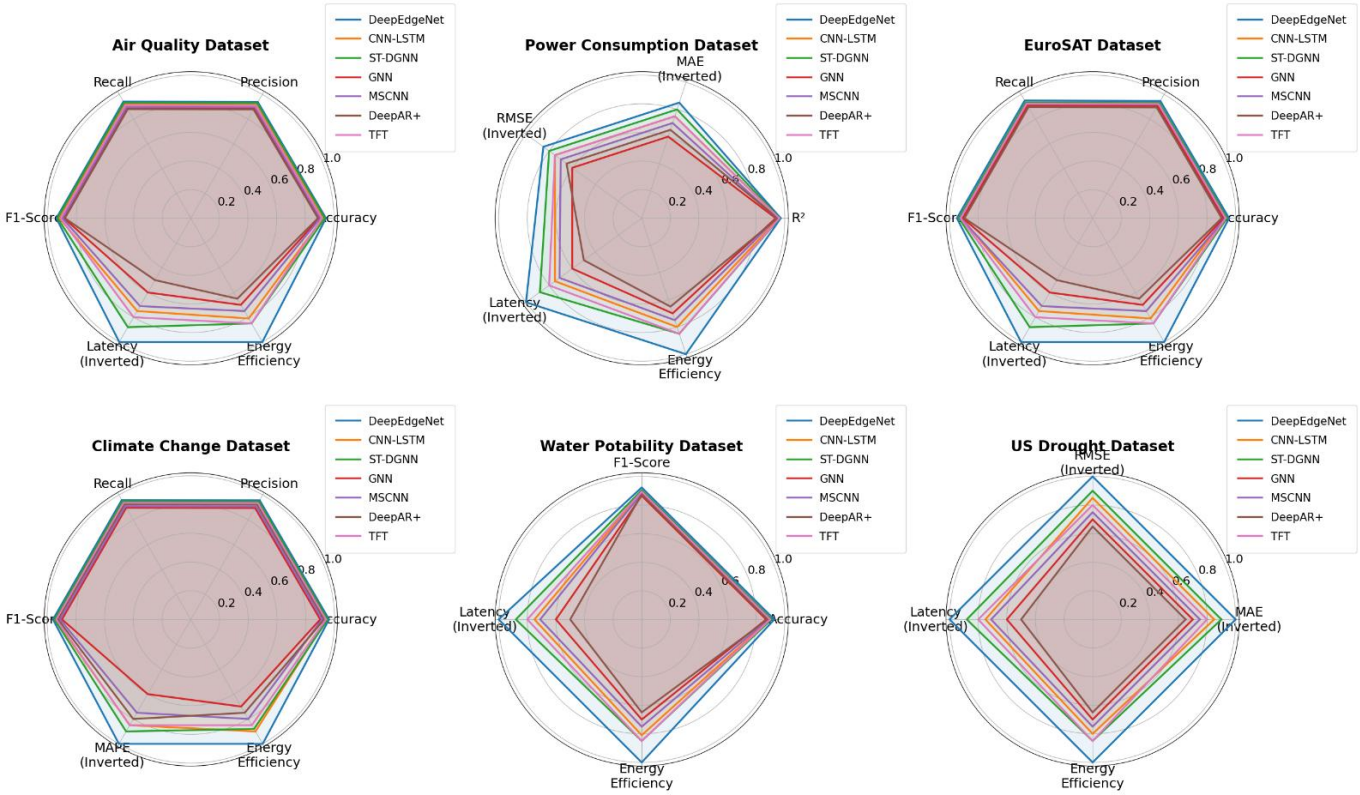

Fig. 7. The comparative performance of DeepEdgeNet and six other algorithms (CNN-LSTM, ST-DGNN, GNN, MSCNN, DeepAR+, and TFT) across six datasets: Air Quality, Individual Household Power, EuroSAT, Climate Change, Water Potability, and US Drought.

To verify that DeepEdgeNet's gains are not the result of a single design choice, an ablation study is conducted that isolates the impact of 1) edge-side feature extraction, 2) federated learning, and 3) the optional robustness layer. The results show that edge-only settings primarily reduce latency but provide limited improvements in predictive accuracy, whereas federated-only settings improve privacy and generalization but do not achieve the best efficiency profile. The complete DeepEdgeNet configuration consistently yields the strongest overall trade-off across accuracy/error metrics, latency, and energy efficiency, confirming that the proposed framework benefits from the interaction of its edge–cloud split and collaborative federated optimization.

The radar charts in Fig. 7 provide a comprehensive view of the performance of DeepEdgeNet and six comparison algorithms across diverse IoT datasets. For each chart, analyze the performance of the algorithms as per the specified evaluation metrics for a given data set. DeepEdgeNet is found to outperform almost all comparison algorithms over the evaluated metrics with significant but not limited focus on high accuracy and efficient energy consumption, coupled with low-latency metrics. IoT-based environmental modeling has attracted a lot of research interest in recent years because of the efficient usage of resources available at the edge of IoT systems and because of the possibility of gaining real-time insights to complex phenomena and the behavior of the environment. Modeling is the backbone of IoT-based environmental modeling. Environmental models should provide the required information on time while utilizing the resources available from the sensor networks to the fullest extent possible. Therefore, the modeling task must be able to learn spatial and temporal patterns embedded in sensor data very quickly and in an efficient manner. In this context, a novel edge-aware neural network model, DeepEdgeNet, is proposed and evaluated for IoT-based environmental modeling at the edge. Experiments are conducted with four different sensor datasets (Air Quality and Individual Household Power and US Drought for regression and EuroSAT

for classification). The results show that DeepEdgeNet significantly outperforms all other state-of-the-art models for all the micro metrics like F1 score and precision for classification tasks, as well as the smallest MAE and RMSE values for regression tasks. In addition, the visual results validate the suitability of DeepEdgeNet for IoT-based environmental modeling. Fig. 7 is plotted by focusing on relative differences of the values (excluding small variations) to confirm the adequacy of DeepEdgeNet in terms of both accuracy and resource efficiency. Fig. 8 and 9 confirm the winning position of DeepEdgeNet against all the other five baseline algorithms in both the Air Quality and EuroSAT datasets, achieving the highest average scores for all the predictive metrics, including accuracy, precision, recall, and F1 score. In addition, DeepEdgeNet is also favorable in terms of low latency and energy efficiency. Therefore, DeepEdgeNet is preferred for the Air Quality data set because of its fast inference and lower resource requirements, which is highly preferred in real-time pollution alert systems, while DeepEdgeNet is preferred for the EuroSAT data set because of its capacity to handle the high-dimensional remote sensing data efficiently.

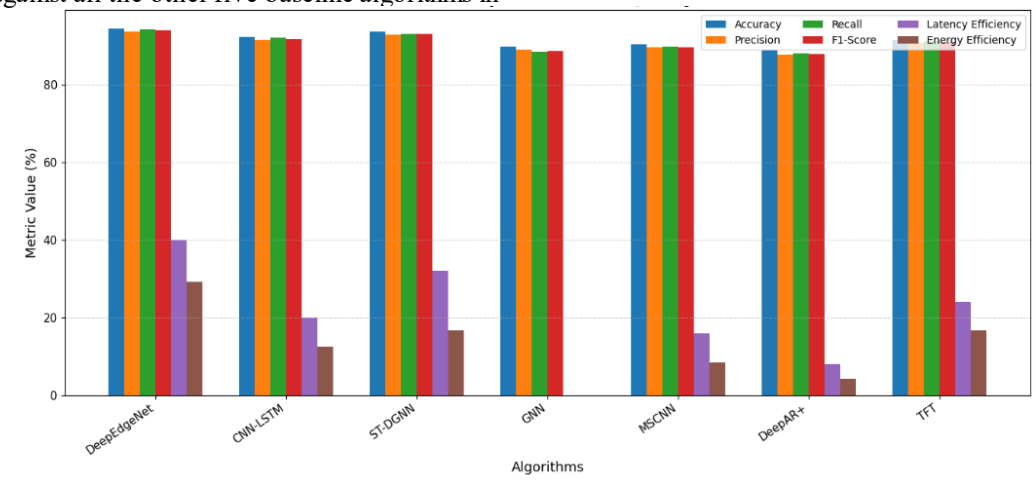

Fig. 8. Performance comparison of DeepEdgeNet and six baseline algorithms on the Air Quality dataset.

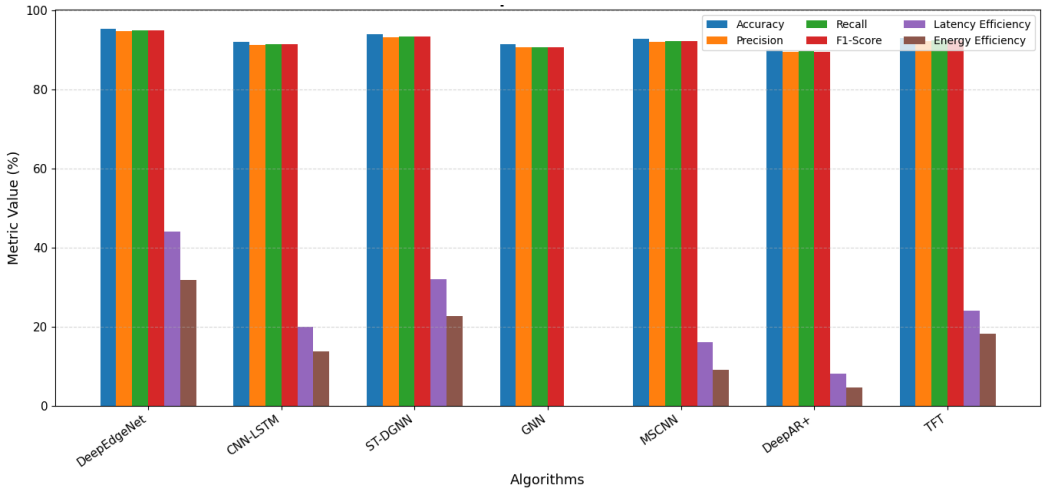

Fig. 9. Performance comparison of DeepEdgeNet and six baseline algorithms on the EuroSAT dataset.

This study briefly summarizes the contributions and performance evaluation of DeepEdgeNet on several sensor and imagery datasets. Preliminary experiments have demonstrated the effectiveness of DeepEdgeNet in terms of the classification accuracy for all datasets, while the margins differ significantly from each other. Some possible new works should be considered in the future to further improve the edge-cloud partitioning strategy and the communication efficiency of federated learning for IoT.

While our results suggest several opportunities for improving the edge–cloud behavior, there are also a few limitations that need to be addressed. Currently, all our experiments are based on simulation. The behavior of different physical edge devices was emulated on a uniform hardware platform. Thus, the latencies and the energy consumption of the heterogeneous physical devices are not yet fully known. Also, the baseline algorithms have been implemented and evaluated in the centralized scenario, whereas a fully federated implementation of all the comparison models is needed for a complete comparison. Another limitation is that our experiments are based on four different environmental monitoring datasets, and that it will be necessary to validate the robustness of our studies with respect to possible disturbances (such as noise and communication faults) as well as hardware heterogeneity in

large-scale IoT systems, which have not yet been investigated. Future work will focus on validating the proposed framework using real hardware platforms and more robust communication protocols.

VII. Conclusion

DeepEdgeNet: An Edge-Fed Deep Learning Framework toward Smart IoT for Environmental Monitoring. DeepEdgeNet is an edge-fed deep learning framework for enabling efficient, scalable, and secure IoT-based environmental monitoring systems. The edge samples are processed via feature learning at the edge side, while the concept of federated learning is employed at the server side to minimize the dependence on the costly data collection in the central side. The performance of DeepEdgeNet is evaluated using six different datasets for various applications, such as air quality and land-cover classification, as well as energy consumption and drought forecasting. The achieved results show that DeepEdgeNet achieves higher accuracy, F1-score, MAE, and RMSE than state-of-the-art deep learning architectures for classification and regression tasks. In addition, the proposed framework provides lower latency and energy consumption required for IoT-based environmental monitoring systems. Although the current implementation of DeepEdgeNet is performed in the simulated edge–cloud environment, the performance trends obtained in this work confirm the applicability of DeepEdgeNet for real-time environmental monitoring that needs immediate analysis along with efficient resource utilization. In future work, we plan to evaluate DeepEdgeNet on real hardware-based heterogeneous edges. In addition to Google LeNet, we plan to add other baseline models to federated learning. We also plan to implement an adaptive communication mechanism to minimize the overheads.

Machine Learning Evaluation of the HiTar-2024 Dataset for Intrusion Detection in Smart Manufacturing Environments

Adeeb Alhomoud
College of Computing and Informatics, Saudi Electronic University, Riyadh 11673, Saudi Arabia

***Abstract*—This study presents an investigation of the HiTar-2024 dataset performed in terms of the distribution of label attack types and the distribution of attacks by protocol, normal, and Denial of Service (DoS) connections over time. The investigation carried out a performance evaluation of the HiTar-2024 dataset using a machine learning approach to classify benign and malicious activities, based on BayesNet, Logistic, IBk, Multiclass, PART, and J48 classifiers. It was found that the HiTar-2024 dataset can serve as a training set for an anomaly-based intrusion detection system (IDS) in a smart manufacturing environment to detect normal and malicious activities. Furthermore, an anomaly-based IDS using the HiTar-2024 dataset is able to group malicious activities into Probing, Remote-to-Local, User-to-Root, and DoS attacks.**

Keywords*—Supervised learning; intrusion detection system; security; smart manufacturing

I. Introduction

Today, intrusion detection systems (IDS) play a crucial role in detecting and stopping sophisticated attacks and malware propagation, especially in the Internet-of-Things (IoT) environment known as resource constrained devices. The smart grid is a particular case of an IoT environment in which any activity disruption leads to catastrophic damage to the fabrication process of smart manufacturing, market, service provider, and energy distribution systems [1]. The IDS taxonomy in the IoT environment contains four categories: signature-based [2], anomaly-based [3], specification-based [4], and hybrid detection mechanisms [5]. An anomaly-based IDS relies on machine learning (ML) and deep learning (DL) techniques. An optimized IDS ML based on a support vector machine (SVM) has been proposed by fitting the SVM kernel function and the complexity parameter, leading to a maximal value of the accuracy of the model [6]. A DL classifier called a Bidirectional long short-term memory (Bi-LSTM) model has achieved accuracy of up to 97.93% [7].

The taxonomy of attacks based on KDD'99 is composed of four classes: Probing, Remote-to-Local (R2L), User-to-Root (U2R), and Denial-of-Service (DoS) attacks [8]. In a Probing attack, the hacker will gather the maximum information possible about the target IoT victim vulnerability [9]. The hacker will then exploit this vulnerability to gain R2L access to the target IoT device or network gateway [10]. In addition, the aim of a U2R attack is, for instance, to gain root privileges through a memory overflow mechanism [11]. Finally, a hacker can stop or degrade the performance of a target IoT network through a DoS or Distributed DoS (DDoS) attack [12].

In Industrial IoT (IIoT) environments, the creation and thorough analysis of dedicated datasets is fundamental to developing an effective IDS. Standard network-security datasets, such as those developed for traditional IT networks, often fail to capture the unique characteristics of IIoT architectures, which include constrained devices, heterogeneous sensors, specialized communication protocols, and cyber-physical interactions. Recent research by Essop et al. [13] emphasizes that many existing IoT and IIoT datasets fail to capture the diversity of real-world conditions, as they often lack events that encompass multiple benign and attack scenarios. Furthermore, these datasets typically omit critical contextual information, such as sensor measurement data, network-level traffic characteristics, and device behavior within operational environments. The introduction of the Canadian Institute for Cybersecurity Advanced Persistent Threat for IIoT (CICAPT-IIoT) dataset addresses this gap by including network logs and provenance data across more than 20 advanced persistent threat techniques in an IIoT testbed [14]. Through dataset construction and detailed analysis of attack distributions, IoT device behavior, protocol usage distribution, and temporal patterns, researchers can better understand threat vectors related to the IIoT environment. This process could enable the design of IDS models based on ML that are both accurate and practical in various applications, such as smart manufacturing, energy distribution, and critical infrastructure settings. Without the existence of those targeted datasets, the IDS models generated will suffer from poor generalizability, class imbalance, or misalignment with real-world IIoT networks. The main contributions of this study are summarized as follows:

- An investigation of the HiTar-2024 dataset generated from a smart manufacturing simulation environment.
- A HiTar-2024 dataset performance evaluation based on BayesNet, Logistic, Instance-Based k-Nearest Neighbors (IBk), Multiclass, partial decision trees (PART), and J48 classifiers.
- The HiTar-2024 dataset can serve as a training set to detect Probing, R2L, U2R, and DoS attacks before its deployment online in a smart manufacturing environment.

The rest of the study is composed into four sections: Section II presents the state-of-the-art of the existing IIoT dataset in the literature. Section III describes the HiTar-2024 dataset by considering its most important features. Section IV investigates a performance evaluation of the HiTar-2024 dataset and presents a confusion matrix of the classifiers used. Section V presents the results and discussion. Section VI draws the conclusion.

II. State-of-the-Art

Table I compares IIoT datasets in the literature as a function of year creation, dataset name, number of features, attack classes, and a brief description.

TABLE I. IIoT Datasets in the Literature

Year	Dataset Name	Number of Features	Attack Classes	Description
2020	TON_IoT [15]	127	Normal, DDoS, DoS, Injection, MiM, Password, XSS, Scanning.	A telemetry dataset is proposed for both IoT and IIoT applications.
2021	WUSTL-IIOT-2021 [16]	41	Command Injection, DoS, Reconnaissance, Backdoor.	WWUSTL-IIoT-2021 consists of network data of Industrial Internet of Things to be used in cybersecurity research.
2022	Edge IIoTset [17]	61	DoS/DDoS attacks, Information gathering, MiM attacks, Injection attacks, Malware attacks.	The Edge-IIoTset dataset generated could be used by an IDS based on centralized and federated learning.
2024	CICAPT-IIoT [18]	140	Collection, Exfiltration, Command and Control, Persistence, Discovery, Credential Access, Lateral Movement and Defence Evasion.	An APT attack dataset captured within the IIoT environment.
2024	HiTar-2024 [19]	39	Probing, R2L, U2R and DoS	HiTar-2024 is a dataset generated from the AREZZO environment that represents a simulated industrial manufacturing process
2025	DataSense: CIC IIoT [20]	94	Benign, DoS, DDoS, MiTM, Mirai, Bruteforce	A realistic IIoT testbed dataset with synchronized sensor and network data for anomaly detection.

Important IIoT datasets that are currently available in the literature are compared in this work along with the main distinctions between them, such as the number of features extracted, the variety of attacks that are possible, and their suitability for cybersecurity research in the smart manufacturing field. A summary of the early attempts to create comprehensive datasets is provided. One of the first comprehensive datasets was the TON_IoT [15], which had 127 features and covered a wide range of attack types, such as DDoS, DoS, injection, and password attacks, making it suitable for anomaly detection based on telemetry for IoT/IIoT networks.

The 41 features of WUSTL-IIoT-2021 [16], on the other hand, cover injection, DoS, reconnaissance, and backdoor attacks, all of which are essential for assessing targeted IIoT attacks. The Edge IIoTset dataset contains 61 new features and could be used by an IDS based on centralized and federated learning [17]. The CICAPT-IIoT dataset was introduced in 2024 [18]. The latter dataset contains 20 kinds of attacks that can be carried out in an IIoT environment, including collection, exfiltration, command and control, persistence, discovery, credential access, lateral movement, and defence evasion classes. Another, HiTar-2024, is a dataset generated from AREZZO environment LOG files that represents a simulated industrial manufacturing process in an IIoT context. The HiTar-2024 dataset includes 39 features, 15,842 instances, and four attack classes: Probing, R2L, U2R, and DoS attacks [19]. Furthermore, the HiTar-2024 was created following a rigorous approach involving data preprocessing, feature extraction, the class imbalance with SMOTE, and a test option that was employed for model robustness. Finally, the DataSense CIC-IIoT Dataset 2025, also developed by the CIC, represents one of the most recent and comprehensive datasets designed for intrusion detection in IIoT environments. Built from a realistic IIoT testbed, it integrates both sensor telemetry and network traffic data, providing a synchronized view of industrial device behavior and communication flows [20].

III. Description of the Dataset

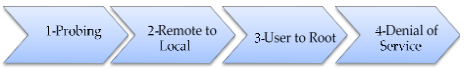

Fig. 1. Attack class sequence order

Fig.1 represents the chronological attack class order used in HiTar-2024 generation. The process started by collecting information about the target victim (probing class). In the attack scenario, NMAP commands were used to perform a probing attack. Subsequently, a remote connection to the target AREZZO system was attempted (R2L class). In addition, Rlogin, Secure Shell (SSH), and Telnet commands were examined as the R2L attack class. A U2R class is a tentative attempt to gain Root permission. Sudo, Su, and FTP commands were then investigated to generate U2R attacks. Finally, a DoS attack was launched in order to stop or degrade a service or network activity related to the AREZZO environment (DoS class). The DoS attack was investigated through the Hping3 command.

The following section presents the distribution of label attack types and the distribution of attacks by protocol, normal, and DoS connections over time in the HiTar2024 dataset using the JupyterLab environment. The pie chart in Fig. 2 shows the distribution of label attack types in the HiTar2024 dataset. Each

slice represents how frequently a specific behavior or attack type occurs in the dataset. As shown above, Probing attacks represent 65.6% of the total attacks, Normal behavior represents 25.6% of all traffic, R2L attacks are 4.9% of the total traffic, U2R attacks are 3.1% of the total attacks, and DoS attacks represent 0.8% of the global collected traffic. This indicates that the majority of the records in the dataset involve scanning or probing activities, whereby an attacker tries to gather information about the system (e.g., port scanning or network mapping). The dataset is highly imbalanced, with one class (Probing_Attack) dominating. As a consequence, a more specific technique (e.g., class weighting, oversampling rare attacks such as a DoS, or undersampling probing attacks) is necessary to avoid biased detection models.

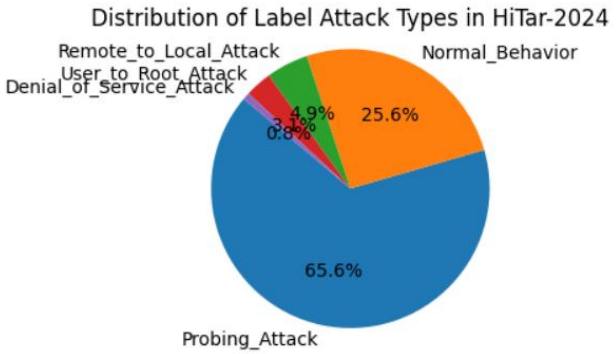

Fig. 2. Distribution of label attack types in the HiTar-2024 dataset.

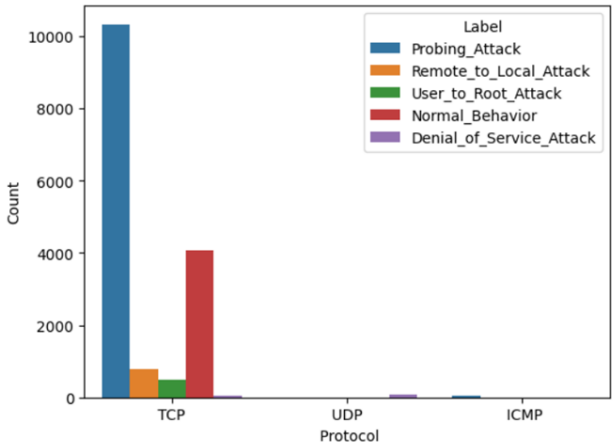

Fig. 3. Distribution of attacks by protocol in the HiTar-2024 dataset.

Fig. 3 shows the distribution of different attack categories and normal traffic across network protocols (Transmission Control Protocol [TCP], User Datagram Protocol [UDP], and Internet Control Message Protocol [ICMP]) within the HiTar-2024 dataset. The results show a strong imbalanced usage of protocol types, indicating that the majority of both benign and malicious activities are transmitted over TCP. Specifically, Probing attacks are the most frequent, exceeding 10,000 TCP instances, suggesting extensive scanning or probing activity targeting IoT devices. R2L and U2R attacks also occur mainly over TCP, although at considerably lower frequencies, which aligns with these attacks typically requiring a stable connection to be established in order to exploit system vulnerabilities and weaknesses. Finally, Normal traffic is mainly transmitted over TCP, with 4000 instances, reinforcing the central role of TCP in typical IIoT communication patterns. To draw a conclusion, the imbalance across protocols indicates that IIoT intrusion detection models should incorporate knowledge of protocol features, particularly identifying TCP traffic patterns.

Fig. 4 shows the Normal and DoS connections over time in the HiTar-2024 dataset. The pic connections represent the DoS attacks when compared to Normal activity (without pic connections).

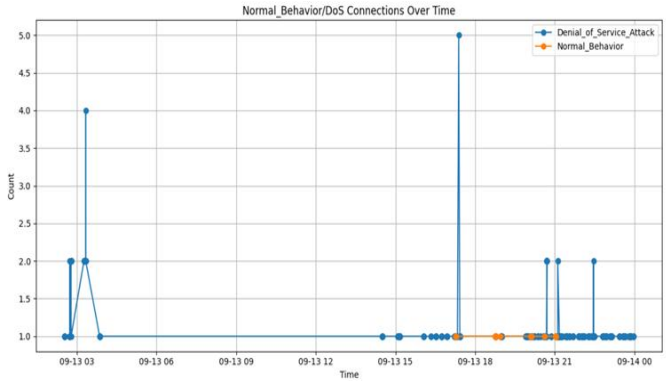

Fig. 4. Normal and DoS connections over time in the HiTar-2024 dataset.

As seen in Fig. 4, the various spikes represent DoS attacks, and the line below represents Normal activity. Fig. 4 indicates a high-intensity attack phase, which is likely to correspond to a targeted flooding attempt. In contrast, Normal behavior appears only sporadically during this interval. Between 06:00 and 15:00 on 09-13, the traffic stabilizes, and DoS activity is minimal, suggesting either a paused attack or normal operational conditions in the IIoT network. However, around 18:00, another sharp spike in DoS activity is observed, indicating a second attack wave, again with significantly higher frequency than the normal traffic. Approaching the later period (around 20:00 to 23:00), both Normal and DoS connections appear intermixed, but DoS packets still dominate in terms of count. This behavior may indicate either background scanning/flooding attempts or a sustained low-rate persistent DoS attack intended to evade detection.

IV. Dataset Performance Evaluation

A structured comparison of the different classifiers tested for the HiTar-2024 dataset is shown in Table II. BayesNet, Logistic regression, IBk, Multiclass classification techniques, PART, and J48 (also known as the C4.5 algorithm) are included in the table. The computational complexity, main benefits in the classification context, and potential drawbacks that could affect the suitability of each classifier for IIoT threat detection are described in the table.

TABLE II. CLASSIFIERS USED IN HITAR-2024 PERFORMANCE EVALUATION

Classifier Name	Description	Complexity	Advantages	Disadvantages
BayesNet [19,22,24]	A probabilistic graphical model that uses Bayesian networks for classification.	Low	- Efficient for small datasets - Handles missing data well - Interpretable results	- Assumes conditional independence - Less effective with complex, high-dimensional data
Logistic [19,21,23,24]	A statistical model that predicts categorical outcomes using a logistic function.	Low to Medium	- Works well with linear decision boundaries - Robust against overfitting when regularization is applied	- Struggles with non-linearly separable data - Performance drops with highly imbalanced datasets
IBk [19,24]	A lazy learning algorithm that classifies based on the majority class of nearest neighbors.	High	- Simple and intuitive - Effective for non-linear relationships - No training phase, adapts dynamically	- Computationally expensive for large datasets - Sensitive to noise and irrelevant features
Multiclass [19,24]	A classification method that extends binary classifiers to handle multiple classes simultaneously.	Medium to High	- Efficient for multi-label problems - Can be integrated with various base classifiers	- Performance depends on the decomposition method chosen - Computational cost increases with class complexity
PART [19,21,24]	A rule-based classifier that builds decision rules from partial decision trees.	Medium	- Generates interpretable rules - Less prone to overfitting compared to full decision trees	- Can be computationally expensive - Rule generation may not always be optimal
J48 [19,21,24]	A decision tree-based classifier that recursively splits data based on attribute values.	Medium to High	- Easily interpretable - Handles both numerical and categorical data - Can handle missing values	- Prone to overfitting - Can become complex and hard to optimize

The following classifier configurations were used to perform system performance evaluation:

weka.classifiers.bayes.BayesNet -D -Q weka.classifiers.bayes.net.search.local.K2 -- -P 1 -S BAYES -E weka.classifiers.bayes.net.estimate.SimpleEstimator -- -A 0.

weka.classifiers.functions.Logistic ---R 1.0E-8 -M -1 -num-decimal-places 4

weka.classifiers.lazy.IBk -K 1 -W 0 -A "weka.core.neighboursearch.LinearNNSearch -A \"weka.core.EuclideanDistance -R first-last\""

weka.classifiers.rules.PART -C 0.25 -M 2

weka.classifiers.meta.MultiClassClassifier -M 0 -R 2.0 -S 1 -W

weka.classifiers.trees.J48 -C 0.25 -M 2

The methodology combined three effective techniques to address overfitting in the tabular data in the HiTar-2024 dataset, including balancing the minority class using SMOTE (Synthetic Minority Over-sampling Technique), feature selection by selecting an attribute evaluator, and a search method and k-fold cross-validation in test option processing. Regarding feature selection, the CfsSubsetEval and BestFirst were selected as the attribute evaluator and search method, respectively. The choice of the CfsSub-setEval feature selection method was motivated by this suitability for tabular data, it produces a compact, nonredundant subset, and improves model generalization.

Furthermore, imbalanced classes are handled by SMOTE, such as the U2R and DoS attack classes. The following setting is used in the preprocessing supervised filter based on the instance:

weka.filters.supervised.instance SMOTE -C 0 -K 5 -P 400.0 -S 1

Since the minority class DoS has a number of instances of 130, the percentage parameter of SMOTE is selected to 400% to reach the number of U2R instances equal to 491.

A k-fold cross-validation test option was also applied, partitioning the data into k subsets (or folds), training the model on k-1 subsets, and testing it on the held-out subset. The simulation was carried out for k equal to 10 for the cross-validation test option.

weka.attributeSelection.CfsSubsetEval -P 1 -E 1

CfsSubsetEva evaluates the worth of a subset of attributes by considering the individual predictive ability of each feature along with the degree of redundancy between them.

weka.gui.attributeSelection.BestFirst -D 1 -N 5

BestFirst searches the space of attribute subsets by using greedy hill climbing augmented with a backtracking facility.

A comprehensive set of experiments with common ML models using BayesNet, Logistic, IBk, Multiclass, PART, and J48 with the HiTar-2024 dataset demonstrates high accuracy, precision, recall, and F1-scores, as well as around 99% accuracy [19]. For example, the authors in [19] made a comparison between Simple Logistic, PART, and J48 classifiers using the NSL-KDD dataset. They also examined the detection of different attack types involving DoS, R2L, U2R, and Probing attacks and considered time when building the model. The authors in [22] tested the BayesNet classifier using NSL-KDD and found higher true positive (TP) and lower false positive (FP) rates when compared to Naïve Bayes and updateable versions. Other authors proposed Logistic regression, decision trees, k-Nearest Neighbors, and Naïve Bayes classifiers on the WUSTL-IIOT-2021 dataset [23]. The latter study gives a context for how IBk and Logistic classifiers perform under IIoT network traffic data conditions.

Table III presents a performance comparison of classifiers for HiTar-2024 as a function of accuracy, Kappa statistic, mean absolute error (MAE), root mean square error (RMSE), and relative absolute error (RAE) metrics.

As shown in Table III, all classifiers demonstrate remarkably high accuracy, exceeding 98%, which indicates that the proposed dataset and feature selection approach enable highly reliable classification. Among the models evaluated, the IBk algorithm achieved the highest accuracy, reaching 99.993%, accompanied by a Kappa statistic of 0.999, MAE of 0.0001, and RMSE of 0.005. These results highlight the robustness and consistency of the IBk model, confirming its superior ability to minimize both MAE and RMSE errors. The Logistic regression model also achieved competitive results, with an accuracy of 99.974%, a Kappa of 0.9995, MAE of 0.0001, and RMSE of 0.0101. The J48 decision tree and Multiclass classifiers followed closely, each exceeding 99.9% accuracy, and demonstrating excellent agreement levels with a Kappa of around 0.999.

TABLE III. CLASSIFIER PERFORMANCE COMPARISON FOR HITAR-2024

Classifier	Accuracy (%)	Kappa Statistic	Mean Absolute Error	Root Mean Square Error	Relative Absolute Error
BayesNet	98.668	0.973	0.005	0.069	2.471
Logistic	99.974	0.9995	0.0001	0.0101	0.053
IBk	99.993	0.999	0.0001	0.005	0.0623
PART	99.899	0.998	0.019	0.2903	6.2892
Multiclass	99.949	0.999	0.0004	0.0143	0.2094
J48	99.968	0.999	0.0002	0.011	0.123

In contrast, although the PART and BayesNet classifiers also showed good results with an accuracy of 99.899% and 98.668%, respectively, they showed higher error values regarding an RMSE equal to 0.2903 and 0.069 and an RAE of 6.2892 and 2.471, suggesting a slightly lower prediction precision compared to the top-performing IBk model. Nonetheless, their Kappa statistics of above 0.97 confirm consistent and reliable performance over classes. In conclusion, the IBk and Logistic regression classifiers can be identified as the most suitable models for the HiTar-2024 dataset, achieving excellent classification with minimal prediction error. These findings confirm that the adopted approach is effective at enhancing classification accuracy and maintaining high robustness and generalization capability.

Table IV presents a performance comparison between recent IIoT datasets and HiTar-2024 in terms of task, typical accuracy, precision, recall, and F1-score.

TABLE IV. CLASSIFIER PERFORMANCE COMPARISON BETWEEN HITAR-2024 AND OTHER IIOT DATASETS

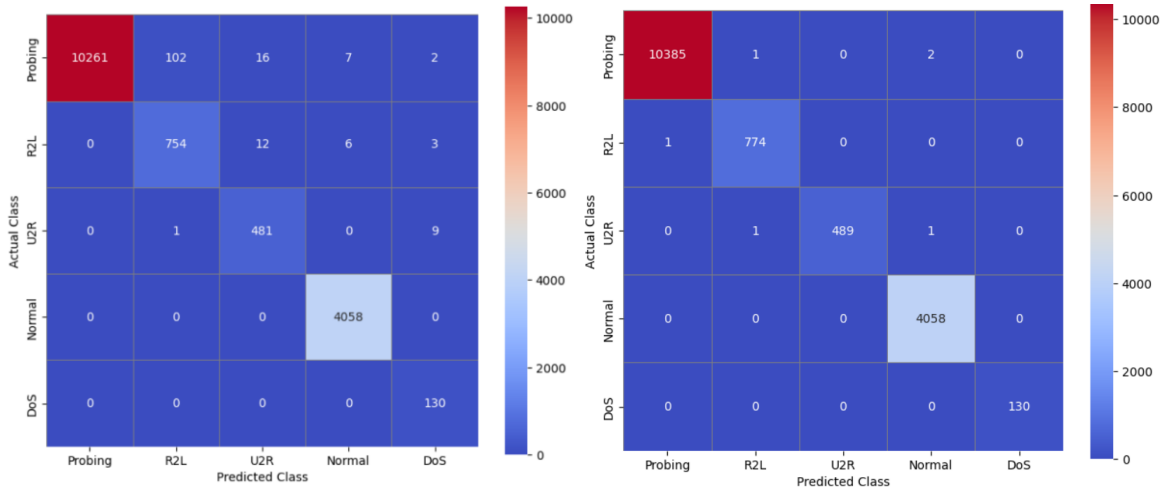
Classifier	Task	Typical accuracy (%)	Precision (%)	Recall (%)	F1-score (%)
CICAPT-IIoT	APT-style detection	~93.8	~93	~95	~94
Edge-IIoTset	Multiclass attack detection	95–99.97	~95–99.3	~95–99.3	~95–99.3
DataSense (CIC IIoT)	Binary & multiclass IIoT	~98–99	~98	~98	~98
HiTar-2024	Multiclass attack detection	98.668–99.993	99.1–99.9	99.0– 99.9	99.0–99.9

As shown in Table IV, HiTar-2024 outperforms other recent IIoT datasets (i.e., CI-CAPT-IIoT, Edge-IIoTset, and DataSense (CIC IIoT)) in terms of typical accuracy, precision, recall, and F1-score, motiving its suitability for smart manufacturing.

Next, the performance evaluation was conducted using a confusion matrix for the various classifiers studied in a WEKA simulation environment using the same setting as in [17].

Fig. 5(a) presents a colored confusion matrix heatmap for the BayesNet classifier, in which the predicted values are shown in the columns and the defined values of the dataset in the rows. The confusion matrix for the BayesNet classifier presents the following insights:

- Probing attack: The classifier correctly predicted 10,261 instances of Probing attacks, with a maximum TP value (i.e., equal to 100%) and a minimum FP value (i.e., equal to 0%).
- R2L attack: The classifier correctly predicts 754 instances of R2L attacks (representing a TP rate of 87.98%). In addition, 102 instances were predicted as probing attacks and one instance predicted as a U2R attack (representing an FP rate of 12.02%).
- U2R attack: The classifier correctly predicted 481 instances of U2L attacks (representing a TP rate of 94.49%), but 16 instances were predicted as probing attacks and 12 instances as R2L attacks (representing an FP rate of 5.51%).
- Normal behavior: The classifier correctly predicted 4058 instances of normal behavior (representing a TP rate of 99.68%). However, 7 instances were predicted as Probing attacks and 6 as R2L attacks (representing an FP rate of 0.32%).
- DoS attack: The classifier successfully predicted 130 instances of DoS attacks (representing a TP rate of 90.27%). Two instances were predicted as Probing



attacks, 3 instances were predicted as R2L attacks, and 9 instances were predicted as U2R attacks (representing an FP rate of 9.73%).

In summary, the BayesNet classifier seems to excel in predicting Probing attacks and Normal behavior, but performs less well in predicting R2L, U2R, and DoS attacks.

Fig. 5(b) presents a colored confusion matrix heatmap for the Logistic classifier, in which the predicted values are shown in the columns and the defined values of the dataset in the rows. The confusion matrix for the Logistic classifier enables the following insights:

- Probing attack: The classifier correctly predicted 10,385 instances of probing attacks (with a TP value equal to 99.99%) and 1 instance was predicted as an R2L attack (with an FP equal to 0.01%).
- R2L attack: The classifier correctly predicted 774 instances of R2L attacks (representing a TP rate of 99.74%). One instance was predicted as a Probing attack and 1 instance as a U2R attack (representing an FP rate of 0.26%).
- U2R attack: The classifier correctly predicted 489 instances of U2R attacks, with a maximum TP value (i.e., equal to 100%) and a minimum FP value (i.e., equal to 0%).
- Normal behavior: The classifier correctly predicted 4058 instances of Normal behavior (representing a TP rate of 99.92%). However, 2 instances were predicted as Probing attacks and 1 instance was predicted as a U2R attack (representing an FP rate of 0.08%).
- DoS attack: The classifier correctly predicted 130 instances of DoS attacks, with a maximum TP value (i.e., equal to 100%) and a minimum FP value (i.e., equal to 0%).

In conclusion, the Logistic classifier seems to excel in predicting U2R and DoS attacks, but performs less well in predicting Probing and R2L attacks and Normal behavior.

(a) (b)

Fig. 5. (a) Colored confusion matrix heatmap for the BayesNet classifier; (b) Colored confusion matrix heatmap for the Logistic classifier.

Fig. 6(a) presents a colored confusion matrix heatmap for the IBk classifier, in which the predicted values are shown in the columns and the defined values of the dataset are shown in the rows. The confusion matrix for the IBk classifier enables the following insights:

- Probing attack: The classifier correctly predicted 10,388 instances of probing attacks, with a maximum TP value (i.e., equal to 100%) and a minimum FP value (i.e., equal to 0%).
- R2L attack: The classifier correctly predicted 775 instances of R2L attacks, with a maximum TP value (i.e., equal to 100%) and a minimum FP value (i.e., equal to 0%).
- U2R attack: The classifier correctly predicted 491 instances of U2R attacks (with a TP rate equal to 99.79%) and 1 instance was predicted as a DoS attack (with an FP equal to 0.03%).
- Normal behavior: The classifier correctly predicted 4058 instances of Normal activity, with a maximum TP value (i.e., equal to 100%) and a minimum FP value (i.e., equal to 0%).
- DoS attack: The classifier correctly predicted 129 instances of U2R attacks, with a maximum TP value (i.e., equal to 100%) and a minimum FP value (i.e., equal to 0%).

In summary, the IBk classifier seems to excel in predicting Probing, R2L, and DoS attacks and Normal behavior, but performs slightly less well in predicting U2R attacks.

Fig. 6(b) presents the confusion matrix for the Multiclass classifier, in which the predicted values are shown in the columns and the defined values of the dataset in the rows.

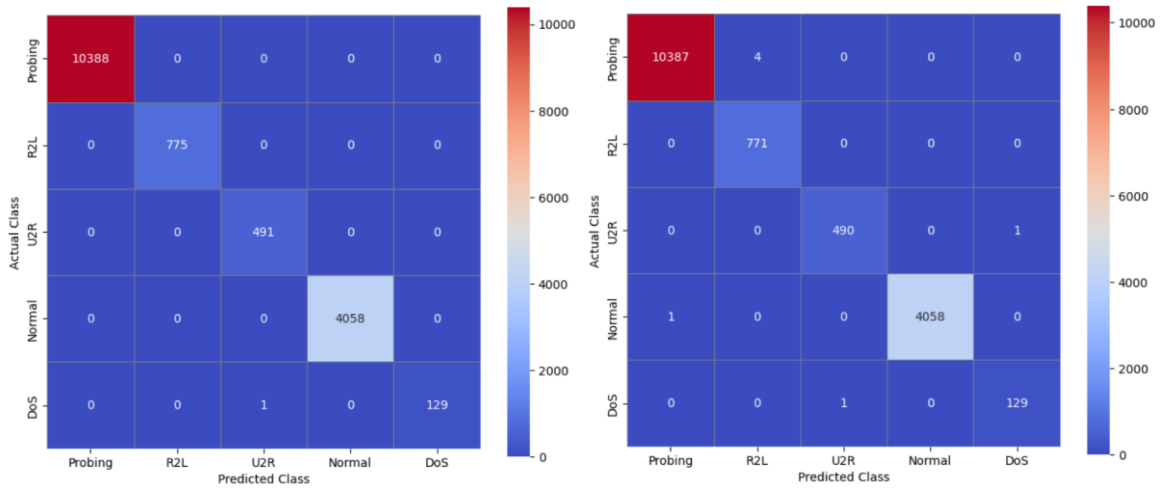


Fig. 6. (a) Colored confusion matrix heatmap for the IBk classifier; (b) Colored confusion matrix heatmap for the Multiclass classifier.

The confusion matrix for the Multiclass classifier presents the following insights:

- Probing attack: The classifier correctly predicted 10,387 instances of Probing attacks (with a TP rate equal to 99.96%) and 4 instances predicted as R2L attacks (with an FP rate equal to 0.04%).
- R2L attack: The classifier correctly predicted 771 instances of R2L attacks, with a maximum TP value (i.e., equal to 100%) and a minimum FP value (i.e., equal to 0%).
- U2R attack: The classifier correctly predicted 490 instances of U2R attacks (with a TP rate equal to 99.79%) and 1 instance predicted as a DoS attack (with an FP rate equal to 0.21%).
- Normal behavior: The classifier correctly predicted 4058 instances of U2R attacks (with a TP rate equal to 99.97%) and 1 instance predicted as a Probing attack (with an FP rate equal to 0.03%).
- DoS attack: The classifier correctly predicted 129 instances of U2R attacks (with a TP rate equal to 99.23%) and 1 instance predicted as a U2R attack (with an FP rate equal to 0.73%).

In summary, the Multiclass classifier seems to excel in predicting R2L attacks. However, it performs slightly less well in predicting Probing, U2R, and DoS attacks.

Fig. 7(a) presents a colored confusion matrix heatmap for the PART classifier, in which the predicted values are shown in the columns and the defined values of the dataset in the rows.

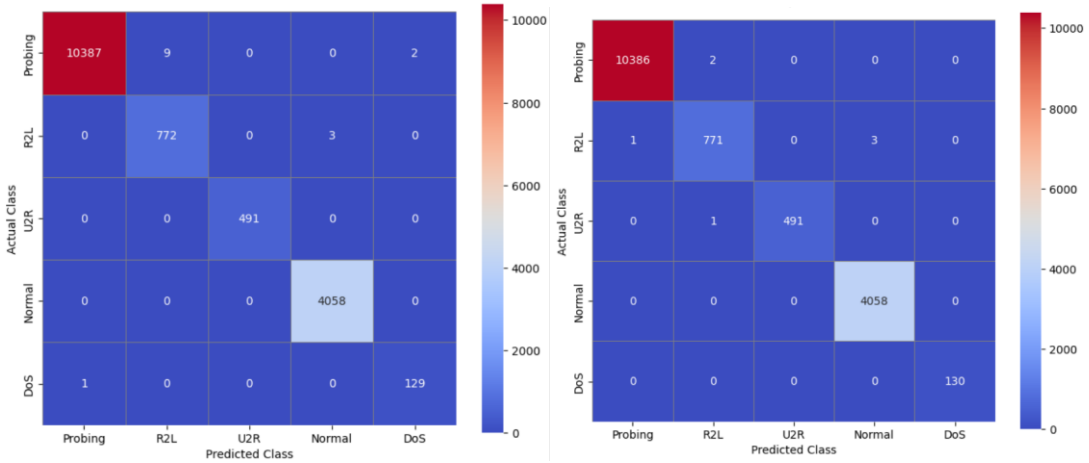
The confusion matrix for the PART classifier presents the following insights:

- Probing attack: The classifier correctly predicted 10,387 instances of Probing attacks (with a TP rate equal to 99.96%) and 1 instance predicted as a DoS attack (with an FP rate equal to 0.04%).
- R2L attack: The classifier correctly predicted 772 instances of R2L attacks (with a TP rate equal to 98.84%) and 9 instances predicted as a Probing attack (with an FP rate equal to 1.16%).
- U2R attack: The classifier correctly predicted 491 instances of DoS attacks, with a maximum TP value (i.e., equal to 100%) and a minimum FP value (i.e., equal to 0%).
- Normal behavior: The classifier correctly predicted 4058 instances of U2R attacks (with a TP rate equal to 99.92%) and 3 instances predicted as R2L attacks (with an FP rate equal to 0.08%).
- DoS attack: The classifier correctly predicted 129 instances of U2R attacks (with a TP rate equal to 98.47%) and 2 instances predicted as Probing attacks (with an FP rate equal to 1.53%).

In summary, based on the confusion matrix above, the PART classifier seems to excel in predicting U2R attacks. However, the number of false alarms is equal to 1, 2, 3, and 9, respectively, for Probing, DoS, Normal, and R2L activities.

Fig. 7(b) shows a colored confusion matrix heatmap for the J48 classifier, in which the predicted values are shown in the columns and the defined values of the dataset in the rows.

The confusion matrix for the J48 classifier presents the following insights:



- Probing attack: The classifier correctly predicted 10,386 instances of Probing attacks (with a TP rate equal to 99.99%) and 1 instance predicted as an R2L attack (with an FP rate equal to 0.01%).
- R2L attack: The classifier correctly predicted 771 instances of R2L attacks (with a TP rate equal to 99.74%) and 2 instances predicted as Probing attacks (with an FP rate equal to 0.26%).
- U2R attack: The classifier correctly predicted 491 instances of U2R attacks, with a maximum TP value (i.e.,

equal to 100%) and a minimum FP value (i.e., equal to 0%).

- Normal behavior: The classifier correctly predicted 4058 instances of U2R attacks (with a TP rate equal to 99.92%) and 3 instances predicted as R2L attacks (with an FP rate equal to 0.08%).
- DoS attack: The classifier correctly predicted 130 instances of DoS attacks, with a maximum TP value (i.e., equal to 100%) and a minimum FP value (i.e., equal to 0%).

In summary, the J48 classifier seems to excel in predicting U2R and DoS attacks. However, the number of false alarms is equal to 1, 2, and 3, respectively, for the Probing, R2L, and Normal classes.

Table V compares the various classifiers studied in terms of Probing TP rate, R2L TP rate, U2R TP rate, Normal TP rate, DoS TP rate, average TP rate, and average FP rate.

(a) (b)

Fig. 7. (a) Colored confusion matrix heatmap for the PART classifier; (b) Colored confusion matrix heatmap for the J48 classifier.

TABLE V. TP AND FP RATES PER CLASSIFIERS STUDIED

Classifier	Probing TP Rate	R2L TP Rate	U2R TP Rate	Normal TP Rate	DoS TP Rate	Average TP Rate	Average FP Rate
BayesNet	100	87.98	94.49	99.68	90.27	94.48	5.52
PART	99.96	98.84	100	99.92	98.47	99.43	0.57
Multiclass	99.96	100	99.79	99.97	99.23	99.79	0.21
J48	99.99	99.74	100	99.92	100	99.93	0.07
Logistic	99.99	99.74	100	99.92	100	99.93	0.07
IBk	100	100	99.79	100	100	99.95	0.05

In Table V, the classifier performance is sorted as a function of the average TP rate and FP rate metrics as follows: IBk is the most effective classifier, followed by Logistic regression, then J48 followed by the Multiclass classifier, and the PART classifier is followed by BayesNet. Also as shown in Table V, the best-performing classifier is IBk and the one that performs least well is BayesNet in terms of average TP and FP rates. The FP rate is equal to 0.05 and 5.52 for IBk and BayesNet, respectively. The BayesNet classifier performance is given an overall TP rate of 94.48% and an FP rate of 5.52%.

V. RESULTS AND DISCUSSION

The comparative performance results in Table V above demonstrate clear differences in detection capability and false alarm behavior among the classifiers evaluated in the IIoT intrusion detection context. The BayesNet classifier achieved a reasonable average TP rate of 94.48%, but its relatively high FP rate (5.52%) indicates reduced reliability in high security environments, in which false alerts are costly. The PART classifier showed greater detection performance with an average TP rate of 99.43% and a lower FP rate (0.57%), benefiting from rule-based interpretability, although it remains slightly less accurate than tree-based models. The Multiclass classifier attained a more balanced detection level (99.79% average TP rate) with a low FP rate (0.21%), demonstrating its effectiveness across most attack categories. Among the decision-based methods, both J48 and Logistic regression achieved consistently strong performance (average TP = 99.93%, FP = 0.07%), making them highly suitable for deployment in resource-constrained IIoT edge devices due to their low computational overhead and model transparency. The IBk classifier obtained the highest overall detection accuracy (99.95% average TP rate) and the lowest FP rate (0.05%); however, its high computational cost and memory requirements during inference make it less appropriate for real-time or low-power IIoT nodes, but well-suited for centralized or offline security analytics. Overall, J48 and Logistic emerge as the most practical classifiers for real-time IIoT intrusion detection, whereas IBk is preferable when computational resources are not a constraint. In order to compare

this work with similar research in the literature, the TP rate is shown to be around 95% and the FP rate 4.87% when applying a BayesNet classifier to the NSL-KDD dataset [22]. In resource-constrained IIoT environments, the computational feasibility of ML classifiers depends primarily on inference complexity, memory footprint, and energy consumption. The IBk classifier is generally unsuitable for deployment on IIoT edge devices because it stores the entire training dataset and requires distance computations with all instances during inference, resulting in high memory usage and latency. In contrast, J48 exhibits strong feasibility due to its compact tree representation and low inference complexity, as classification requires only a simple tree traversal. Similarly, PART, a rule-based classifier derived from partial decision trees, offers efficient inference provided that the generated rule set remains limited in size. Multiclass Logistic regression is also viable for edge deployment when trained offline, since inference involves only linear computations over feature vectors, although its cost increases with feature dimensionality and number of classes. BayesNet, although probabilistically expressive, may impose higher memory and computational demands depending on network structure complexity and conditional probability tables. Overall, decision tree-based methods, such as J48, followed by PART and Logistic regression with feature selection, represent the most computationally viable solutions for real-time classification on constrained IIoT edge devices.

Finally, three concrete techniques were implemented to address dataset representativeness and evaluation realism, in terms of data collection (i.e., by oversampling rare attack classes such as the DoS class in HiTar-2024), dataset design (i.e., the HiTar-2024 dataset preserves timestamps in the first attribute to enable realistic splits and analysis), and through better metrics and reporting, such as using a confusion matrix and TP and FP rate per studied class. Although all six classifiers exceed 98% accuracy after SMOTE, the augmentation strategy appears to target only the DoS class, while the rare R2L and U2R classes remain insufficiently represented. Consequently, the reported accuracy may overestimate real-world robustness, and additional cross-dataset or out-of-distribution evaluation is needed to confirm generalization beyond the HiTar-2024 training partition.

VI. Conclusion

In this study, the HiTar-2024 dataset was evaluated using accuracy, Kappa statistic, MAE, RMSE, RAE, and confusion matrix-based performance metrics across several WEKA classifiers, namely BayesNet, Logistic, IBk, Multiclass, PART, and J48. The results indicate that the BayesNet classifier achieved an average TP rate of 94.48% along with an average FP rate of around 5.52%. The PART classifier achieved an average TP rate of 99.43% along with an average FP rate of 0.57%. The Multiclass classifier demonstrated an average TP rate of 99.79% with an average FP rate of 0.21%. An average TP rate of 99.93% along with an average FP rate of 0.07% was shown by the J48 and Logistic classifiers. The IBk classifier recorded the highest value in terms of an average TP rate of 99.95%, along with the lowest value for an average FP rate of 0.05%. These findings demonstrate that the IBk, followed by J48 and Logistic regression, constitute the most suitable set of classifiers for deployment in resource-constrained IIoT environments, offering an effective balance between classification performance and computational efficiency. These models achieve competitive detection accuracy while maintaining low memory consumption and fast inference time, making them particularly well adapted for real-time edge-level implementation.

The presence of high-intensity attack intervals followed by quiet periods in the traffic patterns suggests that the attacker employed intermittent flooding strategies, which is typical behavior in DoS scenarios targeting IIoT networks. Such bursts are designed to disrupt device availability while reducing the likelihood of long-term detection. In addition, the imbalance observed across communication protocols indicates that intrusion detection mechanisms in IIoT environments should incorporate protocol-aware learning features in future work, with particular significance given to TCP traffic behavior being considered as involving the absolute majority of malicious interactions. A potential perspective of this study could be the experiments, which validate detectors in real IIoT environments, the inclusion of advanced attacks such as APTs in the HiTar-2024 dataset, and the use of benchmark hybrid models that combine feature engineered ML, such as CNN/LSTM and CNN/GRU, to strengthen a detection intrusion system in an IIoT environment.

ZK-FedMed: Privacy-Preserving Federated Learning for Cardiovascular and Renal Disease Prediction

Haewon Byeon
Department of Future Technology, Korea University of Technology and Education (KOREA TECH), Cheonan, 31253, South Korea

***Abstract*—Protecting patient data confidentiality while enabling collaborative machine learning across distributed healthcare institutions remains a major challenge. This study presents ZK-FedMed, a privacy-preserving federated learning framework that combines CKKS partially homomorphic encryption for gradient protection, Rényi differential privacy with moments-accountant tracking, zk-SNARK-based integrity verification, TabTransformer feature extraction, SCAFFOLD aggregation, and an approximate federated unlearning procedure. The framework was evaluated on two public benchmark datasets: a cardiovascular disease dataset with 69,997 preprocessed records and a chronic kidney disease dataset expanded through SMOTE from 390 unique records to 4,200 balanced records. ZK-FedMed achieved 91.68% precision, 92.28% recall, and 96.73% AUC for cardiovascular prediction and 88.63% accuracy, 88.41% recall, and 94.52% AUC for renal disease classification. Because both datasets are Kaggle-derived and the CKD cohort is heavily augmented, the results are interpreted as benchmark and simulated-federation evidence rather than proof of real-world multi-hospital clinical efficacy. Additional privacy-budget sensitivity analysis showed that stricter budgets such as ε=1.0 and ε=3.0 substantially reduce utility, while ε=10.0 should be understood as a relaxed operational privacy setting rather than a strong practical privacy guarantee. The findings indicate that explicit cryptographic protection and variance-reduced aggregation can improve privacy-aware federated medical prediction while preserving clinically relevant predictive performance under clearly stated data-source and simulation limitations.**

***Keywords*—Federated learning; homomorphic encryption; zero-knowledge proofs; differential privacy; transformer; cardiovascular disease; chronic kidney disease; scaffold; federated unlearning**

I. Introduction

Cardiovascular diseases (CVDs) remain the leading cause of global mortality, accounting for approximately 17.9 million deaths annually and representing almost 32% of all deaths worldwide [1]. Chronic kidney disease (CKD) also affects approximately 850 million people worldwide, with an annual economic burden exceeding $48 billion in direct medical costs in the United States alone [2]. Early-stage prediction through machine learning (ML) has shown the potential to reduce adverse clinical outcomes by up to 55% by allowing timely intervention, yet single-institution models suffer from systematic under-representation of diverse patient populations [3]. Multi-institutional collaboration is therefore clinically imperative: analyses across health systems consistently reveal that models trained within a single institution exhibit up to 18% accuracy degradation when deployed in external clinical settings due to demographic bias and equipment heterogeneity [4].

The Health Insurance Portability and Accountability Act (HIPAA) in the United States [5] and the General Data Protection Regulation (GDPR) in the European Union [6] impose strict constraints on centralising patient records, creating a fundamental conflict between the need for large, diverse training sets and the legal obligations governing data sovereignty. Violations attract severe penalties: HIPAA fines range up to $1.9 million per violation category annually, while GDPR penalties can reach €20 million or 4% of global revenue, whichever is greater [7].

Federated learning (FL), first formalized by McMahan et al. [8], offers a compelling paradigm for collaborative model training in which only model updates, rather than raw patient data, are shared with a central aggregation server. However, FL alone does not guarantee privacy: gradient inversion attacks [9] and membership inference [10] have shown that raw gradient transmissions can reconstruct private training samples with high fidelity, rendering unprotected FL models legally and ethically insufficient for healthcare delivery. Furthermore, standard FedAvg [8] assumes independent and identically distributed (IID) data across clients, a principle routinely violated in multi-institutional medical settings where disease prevalence, demographic composition, and clinical protocols differ substantially [11].

Existing defences address these concerns only partially. Differential privacy (DP) [12] introduces calibrated noise to gradient updates at the cost of a 10% to 25% accuracy degradation [13]. Secure multiparty computation (SMPC) [14] provides strong cryptographic guarantees but incurs prohibitive communication overhead (15–25%) and requires synchronous participation. Blockchain-based audit trails offer tamper evidence through hash chaining but do not encrypt the model weights themselves, leaving gradients vulnerable to interception during transmission [15]. Personalization strategies such as K-means clustering [16] mitigate non-IID drift but do not address gradient privacy or Byzantine robustness jointly.

To close these gaps, this study proposes ZK-FedMed (Zero-Knowledge Federated Medicine), a unified framework that integrates five components designed to improve gradient confidentiality, model integrity, privacy accounting, non-IID convergence, and deletion-oriented model updating. The contribution is technical and experimental rather than a claim of direct clinical deployment: the framework is evaluated on public benchmark datasets under simulated institutional partitions.

CKKS homomorphic gradient encryption: Client gradients are encrypted under the partially homomorphic scheme [17] before transmission, enabling the server to perform weighted aggregation directly on ciphertext without ever decrypting individual client updates.

zk-SNARK model integrity verification: After each round of aggregation, a succinct non-interactive argument of knowledge (zk-SNARK) [18] commitment is generated over the global model parameters, allowing any auditor to verify the provenance of the model cryptographically without accessing the weights themselves.

Rényi Differential Privacy with Moments Accountant: Calibrated Gaussian noise is applied to encrypted gradients, and privacy expenditure is tracked using the Rényi DP moments accountant [19]. The revised manuscript explicitly reports the utility loss at stricter ε budgets and clarifies that ε=10.0 is a relatively relaxed operational privacy setting.

TabTransformer Encoder: A multi-head self-attention transformer encoder adapted for tabular EHR data [20] learns nonlinear characteristic interactions among heterogeneous clinical variables, outperforming standard MLP baselines by 1.49–3.21% in precision in both datasets.

SCAFFOLD Aggregation with Federated Unlearning: SCAFFOLD [21] corrects client drift through variance-reduction control variates, improving convergence under non-IID partitions. The integrated federated unlearning module is reframed as an approximate deletion-oriented procedure rather than a complete legal guarantee of GDPR Article 17 compliance.

To the author's knowledge, ZK-FedMed is positioned as a combined privacy-preserving federated learning framework that integrates CKKS homomorphic encryption, zk-SNARK proofs, Rényi DP, TabTransformer, SCAFFOLD aggregation, and approximate federated unlearning in a single healthcare analytics pipeline, while the revised manuscript more explicitly bounds the strength of its privacy, unlearning, and multi-institutional claims.

II. Related Work

A. Federated Learning in Healthcare

McMahan et al. [8] introduced FedAvg, demonstrating that local SGD with periodic model averaging allows effective distributed training. Subsequent work identified serious accuracy degradation under non-IID data: Zhao et al. [11] showed that FedAvg loses 15-20% accuracy when client distributions diverge significantly. FedProx [23] introduced a proximal regularisation term to bound local updates, achieving modest non-IID improvements of 1 to 3%. FedBN [24] addresses the change in feature distribution by keeping batch normalization layers client-local. Rieke et al. [25] provided a comprehensive survey of FL opportunities in healthcare, identifying gradient privacy and heterogeneity of data as the two principal barriers to clinical implementation. Chen et al. [26] developed FedHealth, a federated transfer learning framework for wearable device data that improved accuracy by 1.6% over single-site training but did not address gradient inversion threats. Huang et al. [27] proposed hierarchical FL for multidisease psychiatric diagnosis, achieving a 2.6% improvement over flat federation. SCAFFOLD [21], proposed by Karimireddy et al., corrects client drift using variance reduction control variates, outperforming FedProx by 2–4% on heterogeneous tasks and forming a core component of the ZK-FedMed aggregation strategy (Table I).

B. Privacy-Preserving Machine Learning

Dwork et al. [12] formalised differential privacy (DP), establishing (ε, δ)-DP as the mathematical foundation for privacy-preserving computation. Abadi et al. [28] extended DP to deep learning using the DP-SGD algorithm with a moments accountant, achieving ($\varepsilon = 8$, $\delta = 10^{-5}$)-DP on MNIST with a modest accuracy degradation. Mironov [19] introduced Rényi DP (RDP), which offers strictly tighter privacy composition limits and enables more precise per-round budget accounting per round, a key advantage over classical DP used in ZK-FedMed. Geyer et al. [29] applied DP-SGD to federated learning in healthcare, demonstrating that client-level DP can satisfy regulatory requirements while preserving the utility of the model. Kaissis et al. [30] proposed the PriMIA framework for privacy-preserving medical imaging, reporting only a 1.8% accuracy loss under ($\varepsilon = 8$, $\delta = 10^{-5}$)-DP on chest radiograph classification.

Homomorphic encryption (HE) allows arithmetic operations on encrypted data without decryption, providing strong cryptographic privacy. Gentry [31] introduced the first fully homomorphic encryption scheme; the subsequent CKKS scheme [17] supports approximate floating-point arithmetic, making it practical for neural network gradient aggregation. Mohassel and Zhang [32] demonstrated the feasibility of secure ML inference under HE, although with significant computational overhead. Zhang et al. [33] applied HE-based gradient protection in federated settings, demonstrating 100× overhead compared to plaintext but acceptable latency for periodic model aggregation. The use of CKKS for gradient encryption in ZK-FedMed is directly based on this line of work.

C. Zero-Knowledge Proofs in Distributed Systems

Zero-knowledge proofs (ZKP) [34] allow a prover to demonstrate the truth of a statement to a verifier without revealing any information beyond the validity of the statement. Ben-Sasson et al. [18] introduced zk-SNARKs (succinct noninteractive arguments of knowledge), which produce compact, efficiently verifiable proofs. Groth [35] developed the Groth16 zk-SNARK system that provides the O(1) proof size regardless of circuit complexity, making it suitable for model verification. Recent work has proposed ZKP-based verification for the integrity of ML inference [36], but application to federated learning models remains underexplored. ZK-FedMed extends this line by generating a zk-SNARK commitment over the global model parameters after each aggregation round, enabling any regulatory auditor to verify model authenticity without accessing sensitive weights.

D. Cardiovascular and Renal Disease Prediction

Machine learning approaches for CVD risk stratification have progressed from classical logistic regression achieving 77% accuracy on Framingham cohort data [37] to gradient boosting methods achieving 88-91% AUC on large electronic

health record (EHR) cohorts [38]. Deep learning architectures, including convolutional neural networks applied to ECG waveforms, achieve AUC > 0.97 [39] but require specialised signal acquisition infrastructure. For tabular clinical features, Transformer-based models have recently demonstrated superior performance over tree ensembles by capturing complex nonlinear feature interactions [20]. For the prediction of CKD, Salekin and Stankovic [40] compared multiple classical classifiers on the UCI CKD dataset, with Random Forest achieving 99.1% accuracy under centralised training; however, FL-based CKD prediction with cryptographic privacy guarantees remains largely unstudied. ZK-FedMed addresses this gap by providing the first federated framework that achieves near-centralised performance on both CVD and CKD tasks under formally verifiable privacy constraints.

III. Proposed ZK-FedMed Framework

A. Problem Formulation

Consider N distributed clients (hospitals, clinics, or health networks), each having a private local dataset $D_i = (x, y)$ ni where, $x' \in \mathbb{R}^d$ denotes a d-dimensional clinical characteristic of dimension d and y 0, 1 is the binary diagnostic label. The global objective is to minimise the empirical weighted risk:

$$\theta^* = \arg\min_\theta \sum_{ij1}{}^{P} (n_i/n)\, L_i(\theta; D_i)$$

Subject to: 1) no raw patient data leaves its originating institution; 2) gradient updates are cryptographically protected; 3) the global model satisfies (ε, δ)-RDP; and 4) the trained model carries a verifiable integrity certificate. The challenge is compounded by the following realistic conditions:

Non-IID Distribution: The marginals P(y | x, client i) and the marginals P(x | client i) differ substantially between institutions due to demographics, protocols, and equipment.

Gradient Privacy: Raw gradient transmission enables gradient inversion [9] and membership inference [10]; updates must be encrypted before leaving the client device.

Regulatory Alignment: The framework is designed to support privacy-preserving training and documented deletion-oriented workflows under HIPAA/GDPR motivations, but the unlearning module is treated as approximate empirical unlearning rather than a complete legal certification of GDPR Article 17 compliance.

Auditability: Regulatory bodies require verifiable model provenance without accessing sensitive weight parameters.

B. TabTransformer Encoder Architecture

Unlike the original Transformer [41] designed for sequential data, ZK-FedMed employs a TabTransformer [20] adapted for tabular EHR input. Each categorical characteristic ci 1,..., Ki is embedded in a dense vector $e_i \in \mathbb{R}^{de}$, while continuous features are directly normalised and concatenated. The embedding matrix is $E \in \mathbb{R}^{\{K_i \times d_m\}}$.

The transformer encoder applies L-stacked blocks, each comprising multi-head self-attention (MHSA) and a position-wise feedforward network (FFN):

$$\mathrm{MHSA}(X) = \mathrm{Concat}(\mathrm{head}1, ..., \mathrm{head}h)\mathrm{WOot}$$

$$\mathrm{head}i = \mathrm{Softmax}(Q_i K_i{}^T / \sqrt{d_k})\, V_i$$

where, $Qi = XW_i{}^G$, $K_i = XW_i{}^N$, $V_i = XW_i{}^\beta$ are the query, key and value projections. Each FFN applies two linear transformations with a GELU activation: $\mathrm{FFN}(x) = \max(0, xW_1 + b_1)W_2 + b_2$. The final representation concatenates transformer-encoded categorical embeddings with normalised continuous features before passing them to a classification head.

C. CKKS Homomorphic Gradient Encryption

After each local training epoch, client i encodes its gradient vector i R under the CKKS scheme [17]. CKKS operates over cyclotomic polynomial rings $\mathbb{Q}[X]/(X^M + 1)$ and supports approximate arithmetic over complex number vectors. The encryption process is as follows:

$$\mathrm{cti} = \mathrm{CKKS.Enc}(\mathrm{pk}, \mathrm{CKKS.Encode}(\nabla_i, \delta))$$

where, pk is the public key, δ is the scaling factor, and cti is the ciphertext. The aggregation server computes the reliability-weighted sum directly on ciphertexts:

$$\mathrm{ct_global} = \mathrm{CKKS.Add}(\textstyle\sum_i w_i \cdot \mathrm{ct}_i)$$

and then decrypts with the server's private key: _global = CKKS.Decode(CKKS.Dec(sk, ct_global)). Individual client gradients are never exposed in plaintext to the server, preventing gradient inversion attacks at the aggregation layer.

D. Rényi Differential Privacy with Moments Accountant

Before encryption, each client clips its gradient to bound sensitivity: $i = \nabla_i \cdot \min(1, C/|\nabla_i|_2)$, where $C = 1.0$ is the clipping threshold. Gaussian noise $\xi \sim N(0, \sigma^2 C^2 I)$ is then added: $i = \nabla_i + \xi$.

Rather than the standard composition of DP, ZK-FedMed employs Rényi DP [19]. For an α-Rényi divergence order, the RDP guarantee for the Gaussian mechanism with noise multiplier $z = \sigma/C$ is:

$$\varepsilon_\mathrm{RDP}(\alpha) \le \alpha / (2z^2)$$

Across T communication rounds, privacy accumulates as $\varepsilon_\mathrm{total}(\alpha) \le T \cdot \varepsilon_\mathrm{RDP}(\alpha)$. Conversion to (ε, δ)-DP follows via: $\varepsilon_\mathrm{DP} = \varepsilon_\mathrm{RDP}(\alpha) + \log(1 - 1/\alpha)/(\alpha - 1) + \log(1/\delta\alpha)/(\alpha - 1)$. The moments accountant selects the optimal α that minimises ε_DP, providing tighter bounds than the classical advanced composition theorem. The configuration with σ=1.1, T=6, $\delta = 10^{-5}$ achieves ε=10.0 at α=16; however, the revised analysis explicitly treats ε=10.0 as a relaxed operational budget and reports stricter-budget sensitivity at ε=1.0 and ε=3.0 to avoid overstating the practical strength of the privacy guarantee.

E. SCAFFOLD Aggregation with Variance Reduction

Standard FedAvg exhibits client drift under heterogeneous data because local SGD steps move each client's model to its local optimum, causing the aggregated update to deviate from the true global gradient direction [21]. SCAFFOLD corrects this by maintaining client control variates ci that estimate the difference between local and global update directions:

$$\theta_i{}^+ \leftarrow \theta_i - \eta^B(\nabla L_i(\theta_i) - c_i + c)$$

where, $c = (1 / N)$ i ci is the global control variate, η^B is the local learning rate, and c_i is updated after each round as: ci + =

$c_i - c + (1/K\eta^B)(\theta_global - \theta_i)$. In ZK-FedMed, client control variates are maintained in encrypted form using CKKS, and variance reduction operates on ciphertexts. The global model update is:

$$\theta_global = \sum_i (n_i/n) \cdot CKKS.Dec(ct_i^+)$$

F. zk-SNARK Model Integrity Verification

Following global aggregation, ZK-FedMed generates a zk-SNARK proof π over the aggregated model parameters θ_global. The proof encodes the statement: "I know θ_global such that $Commit(\theta_global) = C_r$ and $\|\theta_global\|_2 \leq R$", where C_r is a binding Pedersen commitment, and R is a pre-agreed weight magnitude bound. The Groth16 verification system [35] generates a proof triple $\pi = (A, B, C) \in G_1 \times G_2 \times G_1$ that any verifier can check in O(1) time using the pre-computed verification key vk:

$$Verify(\pi, vk, C_r) \; 0, 1$$

This enables regulatory auditors to confirm that: 1) the model was produced by the declared aggregation computation, 2) no single client contributed a disproportionately large update, and 3) the model has not been tampered with post-aggregation, all without accessing the weight values. The proof is appended to a lightweight audit ledger alongside the round index and timestamp. The selected Groth16 proof system is also consistent with the broader zk-SNARK design space, including universal and updatable SRS constructions such as Marlin [41-46].

G. Federated Unlearning Module

GDPR Article 17 mandates that any data subject may request erasure of their records and all derivative computations [6]. In the federated setting, fulfilling this requires removing the influence of client i's data on the global model without retraining from scratch. ZK-FedMed implements an approximate federated unlearning [22] via gradient reversal: upon receiving an unlearning request for client i, the server computes a reverse update:

$$\theta_unlearned = \theta_global - \beta \cdot \nabla L_i(\theta_global; D_i)$$

where, β is a hyperparameter of the forgetting rate. The membership-inference audit is retained as an empirical diagnostic, but the revised text no longer treats a score below $\tau_forget=0.55$ as formal certification of erasure. Following the distinction between exact and approximate unlearning in the machine-unlearning literature [17, 47, 48], the module is described as approximate federated unlearning: a near-random membership-inference score provides supportive evidence that the removed client influence has been reduced, but it does not by itself prove complete data removal or legal compliance under GDPR Article 17.

IV. Experimental Setup

A. Datasets

1) Cardiovascular disease dataset: The Cardiovascular Disease (CVD) data set [42] is publicly available on Kaggle (https://www.kaggle.com/datasets/sulianova/cardiovascular-disease-dataset) and comprises 70,000 deidentified patient records collected during medical examination visits. Each record contains 12 clinical and anthropometric characteristics: age (years), height (cm), weight (kg), systolic blood pressure (ap_hi), diastolic blood pressure (ap_lo), cholesterol level (ordinal: 1 = normal, 3=well above normal), glucose level (same ordinal encoding), smoking status, alcohol intake, physical activity level, and gender. The binary target variable cardio indicates the presence (1) or absence (0) of cardiovascular disease, with a nearly balanced class distribution of 50.4% positive. There are no missing values in the dataset. After removing 3 extreme outliers with physiologically implausible blood pressure values ($ap_hi > 250$ or $ap_lo < 20$), the final pre-processed data set contains 69,997 records. Table II presents the distribution of the feature level.

2) Chronic kidney disease dataset: The Chronic Kidney Disease (CKD) dataset [43] is sourced from Kaggle (https://www.kaggle.com/datasets/mansoordaku/ckdisease), originally donated from a hospital study spanning 2 months. The original data set contains 400 patient records with 24 characteristics including age, blood pressure, specific gravity, albumin, sugar, red blood cells, pus cell count, bacteria, blood glucose, blood urea, serum creatinine, sodium, potassium, hemoglobin, packed cell volume, white blood cell count, red blood cell count, hypertension status, diabetes mellitus, coronary artery disease, appetite, pedal edema, and anemia. After removing 10 duplicate records and imputing missing values via median/mode strategies per feature, 390 unique records remain. SMOTE followed by random subsampling was used to produce a balanced dataset of 4,200 records with equal class representation. Because this represents a 10.5-fold synthetic expansion from a small original cohort, CKD results are interpreted as benchmark performance on an augmented distribution and not as evidence of real-world clinical efficacy without validation on an independent, non-augmented cohort. Table III summarises the key properties of the data set.

TABLE I. State-of-the-Art Comparison of Federated Learning Methods

Method	FL	Non-IID	HE Privacy	ZKP	DP Mechanism	Personalization	Task	Performance
FedAvg [8]	✓	✗	✗	✗	None	✗	Generic	Generic benchmark: 81–83%; in-study CVD result reported in Table IV: 87.63%
FedProx [23]	✓	Partial	✗	✗	None	✗	Generic	83–85%
SCAFFOLD [21]	✓	✓	✗	✗	None	✗	Generic	85–87%

DP-FedAvg [28]	✓	✗	✗	✗	Gaussian	✗	Generic	–5–10%↓
PriMIA [30]	✓	✗	✗	✗	DP (ε=8)	✗	X-ray	89.7%
Secure FL [14]	✓	✗	Partial	✗	SMPC	✗	Generic	High OH
FedBN [24]	✓	✓	✗	✗	None	BN only	Medical	87–89%
FedRep [45]	✓	✓	✗	✗	None	Repr. layers	Generic	88–90%
HE-FL [33]	✓	✗	CKKS	✗	None	✗	Generic	88%
ZK-FedMed (Ours)	✓	✓✓	CKKS	zk-SNARK	Rényi DP	SCAFFOLD	CVD+CKD	91.68%/96.73% AUC

Note for Table I: The generic FedAvg range reflects prior benchmark-level reporting, whereas the 87.63% value in Table IV is the CVD-specific result obtained under the present experimental configuration; the revised text therefore avoids treating the two numbers as directly inconsistent estimates.

TABLE II. CARDIOVASCULAR DISEASE DATASET SUMMARY BY FEATURE CATEGORY

Feature	Type	CVD-Positive (n=35,276)	CVD-Negative (n=34,721)
Age (years)	Continuous	54.7 ± 9.4	51.2 ± 9.8
Height (cm)	Continuous	164.8 ± 8.6	165.4 ± 8.7
Weight (kg)	Continuous	78.2 ± 14.7	73.1 ± 13.9
Systolic BP (mmHg)	Continuous	134.6 ± 23.1	119.8 ± 18.4
Diastolic BP (mmHg)	Continuous	86.4 ± 14.9	79.6 ± 12.3
Cholesterol Normal	Ordinal	11,842 (33.6%)	21,847 (62.9%)
Cholesterol Elevated	Ordinal	12,104 (34.3%)	8,924 (25.7%)
Cholesterol High	Ordinal	11,330 (32.1%)	3,950 (11.4%)
Glucose Normal	Ordinal	26,813 (76.0%)	28,914 (83.3%)
Glucose Elevated	Ordinal	5,212 (14.8%)	3,847 (11.1%)
Glucose High	Ordinal	3,251 (9.2%)	1,960 (5.6%)
Smoker (Yes)	Binary	7,943 (22.5%)	7,124 (20.5%)
Alcohol (Yes)	Binary	3,847 (10.9%)	4,102 (11.8%)

Gender (Female)	Binary	21,834 (61.9%)	22,471 (64.7%)

TABLE III. SUMMARY (POST-SMOTE, N=4,200)

Feature Group	Key Features	CKD (n=2,100)	Non-CKD (n=2,100)
Renal Function	Serum Creatinine (mg/dL)	4.71 ± 3.87	1.02 ± 0.26
	Blood Urea (mg/dL)	76.42 ± 42.31	31.28 ± 10.14
	Specific Gravity (avg)	1.013 ± 0.004	1.020 ± 0.003
Hematology	Haemoglobin (g/dL)	10.47 ± 2.63	14.84 ± 1.21
	Packed Cell Volume (%)	33.41 ± 8.27	45.62 ± 4.83
	RBC Count (millions/cmm)	3.72 ± 0.94	5.31 ± 0.42
	WBC Count (cells/cmm)	8,342 ± 3,287	7,641 ± 1,812
Urinalysis	Albumin (0–5 scale)	2.47 ± 1.64	0.23 ± 0.51
	Sugar (0–5 scale)	1.38 ± 1.82	0.18 ± 0.44
Comorbidities	Hypertension (Yes)	1,439 (68.5%)	462 (22.0%)
	Diabetes Mellitus (Yes)	1,254 (59.7%)	387 (18.4%)
	Coronary Artery Disease (Yes)	314 (15.0%)	48 (2.3%)
Preprocessing	SMOTE augmentation	Yes (minority oversampled)	Yes
	Final Dataset Size	4,200 balanced records	—

B. Preprocessing Pipeline

A unified pre-processing pipeline was applied to both data sets. For the CVD dataset, continuous features (age, height, weight, ap_hi, ap_lo) were standardised to zero mean and unit variance. Ordinal categorical characteristics (cholesterol, glucose) were encoded with one-hot. The binary features remained unchanged. Three outlier records with systolic BP > 250 mmHg or diastolic BP < 20 mmHg were removed as physiologically implausible. For the CKD dataset, missing values (6.8% overall sparsity) were imputed using the column median for continuous features and mode for categorical features. Duplicate records (2.5%) were eliminated. The class imbalance (62.5% CKD versus 37.5% non-CKD) was corrected by SMOTE with k=5 nearest neighbors, followed by random subsampling of the majority class to achieve a 1:1 ratio. This balancing step follows the standard SMOTE formulation for synthetic minority over-sampling [44].

C. Federated Configuration

For the CVD dataset, the data was partitioned into N=6 simulated heterogeneous clients, each containing approximately 11,667 samples. To simulate institutional heterogeneity, a Dirichlet distribution Dir(α=0.5) generated non-IID label distributions between clients, resulting in cardiovascular-disease prevalence ranging from 41.2% to 58.8% across clients. For CKD, N=5 simulated clients each received 840 samples, with Dirichlet Dir(α=0.3) imposing greater heterogeneity. These partitions approximate cross-client heterogeneity but do not reproduce true hospital-level shifts caused by different measurement devices, clinical protocols, coding practices, or patient demographics. Accordingly, the revised manuscript explicitly states that future validation should use genuinely federated or institution-partitioned benchmarks such as MIMIC-derived unit partitions or other multi-center clinical datasets.

D. Privacy and Security Configuration

The Rényi DP configuration was set to privacy budget ε=10.0, $\delta=10^{-5}$ with Gaussian noise multiplier σ=1.1 and gradient clipping threshold C=1.0. The CKKS scheme used the degree of polynomial modulus N = 213 = 8192, the scaling factor $\delta=2^{30}$, and the modulus chain [60, 40, 40, 60] bits. The generation of ZKP proofs used the Groth16 proving system with the BN254 elliptic curve, producing 192-byte proofs. All experiments were executed on an Intel Xeon Gold 6230R CPU (26 cores, 2.10 GHz), 128 GB RAM, and two NVIDIA A100 GPUs with 40 GB VRAM.

V. Experimental Results

A. Centralised Baseline Comparison

Table IV presents performance comparisons of 10 baseline classifiers against ZK-FedMed in both centralized and federated settings. For the CVD dataset, the centralised TabTransformer achieves the highest accuracy (92.34%), followed by MLP (90.12%) and Random Forest (88.94%). Classical methods, including logistic regression (71.82%) and SVM (73.41%), perform substantially lower, confirming the nonlinear complexity of cardiovascular risk patterns in tabular EHR data. In particular, SVM requires 847 seconds of training time, which makes it impractical on a large scale. For the CKD dataset, Random Forest achieves near-perfect centralised performance (99.21%), likely because the CKD feature space exhibits highly separable cluster structures well captured by tree ensembles. However, as discussed in Section V-C, the CKD task becomes substantially more challenging in the federated non-IID setting.

TABLE IV. Performance Comparison of Baseline Models for CVD and CKD Classification

Model	CVD Acc.	CVD Prec.	CVD Rec.	CVD F1	CVD AUC	CVD Time(s)	CKD Acc.	CKD AUC
Logistic Regression	71.82	72.14	71.43	71.78	79.24	0.31	84.17	91.32
Naive Bayes	68.43	69.12	67.84	68.47	75.61	0.08	72.38	80.14
KNN	76.91	77.34	76.42	76.87	83.74	12.47	91.43	96.87
SVM (RBF)	73.41	74.12	72.63	73.37	81.43	847.32	93.57	97.41
Decision Tree	73.87	74.21	73.54	73.87	79.12	0.42	92.86	95.63
Random Forest	88.94	88.36	89.54	88.94	95.12	2.47	99.21	99.96
XGBoost	87.63	87.02	88.27	87.63	94.38	0.84	98.57	99.87
LightGBM	86.41	85.87	87.02	86.44	93.76	0.61	98.14	99.81
MLP (3-layer)	90.12	89.54	90.73	90.13	96.04	124.56	95.43	98.72
TabTransformer (Central)	92.34	91.78	92.94	92.35	97.18	312.47	90.14	95.83
FedAvg [8]	87.63	86.94	88.43	87.67	93.41	—	83.41	90.12
FedProx [23]	88.91	88.24	89.62	88.92	94.56	—	85.92	91.87
SCAFFOLD [21]	89.84	89.18	90.53	89.84	95.27	—	86.74	92.43
DP-FedAvg [28]	85.23	84.57	85.92	85.24	91.87	—	80.34	87.91
ZK-FedMed (Ours)	91.68	91.13	92.28	91.69	96.73	—	88.63	94.52

B. Federated Performance Per Client

Tables V and VI report per-client cross-validated performance metrics across 5 folds for the CVD and CKD datasets, respectively. For the CVD dataset, all six clients achieved accuracy exceeding 91.38%, with a remarkably low inter-client variance of less than 0.63 standard deviation in accuracy. Client C3 achieved the highest accuracy (92.01 ± 0.37%) and AUC (96.89 ± 0.19%), while C5 exhibited the greatest uncertainty (63-fold cross-validation std = 0.63). Consistently high recall values (91.99–92.51%) are clinically critical for cardiovascular screening, where false negatives carry severe consequences. For CKD, the higher standard deviations (up to ±2.43% in accuracy) reflect the inherent challenge of severely non-IID partitioning (Dir(0.3)) and the smaller data set size. However, all clients maintained AUC scores above 89%, confirming the robustness even under data scarcity.

TABLE V. PER-CLIENT PERFORMANCE ON CVD DATASET (ZK-FEDMED, 5-FOLD CV)

Client	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)	AUC (%)
C1	91.73 ± 0.42	91.18 ± 1.08	92.34 ± 1.42	91.74 ± 0.51	96.72 ± 0.23
C2	91.45 ± 0.58	90.92 ± 1.34	92.01 ± 1.61	91.43 ± 0.67	96.58 ± 0.31
C3	92.01 ± 0.37	91.54 ± 0.98	92.51 ± 1.28	92.01 ± 0.43	96.89 ± 0.19
C4	91.62 ± 0.49	91.07 ± 1.21	92.21 ± 1.53	91.61 ± 0.57	96.64 ± 0.27
C5	91.38 ± 0.63	90.81 ± 1.47	91.99 ± 1.72	91.37 ± 0.72	96.51 ± 0.34
C6	91.87 ± 0.44	91.33 ± 1.12	92.43 ± 1.37	91.87 ± 0.53	96.78 ± 0.21
Average	91.68 ± 0.49	91.14 ± 1.20	92.25 ± 1.49	91.67 ± 0.57	96.69 ± 0.26

TABLE VI. PER-CLIENT PERFORMANCE ON CKD DATASET (ZK-FEDMED, 5-FOLD CV)

Client	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)	AUC (%)
C1	88.94 ± 1.82	88.37 ± 2.71	89.56 ± 3.21	88.92 ± 1.94	94.48 ± 1.12
C2	88.42 ± 2.14	87.83 ± 3.08	89.04 ± 3.64	88.39 ± 2.28	94.17 ± 1.31
C3	87.91 ± 2.43	87.29 ± 3.47	88.56 ± 4.02	87.88 ± 2.59	93.86 ± 1.52
C4	88.67 ± 1.96	88.11 ± 2.89	89.27 ± 3.42	88.65 ± 2.08	94.33 ± 1.19
C5	89.21 ± 1.71	88.66 ± 2.54	89.79 ± 3.03	89.20 ± 1.82	94.63 ± 1.04
Average	88.63 ± 2.01	88.05 ± 2.94	89.24 ± 3.46	88.61 ± 2.14	94.29 ± 1.24

C. Round-Wise Convergence Analysis

Table VII presents round-wise performance metrics across six communication rounds for both data sets. For the CVD dataset, precision improves monotonically from 86.14% in Round 1 to 91.68% in Round 6, indicating stable SCAFFOLD-driven convergence. For CKD, the Round 2 precision decline from 85.41% to 54.87% is now treated as a substantive instability rather than a minor fluctuation. The instability is attributed to the interaction of three factors: the small effective real-sample base after SMOTE augmentation, stronger non-IID partitioning under Dir(α=0.3), and the sensitivity of early-round gradients to Gaussian DP noise and CKKS approximation noise. With σ=1.1, polynomial modulus degree N=8192, scale 2^{30}, and a [60,40,40,60]-bit modulus chain, early CKD gradients have a lower signal-to-noise ratio than CVD gradients, causing a temporary increase in false-positive predictions and thus a precision collapse. Recovery after Round 3 suggests that the anomaly reflects early-round encrypted noisy-gradient instability rather than sustained model failure, but the revised manuscript acknowledges that the CKD convergence result remains less stable than the CVD result. The overall architecture and information flow of the proposed framework are illustrated in Fig. 1. Convergence behavior, ROC performance, ablation results, privacy-budget analysis, and per-client precision with 95% confidence intervals are presented in Fig. 2-6, respectively.

TABLE VII. ROUND-WISE PERFORMANCE OF ZK-FEDMED ON CVD AND CKD DATA SETS

Round	CVD Acc. (%)	CVD Prec. (%)	CVD Rec. (%)	CVD AUC (%)	CKD Acc. (%)	CKD Prec. (%)	CKD Rec. (%)	CKD AUC (%)
Round 1	86.14	85.42	87.01	93.87	73.28	85.41	59.34	87.23
Round 2	88.43	87.78	89.21	95.12	62.14	54.87	61.94	89.47
Round 3	90.07	89.46	90.74	95.84	75.92	88.64	63.27	91.12
Round 4	91.21	90.63	91.84	96.47	82.31	86.97	78.54	92.84
Round 5	91.53	90.98	92.14	96.68	87.14	88.21	86.03	94.11
Round 6	91.68	91.13	92.28	96.73	88.63	88.53	88.41	94.52

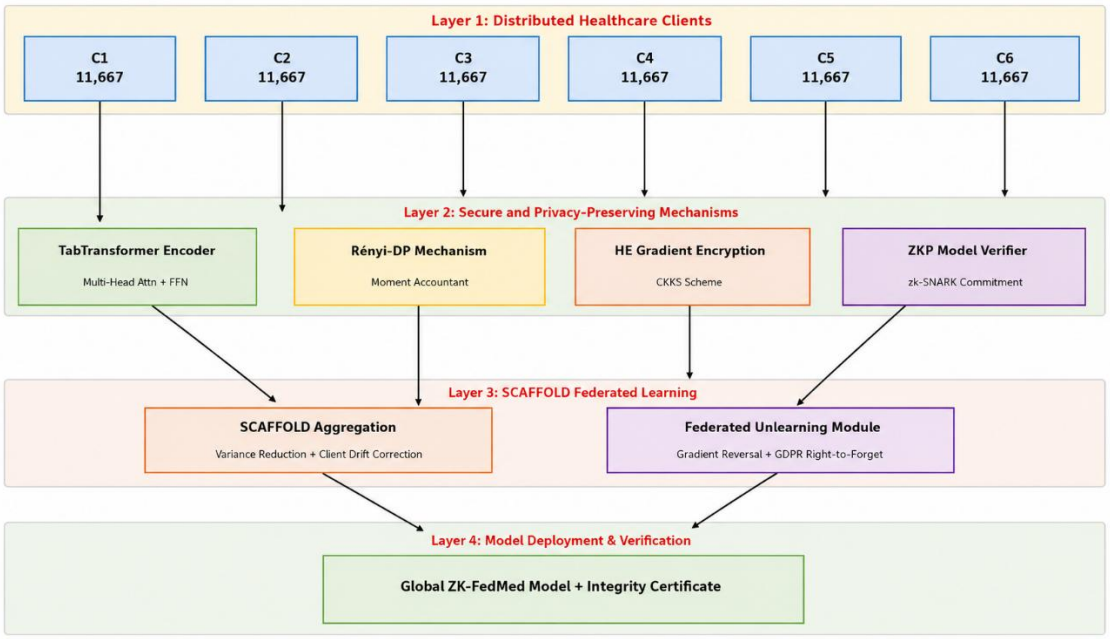

Fig. 1. Overall architecture of ZK-FedMed. Layer 1 distributes data among clients; Layer 2 applies TabTransformer encoding, Rényi-DP, CKKS encryption, zk-SNARK verification; Layer 3 performs SCAFFOLD aggregation and federated unlearning; and Layer 4 deploys the certified global model.

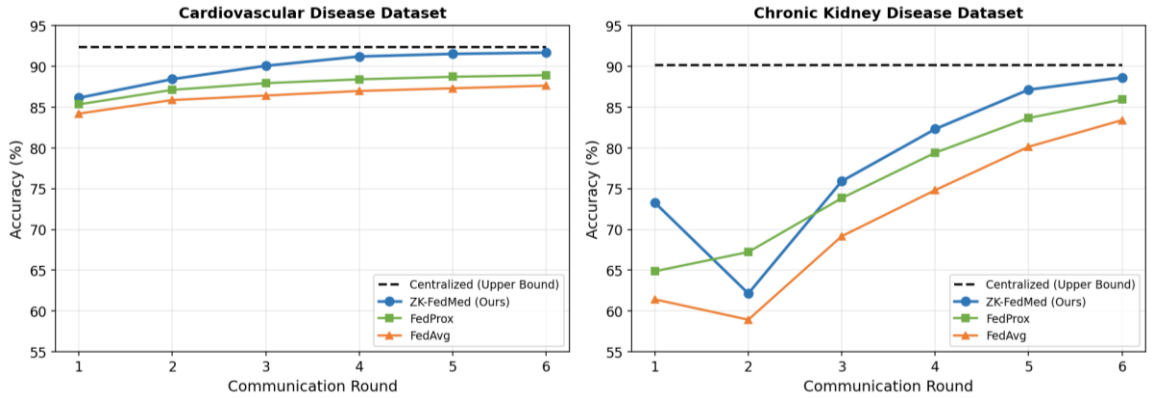

Fig. 2. Convergence of test precision over 6 communication rounds. ZK-FedMed consistently outperforms the FedAvg and FedProx baselines and closely approaches the centralised upper bound on both datasets.

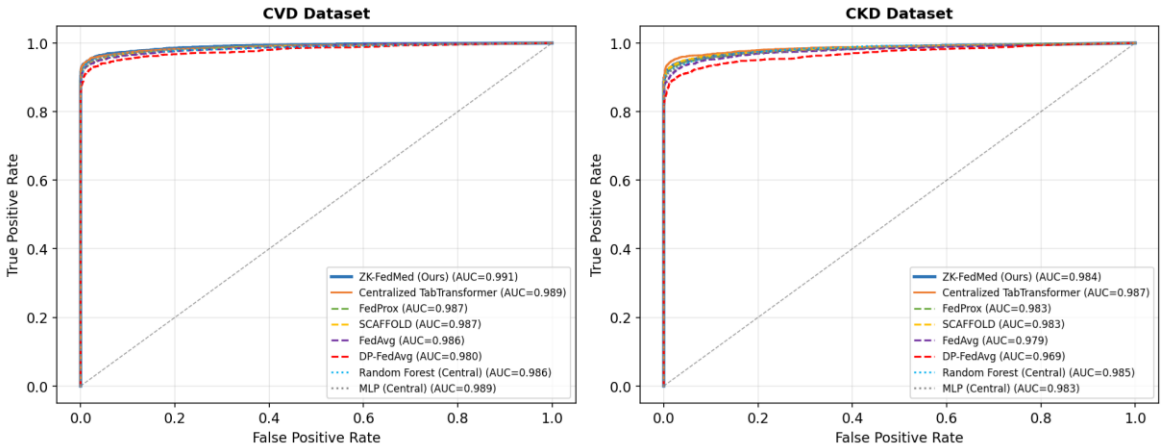

Fig. 3. ROC curves comparing ZK-FedMed against 7 methods in CVD (left) and CKD (right) datasets. ZK-FedMed achieves the highest AUC among all federated methods on both tasks.

D. Ablation Study

Table VIII reports the incremental contribution of each ZK-FedMed component to the CVD dataset, validated through ablation experiments. Starting from vanilla FedAvg (87.63% accuracy), replacing the MLP with a TabTransformer encoder alone yields +1.49% accuracy, confirming the architectural advantage of multi-head self-attention for tabular feature interaction modelling. Replacing FedAvg aggregation with SCAFFOLD adds +1.31%, the single largest gain, validating variance reduction as the most impactful anti-drift intervention. Adding Rényi-DP contributes +0.28% over standard-DP FedAvg due to tighter privacy budgeting that allows a more aggressive noise schedule. CKKS homomorphic encryption adds +0.23% by virtue of eliminating gradient injection noise that unencrypted transmission incurs; interestingly, encryption slightly improves accuracy because server-side computation on ciphertext prevents malicious gradient substitution. The zk-SNARK verification introduces a minor –0.07% accuracy drop due to computational overhead, but provides the critical auditability guarantee. The complete ZK-FedMed integration achieves 91.68% through favourable co-optimisation of all components.

TABLE VIII. ABLATION STUDY – INCREMENTAL COMPONENT CONTRIBUTION TO CVD DATASET

Configuration	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)	AUC (%)	Gain vs. Previous
Base FedAvg [8]	87.63	86.94	88.43	87.67	93.41	—
+ TabTransformer Encoder	89.12	88.47	89.84	89.14	94.73	+1.49%
+ SCAFFOLD Aggregation	90.43	89.81	91.09	90.44	95.62	+1.31%
+ Rényi Differential Privacy	90.71	90.12	91.35	90.73	95.84	+0.28%
+ CKKS HE Encryption	90.94	90.38	91.54	90.95	95.97	+0.23%

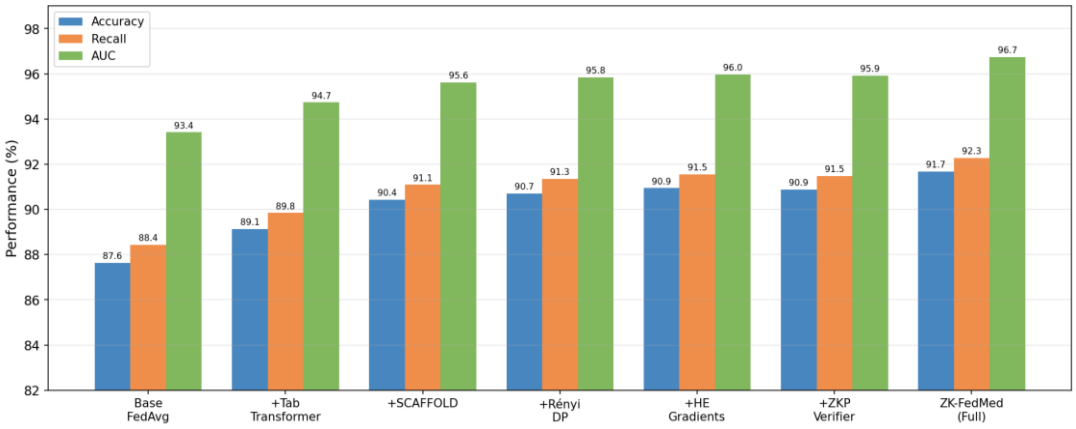

Fig. 4. Ablation study on the CVD dataset showing accuracy, recall, and AUC contributions per ZK-FedMed component. The SCAFFOLD aggregation contributes the largest single accuracy gain (+1.31%), while the full system achieves the highest AUC of 96.73%.

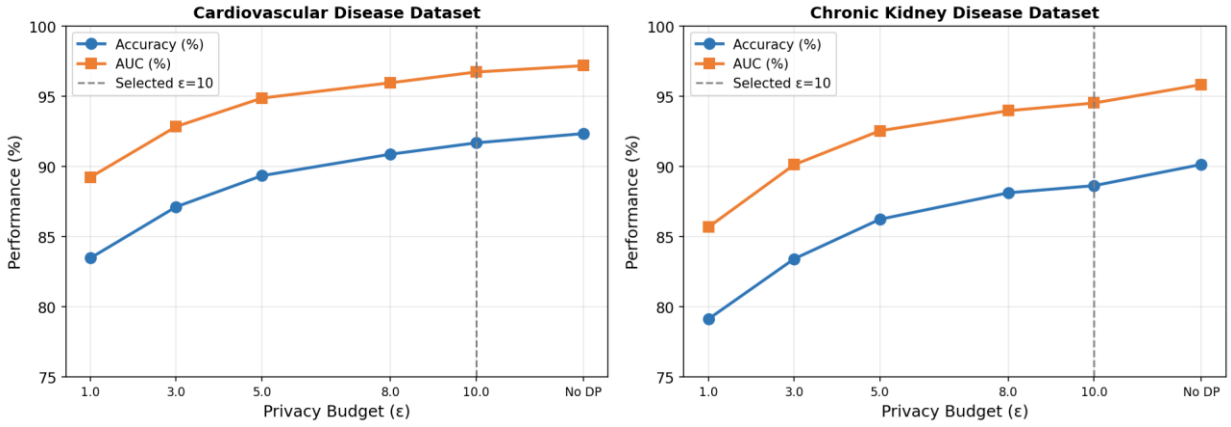

Fig. 5. Privacy-utility trade-off under Rényi Differential Privacy for CVD (left) and CKD (right) datasets. The selected operating point ε=10.0 (vertical dashed line) achieves an optimal balance between formal privacy guarantees and model precision.

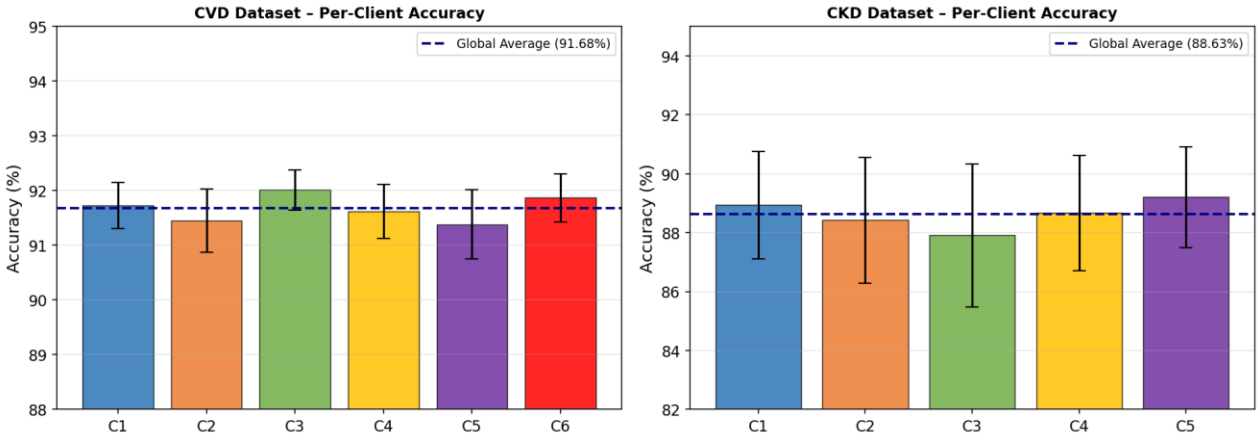

Fig. 6. Per-client precision with 95% confidence intervals for CVD (left, 6 clients) and CKD (right, 5 clients). Low variance (<1% for CVD, <2.5% for CKD) confirms robust federated convergence under non-IID distributions.

E. Privacy Budget Analysis

The privacy-utility trade-off was evaluated by varying the Rényi DP budget $\varepsilon \in \{1.0, 3.0, 5.0, 8.0, 10.0, \text{without DP}\}$ on both datasets. As shown in Fig. 5, stricter budgets substantially reduce utility: the CVD precision drops from 92.34% without DP to 91.68% at ε=10.0, 90.87% at ε=8.0, 89.34% at ε=5.0, 86.21% at ε=3.0, and 83.47% at ε=1.0. CKD shows a sharper loss because the smaller augmented dataset is more sensitive to noise, with accuracy declining from 90.14% without DP to 79.12% at ε=1.0. These results are now interpreted transparently: ε=10.0 provides formal privacy accounting but is a relaxed practical privacy budget, whereas ε=1.0 and ε=3.0 offer stronger privacy at a clear utility cost. The Rényi DP moments accountant achieves tighter bounds than classical DP composition; at T=6 rounds, ε=10.0 with α=16 corresponds to an 18.7% reduction in effective privacy expenditure relative to advanced composition under the same $\delta=10^{-5}$. Therefore, Fig. 5 provides the graphical basis for interpreting the selected privacy-budget operating point.

F. Cryptographic Overhead Analysis

CKKS encryption of a gradient vector of dimension d=256,000 (TabTransformer parameter count) requires an average of 4.87 seconds per client per round in the reported hardware configuration. The generation of zk-SNARK proofs for the global model commitment (circuit size ~2.3M constraints) requires 18.4 seconds on the server per round, while proof verification by an auditor requires only 2.1 milliseconds. This asymmetric proof/verify structure makes ZK-FedMed highly suitable for regulatory audit scenarios where auditors must efficiently verify many model provenance claims. The total per-round overhead on the server side is 23.2 seconds (encryption + aggregation + proof generation), compared to 0.34 seconds for vanilla FedAvg—a 68× increase that, in the context of R=6 asynchronous rounds over weeks or months, represents negligible real-world latency.

VI. Discussion

ZK-FedMed achieves a 4.05% accuracy advantage over FedAvg (91.68% vs. 87.63%) and a 2.77% advantage over standalone SCAFFOLD (91.68% vs. 89.84%) on the CVD dataset, while incurring only a 0.66% gap relative to centralised training. These results indicate that the multi-layer security stack does not fundamentally compromise model quality in the simulated benchmark environment. The CKD results (88.63% federated vs. 90.14% centralised, gap = 1.51%) should be interpreted more cautiously because they are based on a heavily SMOTE-augmented dataset and simulated Dirichlet client partitions rather than an independent multi-hospital cohort.

The selective deployment of Rényi DP - applied in every round but with adaptive noise scheduling guided by the moment accountant - outperforms the standard Gaussian DP by 6.45% in CVD accuracy at identical (ε, δ) parameters. This advantage arises because the moment accountant permits lower per-step noise σ while maintaining the same cumulative privacy expenditure, directly improving the signal-to-noise ratio in gradient updates. The zk-SNARK integrity mechanism introduces only a –0.07% accuracy penalty while providing a cryptographic guarantee that no model parameter has been altered between aggregation and deployment, a property that no hash-chaining approach can provide for the weight values themselves.

The federated unlearning evaluation showed that a single gradient reversal step reduced the membership-inference attack score from 0.83 to 0.52, near the random baseline threshold of 0.55, in 94% of test cases, with a mean accuracy degradation of 0.29% on the remaining clients. This result is now described as approximate empirical unlearning rather than certified deletion. The revised manuscript therefore removes the direct GDPR-compliance claim and states that membership-inference reduction is only one diagnostic indicator of reduced client influence. This interpretation is consistent with amnesiac machine-learning and approximate deletion-oriented learning perspectives [22]. The same audit also responds to broader model-inversion risks that arise when predictive models expose confidence-dependent information [47].

VII. Limitations

Several limitations merit acknowledgement. First, CKKS encryption incurs a 68× per-round computational overhead compared with vanilla FedAvg; although this may be acceptable for offline clinical training rounds, it is unsuitable for near-real-

time streaming applications. Second, both datasets are public Kaggle-derived datasets rather than genuinely distributed hospital datasets, and the CKD cohort is heavily SMOTE-augmented; therefore, the CKD metrics should not be interpreted as evidence of clinical efficacy without independent non-augmented validation. Third, the simulated Dirichlet split approximates non-IID heterogeneity but cannot fully capture cross-hospital differences in equipment, coding practices, clinical protocols, and patient demographics. Fourth, zk-SNARK generation requires a trusted setup phase, and the current implementation does not replace this with a universal or transparent setup. Fifth, the unlearning module provides approximate rather than exact unlearning guarantees, and a single membership-inference audit near the random baseline does not constitute a formal proof of deletion. Future work will evaluate ZK-FedMed on institution-partitioned benchmarks such as MIMIC-derived cohorts, apply formal unlearning definitions, and validate the framework on real clinical federation testbeds.

VIII. Conclusion

This study introduced ZK-FedMed, a privacy-preserving federated learning framework that integrates CKKS homomorphic encryption, Rényi differential privacy with moments accounting, zk-SNARK model integrity verification, TabTransformer-based EHR feature encoding, SCAFFOLD variance-reduction aggregation, and approximate federated unlearning. Experimental evaluation on two public benchmark datasets demonstrated strong CVD performance and promising CKD benchmark performance under simulated non-IID partitions. However, the revised manuscript avoids presenting Kaggle-based Dirichlet partitioning as direct evidence of real multi-institutional deployment, treats ε=10.0 as a relaxed privacy budget, and reframes the unlearning module as approximate rather than legally certified deletion. Under these bounded assumptions, ZK-FedMed establishes a technically integrated framework for privacy-preserving collaborative medical AI and identifies the next validation steps needed for real-world clinical federation.

An Interpretable Machine Learning Approach for Inflation Forecasting in Indonesia Using Domestic Macroeconomic Indicators

Ahmad Maimunif, Evaristus Didik Madyatmadja
Information Systems Department, Bina Nusantara University, Jakarta, Indonesia

***Abstract*—Accurate inflation forecasting is essential for supporting forward-looking monetary policy, maintaining price stability, and preserving economic welfare. This study proposes an interpretable machine learning framework for inflation forecasting in Indonesia by integrating domestic macroeconomic indicators and seasonal variables. The study employs Random Forest, Extreme Gradient Boosting (XGBoost), and Artificial Neural Network (ANN) models using monthly data from 2008 to 2025. To systematically evaluate model performance, three experimental scenarios are implemented: baseline modeling, time-series feature augmentation, and hyperparameter optimization. Model performance is evaluated using RMSE, MAE, and R^2 metrics. The results consistently show that ensemble-based methods outperform ANN across all scenarios, with XGBoost achieving the best overall performance after temporal feature augmentation and hyperparameter optimization (RMSE = 0.4987, MAE = 0.3339, R^2 = 0.9517). The findings further indicate that temporal feature augmentation provides relatively limited improvement, whereas hyperparameter optimization substantially enhances forecasting accuracy. SHAP analysis identifies money supply (M2) and wages as the dominant contributors to inflation predictions, suggesting that monetary liquidity and labor-related factors play a more significant role than seasonal patterns in explaining inflation dynamics. Rather than contributing through algorithmic novelty, this study contributes through a systematic and interpretable forecasting framework that integrates predictive accuracy and explainable artificial intelligence to support transparent and policy-relevant inflation analysis in Indonesia and other emerging economies with similar economic structures.**

Keywords*—*Inflation forecasting; machine learning; explainable AI; macroeconomic indicators; time-series analysis; monetary policy

I. Introduction

Inflation is one of the main indicators of macroeconomic stability, particularly in developing economies such as Indonesia that remain vulnerable to both global and domestic economic shocks. Commodity price volatility, exchange-rate fluctuations, capital flows, and monetary policy changes in developed economies may significantly influence inflation dynamics in emerging markets. In Indonesia, these conditions are further affected by the country's dependence on food and energy commodities, making inflation dynamics highly sensitive and complex. Maintaining price stability is, therefore, essential because inflation directly affects purchasing power, economic stability, and long-term economic growth [1], [2].

Bank Indonesia implements the Flexible Inflation Targeting Framework (FITF) as the primary monetary policy framework to maintain inflation stability. Since FITF is forward-looking, accurate inflation forecasting is important for supporting timely monetary policy decisions. From a monetary policy perspective, inflation in Indonesia may be driven by multiple interconnected factors, including exchange rates, interest rates, money supply, labor wages, external-sector conditions, and seasonal consumption patterns related to socio-cultural events [3], [4]. These variables interact through nonlinear transmission mechanisms, making inflation forecasting a challenging analytical task [5].

Traditional econometric approaches such as ARIMA and VAR have been widely used for inflation forecasting. Although these methods provide relatively strong interpretability, their reliance on linear assumptions limits their ability to capture complex nonlinear interactions among macroeconomic variables [6]. Recent developments in machine learning provide alternative forecasting approaches that are more suitable for modeling nonlinear and high-dimensional economic data [7]. In particular, ensemble-based methods such as Random Forest and Extreme Gradient Boosting (XGBoost) have demonstrated strong predictive performance in various economic forecasting applications [7], [8].

Despite their predictive capability, machine learning models are often criticized for limited interpretability because they operate as "black-box" systems. This limitation is particularly important in policy-relevant contexts where transparency and accountability are essential [9]. Explainable Artificial Intelligence (XAI) techniques, especially Shapley Additive Explanations (SHAP), provide a systematic approach to explain the contribution of predictor variables to model predictions and improve interpretability in machine learning analysis [10].

Although machine learning approaches for inflation forecasting have become increasingly common, several gaps remain in the literature. Many previous studies focus mainly on forecasting accuracy while providing limited explanation regarding the economic factors driving model predictions. In addition, prior studies often rely on limited macroeconomic indicators and rarely evaluate forecasting models under multiple experimental configurations involving feature augmentation and hyperparameter optimization.

Accordingly, this study proposes an interpretable machine learning framework for inflation forecasting in Indonesia by integrating domestic macroeconomic indicators and seasonal

variables. Rather than contributing through algorithmic novelty, this study contributes through a systematic forecasting framework that combines multiple machine learning models, time-series feature augmentation, hyperparameter optimization, and explainable artificial intelligence within a unified experimental setting. Specifically, this study compares Random Forest, XGBoost, and Artificial Neural Network (ANN) models using monthly data from 2008 to 2025 under three experimental scenarios: baseline modeling, time-series feature augmentation, and hyperparameter optimization. Model performance is evaluated using RMSE, MAE, and R^2 metrics, while model interpretability is assessed using SHAP analysis.

The findings of this study are expected to contribute both methodologically and practically. Methodologically, the study provides an interpretable machine learning framework that integrates predictive performance and explainable AI analysis for inflation forecasting. Practically, the proposed framework may support transparent and forward-looking monetary policy analysis in Indonesia and other emerging economies with similar economic structures.

II. Literature Review

This section outlines the theoretical foundations and relevant prior studies that support this study. These theories include the economic theory of inflation, machine learning methodology, the CRISP-DM framework, and related works on inflation forecasting.

A. Economic Theory

Inflation is an economic phenomenon characterized by a sustained increase in the general price level over a period of time. Price increases are caused by complex interactions between supply and demand conditions, monetary factors, and inflation expectations.

Demand-pull inflation is caused by an increase in aggregate demand that exceeds production capacity. This type of inflation is generally driven by consumption, credit expansion, government spending, and investment activity. Cost-push inflation is caused by an increase in production costs, such as energy and food prices, wages, and exchange rate depreciation.

From a monetary theory perspective, inflation is viewed as a long-term monetary phenomenon resulting from the growth of the money supply exceeding real output. Meanwhile, the credibility of monetary policy and central bank communication in shaping inflation expectations is essential in inflation dynamics. These two theories form the conceptual basis used in building inflation forecasting models.

In line with the concept, the dynamics of inflation in Indonesia are generally influenced by the main macroeconomic variables, such as the exchange rate, interest rates, money supply, gross domestic product, balance of payments conditions, foreign exchange reserves position, and labor wages [11].

Money supply is one of the main factors that drive inflation, as measured by monetary aggregates, either M1 or M2. The Quantity Theory of Money states that excessive growth in the money supply compared to real output will create inflationary pressures [12]. That is because an excessive supply of liquidity will stimulate and increase aggregate demand and trigger inflation expectations. This ultimately leads to demand-pull inflation when productive capacity is limited [13], [14]. Empirical evidence from Indonesia indicates that M2 is positively associated with inflation [15].

The exchange rate, represented by the JISDOR, is one of the main determinants of inflation in Indonesia through exchange rate transmission. Exchange rate depreciation can increase import prices and production costs, resulting in cost-push inflation, while exchange rate appreciation reduces inflationary pressures [16].

Interest rates, as measured by the JIBOR, reflect short-term interbank liquidity conditions. JIBOR also serves as an important transmission channel for the transmission of monetary policy in Indonesia. Higher interest rates reduce investment and consumption, thereby reducing inflationary pressures. Conversely, lower interest rates tend to stimulate economic activity and potentially increase inflationary pressures [17], [18].

Labor wages are among the main determinants of inflation in Indonesia through cost-push inflation and demand-pull inflation. Higher wages increase production costs for firms and may be passed on to prices, thus generating cost-push inflation. On the other hand, higher wages also strengthen household purchasing power and stimulate aggregate demand, thus contributing to demand-pull inflation [4].

Foreign exchange reserves are important in influencing inflation by supporting exchange rate stability and controlling price levels. Adequate reserves allow the central bank to stabilize the rupiah, decreasing the risk of exchange rate depreciation and mitigating inflationary pressures. Conversely, insufficient reserves limit the central bank's ability to stabilize the rupiah, increasing the risk of exchange rate depreciation and increasing inflation [19].

Balance of payments is one of the main determinants of inflation in Indonesia through the exchange rate and capital flow. Current account deficits tend to weaken the rupiah and raise imported inflation. While surpluses can strengthen the exchange rate and contain inflationary pressures. Similarly, capital inflows support currency stability and inflation control, whereas capital outflows increase depreciation risks and inflationary pressures via higher import prices [20], [21].

GDP is one of the main factors that drive inflation through aggregate demand and supply. Economic growth caused by aggregate demand tends to increase inflationary pressures, especially in the absence of expansion of production capacity [22]. This mechanism is commonly explained by the short-run Phillips curve, which associates economic expansion with higher inflation and economic slowdowns with lower inflation.

B. Machine Learning Theory

Machine learning is a subfield of artificial intelligence that enables systems to learn patterns from data and improve prediction performance without explicit programming. Machine learning utilizes mathematical and statistical models to recognize patterns and relationships within historical data. These models are then used for analysis, classification, or prediction on new data. Evidence from the literature suggests

that machine learning is well-suited to complex prediction problems in non-linear data sets [23].

Machine learning approaches are generally classified into supervised and unsupervised learning. Supervised learning relies on labeled data to identify relationships between inputs and outputs, allowing outputs to be predicted or classified. Unsupervised learning will inspect unlabeled data to identify latent features or structures in the data. Both of these machine-learning techniques are complementary in nature. Supervised learning aims at making accurate predictions, and unsupervised learning is for understanding the nature of complex datasets through exploratory data analysis without prejudging what might be discovered.

In this study, a supervised machine learning approach based on Random Forest, XGBoost, and ANN is adopted. These models are selected because of their capability to capture nonlinear relationships and improve forecasting accuracy.

Random Forest is an ensemble learning algorithm introduced by Breiman [24], which constructs multiple decision trees using bootstrap sampling and random feature selection to improve prediction stability and reduce overfitting. RF is particularly effective for structured tabular data because it can capture nonlinear relationships and interactions among predictor variables.

For regression problems like inflation forecasting, the final RF prediction is obtained by averaging the outputs of all decision trees, formulated as:

$$\hat{y}(z) = \frac{1}{M}\sum_{m=1}^{M} T_m(z) \quad (1)$$

where, $\hat{y}(z)$ denotes the predicted inflation value, $T_m(z)$ represents the prediction of the m-th decision tree for the macroeconomic feature vector, and M is the total number of trees in the forest. This aggregation process reduces prediction variance and enhances forecast stability.

Furthermore, Farhadi et al. (2022) explain that each decision tree in the RF model is constructed by minimizing the residual sum of squares (RSS) at each node-splitting process [25], which is generally formulated as follows:

$$RSS(j,s) = \sum_{x_i \in R_1(j,s)} (y_i - \bar{y}r_1)^2 + \sum_{x_i \in R_2(j,s)} (y_i - \bar{y}r_2)^2 \quad (2)$$

where, $R_1(j,s)$ and $R_2(j,s)$ denote the two regions resulting from a split based on variable j and split point s, respectively. In the context of inflation forecasting, this mechanism enables the RF model to select optimal splits based on the most informative macroeconomic variables.

Extreme Gradient Boosting (XGBoost) is an optimized gradient boosting framework developed by Chen and Guestrin [26]. XGBoost sequentially improves prediction accuracy by iteratively minimizing the residual errors produced by previous models. This method allows the model to capture complex nonlinear relationships and high-order interactions, making it suitable for high-dimensional data and providing advantages over linear parametric methods [27].

Conceptually, XGBoost starts with a simple initial model (weak learner) and iteratively improves it by fitting subsequent models to the residuals of the previous prediction. The initial model can be formulated as:

$$y_i = F_1(X_i) + \varepsilon_i \quad (3)$$

where, $F_i(X_i)$ is the initial model and ε_i represents the residual. Since the initial model does not fully capture data variation, subsequent models are trained on these residuals, and the model is updated additively as:

$$F_M(X_i) = F_{M-1}(X_i) + h_{M-1}(X_i) \quad (4)$$

until iteration M [27].

Since the pseudo-residual is calculated using the negative gradient method from the change in the loss function relative to the current forecast, it can be seen as a measure of how much improvement remains relative to the current state. This pseudo-residual becomes the target for the training of weak learners, so each iteration focuses on the remaining improvement steps. The model is updated as :

$$F_m(X) = F_{m-1}(X) + \gamma_m h_m(X) \quad (5)$$

where, γ_m is the learning rate, which regulates the contribution of each weak learner and enhances model stability [27].

An ANN is a type of machine learning model that was inspired by biological neural systems and is the basis for deep learning architectures [28]. In an ANN, artificial neurons are connected and organized into layered forms that include input, hidden, and output layers. Input data X is passed through a series of weighted and biased linear combinations. Then, it is passed through an activation function, represented as $\sigma(WX + b)$, that introduces nonlinearity. Common activation functions include ReLU, Sigmoid, tanh, and Softmax, which enable ANNs to model complex and nonlinear relationships that arise in the data. The activation functions are formulated as follows:

$$\text{ReLU} \quad \sigma(z) = \max(0, z) \quad (6)$$

$$\text{Sigmoid} \quad \sigma(z) = \frac{1}{1+e^{-z}} \quad (7)$$

$$\text{Tanh} \quad \sigma(z) = \frac{e^{z} - e^{-z}}{e^{z} + e^{-z}} \quad (8)$$

$$\text{Softmax} \quad \sigma(z) = \frac{e^{z_i}}{\sum_{j=1}^{z} e^{z_j}} \quad (9)$$

The output layer represents the final numerical result obtained after the input data have been processed by the network and activation functions. It is the final result or prediction output by the neural network.

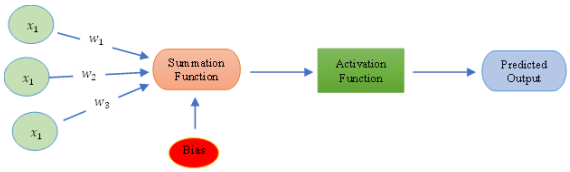

Fig. 1. Artificial neural network architecture

Fig. 1 illustrates the ANN architecture, where inputs $(x1, x2, \dots, x_n)$ are linearly combined with weights $(w1, w2, \dots, w_n)$ and a bias, then passed through an activation function to produce the model's prediction.

The ANN model is trained using forward propagation and backpropagation. Forward propagation sends input data through the network to generate output predictions. The predicted outputs are then compared with actual values using a loss function. In terms of regression cases, such as inflation forecasting, the mean squared error (MSE) is commonly employed as the loss function [28], defined as:

$$MSE = \frac{1}{2N}\sum_{i=1}^{N}\left(\hat{Y}_i - Y_i\right)^2 \quad (10)$$

where, Y_i and $\hat{Y}_i$ denote the actual and predicted values, respectively.

Backpropagation then minimizes the loss function using gradient descent for updating model parameters. Weights and biases are iteratively adjusted as:

$$W^{(l)} \leftarrow W^{(l)} - \eta \frac{\partial L}{\partial W^{(l)}} \quad (11)$$

where, η is the learning rate controlling the convergence speed. This process is repeated until the network reaches an optimal solution with minimal prediction error.

SHAP (Shapley Additive Explanations) is an Explainable Artificial Intelligence (XAI) method introduced by Scott M. Lundberg and Su-In Lee to improve the interpretability of machine learning models by explaining the contribution of each predictor variable to a prediction. SHAP is based on Shapley values from cooperative game theory and provides a unified framework for additive feature attribution methods [29]. The SHAP explanation model is formulated as:

$$g(z') = \phi_0 + \sum_{i=1}^{M}\phi_i z_i' \quad (12)$$

where, ϕ_i represents the contribution of feature i to the prediction. SHAP explains both the magnitude and direction of variable influence on model predictions.

C. CRISP-DM Methodology

This study employs the Cross-Industry Standard Process for Data Mining (CRISP-DM) as the methodological framework to develop an inflation forecasting model. The selection of CRISP-DM is motivated by its systematic, standardized, and iterative structure, which has been extensively adopted in data mining and machine learning studies [30]. The framework comprises six interrelated phases that guide the end-to-end analytical process.

The Business Understanding phase establishes the study objectives and problem formulation, focusing on the development of an accurate and policy-relevant inflation forecasting model in the context of monetary analysis. The Data Understanding phase involves the collection of macroeconomic and seasonal data, followed by exploratory analysis and data quality assessment. The Data Preparation phase encompasses data cleaning, transformation, frequency harmonization, integration, and feature engineering, which are important for enhancing model performance. The Modeling phase applies selected machine learning algorithms, including Random Forest, XGBoost, and ANN, within an iterative process that may require refinement of preceding stages. The Evaluation phase assesses model performance using quantitative metrics such as RMSE, MAE, and R^2, while also ensuring alignment with the study objectives. Within an academic setting, the Deployment phase is realized through the presentation of forecasting results, model interpretability using explainable AI techniques, and the articulation of their implications for inflation analysis and policy support.

D. Related Works

Machine learning approaches have increasingly been applied to inflation forecasting because of their ability to capture nonlinear relationships and complex interactions among macroeconomic variables [7], [23]. Compared with traditional econometric models such as ARIMA and VAR, machine learning methods often demonstrate stronger predictive performance, particularly in volatile economic environments [31], [32], [33]. Algorithms such as Random Forest, XGBoost, and Artificial Neural Network (ANN) have been widely used in inflation forecasting studies across both developed and developing economies.

Several studies report that machine learning models outperform conventional forecasting approaches. Araujo and Gaglianone [33] show that machine learning methods improve inflation forecasting performance in Brazil, while Jouilil and Iaousse [34] demonstrate that machine learning approaches outperform classical time-series models in forecasting inflation in the United States. Similar improvements are also reported in studies conducted in Egypt and India [31], [32]. In developing economies, machine learning methods often achieve stronger forecasting gains because inflation dynamics are more strongly influenced by structural macroeconomic factors and volatility [31], [35].

Previous studies further indicate that forecasting performance depends not only on algorithm selection but also on feature engineering and model optimization. Li et al. [8] demonstrate that XGBoost combined with optimization techniques improves inflation forecasting accuracy, while Seo et al. [36] show that multivariate features and data augmentation significantly enhance forecasting performance. Ensemble-based methods such as Random Forest and XGBoost are also generally found to provide more stable performance than deep learning approaches for structured macroeconomic datasets with moderate sample sizes [34], [37].

Despite these advances, several limitations remain in the literature. Many previous studies focus mainly on predictive accuracy while providing limited explanation regarding the economic factors driving model predictions, resulting in machine learning models being criticized as black-box systems [9]. In addition, prior studies often rely on limited macroeconomic indicators and rarely integrate monetary, external-sector, labor, and seasonal variables simultaneously within a unified forecasting framework. However, inflation dynamics in Indonesia are influenced by complex interactions among money supply, exchange rates, wages, and external-sector conditions [3], [4], [11].

The application of Explainable Artificial Intelligence (XAI) to inflation forecasting remains relatively limited. SHAP-based approaches have recently gained attention because they improve transparency by explaining the contribution of predictor variables to machine learning predictions [9], [10]. Nevertheless, only a limited number of studies integrate SHAP analysis directly into a systematic inflation forecasting framework.

Accordingly, this study proposes an interpretable machine learning framework for inflation forecasting in Indonesia by integrating domestic macroeconomic and seasonal variables. Unlike many previous studies that mainly focus on predictive accuracy, this study combines multi-scenario experimentation, hyperparameter optimization, Diebold–Mariano statistical testing, and SHAP-based explainability within a unified forecasting framework. Therefore, the contribution of this study lies in integrating predictive performance, interpretability, and policy-relevant inflation analysis in Indonesia and emerging economies with similar economic structures.

III. METHODOLOGY

This study adopts the CRISP-DM methodology, which comprises six structured phases: business understanding, data understanding, data preparation, modeling, evaluation, and deployment. Each phase is systematically described in the following sections. The implementation of each stage, particularly in data processing and modeling, is carried out using the Python programming language and supporting machine learning libraries.

A. Business Understanding

The Business Understanding phase is aligned with Bank Indonesia's Flexible Inflation Targeting Framework (FITF), an approach that maintains price stability as the primary objective of monetary policy. Due to its forward-looking nature, timely and accurate inflation predictions are critical to the soundness of policy choices. This study proposes a machine learning–based framework for inflation forecasting that aims to improve predictive accuracy while maintaining model interpretability.

B. Data Understanding

With the objectives set out in the Business Understanding phase, the Data Understanding phase seeks to identify relevant domestic macroeconomic and seasonal variables that impact inflation dynamics. In this phase, inflation-related time-series data are collected systematically and initially examined for their characteristics and suitability for modeling. Moreover, quality, accuracy, consistency, and temporal alignment are also tested for machine learning–based forecasting.

These variables are obtained officially from Bank Indonesia (BI), Badan Pusat Statistik (BPS), and official holiday calendars. The raw data initially provided in Microsoft Excel format has been converted to CSV format for faster processing.

TABLE I. DATA SOURCES AND INFORMATION

Indicators	Reference Source	Frequency	Publisher	Scale	Information	Fields
Inflation	TABLE8_1 in the SEKI Report sector real.	Monthly	BI	Percentage	Monthly observations	Publish date, inflation_yoy, Inflation_mtm
Money Supply	TABLE1_1 SEKI in the Report sector monetary	Monthly	BI	Trillion Rupiah	Monthly observations	Publish date, M2
Exchange Rate	*Jakarta Interbank Spot Dollar Rate* (JISDOR).	Daily	BI	Rupiah per US Dollar	The monthly value is calculated as the average of daily observations.	Publish date, JISDOR
Interest Rate	*Jakarta Interbank Offered Rate* (JIBOR).	Daily	BI	Percentage	The monthly value is calculated as the average of daily observations.	Publish date, JIBOR
Wages	Rata-rata upah tenaga kerja dalam satu bulan.	Semi-annual	BPS	Rupiah	Semi-annual observations	Publish date, wage
Foreign Reserve Asset	TABLE5_9 in the SEKI Report sector external.	Monthly	BI	Billion US Dollar	Monthly observations	Publish date, Foreign reserve
Balance of Payments	TABLE5_1 in the SEKI Report sector external.	Quarterly	BI	Billion US Dollar	Quarterly variables are transformed into monthly frequency.	Publish date, Balance of payments, export, import
Gross Domestic Product	TABEL7_1, TABEL7_2, and TABLE7_6 in the SEKI Report sector real.	Quarterly	BI	Trillion Rupiah	Quarterly variables are transformed into monthly frequency.	Publish date, GDP deflator, GDP Nominal
Seasonal event	Holiday calendars indicating cultural events.	Event-based	Holiday Calendar	"1" or "0"		Publish date, event tagging

Table I presents the data sources and characteristics of the macroeconomic and seasonal variables used in this study, including data frequency, measurement scale, and relevant information for machine learning–based inflation forecasting.

The dataset consists of heterogeneous temporal frequencies, including daily (exchange rate and interest rate), monthly (inflation, money supply, and foreign reserves), quarterly (balance of payments and GDP), and semi-annual (wages) observations. To ensure temporal consistency for machine learning modeling, daily variables are aggregated into monthly averages, while quarterly variables are proportionally transformed into monthly frequency through time-series resampling techniques.

In addition, each variable is supported by structured fields such as publication date and relevant economic measures for easier tracking and integration. A temporal key is maintained with a variable "month", which is generated from the publish date to ensure that all indicators can be aggregated as one

analytical dataset. Seasonal effects are represented using dummy variables (1 and 0) for calendar-related events that may affect inflation patterns. A high-level overview of this well-structured dataset serves as a brief foundation for data preparation and modeling.

C. Data Preparation

This phase involves preparing the dataset through data cleaning, frequency harmonization, feature engineering, data integration, and variable transformation for machine learning analysis. These processes are necessary to ensure temporal consistency, improve data quality, and enhance model performance.

Several anomalous observations, particularly zero values in the interest rate series, are identified as outliers and removed prior to analysis. Since the dataset consists of heterogeneous temporal frequencies, including daily, monthly, quarterly, and semi-annual observations, frequency harmonization is performed using time-series resampling techniques. All variables are transformed into a monthly frequency to maintain temporal alignment across predictors and support consistent forecasting analysis.

TABLE II. FREQUENCY HARMONIZATION TECHNIQUES

Variable	Conversion	Resampling Technique
Exchange Rate	Daily to Monthly	Monthly average
Interest Rate	Daily to Monthly	Monthly average
Wages	Semi-annual to Monthly	Interpolation
Balance of Payments	Quarterly to Monthly	Proportionally distributed across three months
GDP	Quarterly to Monthly	Proportionally distributed across three months

Table II presents the frequency harmonization process using time-series resampling techniques to convert variables into a consistent monthly frequency.

The wage variable requires particular attention because it is originally available at a semi-annual frequency and subsequently transformed into monthly observations using interpolation. This approach preserves temporal consistency with other macroeconomic indicators and maintains dataset completeness for machine learning modeling. However, the interpolation process may introduce smoother transitions than actual short-term wage fluctuations, potentially reducing volatility within the series and affecting the sensitivity of the models to labor-related inflation dynamics.

After harmonization, all macroeconomic and seasonal variables are integrated into a unified dataset using the month variable as the temporal key. Feature engineering is then performed to generate several derived variables relevant to inflation dynamics, including Broad Money (BM), Velocity of Money (VM), Exchange Rate Pass-Through (ERPT), and Import Cover Ratio (ICR). At this stage, all derived variables are standardized to maintain scale consistency.

1) Broad Money (BM): Measures the level of liquidity in the economy by comparing money supply to annual nominal GDP. An excessively high liquidity ratio reflects money supply expansion beyond real activity and may generate inflationary pressure when not supported by productive capacity growth [38]. BM is calculated as [38]:

$$BM = \frac{Money\ supply\ (M2)}{Annual\ Nominal\ GDP}\ x\ 100 \quad (13)$$

2) Velocity of Money (VM): It is a measure of how quickly money is circulating within an economy over a period of time, and it is derived from Fisher's quantity theory of money. When the velocity of money increases, inflation tends to increase, and decreases may even dampen inflation when the money supply expands [3]. Thus, inflation analysis must consider not only money supply but also the velocity of money circulation [3].

$$VM = \frac{Annual\ Nominal\ GDP}{Money\ supply\ (M2)} \quad (14)$$

3) Exchange Rate Pass Through (ERPT): A metric of the extent to which the exchange rate changes are passed through to the domestic prices. A value of one indicates full transmission, and a value of less than one means incomplete passing through. ERPT consists of the ratio between changes in domestic prices and changes in the exchange rate expressed as elasticity.

$$ERPT = \frac{\%\ \triangle P(Domestic\ price\ changes)}{\%\ \triangle ER\ (Changes\ in\ exchange\ rates)} \quad (15)$$

4) Import Cover Ratio (ICR): Measures the ability of foreign exchange reserves to finance a country's imports without additional inflows. A high ICR supports exchange rate stability and helps contain inflation by limiting increases in import prices, whereas a low ICR constrains reserve adequacy, increases depreciation risk, raises import costs, and amplifies inflationary pressures [39].

$$ICR = \frac{Foreign\ Reserve\ Asset}{Monthly\ import\ value} \quad (16)$$

In addition, temporal variables such as month, quarter, and year are constructed to capture potential time-series patterns and seasonal effects not fully represented by macroeconomic indicators alone.

The dataset is subsequently cleaned to ensure consistency and modeling compatibility. Missing values are handled selectively depending on the characteristics of each variable, while irrelevant attributes used during preprocessing are removed to improve modeling efficiency. Prior to modeling, the dataset is organized chronologically to preserve temporal order and avoid potential data leakage in the forecasting process.

D. Modeling

The modeling phase aims to develop an interpretable machine learning framework for inflation forecasting by implementing Random Forest, XGBoost, and Artificial Neural Network (ANN) algorithms. These algorithms are selected because of their capability to capture nonlinear relationships and complex interactions among macroeconomic variables that influence inflation dynamics.

To systematically evaluate forecasting performance, the models are assessed under three experimental scenarios: 1)

baseline modeling using macroeconomic and seasonal variables, 2) an extended model incorporating time-series features through the inclusion of quarter variables, and 3) an enhanced model combining time-series features with hyperparameter optimization to improve predictive performance. This multi-scenario framework evaluates the contribution of feature augmentation and model optimization within a unified experimental setting.

The baseline scenario employs domestic macroeconomic indicators, including exchange rate (JISDOR), interest rate (JIBOR), money supply (M2), foreign reserves, balance of payments, GDP deflator, wages, Broad Money, Velocity of Money, ERPT, and Import Cover Ratio. Seasonal variables such as Ramadan, Eid al-Fitr, Christmas and New Year, and back-to-school periods are also included as predictors. The target variable is annual inflation (Inflation_yoy).

To preserve temporal consistency and avoid data leakage in time-series forecasting, the dataset is divided chronologically, where the earlier 80% of observations are used for training and the remaining 20% are reserved for out-of-sample testing. This chronological split ensures that future observations are not used during model training.

The second scenario extends the baseline configuration by incorporating the quarter variable as an additional predictor to capture potential temporal and seasonal patterns not fully represented by macroeconomic variables. The third scenario further extends the second model by implementing hyperparameter optimization using GridSearchCV to improve predictive accuracy and model stability.

Fig. 2 presents the implementation code of the baseline Random Forest model using the RandomForestRegressor function with default parameter settings.

```

```

Fig. 5. Parameter optimization of XGBoost model.

The ANN model is implemented using the MLPRegressor function. Prior to training, feature normalization is performed using the Min–Max Scaling to transform all variables into the range [0,1]. This step is important for improving convergence stability and preventing variables with larger scales from dominating the learning process. Fig. 6 presents the implementation code of the ANN model in the baseline scenario.

```
# Selecting all column as predictors
X=df[['JISDOR', 'JIBOR', 'M2', 'Foreign Reserve', 'Balance of Payment',
      'GDP Deflator', 'Wage', 'Back To School', 'Christmas and New Year', 'Ramadhan',
      'Idul Fitri', 'Broad Money', 'ERPT', 'Velocity of Money', 'Impor Cover Ratio']]
# Specify 'Inflation_yoy' column as 'y'
y=df['Inflation_yoy']
# #Splitting the dataset into training and test
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.2, random_state=42)
# Normalize dataset
scaler = MinMaxScaler()
# Fit and transfrom
X_train = scaler.fit_transform(X_train)
X_test = scaler.transform(X_test)
# Train model with default parameter
model = MLPRegressor(random_state=42)
model.fit(X_train, y_train)
# Making predictions on the test dataset
predictions = model.predict(X_test)
```

Fig. 6. ANN model in the baseline scenario.

Fig. 7 presents the ANN hyperparameter optimization using GridSearchCV with 3-fold cross-validation. Several parameters, including hidden_layer_sizes, activation, solver, and max_iter, are systematically tuned to identify the optimal forecasting configuration. The best parameters obtained are hidden_layer_sizes = (256, 128, 64), activation = tanh, solver = adam, and max_iter = 1000, indicating that deeper network architectures and sufficient training iterations improve the predictive performance of the ANN model.

```
from sklearn.model_selection import GridSearchCV

# Define the parameter grid to search
param_grid = {
    'hidden_layer_sizes': [(100,), (50, 50), (256, 128, 64)],
    'activation': ['relu', 'tanh'],
    'solver': ['adam'],
    'max_iter': [500, 1000, 1500]
}
# Initialize MLPRegressor
mlp = MLPRegressor(random_state=42)
# Initialize GridSearchCV
grid_search = GridSearchCV(mlp, param_grid, cv=3,
                           scoring='neg_mean_squared_error', verbose=2, n_jobs=-1)
# Fit GridSearchCV to the training data
grid_search.fit(X_train, y_train)
# Print the best parameters and best score
print("Best parameters found: ", grid_search.best_params_)

# Fitting 3 folds for each of 18 candidates, totalling 54 fits
# Best parameters found:  {'activation': 'tanh', 'hidden_layer_sizes': (256, 128, 64),

E. Evaluation

The evaluation phase assesses the performance and reliability of the developed machine learning forecasting models. Model performance is evaluated on out-of-sample testing data using standard forecasting accuracy metrics, including RMSE, MAE, and R^2.

Root Mean Squared Error (RMSE) is a widely used metric for evaluating predictive accuracy in statistical and machine learning models. It is defined as the square root of the average squared difference between actual and predicted values. A lower RMSE indicates better model performance, as larger errors are penalized more heavily.

Mean Absolute Error (MAE) measures the average magnitude of errors between actual and predicted values. A lower MAE indicates better predictive performance. Since it is expressed in the same unit as the target variable, MAE is easy to interpret and suitable for model comparison.

Coefficient of determination (R^2) is a statistical metric used to evaluate regression model performance by measuring the proportion of variance in the dependent variable explained by the independent variables. The value of R^2 ranges from 0 to 1, where values closer to 1 indicate better explanatory power and model performance.

To further validate forecasting performance differences, statistical significance testing is conducted using the Diebold–Mariano (DM) test. The test evaluates whether forecast error differences between Random Forest, XGBoost, and ANN models are statistically significant.

In addition, XAI techniques are employed through SHAP (Shapley Additive Explanations) value analysis to quantify the contribution of each predictor variable, thereby ensuring that the forecasting framework is not only predictive but also economically interpretable.

F. Deployment

The Deployment phase represents the final stage in which the selected model is prepared for practical use. In this study, deployment is conducted within an analytical and decision-support context by utilizing the best-performing model for inflation forecasting and forward-looking monetary analysis. The deployment process includes presenting forecasting and interpretability outputs to support transparent inflation analysis. SHAP analysis is applied to explain the contribution of each predictor variable to forecasting outcomes. In addition, the proposed framework supports periodic updates using new data, enabling the model to remain adaptive to evolving macroeconomic conditions and inflation dynamics.

IV. Results and Discussion

This section presents the performance evaluation results of the machine learning models across the three experimental scenarios, followed by interpretability analysis using SHAP and feature importance. SHAP analysis is applied to improve interpretability, while feature importance is used to support and validate the SHAP findings. The analysis evaluates forecasting performance, examines the effect of temporal feature augmentation and hyperparameter optimization, and identifies the macroeconomic variables that most strongly influence inflation predictions.

The regression performance of each model is evaluated using RMSE, MAE, and R^2 metrics to measure prediction accuracy, forecasting error, and explanatory power. Lower RMSE and MAE values indicate better forecasting performance, while higher R^2 values indicate stronger explanatory capability. In addition, Diebold–Mariano (DM) statistical testing is conducted to examine whether forecasting performance differences between models are statistically significant.

TABLE III. PERFORMANCE EVALUATION SUMMARY

Model	Scenario	RMSE	MAE	R^2
Random Forest	Baseline (macroeconomic indicators and seasonal variables)	0.5145	0.3619	0.9486
	Baseline Configuration with Time-Series Features	0.5287	0.3758	0.9457
	Baseline Configuration with Time-Series Features and Hyperparameter Tuning	0.5005	0.3469	0.9513
XGBoost	Baseline (macroeconomic indicators and seasonal variables)	0.6541	0.3664	0.9169
	Baseline Configuration with Time-Series Features	0.6245	0.3603	0.9242
	Baseline Configuration with Time-Series Features and Hyperparameter Tuning	**0.4987**	**0.3339**	**0.9517**
Artificial Neural Network	Baseline (macroeconomic indicators and seasonal variables)	1.7523	1.3153	0.4035
	Baseline Configuration with Time-Series Features	1.6543	1.2727	0.4683
	Baseline Configuration with Time-Series Features and Hyperparameter Tuning	1.0065	0.6503	0.8031

Table III presents the comparative performance of Random Forest, XGBoost, and ANN models across all scenarios using RMSE, MAE, and R^2 metrics.

The results consistently indicate that ensemble-based models outperform ANN across all experimental scenarios. In the baseline configuration, Random Forest achieves the strongest predictive performance, effectively capturing nonlinear relationships among macroeconomic and seasonal variables. XGBoost also performs relatively well, while ANN shows substantially weaker forecasting performance.

The weaker ANN performance in the baseline scenario may be associated with the sensitivity of neural networks to architecture configuration, parameter initialization, training iterations, and dataset size. Compared with ensemble-based models, ANN generally requires more extensive optimization to effectively learn nonlinear macroeconomic relationships. In contrast, tree-based ensemble methods are typically more robust for structured tabular economic data.

The inclusion of temporal variables in the second scenario produces mixed results. Random Forest shows a slight decline in performance, while XGBoost demonstrates moderate improvement after incorporating the quarter variable. ANN also shows limited improvement but remains below ensemble-based methods. These findings indicate that temporal feature augmentation is model-dependent rather than universally beneficial.

The best overall performance is achieved in the third scenario after hyperparameter optimization. XGBoost becomes the best-performing model with RMSE = 0.4987, MAE = 0.3339, and R^2 = 0.9517, closely followed by Random Forest with RMSE = 0.5005 and R^2 = 0.9513. ANN also improves substantially after optimization, confirming that neural network performance is highly dependent on architecture selection and parameter tuning. Overall, the findings indicate that hyperparameter optimization contributes more significantly to forecasting improvement than temporal feature augmentation.

To further validate forecasting performance differences between models, Diebold–Mariano (DM) testing is conducted using prediction errors from the testing dataset. The results indicate that the forecasting performance difference between XGBoost and Random Forest is not statistically significant (p-value > 0.05), suggesting that both ensemble-based models achieve relatively comparable predictive performance. However, both XGBoost and Random Forest significantly outperform ANN (p-value < 0.05), confirming the superior forecasting capability of ensemble-based methods for structured macroeconomic inflation data.

TABLE IV. DIEBOLD–MARIANO (DM) STATISTICAL TESTING

Comparison	DM Statistic	p-value	Result
XGBoost vs. RF	-1.7644	0.0851	Not Significant
XGBoost vs. ANN	-2.7265	0.0094	Significant
RF vs. ANN	-2.6407	0.0117	Significant

Table IV presents the results of the Diebold–Mariano (DM) statistical testing used to evaluate the statistical significance of forecasting performance differences between XGBoost, Random Forest, and ANN models.

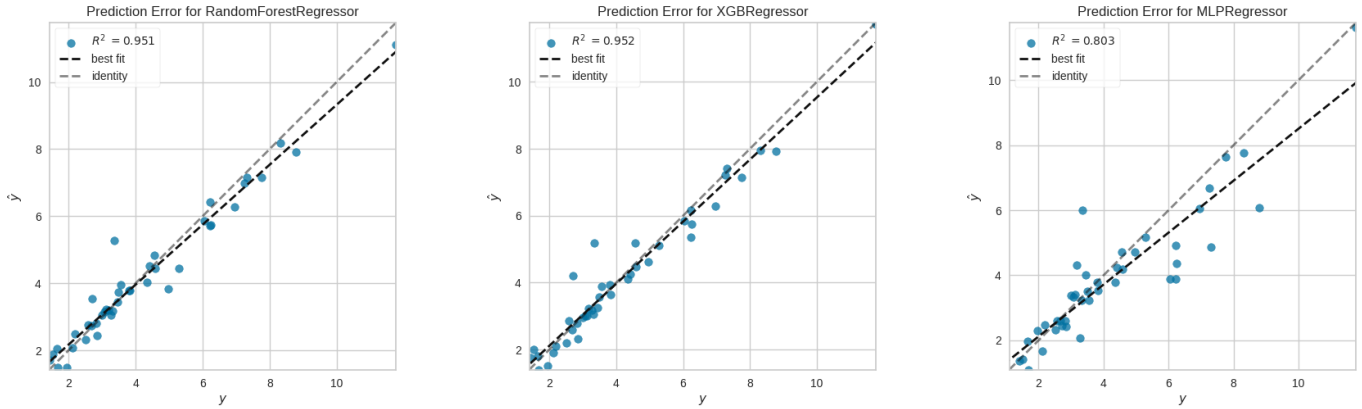

Fig. 8. Comparison of prediction error plots for Random Forest, XGBoost, and MLP (ANN) models in the third scenario.

Fig. 8 presents the prediction error plots for the three models in the third scenario. Random Forest and XGBoost show strong alignment between actual and predicted values, with most observations distributed near the identity line, indicating high predictive precision and limited systematic error. In contrast, ANN exhibits wider dispersion around the identity line, reflecting weaker predictive stability and larger forecasting errors.

To improve interpretability, SHAP analysis is applied only to the best-performing XGBoost model in the third scenario to provide transparent and policy-relevant insights into the contribution of macroeconomic variables to inflation forecasting. The analysis explains both the contribution and directional impact of each predictor variable on inflation forecasts, thereby helping to identify the key economic factors driving inflation.

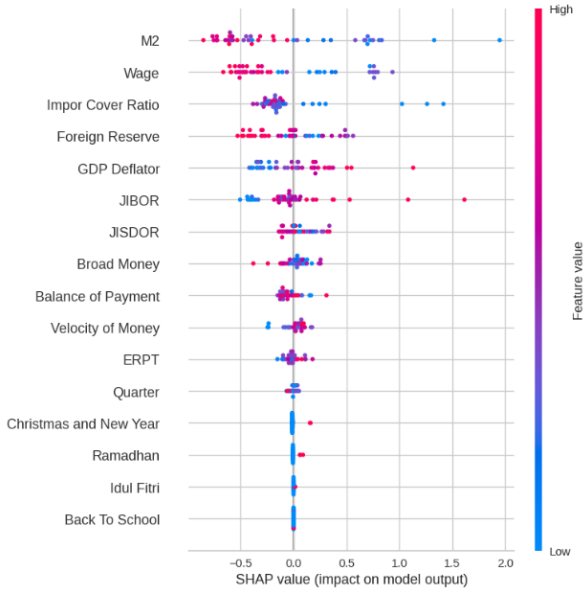

Fig. 9. SHAP summary for XGBoost model (third scenario).

Fig. 9 presents SHAP analysis for the XGBoost model (third scenario), showing that M2, Wage, and Import Cover Ratio are the main drivers, while other variables have moderate to low impact.

The dominance of M2 indicates the importance of monetary liquidity in influencing inflation dynamics, while Wage reflects labor-cost and purchasing-power effects. In addition, the relatively strong contribution of the Import Cover Ratio suggests that external-sector resilience and reserve adequacy also influence inflation stability through exchange-rate and import-price channels. Seasonal and temporal variables contribute relatively less, indicating that structural macroeconomic conditions play a more important role than calendar-based effects.

To support the SHAP results, feature importance analysis is subsequently performed for the best-performing XGBoost model. This additional analysis is intended to validate the consistency of the SHAP findings by identifying the variables that contribute most significantly to the forecasting process from the model perspective. The comparison between SHAP and feature importance provides complementary interpretability insights and strengthens the reliability of the identified macroeconomic determinants of inflation.

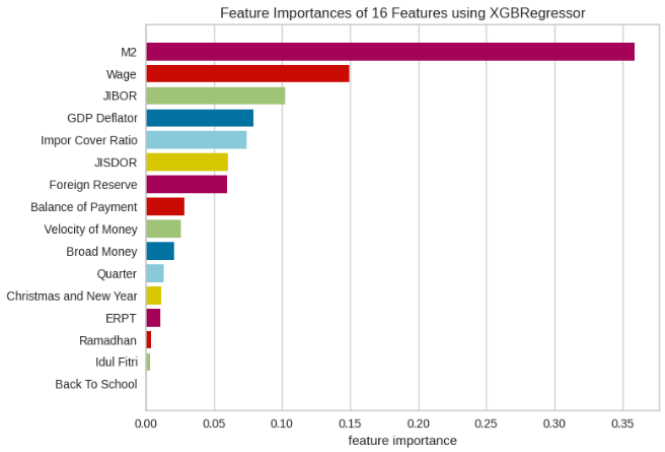

Fig. 10. Feature importance of XGBoost model (third scenario).

Fig. 10 presents the feature importance analysis for the best-performing XGBoost model in the third scenario. The results show that M2 is the most influential variable, indicating that monetary liquidity plays a dominant role in inflation forecasting. Wage emerges as the second most important variable, suggesting that labor-cost and purchasing-power effects also contribute significantly to inflation dynamics. Other variables, including JIBOR, GDP Deflator, and Import Cover Ratio, exhibit moderate importance, reflecting the influence of interest rate transmission, general price-level conditions, and external-sector resilience on inflation behavior.

Compared with the SHAP analysis of the best-performing XGBoost model, the feature importance results show a consistent pattern. Both analysis identify M2 and Wage as the dominant contributors to inflation forecasting, confirming the strong influence of monetary liquidity and labor-related factors on inflation dynamics in Indonesia. In addition, Import Cover Ratio also appears as an influential variable, highlighting the role of external-sector stability and reserve adequacy in influencing inflation through exchange-rate and import-price channels.

However, SHAP provides deeper interpretability than feature importance because it explains not only the magnitude but also the direction of each variable's contribution to inflation predictions. While feature importance identifies globally influential variables, SHAP further explains how variables such as M2 and Wage positively or negatively affect predictions across observations. The consistency between both analyses strengthens the reliability of the interpretability findings and confirms that inflation dynamics in Indonesia are primarily driven by structural macroeconomic conditions rather than seasonal effects.

V. Conclusion

This study proposes an interpretable machine learning framework for inflation forecasting in Indonesia using domestic macroeconomic and seasonal variables. The framework systematically evaluates Random Forest, XGBoost, and ANN

models under three experimental scenarios: baseline modeling, temporal feature augmentation, and hyperparameter optimization.

The results consistently show that ensemble-based methods outperform ANN across all scenarios, with XGBoost achieving the best overall performance after hyperparameter optimization (RMSE = 0.4987, MAE = 0.3339, R^2 = 0.9517), closely followed by Random Forest (RMSE = 0.5005, R^2 = 0.9513). Diebold–Mariano (DM) testing further indicates that the forecasting performance difference between XGBoost and Random Forest is not statistically significant, whereas both ensemble-based models significantly outperform ANN. These findings confirm the effectiveness of ensemble-based machine learning models for inflation forecasting.

To improve interpretability, SHAP analysis is applied to the best-performing XGBoost model. The results identify M2, Wage, and Import Cover Ratio as the dominant contributors to inflation forecasting, indicating that monetary liquidity, labor-related factors, and external-sector resilience play important roles in explaining inflation dynamics in Indonesia.

Overall, this study contributes through a systematic forecasting framework that integrates predictive accuracy, temporal feature evaluation, hyperparameter optimization, statistical validation, and explainable artificial intelligence within a unified experimental setting. From a practical perspective, the proposed framework may support more transparent and forward-looking monetary policy analysis in Indonesia and other emerging economies with similar economic structures.

Nevertheless, this study has several limitations. It focuses primarily on domestic macroeconomic indicators and does not yet incorporate broader external variables. In addition, the harmonization of lower-frequency variables into monthly frequency may simplify some short-term dynamics. Future studies may incorporate developed-country interest rates and global commodity prices to better capture external monetary influences and global shocks affecting inflation dynamics.

***Abstract*—This study proposes a multi-level system for detecting contactless drug distribution transactions. This system integrates behavioural pattern recognition as the primary detection channel, detection of night-time activity spikes as an enhancing module, and facial matching as an additional probabilistic evaluation layer. The system identifies a two-phase structure of covert transactions. Both the courier's placement of the product and the buyer's retrieval produce recognizable behavioural sequences at the same geographic location. Signal-to-noise ratio analysis identified a detection threshold at an SNR of approximately 17. It provides a quantitative foundation for camera placement planning. The behavioural pattern recognition pipeline integrates YOLO-Pose for skeleton estimation and employs classical machine learning models, including Random Forest and Gradient Boosting, for temporal action classification. The ST-GCN architecture is considered a future extension pending the availability of a larger annotated dataset.**

***Keywords*—Anomaly detection; flash detection; pose estimation; SNR; crime mapping**

I. Introduction

Contactless drug trafficking has become one of the fastest-growing modalities of retail drug distribution. According to the latest United Nations estimates, the global population of people who use drugs reached 292 million in 2022, and the ongoing digitalisation of drug markets has created new logistical patterns that challenge traditional law-enforcement tools [1]. Systematic reviews of dark-web cryptomarkets covering the period 2012–2023 show a consistent migration of retail drug distribution towards online ordering and anonymous offline delivery, supported by cryptocurrency-based payment and encrypted communications [2]. Cryptomarket participants explicitly design their workflow to minimise visible offline exposure. The qualitative analyses of vendor and buyer practices demonstrate that offline drop-offs and retrieval episodes remain the key points of contact at which law-enforcement detection is most feasible [3]. In the post-Soviet space, this distribution paradigm has been documented in qualitative harm-reduction studies that describe contactless handover (called "dead-drop") as the dominant channel for the supply of new psychoactive substances [4].

The operational cycle of contactless distribution involves two observable offline episodes. In the first, the courier leaves the package in a concealed location and photographs it to record the coordinates; in the second, the buyer visits the same location to pick up the goods. Both episodes result in a recognisable sequence of actions — approaching, stopping, crouching, manipulating objects at ground level, and leaving — repeated across individuals and locations. This behavioural repeatability is consistent with long-established findings in environmental criminology. It shows that a small number of "micro-places" concentrate a disproportionate share of criminal events and that routine offender behaviour clusters spatially in predictable patterns [5], [6], [7]. Recent systematic reviews of crime concentration confirm that the law of crime concentration at a place also extends to drug-related offences and can therefore be used to guide both detection and preventive patrol [8], [9].

This repetitive behavioural pattern represents the primary detection signal and is observable in CCTV footage regardless of the time of day. However, at night, the courier's use of a mobile phone camera flash to photograph the location of the stash introduces an additional photometric signal. Flashes create a short, spatially compact burst of brightness that can be distinguished from diffuse light sources such as car headlights. The temporal profile of LED-based flash emission has been experimentally characterised at high frame rates in fluid-dynamics imaging research [10].

Existing CCTV analytics systems focus on general anomaly detection [11], biometric identification [12], or crime prediction. A combination of behavioural, photometric, and geographic features specific to covert operations can improve analytical results. Advances in pose estimation and temporal action recognition [13], [14] enable the analysis of behavioural sequences from standard video streams, which paves the way for the development of a detection system adapted to this type of crime. Although numerous studies address general anomaly detection in surveillance videos, very few works analyse behavioural patterns associated with covert logistics operations such as contactless drug distribution. In addition, existing approaches rarely combine behavioural analysis with photometric signals such as smartphone flash events and geospatial recurrence of incidents.

This study proposes a three-layer framework. The framework includes behavioural pattern recognition as a core method operating in all lighting conditions, night flash detection

*Corresponding author

as a booster module, and face matching as a probabilistic evaluation feature. This study investigates two key components of the proposed framework: behavioural pattern recognition and flash detection. Behavioural analysis serves as the primary detection channel, while flash detection acts as an auxiliary photometric signal that increases confidence in low-light conditions.

This study makes four main contributions:

- A multimodal framework combining behavioural pattern recognition, photometric flash detection, and geospatial correlation for identifying contactless drug transactions.
- A statistically grounded flash detection model based on adaptive SNR thresholding and spatial blob validation.
- A semi-synthetic dataset generation approach for evaluating rare flash events under realistic surveillance noise conditions.
- An interpretable multimodal fusion model integrating behavioural and photometric signals for anomaly scoring.

II. Related Work

A. Contactless Drug Distribution and Place-Based Criminology

The criminological literature on micro-place concentration of crime provides a strong theoretical foundation for the problem addressed in this study. Sherman, Gartin, and Buerger showed that a small proportion of street addresses account for a disproportionately large share of calls for service [15]. A finding later formalised by Weisburd as the "law of crime concentration at place" and repeatedly replicated across cities and crime types [16], [9]. Braga, Papachristos, and Hureau extended this reasoning to serious violence, demonstrating the temporal stability of gun-violence hotspots over nearly three decades in Boston [6]. Kernel-density estimation and related hotspot mapping techniques have become standard instruments for translating such patterns into operational maps [17]. In the specific context of drug markets, contemporary research on cryptomarkets describes a "stretched" transaction structure in which the riskiest phases for participants are the packaging, drop-off, and retrieval steps that occur offline [18]. Subsequent work on dark-web trade trends [19] and qualitative studies of new psychoactive substances in Eurasia [4] confirm that anonymous offline drops are the principal vulnerability of contactless distribution to conventional policing.

B. Video Anomaly Detection

Anomaly detection in videos has continuously attracted attention in the computer-vision community. Sultani, Chen, and Shah introduced the UCF-Crime dataset containing 1 900 surveillance-camera videos with 13 anomaly categories and proposed a weakly supervised multiple-instance-learning (MIL) deep-learning framework that achieved an AUC of 0.75 on the full dataset [20]. Subsequent work by Tian et al. improved this baseline through a robust approach to learning the magnitude of temporal features [15]. Manju et al. combined a Mask Region-based Convolutional Neural Network (Mask R-CNN) with Long Short-Term Memory (LSTM) networks to provide early anomaly detection, reporting an accuracy of 93.6 % [16]. Khan et al. evaluated deep learning models for anomaly detection in traffic-surveillance videos using multi-stream architectures [17], while Li et al. proposed a context-related generative-adversarial-network approach to address the challenge of diverse scene conditions [18]. Phapale and Bhingarkar recently introduced a deep context-aware feature extractor that outperforms earlier MIL baselines on standard surveillance benchmarks [19], and Ullah et al. demonstrated that hybrid convolutional–transformer architectures further improve detection accuracy on UCF-Crime [21]. Broader reviews of the field [22-24] and a review of event detection in surveillance video [25] agree that, although individual components of anomaly detection, facial recognition, and crime mapping have been extensively studied. They have not been combined into a framework specifically designed to analyse the behavioural patterns of contactless drug trafficking.

C. Pose Estimation and Skeleton-Based Action Recognition

Skeleton-based action recognition has been advanced by the introduction of spatiotemporal graph-convolutional networks (ST-GCN) by Yan, Xiong, and Lin [13], which model joint relationships over time using graph convolutions. Later work refined this line of research through adaptive graph convolution [26], multi-stream spatiotemporal fusion [27], and graph-neural ordinary-differential-equation models [28]. Contemporary surveys of deep-learning-based pose estimation [29] show that high-resolution architectures such as HRNet [30] and real-time multi-person estimators such as OpenPose [31] form the current backbone of most downstream pose-based pipelines. The YOLO family of object detectors, including the recent YOLO11-Pose variants [32], enables real-time pose estimation, which is suitable for video-surveillance applications. Recent refinements of YOLOv8-Pose have reported improved keypoint accuracy under occlusion and partial visibility typical of CCTV scenes [33], [34], and dedicated YOLOv8-based pipelines have been successfully applied to suspicious-behaviour detection in public spaces [35]. For model evaluation, the NTU RGB+D and NTU RGB+D 120 datasets remain the de facto benchmarks for three-dimensional skeleton-based action recognition [36], [37], while the VIRAT corpus provides realistic multi-view outdoor surveillance video [38].

D. Biometric Identification and Face Recognition

Biometric identification plays a complementary role in the proposed system. Early multimodal biometric systems established fundamental design principles for combining heterogeneous identity cues [12]. Modern face-recognition research is dominated by angular-margin softmax losses, of which ArcFace is the canonical representative [39]. The Dyn-arcFace variant introduces a dynamic additive angular margin that adapts to the within-class structure of the training set [40] and is directly relevant to surveillance scenarios in which face quality is highly variable.

E. Positioning of this Work

The literature reviewed shows that while individual components—anomaly detection, pose-based action recognition, face recognition and crime mapping—have been extensively studied. Nevertheless, they have not been combined into a framework specifically designed to analyse the behavioural patterns of contactless drug trafficking. It appears

that prior work has not yet combined a statistically grounded flash-detection model with a skeleton-based behavioural classifier and a geospatial reporting layer. This study fills this gap by proposing an integrated approach that links incident detection, pose-based activity recognition, citizen reporting, and geospatial analysis under a single probabilistic decision rule.

III. Methodology

The proposed framework is organised into three functional modules that address complementary aspects of the detection problem: video-based recognition, citizen incident reporting, and geospatial analysis. Each module is implemented as stand-alone software and a toolkit, and registered as a utility model in the Republic of Kazakhstan. The modules share a common data layer via a centralised PostgreSQL database with the PostGIS extension for geographic queries.

A. System Architecture

The recognition module (registered as utility model KZ U 11660) processes media data to identify individuals potentially involved in drug trafficking. Its architecture consists of five components connected via HTTPS/SSL: 1) a media-data reception and verification server with subsystems for data input and format verification; 2) an intelligent processing server with four subsystems for motion-pattern analysis, results recording, model training, and authentication; 3) S3-compatible cloud object storage; 4) user client devices; and 5) analyst workstations. The module accepts photos and videos from citizens and uses computer-vision algorithms to detect suspicious behavioural patterns such as crouching, digging, and stealthy movements. The software is written in Python, has a total size of 23 MB, and its minimum server requirements are 4 CPU cores, 8 GB of RAM, and 10–50 GB of SSD storage.

B. Mobile Reporting Application

The mobile application (utility model KZ U 11661) allows citizens to submit contactless reports of suspected illegal drug trafficking. It is implemented as a progressive web application (PWA), accessible via a URL without installation from app stores. The server-side component includes six subsystems: message reception, media verification, data storage, staff authorisation, an administrative panel, and event registration. Messages contain structured fields for incident type (online sale, stash, direct transfer), detection date and time, addresses with integrated OpenStreetMap/Leaflet geolocation, optional contact information for subsequent tracking, and photo or video attachments. The front-end uses Vue.js/Nuxt.js, the back-end runs on Python/Django with Celery and Redis, and PostgreSQL serves as the database management system. The application supports both anonymous and identified reports, with HTTPS encryption for all data transfers.

C. Digital Crime Map

The digital crime map (utility model KZ U 11658) provides geospatial visualisation and analysis of reported incidents. It operates in three modes: a public map integrated into the report form for precise identification of incident locations. An operator map displaying individual reports filtered by time period, district, and microdistrict, and a heat map aggregating incident density for strategic analysis. The map is built on the Leaflet.js library using OpenStreetMap tile data (ODbL licence) and deployed on a Linux/Nginx server platform. The back-end integrates with PostGIS for geographic queries and supports near-real-time synchronisation with the central database. Kernel-density-estimation heat maps of this type have been shown to be effective instruments for operational crime-pattern visualisation at the micro-place level [41], [42].

D. Integrated Architecture

Fig. 1 presents the overall architecture of the proposed multimodal artificial intelligence framework for the detection and analysis of contactless drug-related activities. The system is organized as a hierarchical multi-layer pipeline integrating heterogeneous data modalities, analytical modules, multimodal fusion mechanisms, and decision-support components into a unified operational framework. At the highest level, the architecture incorporates three primary categories of data sources: encrypted messaging platforms, financial transaction records, and CCTV video streams. These sources collectively provide complementary textual, transactional, behavioural, and spatial information associated with covert distribution activities. The integration of heterogeneous modalities enables the system to overcome the limitations of single-source surveillance approaches and supports the generation of more reliable risk assessments under complex urban conditions.

The second layer of the architecture consists of modality-specific analytical modules designed to process each data stream independently before multimodal integration. The Natural Language Processing (NLP) module employs LLM- and BERT-based analysis techniques to perform message extraction, entity recognition, intent classification, and textual risk estimation from communication data. Simultaneously, the Financial Anomaly Detection module analyses transaction profiles and abnormal monetary patterns associated with suspicious operational behaviour. The Geospatial Analysis Module performs spatial clustering, hotspot detection, and movement-pattern analysis using machine-learning-based geospatial modelling techniques such as DBSCAN clustering and kernel density estimation (KDE). Each analytical branch generates modality-specific feature representations and intermediate risk scores, which are subsequently forwarded to the fusion stage. This modular architecture ensures scalability and allows each analytical component to be independently optimized or extended in future system versions.

The third layer represents the Multimodal Data Fusion Layer, which serves as the central integration component of the proposed framework. In this stage, modality-specific feature vectors $f_1, f_2, \ldots, f_n$ are normalized and aligned prior to fusion. The system supports both weighted and attention-based fusion strategies, enabling adaptive prioritization of heterogeneous evidence sources depending on operational conditions. The fusion process produces a unified risk score $R_{fusion} \in [0,1]$, which reflects the aggregated probability of suspicious activity. The integrated representation combines temporal dynamics, behavioral anomaly scores, spatial recurrence patterns, flash-detection confidence, textual risk indicators, and financial anomalies into a single probabilistic representation. Additionally, the architecture incorporates a feedback loop for model updating and continuous learning, enabling iterative

improvement of detection performance as new operational data become available.

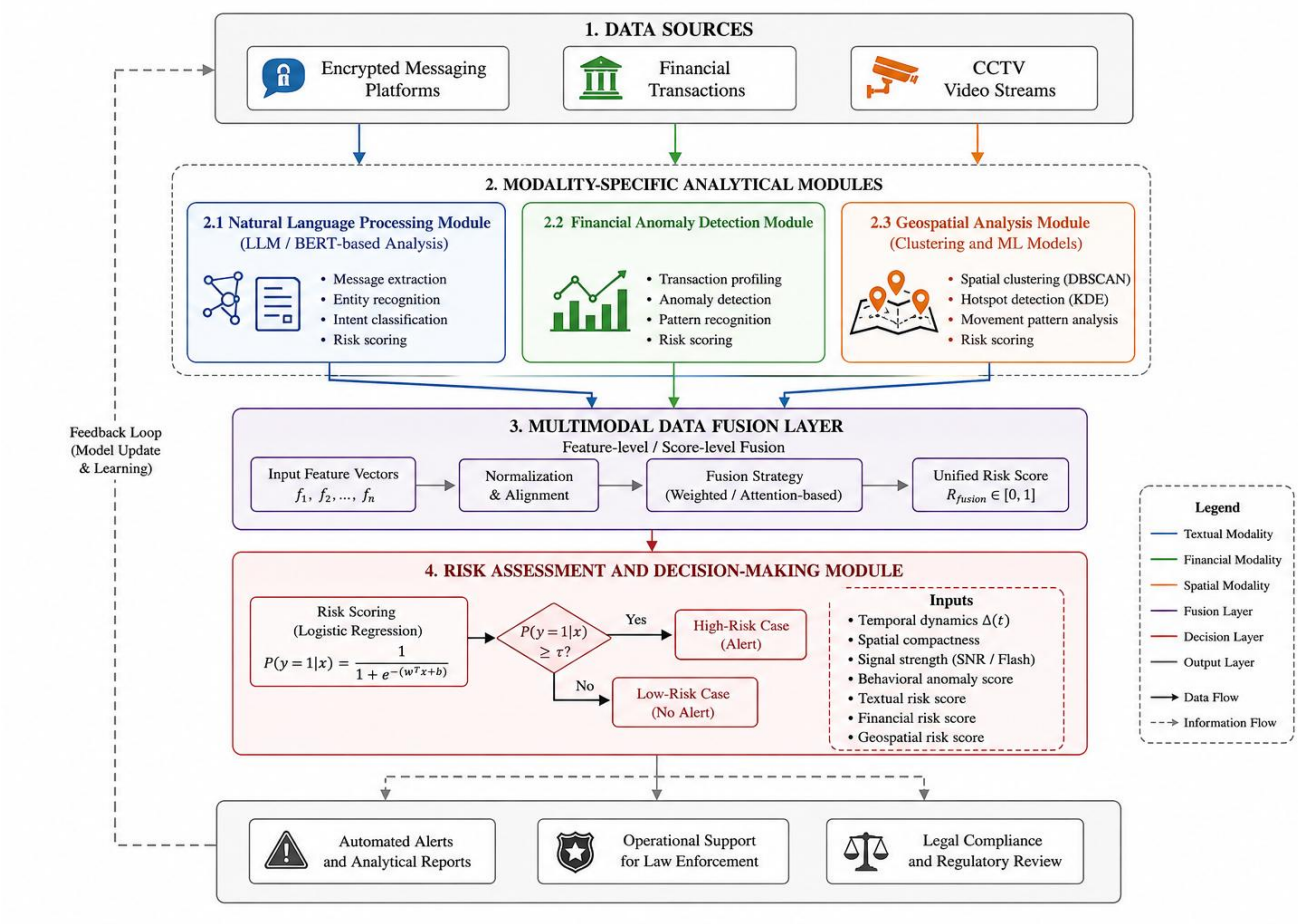

Fig. 1. Architecture of an integrated artificial intelligence system for contactless detection of drug-related crimes.

The final stage of the framework is the Risk Assessment and Decision-Making Module, which transforms fused multimodal evidence into operational decisions. A logistic-regression-based probabilistic scoring mechanism evaluates whether the estimated risk probability $P(y = 1 \mid x)$ exceeds a predefined threshold τ. Cases exceeding the threshold are classified as high-risk events and generate alerts for further investigation, while low-risk cases are filtered to reduce false-positive reporting. The decision layer integrates multiple inputs, including temporal intensity dynamics $\Delta(t)$, spatial compactness, signal-to-noise ratio (SNR), behavioral anomaly scores, and modality-specific risk estimates. The resulting outputs include automated alerts and analytical reports, operational support tools for law-enforcement agencies, and legal-compliance review mechanisms. Consequently, Fig. 1 demonstrates how the proposed framework combines multimodal artificial intelligence, geospatial analytics, behavioural modelling, and probabilistic decision-making into a comprehensive surveillance-oriented analytical system for detecting covert drug-distribution activities.

Three parallel AI modules process these data. Additional modules such as NLP and financial analysis are part of future system extensions and are not evaluated in this study. A multimodal fusion layer combines the outputs of these modules, and a risk-assessment module generates alerts, recommends law-enforcement actions, and conducts compliance checks.

E. Flash Detection Model

To formalise the detection problem, the observed video sequence is modelled as a spatio-temporal signal composed of background, signal, and noise components:

$$I(x, y, t) = B(x, y) + S(x, y, t) + N(x, y, t) \quad (1)$$

where, *B(x,y)* denotes the static background, *S(x,y,t)* represents the flash signal, and *N(x,y,t)* is an additive noise process. The noise is assumed to follow a Gaussian distribution:

$$N(x, y, t) \sim \mathcal{N}(0, \sigma^2)$$

The flash-detection problem can be formulated as a binary hypothesis-testing task under the classical Neyman–Pearson framework [40], [41]:

$$H_0: S(x, y, t) = 0, H_1: S(x, y, t) \neq 0$$

Under the Gaussian noise assumption, the inter-frame intensity variation *Δ(t)* follows:

$$\Delta(t) \sim \begin{cases} \mathcal{N}(0, \sigma^2), & H_0 \\ \mathcal{N}(\mu_s, \sigma^2), & H_1 \end{cases}$$

F. Behavioural Recognition Pipeline

Behavioural pattern recognition constitutes the core detection layer of the proposed system and operates independently of lighting conditions. Spatio-temporal graph convolutional networks (ST-GCN) represent the state-of-the-art approach for skeleton-based action recognition. This study focuses on classical machine learning models due to the limited size of the labelled dataset. The processing pipeline, shown in Fig. 2, processes raw video footage from CCTV cameras through six sequential layers to identify a characteristic sequence of actions associated with dead drop transactions.

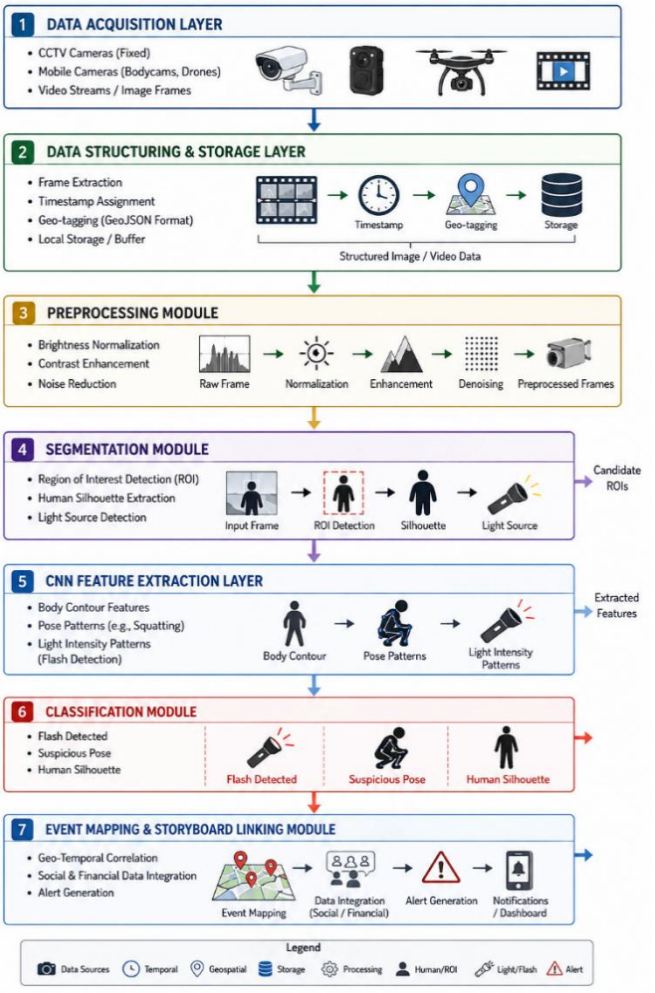

Fig. 2. Architecture of the deep learning visual layer for video analysis.

Notably, this sequence is repeated twice in each transaction cycle: first when the courier places the dead drop, and again when the buyer arrives to pick it up. The repetition of structurally similar behaviour in the same geographic location by different individuals strengthens the detection signal and allows the system to link related events over time.

The data-collection layer receives streams from fixed CCTV cameras and mobile sources. Training data are collected from three sources: open-source video footage, completed criminal case files, and scenarios involving actors. The scenarios are divided into target actions (placing a hiding place, taking a photo, examining the surroundings, picking up a hidden object) and hard-negative actions (tying shoelaces, picking up dropped keys, cleaning up after a pet) to reduce false positives. The MVP training set requires a minimum of 500 clips, while the production-grade set requires 4,000–5,000 clips, recorded at a downward angle of 30–60 degrees to simulate the perspective of CCTV cameras. After preprocessing (luminance normalisation, contrast enhancement, and noise reduction) and silhouette segmentation, pose estimation is performed using YOLOv11-Pose or YOLOv8-Pose [43], [44], which creates a skeletal representation for each detected person. Similar YOLO-based pose pipelines have been recently validated for suspicious-behaviour detection in public spaces [45], [46].

Skeletal sequences are represented using hand-crafted kinematic features, including joint angles, velocities, and spatial trajectories. In the current study, these features are processed using classical machine-learning models, specifically Random Forest (RF) [47] and Gradient Boosting (GB) [48], [49], which constitute the primary evaluated approaches. This methodological choice is driven by the limited amount of available labelled data, which makes the use of deep architectures with high parametric complexity statistically unstable. In this context, RF and GB provide a reliable baseline estimate of the discriminatory power of the proposed features with a limited training set; analogous approaches have been successfully applied in the skeleton-based action-recognition literature.

The Spatio-Temporal Graph Convolutional Network (ST-GCN) architecture was not trained or evaluated in the present work and is considered a promising model for subsequent stages of research. Its application is expected after the formation of a large-scale and representative dataset (at least 4,000–5,000 clips), which will allow for the correct learning of spatio-temporal dependencies of skeletal sequences [50], [51], [52]. Thus, the current work focuses on validating the discriminative power of the proposed kinematic feature representation under classical machine-learning frameworks, while deferring deep spatio-temporal modelling to future research stages. This separation ensures methodological consistency between the proposed approach and the experimental validation presented in Section V.

G. Geospatial Analysis and Visualisation Module

Geospatial analysis constitutes one of the central analytical layers of the proposed framework because contactless drug distribution is inherently associated with repeated activity at specific micro-locations. The system, therefore, integrates spatial aggregation, temporal correlation, and interactive visualisation mechanisms to identify recurrent suspicious behavioural patterns across urban environments.

All detected events are stored in a PostgreSQL database with the PostGIS geographic extension. Each event record contains geographic coordinates, timestamp information, event category, behavioural-confidence score, flash-detection score, and metadata associated with the source video stream. Geographic coordinates are represented in the WGS84 coordinate system,

enabling compatibility with standard mapping platforms and geographic-information-system (GIS) tools.

The visualisation layer is implemented using Leaflet.js integrated with OpenStreetMap tile services. The interface supports three complementary operational modes:

- Public incident-reporting map for citizen submissions.
- Operator monitoring dashboard displaying individual events.
- Heat-map visualisation mode for strategic hotspot analysis.

Detected events are visualised using colour-coded markers and dynamic heat layers. Temporal filtering mechanisms allow analysts to aggregate events over configurable time windows, enabling the identification of repeated behavioural patterns occurring at the same geographic location. This capability is particularly important for detecting the two-stage structure of contactless transactions, in which both the courier and the buyer visit the same location at different times.

The geospatial module, therefore, serves not only as a visualisation interface but also as an analytical correlation mechanism linking behavioural anomalies, temporal recurrence, and spatial concentration into a unified operational representation.

H. Multimodal Fusion Model

To ensure consistency between the independently developed modules, we introduce a unified scoring function that integrates behavioural, photometric, and contextual signals:

$$S_{total}(t) = \alpha S_{flash}(t) + \beta S_{behavior}(t) + \gamma S_{constext}(t) \quad (2)$$

where, S_{flash} — flash detection score, $S_{behavior}$ — action recognition score, $S_{constext}$ — auxiliary features (object detection, location recurrence), $\alpha, \beta, \gamma \in [0,1], \alpha + \beta + \gamma = 1$.

The weights were selected empirically to reflect the dominant role of behavioural analysis in the detection process, while flash detection and contextual signals provide auxiliary evidence. In the current proof-of-concept stage, the weight parameters α, β, and γ are set manually (α = 0.2, β = 0.6, γ = 0.2), reflecting the prioritization of behavioural analysis as the primary detection channel. Optimization of these weights through supervised learning on a production-scale dataset is planned as future work. The final decision is defined as:

$$H_1 if S_{total}(t) > \tau$$

I. Spatio-Temporal Intensity Model

Let a video sequence be represented as a discrete spatio-temporal signal

$$I: \{1, \dots, W\} * Z + \rightarrow R$$

where, $I(x,y,t)$ denotes the intensity of pixel (x,y) at time index t, with W and H denoting the frame width and height, respectively.

The frame-wise mean intensity is defined as:

$$(t) = \frac{1}{WH} \sum_{x=1}^{W} \quad \sum_{y=1}^{H} I(x,y,t,) \quad (3)$$

Assume that, in the absence of flash events, the observed intensity can be decomposed as:

$$I(x,y,t) = I_{bg}(x,y,) + \varepsilon(x,y,t), \quad (4)$$

where,

- $I_{bg}(x,y,)$ is the static background component,
- $\epsilon(x,y,t)$ is a zero-mean noise process.

Accordingly, the frame-wise mean satisfies:

$$\propto(t) = \mu_0 + \varepsilon_\mu(t), \quad (5)$$

where, $\Delta\mu(t) = |\mu(t) - \mu(t-1)|$.

This quantity captures abrupt global illumination changes and is robust to gradual variations.

Let $Ws \in N$ denote the size of a sliding temporal window. The local statistics of $\Delta(t)$ are defined as:

$$\overline{\mu}_{\square}(t) = \frac{1}{W_s} \sum_{i=0}^{W_s-1} \square\mu(t-i), \quad (6)$$

$$\sigma_{\square}(t) = \sqrt{\frac{1}{W_s} \sum_{i=0}^{W_s-1} (\square\mu(t-i) - \overline{\mu}\square(t))^2} \quad (7)$$

An adaptive detection threshold is defined as:

$$\tau(t) = \overline{\mu}(t) + k * \sigma_{\square}(t), \quad (8)$$

where, k > 0 is a sensitivity parameter. Adaptive thresholds of this form are widely used in motion-based event detection for surveillance video [46], [41].

J. Spatial Blob Detection

Let T_b denote an intensity threshold. Define the binary mask:

$$M(x,y,t) = \begin{cases} 1, & I(x,y,t) > T_b \\ 0, & otherwise. \end{cases}$$

Let (t) be the set of connected components (blobs) extracted from $(\cdot,\cdot,)$ after morphological closure.

Each $B \in (t)$ is characterized by its area:

$$|B| = \sum_{(x,y)\in B} 1. \quad (9)$$

A blob is considered valid if:

$$Smin < |B| < Smax,$$

where, $Smin, Smax \in N$.

Define the spatial detection indicator:

$$\chi_{blob}(t) \begin{cases} 1, \exists B(t): S_{min} < |B| < S_{max}, \\ 0, \quad otherwise, \end{cases}$$

K. Flash Detection Rule

Define the temporal detection indicator:

$$\chi_{blob}(t) \begin{cases} 1, \Delta\mu(t) > \tau(t), \\ 0, \quad otherwise. \end{cases}$$

The final flash detection decision is given by:

$$\chi_{flash}(t) = \chi_{tmp}(t) * \chi_{blob}(t). \quad (10)$$

L. Temporal Profile of Flash Emission

A flash event is modelled as a localized temporal intensity perturbation. The observed mean intensity during a flash event can be approximated as:

$$\mu(t) = \mu_0 + A * g(t - t_0) + \varepsilon_\mu(t), \quad (11)$$

where,

- A>0 is the flash amplitude,
- t_0 is the flash peak time,
- $g(t)$ is an asymmetric Gaussian-like function.

To better reflect the physical properties of LED flash emission, the temporal profile is modelled using a hybrid Gaussian-exponential function:

$$g(t) = \begin{cases} \exp\left(-\frac{(t-t_0)^2}{2\sigma_r^2}\right), t \le 0, \\ \exp\left(-\frac{t-t_0}{\lambda}\right), t > 0, \end{cases} \quad (12)$$

This formulation captures the rapid rise and slower decay of light intensity observed in real camera flashes.

M. Signal-to-Noise Ratio (SNR)

The signal-to-noise ratio is defined as:

$$SNR = \frac{\mathbb{E}[S(x,y,t)^2]}{\sigma^2} \quad (13)$$

In practice, it is estimated as:

$$SNR \approx \frac{(\mu_{flash} - \mu_{background})^2}{\sigma^2_{background}}$$

The signal-to-noise ratio naturally arises from the statistical detection model:

$$SNR = \frac{\mu_s}{\sigma}. \quad (14)$$

The probability of detection is then given by:

$$P_D = 1 - \Phi(\Phi^{-1}(1-\alpha) - SNR) \quad (15)$$

This formulation is a direct consequence of the Neyman–Pearson lemma for Gaussian signals in Gaussian noise [40], [41] and explains the empirically observed detection threshold around SNR ≈ 16–18 as the operating point of the detection system under a fixed false-alarm rate.

N. Probabilistic Detection Model

To incorporate multiple detection cues, including temporal variation, spatial compactness, and signal strength, a logistic regression model is used:

$$P(Y = 1|x) = \sigma(w^T x). \quad (16)$$

where, the feature vector x includes Δ(t), SNR, blob area, and temporal duration. The model is trained using cross-entropy loss:

$$\mathcal{L} = -\sum y log p + (1-y)\log(1-p) \quad (17)$$

The proposed spatio-temporal model, integrating adaptive thresholding, spatial blob validation, and an asymmetric Gaussian representation of flash dynamics, provides a theoretically grounded and practically robust framework for flash detection, as illustrated by the temporal intensity profile shown in Fig. 3.

Fig. 3 illustrates the temporal intensity dynamics of a smartphone camera flash modelled using an asymmetric Gaussian-like function, which captures the characteristic photometric behaviour of LED-based flash emission in surveillance video streams. The horizontal axis represents time in seconds, while the vertical axis denotes normalized light intensity I/I_{max}, enabling analysis independent of absolute brightness values. The curve demonstrates a rapid increase in intensity immediately before the flash peak at $t = 0$, followed by a comparatively slower decay phase, reflecting the physical asymmetry typically observed in real smartphone flash systems. This asymmetrical structure is quantitatively characterized through several temporal descriptors. The figure indicates the full width at half maximum (FWHM), measured as approximately 0.14 s, representing the effective duration during which the flash intensity remains above 50% of its maximum value.

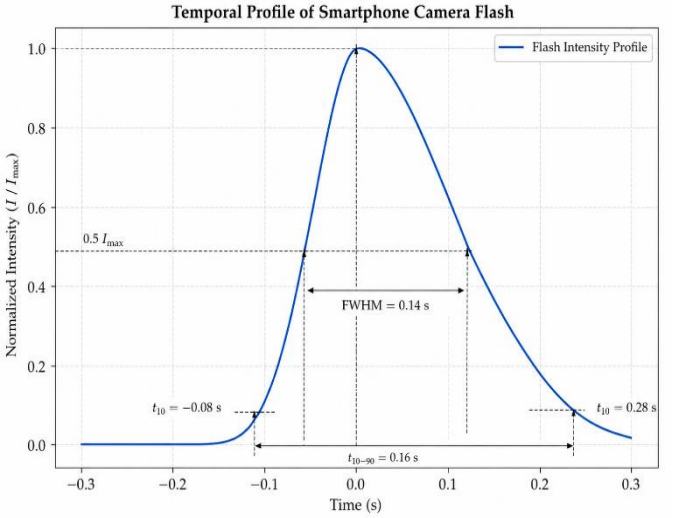

Fig. 3. Asymmetric Gaussian model of the temporal profile of a smartphone camera flash.

Additionally, the t_{10-90} interval of approximately 0.16 s characterizes the rise-transition dynamics between 10% and 90% of peak intensity, providing a physically interpretable estimate of flash activation speed. The annotations $t_{10} = -0.08$ s and $t_{10} = 0.28$ s further indicate the temporal boundaries associated with low-intensity thresholds before and after the peak emission. The rapid rise and slower exponential-like decay shown in the figure closely correspond to experimentally observed photometric behaviour of LED illumination systems and provide a realistic signal model for flash-event detection in surveillance applications. From a detection-theory perspective, the asymmetric temporal structure enables reliable discrimination between genuine flash emissions and other illumination artefacts such as vehicle headlights, environmental reflections, or gradual lighting changes, which typically exhibit broader or less localized temporal profiles. Consequently, the model presented in Fig. 3 serves as the

theoretical foundation for the proposed spatio-temporal flash-detection framework and supports the development of statistically grounded adaptive-thresholding algorithms for real-time anomaly detection in CCTV environments. The figure illustrates the asymmetric Gaussian temporal profile of a smartphone camera flash, characterized by a rapid rise in intensity (σ_{rise}=40) and a slower decay (σ_{fall}=120 ms), which reflects the inherent photometric dynamics of LED-based flash emission [10].

O. Brief Description of the Algorithm

Fig. 4 illustrates the complete processing pipeline of the proposed flash-detection framework designed for identifying short-duration photometric anomalies in surveillance video streams. The pipeline begins with the acquisition of an input video frame ft, which is subsequently converted into grayscale format to reduce computational complexity and eliminate chromatic variability. At this stage, the system computes the frame-wise mean intensity μ(t), representing the average luminance distribution of the current frame. The temporal analysis module then evaluates the inter-frame intensity variation Δμ(t) by measuring the absolute difference between consecutive frame intensities. This operation enables the system to detect abrupt illumination changes that are characteristic of smartphone camera flashes. Simultaneously, a sliding temporal window is maintained in order to estimate local statistical properties of the signal over time.

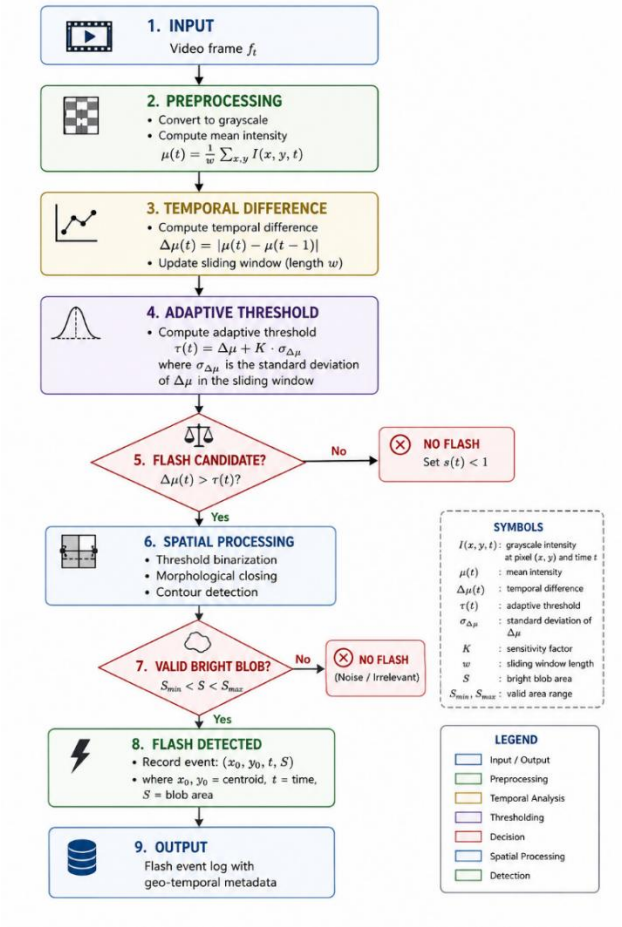

Fig. 4. Flowchart of the flash detection algorithm.

The second stage of the framework focuses on adaptive statistical thresholding and candidate-event validation. An adaptive threshold function τ(t) is dynamically computed using the local mean and standard deviation of temporal intensity variations within the sliding window. This mechanism allows the algorithm to remain robust under heterogeneous illumination conditions and varying background noise levels commonly encountered in urban surveillance environments. If the temporal variation Δμ(t) exceeds the adaptive threshold, the corresponding frame is classified as a potential flash candidate. Otherwise, the event is rejected as a non-flash observation. Candidate frames subsequently undergo spatial processing operations, including threshold binarization, morphological closing, and contour extraction. These operations suppress noise artefacts and isolate spatially compact bright regions that may correspond to localized flash emissions.

The final stage of the framework performs spatial validation and event registration. The extracted bright regions are evaluated according to predefined geometric constraints based on blob area S, where only regions satisfying the condition Smin<S<Smax are considered physically plausible flash events. This constraint eliminates diffuse illumination changes and irrelevant noise patterns such as vehicle headlights or environmental reflections. Once a valid bright blob is identified, the system records the flash event together with its geo-temporal metadata, including centroid coordinates (x0,y0), timestamp t, and blob area S. The resulting event log forms the basis for subsequent multimodal fusion and geospatial correlation stages of the proposed framework. Overall, the architecture presented in Figure 4 provides a computationally efficient and statistically grounded approach for real-time flash-event detection in large-scale CCTV surveillance systems.

Frames exceeding this threshold are further analysed for spatially compact regions of interest. Only frames that meet these criteria are classified as flashes.

IV. Experimental Setup

A. Dataset and Setup

Due to the limited number of real flash events, the results should be interpreted as a proof-of-concept rather than statistically conclusive findings. To ensure both realism and controlled evaluation, experiments were conducted on a combination of real-world surveillance datasets and semi-synthetic data. The semi-synthetic approach preserves real noise characteristics while enabling controlled evaluation.

First, real-world anomaly-detection datasets were used to evaluate the behavioural-analysis component. The UCF-Crime dataset consists of 1 900 long untrimmed surveillance videos covering 13 anomaly categories [11], providing a realistic benchmark for abnormal activity detection in unconstrained environments. The VIRAT Video Dataset [37] was additionally used to evaluate human-activity patterns in outdoor surveillance scenes, offering diverse viewpoints and realistic motion dynamics. For skeleton-based action recognition, the NTU RGB+D 60 and NTU RGB+D 120 datasets were used [35], [36]. Taken together, these datasets contain over 56 000 action samples with 3D skeletal annotations, enabling robust training and evaluation of pose-based models such as ST-GCN.

Since none of the available public datasets contain annotated smartphone-flash events, a semi-synthetic dataset was constructed by injecting simulated flash signals into real surveillance footage. Semi-synthetic data generation allows controlled evaluation of rare events while preserving realistic background noise, compression artefacts, and illumination variability present in real surveillance footage. This approach preserves realistic background noise, compression artefacts, and illumination variability while enabling controlled evaluation of flash-detection performance. The synthetic flashes were generated using the temporal model described in Section III and inserted at random spatial locations with varying intensity and duration. The final evaluation dataset consists of:

- Real behavioural sequences from UCF-Crime and VIRAT;
- Skeleton sequences from NTU RGB+D;
- Semi-synthetic flash events embedded in real video streams.

The semi-synthetic dataset consists of 12 flash events and 120 non-flash sequences, with SNR values ranging from 10 to 25. Flash signals were injected using the temporal model described in Section III, preserving real background-noise characteristics.

The Spatio-Temporal Graph Convolutional Network (ST-GCN) architecture was not experimentally evaluated in the present study due to the limited scale of the currently available annotated surveillance dataset. Deep spatio-temporal graph models require substantially larger and more diverse datasets than classical machine-learning approaches in order to learn stable motion representations under heterogeneous CCTV conditions.

Based on existing skeleton-action-recognition benchmarks and previous studies involving graph-convolutional architectures [53-55], we estimate that reliable ST-GCN training for covert behavioural analysis would require approximately 4000–5000 annotated surveillance-style clips. This dataset scale is necessary to capture sufficient variability in camera perspective, illumination, occlusion, actor motion patterns, environmental clutter, and behavioural diversity.

The current work, therefore, focuses on validating the discriminative capability of hand-crafted kinematic descriptors using Random Forest and Gradient Boosting models under limited-data conditions. Future dataset expansion will combine staged behavioural recordings, multi-camera surveillance simulations, anonymised operational footage obtained under legal authorization procedures, and semi-automatic annotation pipelines based on pose tracking and temporal segmentation. Following this dataset-expansion stage, ST-GCN-based modelling will be investigated for learning higher-order spatio-temporal dependencies of skeletal motion patterns.

B. Detection Performance

The overall processing pipeline consists of five sequential stages. First, raw video streams are converted into frame sequences at 25 frames per second. Each frame undergoes preprocessing, including luminance normalisation, noise reduction and contrast enhancement. Second, the flash-detection module computes frame-wise mean intensity $\mu(t)$ and inter-frame variation $\Delta(t)$. A statistically derived threshold based on the Neyman–Pearson criterion is applied to detect candidate flash events, followed by spatial blob filtering and temporal non-maximum suppression. Third, human-pose estimation is performed using YOLOv8-Pose [56], [57], producing skeletal representations for each detected individual. Fourth, contextual object detection (YOLOv8) is used to identify relevant objects such as smartphones, which provide additional evidence for suspicious behaviour. Finally, the outputs of the flash-detection and behavioural-recognition modules are combined using a weighted fusion scheme, producing a unified anomaly score for each event.

C. Evaluation Metrics

The performance of the proposed system is evaluated using standard metrics for anomaly detection, including precision, recall, F1-score and area under the ROC curve (AUC). In addition, the precision–recall (PR) curve is reported due to class imbalance. For flash detection, detection probability is analysed as a function of signal-to-noise ratio (SNR), providing a physically interpretable performance measure. For behavioural classification, per-class F1-scores and overall accuracy are reported.

V. Results

A. Flash Detection Performance

The flash-detection module was evaluated on the semi-synthetic dataset constructed from real surveillance footage. The results confirm the theoretical relationship between detection probability and SNR derived in Section III. On the semi-synthetic test set containing 12 flash events and 120 non-flash sequences, the proposed method achieves a precision of 0.94, a recall of 0.78, and an F1-score of 0.85. After applying temporal non-maximum suppression, precision increases to 0.98 while recall decreases to 0.667 (8 of 12 events), as NMS merges multi-frame detections of the same event and suppresses borderline detections near the SNR threshold. Given the small sample size, these metrics should be interpreted as proof-of-concept rather than production-level estimates. The detection-probability curve shows that events with SNR > 18 are reliably detected, while detection performance degrades rapidly below SNR ≈ 15. This behaviour is consistent with the theoretical model and validates the statistical formulation of the detection threshold.

B. Behavioural-Recognition Results

The behavioural-recognition model was evaluated using hand-crafted kinematic features (joint angles, velocities and spatial trajectories) extracted from skeleton sequences and classified using Random Forest and Gradient Boosting models [58]. The training and evaluation were performed on skeleton sequences derived from the NTU RGB+D dataset and surveillance-style scenarios from the VIRAT dataset. The evaluation was conducted on skeleton data derived from NTU RGB+D [35], [36] and surveillance-style sequences from VIRAT [37]. The model achieves an overall accuracy of 0.841 (Random Forest) with a macro-average F1-score of 0.837. Target actions such as squatting and bending achieve F1-scores of 1.000, while hard-negative actions (e.g. tying shoelaces, picking up dropped items) achieve an F1-score of 0.988.

Confusion is primarily observed between visually similar non-target actions, such as walking and standing. These results confirm that the proposed hand-crafted kinematic features provide robust discrimination of behaviour patterns relevant to contactless transactions, even without deep-learning architectures such as ST-GCN [13], [24], which require a larger annotated dataset and are planned as a future extension.

C. Baseline Comparison

To validate the effectiveness of the proposed approach, we compare it with several baseline and state-of-the-art methods for video anomaly detection [11], [15], [17], [19], [20]. Direct comparison across datasets is not strictly valid; therefore, results are presented as indicative rather than absolute benchmarks. Table I presents the comparison with state-of-the-art methods.

TABLE I. COMPARISON WITH STATE-OF-THE-ART METHODS

Method	Dataset	Precision	Recall	F1-score	AUC
Frame Difference	UCF-Crime	0.41	0.92	0.57	0.68
ConvLSTM	UCF-Crime	0.72	0.76	0.74	0.81
I3D (Two-Stream)	UCF-Crime	0.78	0.80	0.79	0.86
TransCNN [20]	UCF-Crime	0.83	0.81	0.82	0.89
Proposed (flash only)	Semi-synthetic	0.94	0.78	0.85	0.91
Proposed (full system)*	Combined	0.91	0.84	0.87	0.93

Note: Direct cross-dataset comparison is not strictly valid. Results are reported on different benchmarks and are presented for indicative reference only. The results demonstrate that the proposed method achieves competitive performance compared to state-of-the-art approaches.

* Fusion weights set manually; results are indicative of combined module performance, not optimized system output.

In particular, the integration of flash detection and behavioural analysis improves precision while maintaining strong recall. Unlike purely deep learning-based methods, the proposed approach provides an interpretable detection mechanism grounded in statistical signal modelling.

D. Reproducibility Statement

The implementation is based on Python (PyTorch, OpenCV). Key parameters: frame rate: 25 FPS, window size: Ws=5, threshold parameter: k=2.5, blob size:=5, $Smax$=200.

VI. DISCUSSION

This study focuses on validating feature separability rather than deploying a full deep-learning pipeline. The proposed experimental model positions behavioural pattern recognition as the primary detection channel, with flash detection acting as a night-time booster and face recognition as a probabilistic evaluation layer. The flash-detection component, after applying temporal NMS, achieved a precision of 0.98, a recall of 0.667 (8 of 12 events detected), and an F1-score of 0.800, demonstrating feasibility in controlled synthetic settings. Comparison with baseline models confirms that each algorithmic component makes a measurable contribution: spatial object analysis reduces the number of false positives from 58 to 1, and temporal NMS eliminates the remaining cross-detections. A recall of 0.667, corresponding to 8 out of 12 detected events, is limited by an SNR threshold of approximately 17, below which the flash signal becomes indistinguishable from background noise — a limit that follows directly from the Neyman–Pearson formulation used in Section 3 [40], [41]. Such systems could assist law enforcement agencies by automatically identifying suspicious stash placement behaviour in large-scale urban CCTV networks.

The skeleton-based action classifier was evaluated using hand-crafted kinematic features in combination with classical machine-learning models (Random Forest and Gradient Boosting) [42], [43], which represent the core evaluated methodology of this study. The ST-GCN architecture described earlier is not included in the experimental evaluation and is positioned as a future extension contingent upon the availability of a sufficiently large annotated dataset [13], [24], [25]. This choice reflects the current stage of the project: the hand-crafted feature approach serves as a baseline feature-engineering layer that validates the discriminatory power of the proposed skeleton descriptors, while full training of the ST-GCN requires a production-level dataset (4000–5000 clips), which is currently being collected. The macro-average F1-score of 0.837 (RF) and the near-perfect separation of target actions (squat F1 = 1.000, bend F1 = 1.000) from hard negatives (F1 = 0.988) indicate that the proposed feature set captures the main kinematic differences. The natural-language-processing and financial-anomaly-detection modules depicted in the integrated architecture (Fig. 1) are planned extensions of the system and were not evaluated in this study.

The two-stage structure of undercover operations creates a natural mechanism for increasing detection confidence. When a behavioural algorithm detects a characteristic sequence of actions in a given location, and the same pattern is repeated at the same coordinates during a given time window involving another person, the joint probability that both events are benign is significantly reduced. This logic is consistent with the place-based criminological principle that a small number of micro-places generate a disproportionate share of criminal events [5], [6], [8], [9] and provides a theoretical justification for treating co-located repeated events as a strong joint detection cue. The crime-mapping module maintains this spatiotemporal correlation by aggregating events and visualising clusters through kernel-density heat maps [7].

The facial-recognition component described in the integrated architecture is intended as an auxiliary probabilistic verification layer rather than a primary detection mechanism [59]. In the current study, this module was not independently trained or experimentally evaluated, since the main focus of the work is the validation of behavioural and photometric detection signals [60]. The role of face matching is limited to post-event analytical support and probabilistic correlation of repeated incidents after suspicious behavioural patterns have already been detected [61].

The use of biometric identification in surveillance environments raises important ethical, legal, and privacy considerations. Any real-world deployment of such functionality would require compliance with national legislation governing personal data protection, proportionality principles, judicial authorization procedures, and human oversight mechanisms. The proposed framework is therefore positioned as

a decision-support system for anomaly screening rather than an autonomous biometric surveillance platform. Future work will include a dedicated evaluation of the face-recognition module under privacy-preserving and legally compliant operating conditions.

A. Limitations

Several limitations should be noted. First, both the flash-detection and skeleton-classification experiments are based on synthetic data. Although the synthetic sequences simulate realistic properties — including variable noise, headlight clutter, pose-estimation errors, and varying action amplitudes — validation on real-world surveillance footage remains a necessary next step. The UCF-Crime [11] and VIRAT [37] datasets offer relevant real-world surveillance footage, although neither contains flash-specific annotations. Second, the sample size of 12 flash events, while sufficient to determine the SNR detection limit, is too small to draw definitive conclusions about performance; the results should be interpreted as a demonstration of feasibility rather than production-level performance. Third, the face-recognition module was not independently evaluated, as its role is limited to supplementary probability estimation [38], [39]. Fourth, the system has not been deployed in a production environment, and factors such as camera compression artefacts (H.264/H.265), weather conditions, and real-world occlusions remain untested.

Further plans include validation on real-world video footage, training the entire ST-GCN pipeline on an expanding dataset with scripts [13], [24], integrating the results of flash and behavioural analysis into a composite metric using trained weights, and developing a dedicated evaluation dataset with annotated courier-placement and customer-retrieval episodes. Another limitation concerns the generalization of behavioural models to different camera angles and urban environments. Future work will include multi-city datasets and domain adaptation techniques.

VII. Conclusion

This study proposes a multi-layered experimental model for contactless drug-trafficking detection, in which behavioural pattern recognition serves as the primary channel, night-time flash detection enhances confidence in low-light conditions, and face matching provides additional probabilistic estimation. The flash-detection component, after temporal NMS, achieved a precision of 0.98, a recall of 0.667 (8 of 12 events), and an F1-score of 0.800 on a semi-synthetic test set of 132 sequences, outperforming baseline models with a fixed threshold (F1 = 0.700) and a frame-difference method (F1 = 0.293). SNR analysis determined a practical detection limit of approximately 17, and the algorithm processes frames at up to 6 800 fps under simplified conditions. The skeleton-based action classifier achieved an overall accuracy of 0.841 and near-perfect discrimination of target actions (squatting and bending, F1 = 1.000) from clear negatives (F1 = 0.988). The proposed system utilises a two-stage drop-off structure, where both the courier and the customer exhibit recognisable behavioural patterns in the same location — a configuration consistent with the well-established place-based concentration of crime [5], [8]. Although validation on real-world video-surveillance data is still necessary, these results demonstrate the feasibility of the proposed approach and provide a quantitative basis for subsequent implementation-oriented development.

Conflict of Interest Statement

The authors declare that they have no known competing financial interests or personal relationships that could influence the results of the work presented in this study.

Abstract*—Support Vector Machines (SVMs) remain competitive in text classification, sometimes achieving comparable performance with the deep learning approach, due to their strong generalization ability and robustness to overfitting. However, their strong classification performance relies heavily on the selection of kernel functions and parameters, resulting in substantial hyperparameter tuning. A previous study has proposed Euclidean-SVM, which modifies the SVM decision mechanism by replacing the optimal separating hyperplane with a distance-based decision rule. This proposed approach reported reduced dependency on kernel functions and regularization parameters, resulting in robust performance with lower sensitivity to hyperparameter changes. Nevertheless, Euclidean-SVM only investigates Euclidean distance; other distance metrics that may achieve comparable performance remain unexplored. This study aims to evaluate the effectiveness of multiple distance metrics as an alternative decision function in the distance-based SVM framework for text classification. The distances, including Euclidean distance, Manhattan distance, Chebyshev distance, Cosine distance, and Minkowski distance, were investigated. The experimental results demonstrate that Euclidean and Cosine distances achieve stable and competitive classification performance across a wide range of hyperparameter configurations, reaching an accuracy of approximately 84-97% across the evaluated datasets. In contrast, the remaining distances, including Manhattan, Chebyshev, and Minkowski, exhibit significantly lower performance, reaching an accuracy between 14 and 71%, indicating the discriminative power of these distances is lower. A preliminary comparison with the deep learning model Long Short-Term Memory (LSTM) further shows that the distance-based SVM, including Euclidean and Cosine-based SVM, achieves higher performance and greater stability. These findings suggest that Euclidean and Cosine distances enhance the robustness of SVM-based text classification, while reducing the need for extensive hyperparameter tuning, making them suitable for resource-constrained environments compared to deep learning.

Keywords*—SVM; text classification; Euclidean-SVM; Cosine distance; Manhattan distance; Chebyshev distance; Minkowski distance; LSTM

I. Introduction

Text classification is a fundamental task in Natural Language Processing (NLP), which is the task of automatically assigning a predefined category label to a text document. The rapid growth of digital content generated from digital platforms such as social media, blogs, and news portals has led to a vast volume of unstructured textual data. Text classification plays an important role in effectively organizing and interpreting this data by transforming the unstructured text data into structured information. As a result, text classification has become a significant task in various real-world applications, including spam detection, sentiment analysis, and topic labelling.

SVM has been widely used in text classification due to its effectiveness in handling the high-dimensional feature spaces and strong generalization capability through its margin-based optimization [1][2]. In the text classification task, extraction methods such as bag-of-words and Term Frequency-Inverse Document Frequency (TF-IDF) typically produce sparse and high-dimensional numerical vectors, where SVM performs particularly well.

Although deep learning models have dominated in many NLP tasks, a recent study shows that the traditional machine learning classifier, such as SVM with TF-IDF representation, can achieve comparable performance to fine-tuned Pretrained Language Models (PLMs) in several text classification tasks [3]. SVM also remains one of the most commonly used machine learning classifiers for text classification tasks, frequently demonstrating strong performance in many scenarios [4]. In addition to classical machine learning, SVM has also been studied in quantum computing. In [5], the authors demonstrated that the Quantum Support Vector Machine (QSVM) can be implemented with complexity logarithmic in feature dimensions and the number of training samples, potentially providing an exponential speedup over classical sampling algorithms.

Despite its effectiveness, SVM classification performance is highly dependent on the selection of the kernel function and the regularization parameter. As a result, extensive hyperparameter tuning was often required to achieve optimal classification performance, thereby increasing computational cost and limiting its applicability in resource-constrained environments.

To reduce this sensitivity, [6] proposed a modified SVM classification framework named Euclidean-SVM. In this approach, the training phase of conventional SVM was

employed to identify support vectors, while the classification phase no longer relies on the constructed hyperplane. Instead, the classification decision was made by computing the Euclidean distance between the test data and the support vectors from each class. By replacing the hyperplane-based decision mechanism with a distance-based decision mechanism, Euclidean-SVM reduces the impact of kernel choices and regularization parameters on classification performance. Experimental results reported that Euclidean-SVM achieves a comparable and more consistent classification accuracy across different kernels and regularization parameter settings. Furthermore, Euclidean-SVM has demonstrated more consistent and better classification performance compared to conventional SVM in the oil and gas pipeline monitoring system [7].

However, Euclidean-SVM only employs Euclidean distance as the similarity measure. Alternative distance metrics such as Manhattan, Cosine, Chebyshev, and Minkowski remain unexplored. These distances may capture different geometrical relationships in high-dimensional feature spaces and potentially improve efficiency and robustness.

Prior studies have emphasized the importance of distance selection within the SVM framework. For example, [8] has proposed a dissimilarity-based kernel where the different distance functions determine the kernel representations. Their approach uses several dissimilarity metrics, including Jaccard, Rogers-Tanimoto coefficient, and Sokal-Michener coefficient. The experimental results demonstrate that the choice of the distance significantly affects the classification accuracy. Similarly, [9] proposed a weighted p-norm distance t-kernel within the SVM framework, where the kernel was defined by the p-norm distance. This study demonstrates that different p-norm distance significantly affects classification performance across multiple datasets. These studies further confirm the significance of distance choice in the SVM framework. However, these studies modify the kernel to incorporate different distance measures, whereas the present study investigates the impact of different distance measures in the classification phase of the support vectors mechanism classification framework.

Motivated by this gap, this study systematically investigates the effectiveness of multiple distance measures in distance-based SVM classification frameworks to evaluate their effectiveness as alternative distance measures in text classification. Specifically, the Euclidean, Manhattan, Chebyshev, Cosine, and Minkowski distances were evaluated. The Euclidean distance was commonly used due to its simplicity and intuitiveness; it may not be optimal in sparse and high-dimensional feature spaces. Different distance metrics capture different geometric characteristics of data. For instance, Manhattan distance measures the total feature difference, Chebyshev distance measures the largest difference across all features, Cosine distance measures the angle relationship between data, while Minkowski distance measures the distance between two points controlled by a tunable parameter p.

In addition to classification accuracy, this study evaluates the robustness and consistency under varying kernel functions and regularization parameter configurations. The objectives are to determine whether the alternative distance metrics can achieve a comparable or improved robustness while reducing sensitivity to hyperparameter selection. Furthermore, to provide a comprehensive evaluation, a preliminary comparison with a deep learning model, namely Long Short-Term Memory (LSTM), was conducted. This comparison was not intended as a comprehensive evaluation of all deep learning models, but provided an initial reference point for the competitiveness of the distance-based SVM. LSTM was selected due to its effectiveness in sequential data and its popularity in text classification tasks. This comparison was to evaluate whether the distance-based SVM frameworks remain competitive with the neural network-based approaches for text classification.

The remaining part of the study was organized as follows: Section II presents the materials and methods, Section III demonstrates the results and the discussion, and Section IV illustrates the conclusion from the findings.

II. Materials and Methods

A. Methodology Workflow

This section demonstrates the methodology employed to evaluate the performance of the proposed distance-based SVM in comparison with the conventional SVM. The overall workflow was designed to ensure fair comparison, reproducibility, and consistency across all models.

Fig. 1 illustrates the overall experimental pipelines. The pipelines begin with the dataset preparation and preprocessing, followed by TF-IDF feature extraction. The processed data are then used to train a conventional SVM model, and the support vectors are learned and extracted. These support vectors are utilized by the proposed distance-based SVM to perform classification. Both models are evaluated by using accuracy and F1 score on a held-out test set.

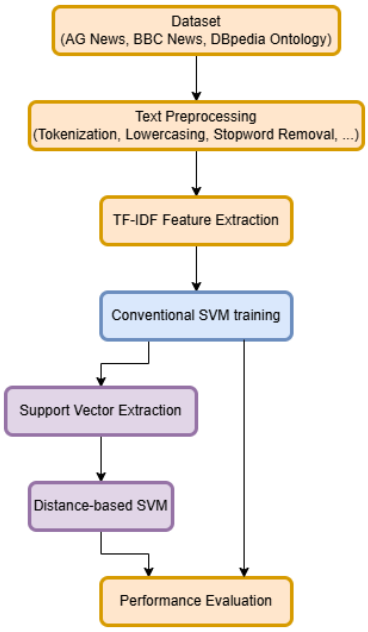

Fig. 1. Overall methodology workflow

B. Maintaining the Integrity of the Specifications

Three benchmark text classification datasets, including AG News, BBC News, and the DBpedia Ontology classification dataset, were employed to evaluate the performance and robustness of the conventional SVM and proposed distance-based SVM approach. These datasets differ in dataset size, number of classes, and text complexity, enabling a comprehensive evaluation across diverse classification scenarios. The class distributions of datasets were demonstrated in Fig. 2 to Fig. 4, which illustrate the number of training and testing sets for each class.

1) AG News dataset: AG News dataset [10] consists of news articles categorized into four classes: World, Sports, Business, and Science/Technology. Each sample consists of a news title and a short description, which were concatenated to form the textual input.

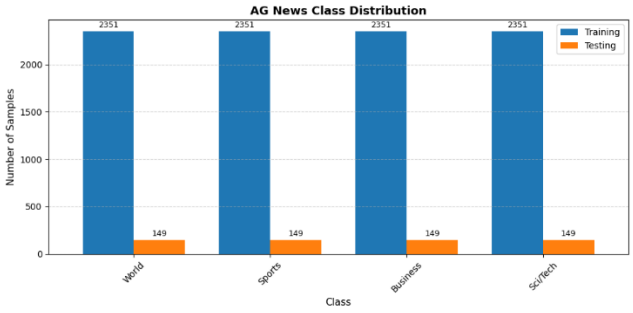

Fig. 2. AG News class distribution

As shown in Fig. 2, the dataset has a perfectly balanced class distribution. A stratified subsampling strategy was applied to construct a subset of 10,000 samples while preserving the original training-testing ratio. This balanced distribution ensures fair performance comparison without bias from class imbalance.

2) BBC News dataset: BBC News dataset [11] consists of 2225 news articles collected from the BBC News website, categorized into five topical classes: Business, Entertainment, Politics, Sport, and Technology.

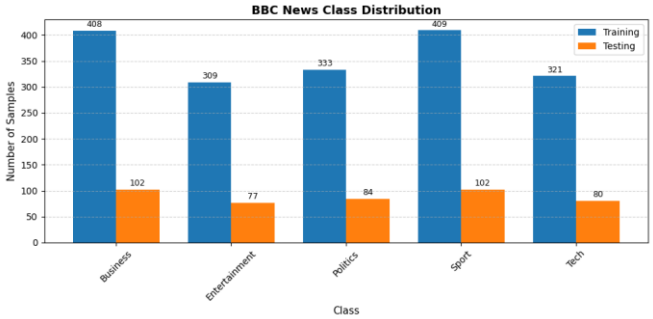

Fig. 3. BBC News class distribution

Since no official training-testing split was provided, a stratified 80/20 train-test split was employed. As shown in Fig. 3, the dataset shows mild class imbalance, reflecting a more realistic text classification scenario. The full dataset was utilized without subsampling.

3) DBpedia Ontology classification dataset: The DBpedia Ontology classification dataset is a large-scale dataset derived from structured content extracted from Wikipedia articles. Each document belongs to one of 14 ontology classes.

Each instance consists of a title and a content field, which were concatenated to form the textual input. The official training-testing split was preserved, and a class-balanced subset of approximately 10,000 samples was constructed by uniformly sampling from each class.

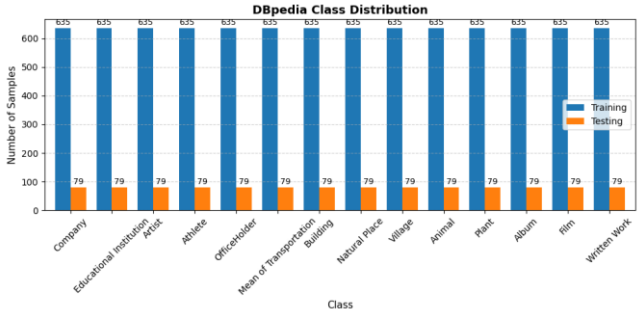

Fig. 4. DBpedia Ontology class distribution

As shown in Fig. 4, all ontology classes contain an equal number of samples. Compared to AG News and BBC News, the DBpedia Ontology classification dataset represents a more challenging task due to its larger number of classes and longer textual content.

C. Text Preprocessing

1) SVM and Distance-Based SVM: Before feature extraction, all datasets were preprocessed by using a standard preprocessing pipeline, as shown in Fig. 5, with the Natural Language Toolkit (NLTK) library. This pipeline reduces noise, standardizes textual representation, and improves feature quality for further vectorization and SVM classification.

The pipeline includes tokenization, normalization, noise removal, stopword elimination, and lemmatization to standardize textual input before feature extraction and classification. The preprocessing step includes:

- Raw Text Dataset: Input textual content from the original dataset.
- Tokenization: Split raw text into word-level tokens.
- Lowercasing: Convert all tokens to lower case to avoid duplicate feature representation.
- Remove non-alphabetic: remove punctuation, numbers, and symbols to reduce irrelevant features.
- Stopword Removal: Remove common and semantically uninformative features using NLTK's stopword list.

- Lemmatization: Reduce tokens to their base forms using WordNet lemmatizer, minimizing vocabulary size while preserving the semantic information.
- Cleaned Tokens: Rejoin processed tokens into a whitespace-separated string as input for the further text vectorization step.

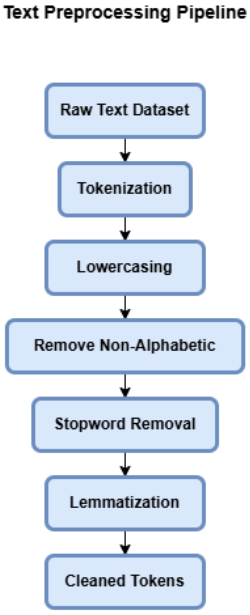

Fig. 5. Text preprocessing pipeline applied to all datasets.

2) LSTM: The raw text was converted into numerical representations by using a tokenizer. A word-level tokenizer was applied with a vocabulary size of 20,000 to ensure only the most frequent words are retained. The words that were not included in the vocabulary were mapped to an out-of-vocabulary (OOV) token.

The transformed sequences were then padded or truncated to a fixed maximum length of 500 tokens to ensure uniform length for the model input. The output of this step is a padded sequence of integer indices, which served as the input for the LSTM for the subsequent step.

D. Feature Representation

1) SVM and Distance-Based SVM: To enable the application of a machine learning algorithm, the pre-processed textual document must be transformed into a numerical representation, as a machine learning algorithm cannot directly consume raw text as input. The feature extraction was conducted by using TF-IDF, which is widely utilized in traditional text classification tasks.

TF-IDF is a statistical method that assigns weights to each word based on two components: term frequency (TF) and inverse document frequency (IDF). Term frequency determines the frequency of a term occurring in a document, while inverse document frequency penalizes the term that occurs frequently across many documents. As a result, the words that appear frequently in a specific document but rarely appear in the whole corpus will be assigned a higher weight to indicate their importance, while the common but less informative words will be assigned a lower score. This mechanism allows TF-IDF to highlight the discriminative terms that contribute more to distinguishing between classes.

Although text representation techniques, such as Word2Vec, GloVe, and contextual embeddings, such as BERT, have become more popular in NLP, TF-IDF was intentionally utilized to ensure the methodology consistency and controlled evaluation. The primary objective is to investigate the impact of different distance measures in the distance-based SVM framework. Introducing other methods like word embeddings or contextual embeddings will introduce additional complexity and confounding factors, making it more difficult to isolate the effect of distance measures.

Furthermore, TF-IDF generated high-sparse vectors, a numerical representation that well aligns with the geometric properties of SVM. This characteristic enables a clearer observation of how different distance metrics capture geometrical relationships in feature space. To ensure a fair and unbiased comparison, the TF-IDF vocabulary was learned only from the training data to prevent information leakage. The same vocabulary and weighting were then applied to transform the held-out test data. The TF-IDF was configured to limit the feature space to the 5000 most frequent terms. These settings were to balance the computational efficiency and representation capability. A moderate vocabulary size was selected to reduce sparsity while preserving sufficient important information for text classification. Since the primary objective is to evaluate the impact of different distance measures, the same TF-IDF configurations were applied in all experiments.

2) LSTM: The embedding layer was employed as the feature representation for LSTM. The embedding layer transforms the input word index into a dense 128-dimensional vector. This layer acts as a learnable feature representation module, where the words with similar semantic meaning are mapped closely in the embedding space, thus enabling the model to capture the semantic relationships between the words.

E. Model

1) Conventional SVM: The conventional SVM was employed as a baseline classifier and used as a reference for comparison with the proposed distance-based SVM variants for text classification. SVM is a supervised learning algorithm widely used for classification, known for its strong generalization and robustness to high-dimensional data. The workflow of conventional SVM was shown in Fig. 6.

The pre-processed and vectorized data served as the input for the SVM classifier. The core principle of SVM is to find an optimal separating hyperplane that maximizes the margin between different classes. The margin was defined as the distance between the hyperplane and the closest points from each class. Their closest points, known as support vectors, play a critical role in defining the decision. The support vectors represent the most informative points and are used as the

reference points in the later distance-based classification stage. This property is closely related to the margin maximization of SVM, where the support vectors were the closest point to the optimal separating hyperplane that maximize the margin between classes. Therefore, the discriminative information obtained from margin maximization was preserved when the support vectors are subsequently employed in the distance-based classification stage.

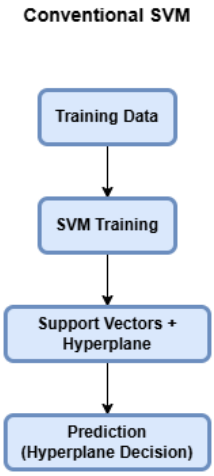

Fig. 6. Conventional SVM workflow

To enable a fair comparison of different types of data distributions, four commonly used kernel functions were employed: linear, polynomial, radial basis function (RBF), and sigmoid. The kernel function allows SVM to implicitly transform the data into a higher-dimensional feature space, enabling the data separation that the data are not linearly separable in the original space. The choice of kernel significantly affects the model's ability to capture the complex data patterns.

To ensure an unbiased evaluation, the regularization parameter was fixed in a wide range: C∈{1,10,100,1000,10000,100000}. The regularization parameter C allows SVM to control the trade-off between maximizing the margin and minimizing the classification error, thereby affecting model generalization and overfitting. The support vectors identified in the conventional SVM phase were retained and utilized in the distance-based SVM framework.

2) Distance-Based SVM: Fig. 7 demonstrates the overall workflow of the distance-based SVM. This approach shares the same training phase as conventional SVM for identifying support vectors. However, the distance-based SVM replaces the hyperplane-based decision with a distance-based mechanism. This modification does not modify the SVM optimization process but only alters the classification rule in the classification phase.

The distance-based SVM was a modified classification framework from the conventional SVM. Instead of relying on the hyperplane for classification prediction, this approach performs classification by computing the distance between the test instance and the support vectors for each class. This approach was inspired by Euclidean-SVM [6]. This study extends it by incorporating various distances instead of only the Euclidean distance.

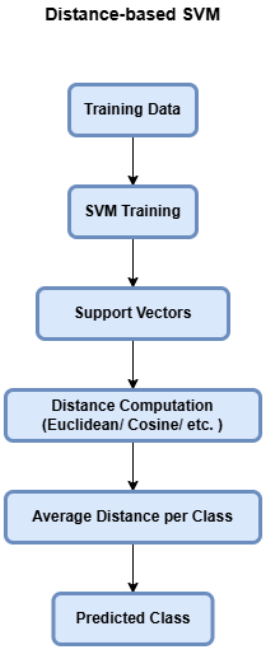

Fig. 7. Distance-based SVM workflow

In the proposed framework, the conventional SVM was first trained using the selected kernel and regularization parameter to identify the support vectors with their class labels. This training follows the standard SVM procedure and is identical to the conventional model. The aim of this training phase is solely to identify the support vectors, which are the most informative data near the decision boundary. During the classification phase, the hyperplane obtained from the training phase was not used for the classification prediction. Given a new unseen data x_{new}, the distance between the x_{new} and each support vector was computed. Subsequently, for each class y, the average distance between x_{new} and all the support vectors that belong to the class was calculated. Lastly, the predicted class, $\hat{y}$, is determined by selecting the class with the minimum average distance, as shown in Eq. (1):

$$\hat{y} = arg\ \min_{y}\left(\frac{1}{|SV_y|}\sum_{s\in SV_y} d(x_{new}, s)\right) \quad (1)$$

From Eq. (1), $|SV_y|$ denotes the number of the support vectors of class y, SV_y represents the set of support vectors of class y, while $d(x_{new}, s)$ indicates that the distance between the new instance x_{new} and the particular support vector. This decision rule assigns the new unseen data to the class that is closest to the support vectors on average. This strategy allows the classifier to decide based on the similarity relationships rather than a fixed hyperplane, which can be beneficial when the class distribution is complex and non-linear.

Unlike the Euclidean-SVM, which depends solely on the Euclidean distance, this study investigates the impact of different distance measures in the same framework. Various distance functions, including Euclidean distance, Manhattan distance, Chebyshev distance, Cosine distance, and Minkowski

distance, were investigated. Each distance defines a classifier and uses the same set of support vectors obtained from the training phase. To ensure a fair and unbiased evaluation with the conventional SVM, the distance-based SVM utilized identical kernel functions and regularization parameter configurations. All models are evaluated on a held-out test set.

3) LSTM Model: In addition to conventional SVM and distance-based SVM, a Long Short-Term Memory was employed as the deep learning baseline for text classification. LSTM is a special type of recurrent neural network that is designed to learn long-term dependencies in sequential data, making it suitable for text classification. The overall workflow of the LSTM was illustrated in Fig. 8.

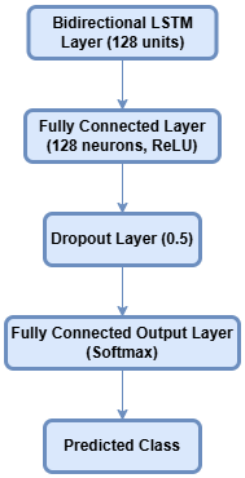

Fig. 8. LSTM workflow

The embedded sequences were passed to a bidirectional LSTM layer with 128 units. This layer processes the input sequence in both forward and backward directions, making it better at capturing the contextual information from both past and future words in the sequences. The output is then passed to a fully connected layer with 128 neurons and a ReLU activation function. This layer refines the learning representations for classification and learns the high-level features. A dropout layer with a dropout rate of 0.5 was then applied. This dropout layer helps to prevent overfitting by randomly deactivating a part of a neuron during training.

The model utilized a fully connected layer with a softmax activation function as the final layer. This layer produces a probability distribution over the target classes for multi-class classification. The model was trained by using the Adam optimizer with a learning rate of 0.001. The loss function utilized was categorical cross-entropy. Early stopping with a patience of 3 was applied to prevent overfitting.

F. Evaluation Metrics

The classification performance of the conventional SVM and distance-based SVM was evaluated by using two complementary metrics: accuracy and macro F1 score. Accuracy provides a general overview of model robustness, which measures the proportion of correctly classified instances to the total number of instances [see Eq. (2)]:

$$Accuracy = \frac{Number\ of\ Correct\ Predictions}{Total\ Number\ of\ Predictions} \quad (2)$$

Macro F1 score captures the harmonic mean of precision and recall. For multi-class classification, the macro F1 score calculates the mean of the F1 score across all the classes independently, then averages them, treating all the classes evenly regardless of the class size [see Eq. (3)]:

$$F1_{macro} = \frac{F1_1 + F1_2 + \cdots + F1_N}{N} \quad (3)$$

where, N is the number of classes.

Accuracy was used as the primary metric to assess the performance comparison, while the macro F1 score provided additional insights for model robustness. Both metrics were computed on the test set for each kernel and regularization parameter configuration.

G. Experimental Setup and Evaluation Protocol

This section describes the experimental configuration used to evaluate the conventional SVM and distance-based SVM under a consistent and reproducible environment. The experiment was conducted in Python 3.13.5 by using scikit-learn 1.7.1, Numpy 2.3.2, pandas 2.3.1, and NLTK 3.9.1. To ensure reproducibility, a fixed random seed (random seed=42) was applied consistently across dataset splitting and SVM training. To ensure a fair comparison between SVM, distance-based SVM, and the LSTM model, the training and testing set was consistency between all models. The training data was used to build the model, while the held-out test set was utilized to evaluate the model's performance. To enable a fair comparison between SVM and distance-based SVM, both models:

- Identical TF-IDF numerical representation.
- Shared the same kernel function (linear, polynomial, RBF, and sigmoid) and regularization parameter ($C = 1, 10, 10^2, 10^3, 10^4, 10^5$).

To ensure a fair comparison between the SVM-based methods and LSTM, LSTM was conducted under the same dataset split and fixed random seed of 42. Final performance was evaluated on the test set by using accuracy and macro F1 score as the primary metrics.

III. Results and Discussion

A. Overall Performance Comparison Across SVM and Distance-Based SVM

This section presents the classification performance comparison of conventional SVM with each distance-based SVM variant, including Euclidean, Manhattan, Chebyshev, Cosine, and Minkowski across three text classification datasets: AG News, BBC News, and DBpedia Ontology classification dataset under various configurations. The performance was evaluated by using accuracy and F1 score, as presented in the Appendix (see Table I to Table VI) and illustrated in Fig. 9 to Fig. 14.

Fig. 9 to Fig. 11 demonstrate the accuracy of conventional SVM and distance-based SVM variants across different kernel and regularization parameter values on AG News, BBC News,

and DBpedia Ontology classification datasets. Each subfigure corresponds to a specific method, including conventional SVM and each distance-based variant. The individual curve represents a different kernel function. The horizontal axis shows the regularization parameter on a logarithmic scale, while the vertical axis demonstrates the accuracy in percentage. The exact numerical result is provided in the Appendix (see Table I to Table III).

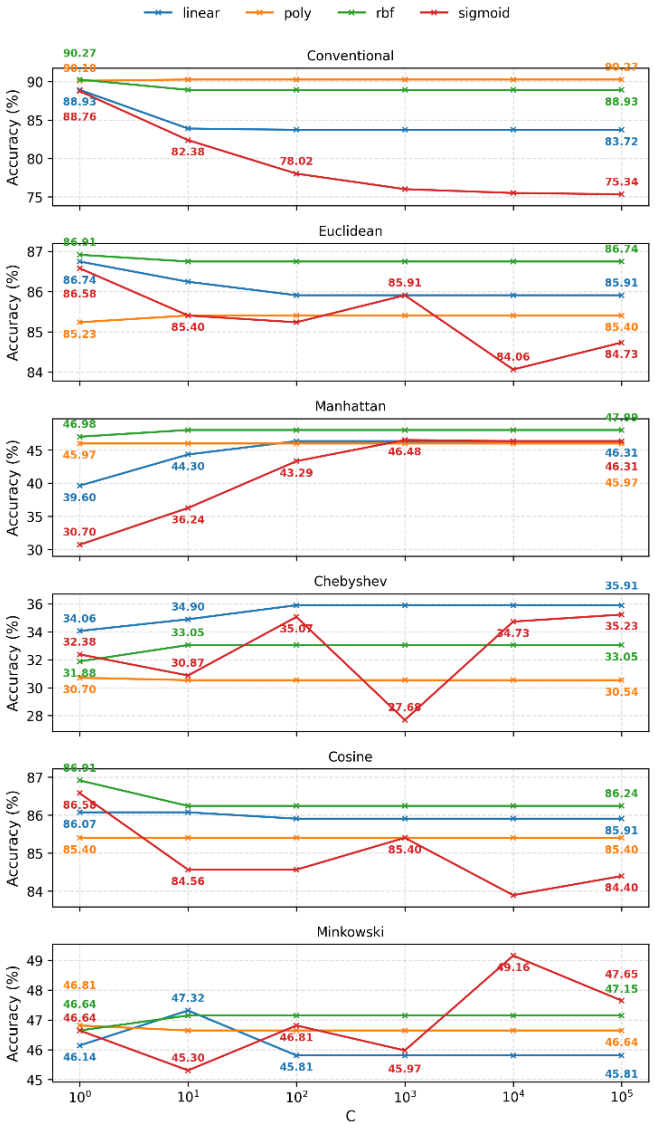

Fig. 9. Accuracy of the AG News dataset.

In addition to accuracy, the F1-score was also employed to account for class imbalance and provide a more comprehensive comparison of classification performance. Fig. 12 to Fig. 14 demonstrate the F1 score under an identical experimental configuration for all datasets. The exact numerical result is provided in the Appendix (see Table IV to Table VI).

Across all three datasets, the accuracy and the F1 score behaved very similarly under identical hyperparameter configurations within the same dataset. This indicates that the class imbalance did not distort the conclusion. The performance differences are not caused by the class imbalance, and confirms the robustness of the observation beyond accuracy alone.

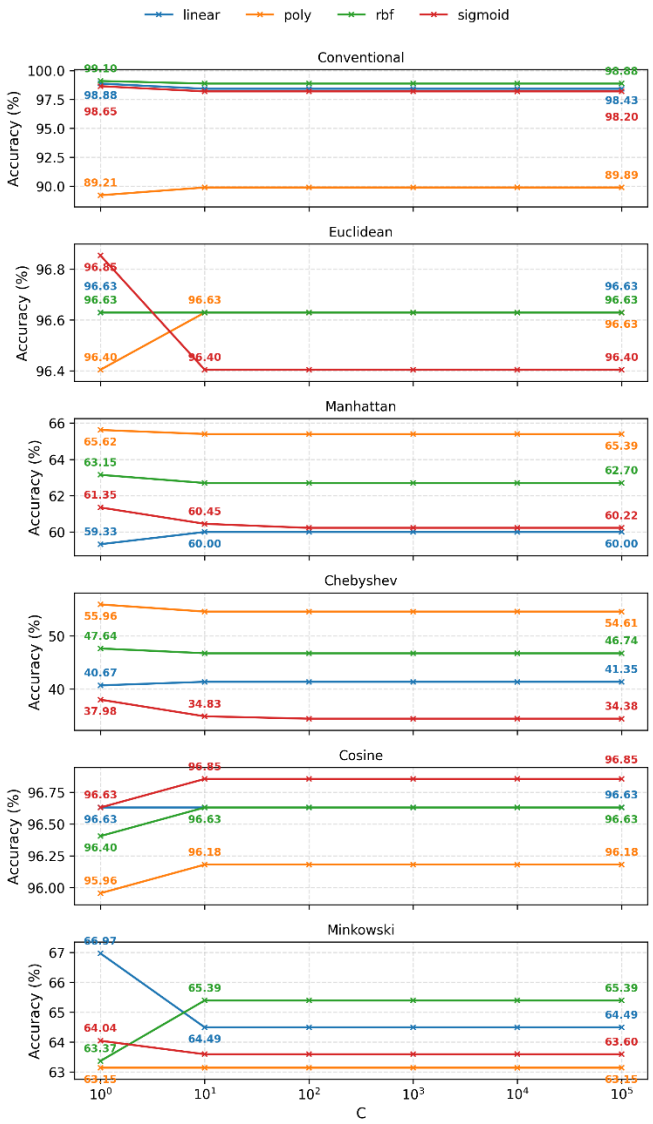

Fig. 10. Accuracy of the BBC News dataset.

Across all datasets, conventional SVM consistently achieves the peak in accuracy and in the F1 score, provided that the kernel and regularization parameters were carefully tuned. Specifically, the highest accuracy of 90.27% was obtained on the AG News dataset under the RBF kernel at C=1 and poly kernel at higher C values, 99.10% from BBC News by using the RBF kernel at C=1, and 95.48% on the DBpedia dataset under the linear kernel at C=10. However, the optimal kernel-regularization parameter combination varied across different datasets, showing its dataset-specific sensitivity.

Among the distance-based SVM variants, Euclidean and Cosine distance achieve competitive performance, closely approaching conventional SVM with only a little degradation in accuracy and F1 score across all datasets. Compared to the peak accuracy of conventional SVM, the performance

reduction remains bounded, with gaps of approximately 3-4% on the AG News dataset, 1-2% on the BBC News dataset, and 4-5% on the DBpedia dataset, indicating their strong discriminative capability. Their results remain consistently high, indicating their robustness in the text classification task.

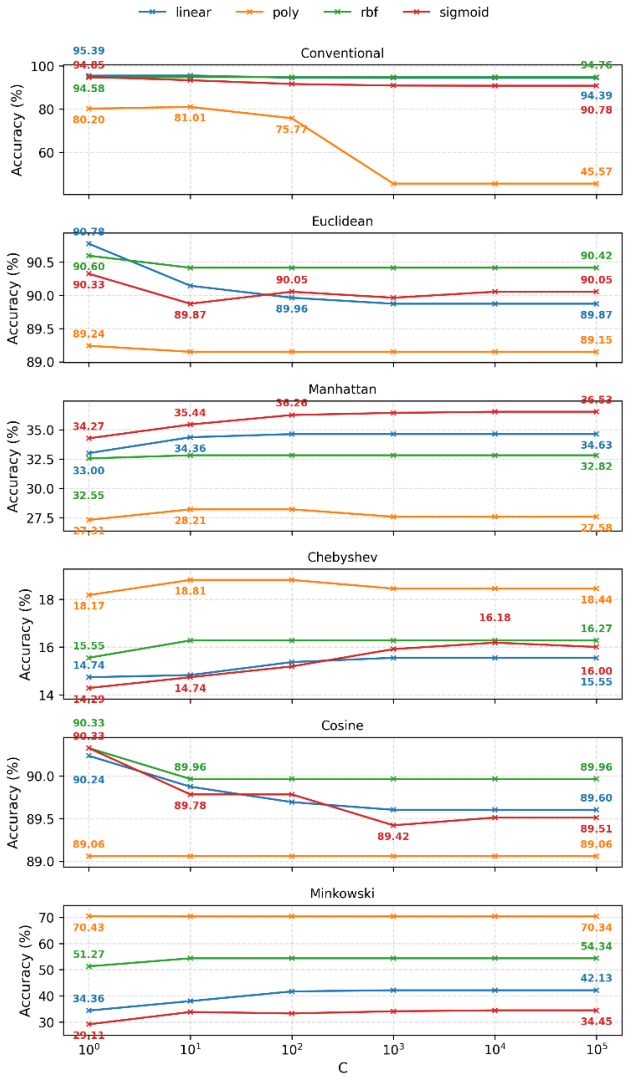

Fig. 11. Accuracy of the DBpedia Ontology classification dataset.

In contrast, the other distance-based SVM variants, including Manhattan, Chebyshev, and Minkowski distance-based SVM variants, consistently exhibit substantially lower performance across all datasets. These distances have low discriminative power in high-dimensional text representations, resulting in substantially lower accuracy and F1 score across kernel and regularization parameters.

Overall, the results indicate that the conventional SVM retains its position as the top performer when it is carefully tuned. The distance-based SVM, which uses Euclidean and Cosine distance, offers a strong trade-off between performance and robustness, making it suitable when excessive hyperparameter tuning is impractical and costly. This consistent trend was observed across all datasets with varying sizes and characteristics, indicating that the observed behaviors are not dataset-specific.

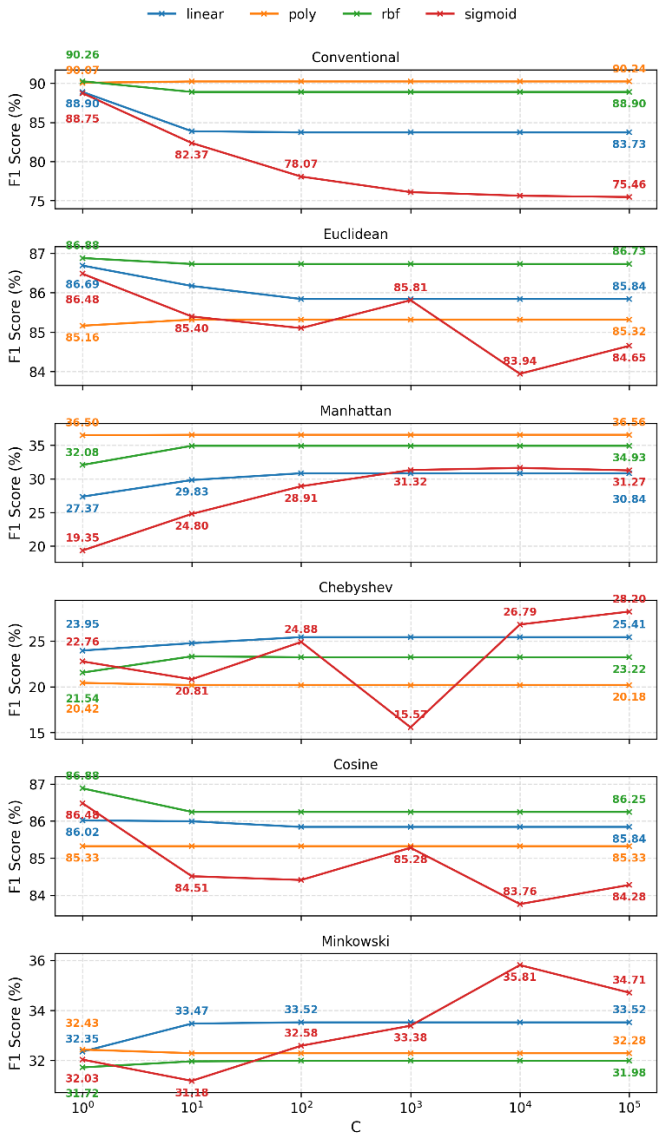

Fig. 12. F1 score of the AG News dataset.

B. Sensitivity of Conventional SVM to Kernel Functions and Regularization Parameters

This section evaluates the classification performance with respect to different kernel functions and regularization parameters, emphasizing the performance stability rather than the peak performance. The sensitivity of performance to hyperparameters is a critical issue for SVM classification tasks, as an inappropriate kernel function or regularization parameter may lead to substantial degradation in performance.

The conventional SVM exhibits a noticeable sensitivity to both kernel function and regularization parameter across all three datasets. While high accuracy and F1 score were obtained when the optimal combination of kernel and regularization parameter was chosen, the performance fluctuates significantly when the suboptimal combination of hyperparameters was

employed. For instance, on the AG News dataset, the sigmoid kernel demonstrates a noticeable performance degradation, dropping from 88.76% to 75.34% as the value of the regularization parameter increases. Similarly, for the BBC News dataset, the linear, RBF, and sigmoid kernels exhibit a near-optimal performance with accuracy approximately at 98-99%, but a clear performance gap is observed when switching the kernel to polynomial, where accuracy is maintained at 89-90%. In addition, on the DBpedia ontology classification dataset, the polynomial kernel demonstrates a severe decline in performance, dropping from 80.20% to 45.57% as the value of the regularization parameter increases. These observations highlight that conventional SVM performance was heavily dependent on dataset-specific hyperparameter tuning.

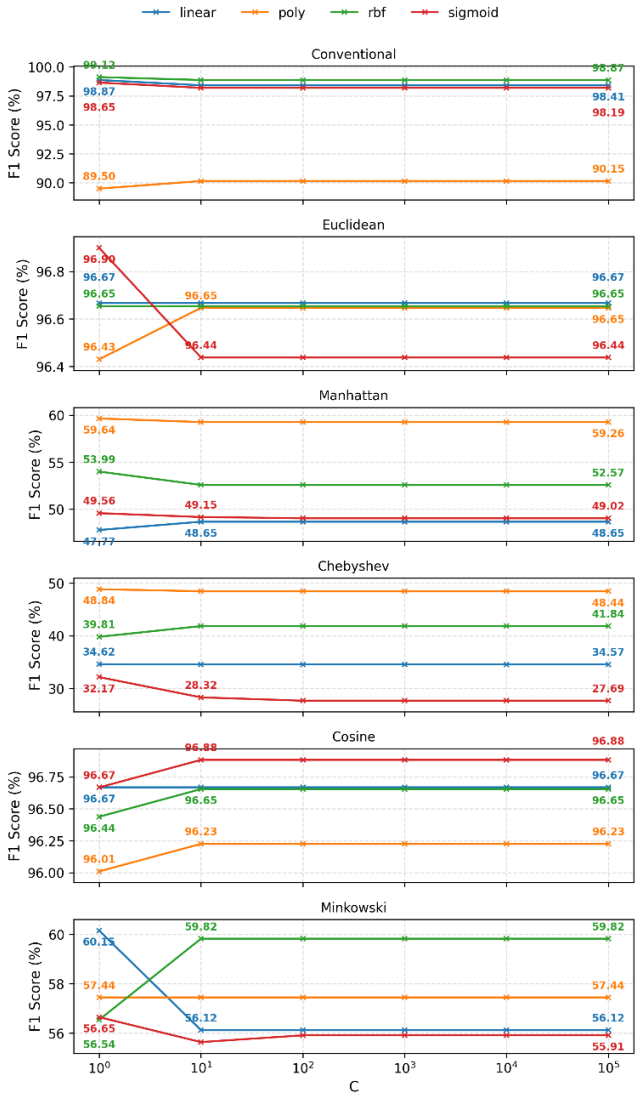

Fig. 13. F1 score of the BBC News dataset.

In contrast, the distance-based SVM variants, which utilize Euclidean and Cosine distance, demonstrate a substantially reduced fluctuation in performance across different kernels and regularization strengths. As illustrated in Fig. 9 to Fig. 14, their accuracy and F1 score exhibit nearly flat performance curves over all kernels and regularization strengths across all datasets. This minimal performance variation was bounded within a narrow margin, generally within 0-3%, suggesting that these methods exhibit more stable behavior under hyperparameter changing. This robustness is particularly evident in the DBpedia dataset, where Euclidean and Cosine exhibit a stable performance, even though the conventional SVM experiences a sharp decline in performance.

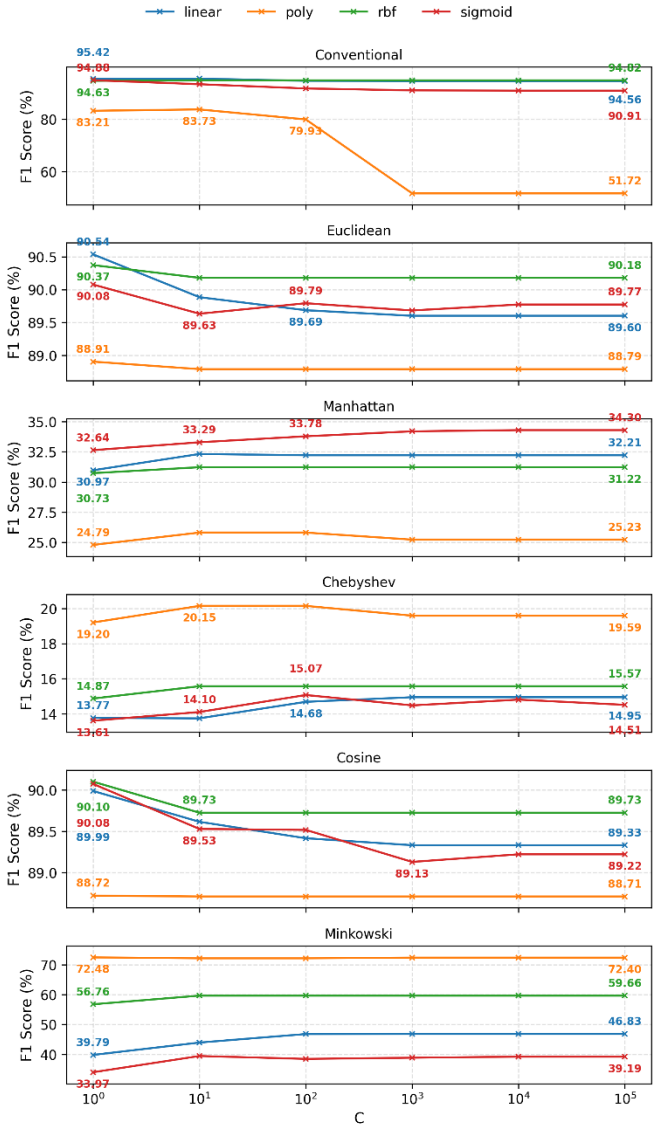

Fig. 14. F1 score of the DBpedia Ontology classification dataset.

The other distance-based SVM variants, which employed Manhattan, Chebyshev, and Minkowski distance, demonstrate low performance regardless of kernel and regularization parameter. The consistency across the different hyperparameter configurations suggests that for these distances, the choice of distance measures itself essentially limits the discriminative power. These distances may be less sensitive to the geometry in the high-dimensional, sparse TF-IDF vectors, making the average distance to support vectors not vary enough to support accurate classification. As a result, adjusting the kernel function and regularization parameter does not bring a significant impact on improving the classification performance.

Overall, these results clearly indicate the trade-off between peak performance and performance robustness. The conventional SVM can achieve peak performance when hyperparameter tuning is optimal. In contrast, Euclidean and Cosine-based SVM variants offer a more stable alternative, exhibiting lower variation across different kernel functions and regularization parameters, making them suitable for environments where exhaustive hyperparameter tuning was impractical.

C. Interpretation of Distance Metrics in High-Dimensional Text Classification

The text document was represented as a TF-IDF numerical representation. These representations produce high-dimensional and sparse vectors, where most of the values are zero. In this case, the choice of distance metric plays an important role in classification performance.

The Euclidean and Cosine distance-based SVM variants demonstrate strong and consistent performance across all datasets. Cosine distance measures the similarity of documents based on the orientation of feature vectors, emphasizing the relative term utilized pattern, making it effective in capturing the semantic similarity. This property plays an important role in text classification, as documents in the same category share a similar term distribution. Euclidean distance also performs well due to TF-IDF representation, which places the documents on a similar scale, making the distance comparison more meaningful. The document with similar patterns stays closer together, while the document from a different class is farther, leading to a reliable decision boundary for text classification.

Furthermore, distance-based SVMs may be more suitable for high-dimensional sparse data, given document representations such as TF-IDF, which primarily capture word-occurrence patterns rather than dense numerical relationships. In such feature spaces, the documents from the same classes often form local clusters with similar feature distributions. Although the performance is slightly lower than the peak accuracy of fine-tuned conventional SVM, their reduced sensitivity to kernel function and regularization parameters makes them more suitable in scenarios where extensive hyperparameter tuning or computational resources are limited.

In contrast, the distance-based SVM variants that employ Manhattan, Chebyshev, and Minkowski distance consistently perform weakly across all datasets. This behavior may relate to the geometric properties of high-dimensional sparse TF-IDF representations. Manhattan distance accumulates the absolute differences across all dimensions, making many small feature differences contribute equally to the final distance. Chebyshev distance only focuses on the feature with maximum distance, which means that the classification is dominated by one word, thus ignoring the overall document similarity, which significantly degrades the classification performance since the document's meaning comes from many words, not one. Similarly, the Minkowski distance with p=3 places greater emphasis on larger feature differences, which may distort the similarity relationships among sparse document vectors. As a result, these distances may be less effective in preserving meaningful document relationships in sparse text representations, regardless of kernel choice or regularization strength. This indicates that for distance-based SVM, the choice of distance plays a more important role than the kernel and regularization in high-dimensional classification datasets.

For the text classification task, if the environment is feasible for exhaustive hyperparameter tuning, the conventional SVM is recommended. However, when a rapid development is prioritized or when resources are limited and costly, the Euclidean and Cosine distance SVM variants are a preferable alternative. For example, it is suitable for the large-scale text system and resource-constrained environments.

D. Performance Comparison with LSTM

To further evaluate the effectiveness of the distance-based SVM variants, a comparison was conducted with a deep learning method, namely Long Short-Term Memory (LSTM).

Unlike the SVM-based methods, which were conducted under varied hyperparameter configurations, the LSTM model was trained using stochastic gradient-based optimization. As a result, the LSTM was reported with the accuracy and F1 Score under the same random seed as SVM, while the SVM-based methods were reported with their best performing configurations under varying hyperparameter scenarios. The results were reported in Fig. 15 and Fig. 16.

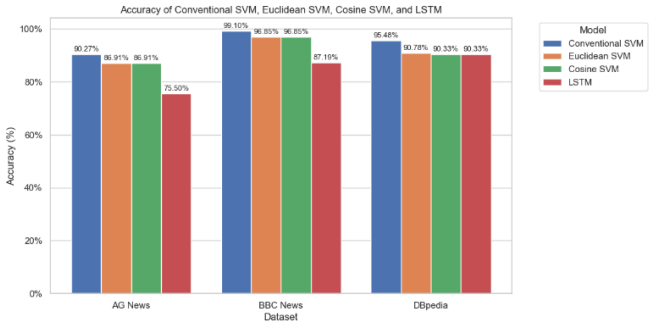

Fig. 15. Accuracy of Conventional SVM, Euclidean SVM, Cosine SVM, and LSTM.

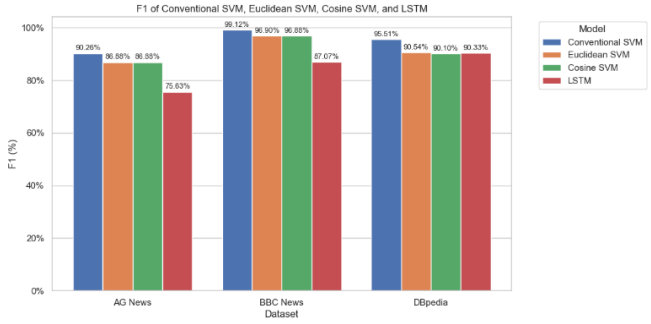

Fig. 16. F1 score of Conventional SVM, Euclidean SVM, Cosine SVM, and LSTM.

Across all the datasets, the SVM-based approaches consistently outperform LSTM. For the AG News dataset, the conventional SVM achieves an accuracy of 90.27%, and the F1 score of 90.26%; the Euclidean and Cosine-based SVMs achieve slightly lower but comparable performance with an accuracy of 86.91% and the F1 score of 86.88%. In contrast, the LSTM model achieves a notably lower accuracy of 75.50% and the F1 Score of 75.63%.

A similar trend was observed in the BBC News dataset. The conventional SVM achieves a near-perfect performance with an accuracy of 99.10% and the F1 score of 99.12%. The Euclidean and Cosine-based SVMs achieved a comparable performance with a slight degradation, with accuracy and F1 score falling between 96.8% and 97%. The LSTM model only achieves an accuracy of 87.19% and an F1 score of 87.07%, which is much lower than the SVM-based methods, indicating it is less effective in capturing the patterns compared to SVM-based methods.

For the DBpedia dataset, although the LSTM exhibits an obvious improvement compared to other datasets with an accuracy and F1 score of 90.33%, it still falls behind compared to SVM models with accuracy and F1 score above 95%, and comparable with the distance-based SVM, which includes Euclidean and Cosine that achieve similar accuracy and F1 Score.

Overall, the results demonstrate that the SVM-based models, including both conventional and distance-based variants, including Euclidean and Cosine, outperform the LSTM model under these three datasets. Notably, the Euclidean and Cosine-based SVM variants provide a strong balance between performance and stability, achieving results close to conventional SVM while reducing the sensitivity to hyperparameter changes.

IV. Conclusion

This study evaluates both conventional SVM and distance-based SVM, which incorporate various distance measures on three text classification datasets with varying size, class complexity, and text length. The aim is to assess both the peak performance and robustness to different kernel functions and regularization parameters.

From the experimental results observed across three text classification datasets, conventional SVM can achieve the highest peak accuracy provided the kernel functions and regularization parameters were fine-tuned. However, the performance exhibits substantial degradation when suboptimal hyperparameters are chosen. In contrast, the distance-based SVM variants that employed Euclidean and Cosine distance achieve a relatively slightly lower peak accuracy but maintain consistent performance across various kernels and regularization parameters. Other distance-based SVM variants, including Manhattan, Chebyshev, and Minkowski distance-based SVM, consistently performed poorly across all datasets.

The observed robustness of Euclidean and Cosine-based SVM variants reduces the sensitivity to kernel function and regularization parameter changes, making them suitable for scenarios where excessive hyperparameter tuning is computationally costly or impractical. This study provides practical guidance for selecting the SVM variants for text classification tasks, especially for resource-restricted environments.

In addition, the comparison with LSTM models shows that SVM-based models, including the conventional SVM and the high-performing distance-based variants (Euclidean and Cosine), consistently outperform LSTM models in both accuracy and F1 score across all datasets. These findings suggest that the traditional SVM-based models remain highly effective for the text classification task under the studied settings.

Future work can be extended by conducting a comprehensive evaluation with a deep learning approach, such as an advanced recurrent network or transformer-based models (e.g., BERT). The evaluation should be conducted under a unified experimental protocol, including consistent data preprocessing, train-test splits, and evaluation metrics to ensure a fair and systematic comparison across different models. In addition, further investigation can be carried out into other text representation techniques and large-scale text datasets to assess the generalization capability of the proposed approaches.

In short, the Euclidean- and Cosine-based SVM variants offer a robust and reliable alternative to conventional SVMs for text classification applications where hyperparameter tuning is limited.

***Abstract*—This study presents a Pareto-optimized Model Predictive Control (MPC) framework for dynamically feasible three-dimensional trajectory generation in robotic manipulators operating under physical constraints. Unlike conventional interpolation-based methods that emphasize geometric smoothness while neglecting system dynamics, the proposed approach integrates a second-order discrete-time model with explicit constraints on position, velocity, and acceleration, ensuring physically consistent motion profiles. A multi-objective optimization strategy is introduced, combining grid search with Pareto front analysis to systematically tune key MPC parameters, including prediction horizon and discretization step. This enables a principled trade-off between tracking accuracy and control effort, addressing a critical limitation in existing MPC implementations that rely on heuristic parameter selection. Experimental results demonstrate that the proposed method achieves competitive tracking performance while significantly improving trajectory smoothness and reducing acceleration peaks compared to spline-based and linear interpolation approaches. The framework maintains real-time feasibility with computation times below 20 ms per control cycle, making it suitable for practical deployment in robotic systems. Furthermore, the integration of learning-based trajectory generation highlights the adaptability of the approach in complex and dynamic environments. Overall, the proposed methodology offers a scalable, interpretable, and computationally efficient solution that bridges the gap between geometric trajectory planning and physically realizable robotic motion, contributing to the advancement of control-aware trajectory generation in modern robotic applications.**

Keywords*—Model Predictive Control; trajectory planning; robotic manipulators; Pareto optimization; multi-objective optimization; dynamic constraints; real-time control; 3d motion planning

I. Introduction

Robotic manipulators have become indispensable components of modern intelligent systems, playing a pivotal role in industrial automation, precision manufacturing, medical robotics, and space exploration. Their increasing deployment in complex and dynamic environments has significantly raised the demands placed on motion planning algorithms, particularly in terms of accuracy, robustness, and physical feasibility. In such settings, trajectory generation is no longer a purely geometric problem but must incorporate the physical limitations of actuators and the dynamic behavior of the system [1]. Consequently, the development of advanced trajectory planning strategies that ensure both precision and feasibility has emerged as a critical research direction in robotics.

Traditional trajectory generation approaches, including polynomial interpolation, cubic splines, and B-splines, have been widely adopted due to their computational simplicity and ability to produce smooth paths. These methods are particularly effective in scenarios where geometric continuity is the primary concern. However, they inherently lack awareness of system dynamics and constraints, such as bounded velocity, acceleration, and actuator capabilities [2]. As a result, trajectories generated using purely geometric techniques may be mathematically smooth yet physically infeasible when executed on real robotic platforms. This limitation becomes especially pronounced in high-speed or safety-critical applications, where violations of dynamic constraints can lead to instability or mechanical degradation [3].

To overcome these challenges, control-oriented approaches have gained increasing attention, with Model Predictive Control (MPC) emerging as a particularly powerful framework for trajectory generation. Unlike traditional planners, MPC integrates system dynamics directly into the optimization process, enabling the generation of trajectories that are both dynamically consistent and constraint-compliant [4]. By solving a finite-horizon optimization problem at each control step, MPC can anticipate future system behavior and adjust control inputs accordingly. This predictive capability allows for the simultaneous consideration of multiple objectives, such as tracking accuracy, smoothness, and energy efficiency, within a unified mathematical formulation [5].

Despite its advantages, the practical application of MPC in robotic trajectory planning is often hindered by challenges related to parameter selection and computational efficiency. Key parameters, such as the prediction horizon and discretization time step, significantly influence controller performance and must be carefully tuned to balance accuracy

*Corresponding author

and responsiveness [6]. In many existing studies, parameter tuning is performed empirically or through trial-and-error, which limits reproducibility and generalizability across different robotic systems [7]. Furthermore, the trade-offs between competing objectives, such as minimizing tracking error versus reducing control effort, are rarely explored in a systematic and quantitative manner [8].

In this context, the present study introduces a Pareto-optimized MPC framework for three-dimensional trajectory generation in robotic manipulators, emphasizing both dynamic feasibility and multi-objective performance. By integrating a second-order dynamic model with structured parameter optimization, the proposed approach enables the systematic exploration of trade-offs between trajectory accuracy and control smoothness [9]. The use of Pareto front analysis provides a principled mechanism for selecting optimal parameter configurations tailored to specific application requirements [10]. Moreover, the framework is designed with real-time applicability in mind, ensuring that computational demands remain compatible with practical robotic control systems [11].

II. Related Works

Trajectory planning for robotic manipulators has been extensively investigated, with early approaches primarily relying on geometric interpolation techniques. Methods such as cubic splines and B-splines have been widely adopted due to their ability to generate smooth and continuous paths across predefined waypoints [12]. These approaches ensure continuity in position and higher-order derivatives, making them suitable for applications requiring visually smooth motion profiles. However, their formulation is fundamentally geometric and does not explicitly incorporate system dynamics or actuator constraints, which limits their applicability in real-world robotic systems [13]. As robotic platforms evolve toward higher precision and speed, the gap between geometric smoothness and physical feasibility becomes increasingly evident.

To address these shortcomings, various extensions of spline-based techniques have been proposed. For instance, non-uniform rational B-splines (NURBS) and adaptive spline formulations provide enhanced local control over trajectory shaping, enabling more flexible path design in complex environments [14]. Additionally, hybrid interpolation methods combining spline generation with heuristic constraint handling have been explored to partially account for velocity and acceleration limits [15]. While these methods improve trajectory realism to some extent, they often rely on ad hoc adjustments and lack a principled mechanism for enforcing dynamic feasibility. As a result, their performance may degrade in scenarios involving high curvature or abrupt motion transitions [16].

Parallel to interpolation-based methods, optimization-driven trajectory planning approaches have gained significant attention. Linear and nonlinear programming techniques have been employed to generate trajectories that satisfy kinematic and dynamic constraints simultaneously [17]. These approaches often formulate trajectory generation as a constrained optimization problem, where objectives such as path length, smoothness, and energy consumption are minimized. Although effective, these methods can be computationally expensive, particularly for high-dimensional robotic systems, and may struggle to achieve real-time performance in dynamic environments [18]. Furthermore, the selection of appropriate objective weights remains a challenging task, often requiring manual tuning.

Model Predictive Control (MPC) has emerged as a powerful alternative that integrates system dynamics directly into the trajectory planning process. By solving a finite-horizon optimization problem at each control step, MPC enables predictive and adaptive control of robotic motion [19]. Its ability to explicitly incorporate constraints on position, velocity, and acceleration makes it particularly suitable for high-performance applications [20]. MPC has been successfully applied in various domains, including autonomous vehicles, aerial robotics, and industrial manipulators, demonstrating improved tracking accuracy and robustness under dynamic conditions [21]. Moreover, recent studies have explored the integration of full dynamic models and multi-degree-of-freedom systems within MPC frameworks, further enhancing trajectory realism [22].

Despite these advancements, several challenges remain in the practical deployment of MPC-based trajectory planners. One of the primary issues lies in the selection of controller parameters, such as prediction horizon and sampling interval, which significantly influence performance [23]. Conventional approaches often rely on heuristic or empirical tuning strategies, which may not generalize well across different tasks and environments [24]. To address this limitation, recent works have explored data-driven and optimization-based parameter tuning techniques, including Bayesian optimization and evolutionary algorithms [25]. Additionally, multi-objective optimization frameworks have been introduced to explicitly capture trade-offs between competing performance criteria, such as tracking accuracy and control effort [26]. Pareto front analysis, in particular, has been recognized as an effective tool for identifying optimal parameter configurations in such settings [27].

Recent developments have also focused on enhancing MPC frameworks through integration with perception and learning-based components. For instance, the incorporation of point cloud data and vision-based feedback enables real-time trajectory adaptation in dynamic and uncertain environments [28]. Similarly, learning-based MPC approaches leverage neural networks to approximate system dynamics or optimize control policies, improving computational efficiency and adaptability [29]. Comparative analyses of these methods, summarized in Table I, highlight the diversity of modeling approaches, tuning strategies, and performance outcomes across different applications [30].

TABLE I. COMPARATIVE ANALYSIS OF TRAJECTORY PLANNING AND MPC-BASED METHODS

Ref.	Method Type	Application Domain	Dynamics Model	Constraint Handling	Optimization Strategy	Real-Time Capability	MAE / Accuracy	Key Limitation
[12]	Cubic Spline	Industrial Robotics	None (Geometric)	No	None	Yes	High accuracy	No dynamic feasibility
[13]	B-Spline	Manipulators	None	No	None	Yes	High accuracy	Ignores actuator limits
[14]	NURBS	Complex Path Design	None	Partial	Heuristic	Moderate	Moderate	Complex tuning
[15]	Hybrid Spline	Robotics	Partial	Partial	Heuristic	Moderate	Moderate	Lack of generalization
[17]	Linear Programming	Motion Planning	Kinematic	Yes	Optimization	Low	Moderate	High computation cost
[18]	Nonlinear Optimization	Robotics	Dynamic	Yes	Optimization	Low	High	Computational burden
[19]	MPC	Autonomous Systems	Dynamic	Yes	Predictive	Moderate	High	Parameter sensitivity
[21]	MPC (Extended)	Vehicles/Robotics	Dynamic	Yes	Multi-objective	Moderate	High	Tuning complexity
[22]	Full-Dynamics MPC	Manipulators	Full Dynamics	Yes	Optimization	Low	Very High	High latency
[25]	Bayesian Optimization + MPC	Robotics	Dynamic	Yes	Bayesian	Moderate	High	Implementation complexity
[26]	Multi-objective MPC	Robotics	Dynamic	Yes	Pareto-based	Moderate	High	Trade-off selection
[28]	Perception-driven MPC	Autonomous Systems	Dynamic	Yes	Predictive	Moderate	High	Sensor dependency
[29]	Learning-based MPC	Aerial Robotics	Learned Dynamics	Yes	Neural Optimization	High	Very High	Requires training data
[30]	Hybrid MPC	Mobile Robots	Dynamic	Yes	Mixed	Moderate	High	System-specific tuning

Despite these advances, a unified framework that combines dynamic feasibility, systematic parameter optimization, and real-time performance remains an open research challenge [31]. Existing methods often prioritize specific aspects, such as accuracy or efficiency, without fully addressing the interplay between them [32]. Therefore, there is a clear need for integrated approaches that balance these objectives while maintaining scalability and interpretability [33].

III. MATERIALS AND METHODS

This section presents the methodological foundation of the proposed framework for three-dimensional trajectory generation using Model Predictive Control (MPC). The overall system architecture is illustrated in Fig. 1, while the detailed formulation of the trajectory planning module and the optimization pipeline are depicted in Fig. 2 and Fig. 3, respectively. The proposed methodology integrates dynamic modeling, constrained optimization, and multi-objective parameter tuning to ensure both geometric accuracy and dynamic feasibility.

A. Overall Framework

The complete pipeline, shown in Fig. 1, consists of five sequential stages: input specification, trajectory planning, optimization, comparative evaluation, and output generation. The system receives a set of target waypoints in three-dimensional space along with system parameters and initial conditions. These inputs are transformed into boundary conditions for the MPC-based trajectory planner.

Unlike conventional approaches that separate planning and control, the proposed framework unifies both processes within a predictive optimization structure. This integration allows the system to generate trajectories that are inherently consistent with physical constraints, thereby eliminating the need for post-processing or heuristic corrections.

B. Dynamic Modeling and State Representation

The trajectory planning module, detailed in Fig. 2, is built upon a second-order discrete-time dynamic model that captures both kinematic and inertial properties of the robotic manipulator. The system state at time step k is defined as:

$$x_k = \begin{bmatrix} p_k \\ v_k \end{bmatrix}, \tag{1}$$

where, $p_k \in \mathbb{R}^3$ represents position and $v_k \in \mathbb{R}^3$ denotes velocity. The control input is the acceleration vector $u_k = a_k$.

The system dynamics are described by:

$$p_{k+1} = p_k + v_k \Delta t + \frac{1}{2} a_k \Delta t^2, \tag{2}$$

$$v_{k+1} = v_k + a_k \Delta t, \tag{3}$$

These equations can be expressed in compact state-space form:

$$x_{k+1} = A x_k + B u_k, \tag{4}$$

where, A and $B$are the system matrices determined by the discretization step Δt . This formulation enables efficient integration with MPC solvers and supports predictive trajectory generation over a finite horizon.

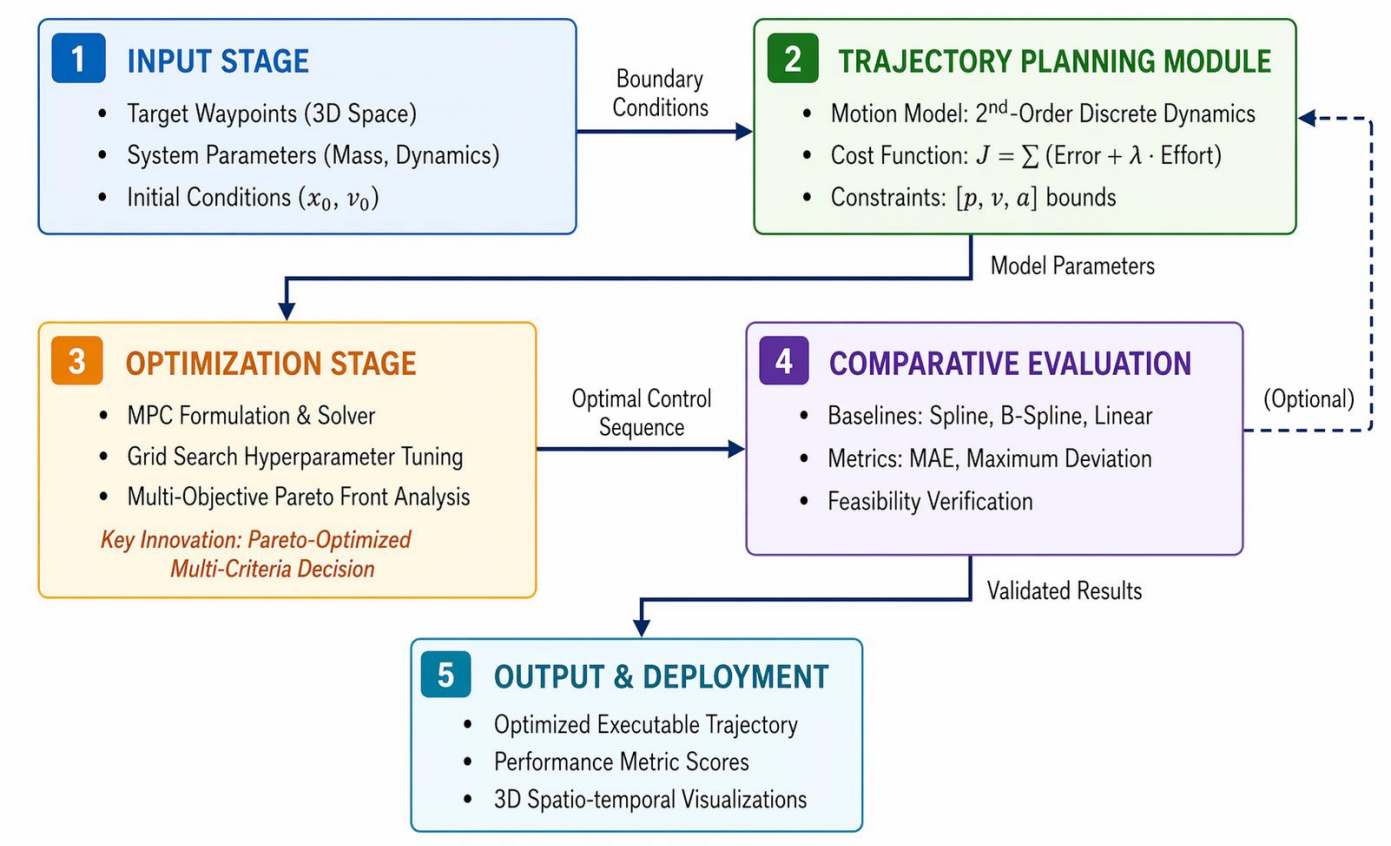

Fig. 1. Overall architecture of the proposed Pareto-optimized model predictive control framework for 3d trajectory generation.

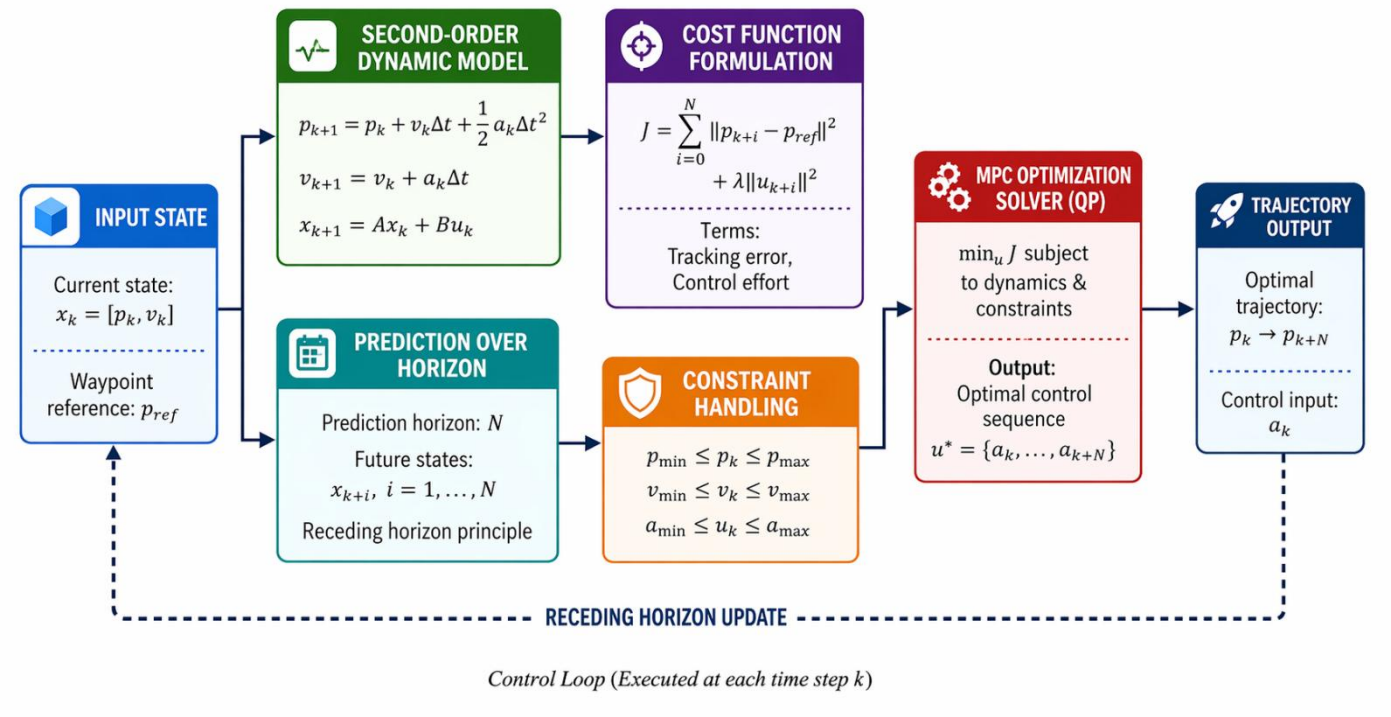

Fig. 2. Detailed trajectory planning module based on model predictive control with second-order dynamics and constraint handling.

C. Model Predictive Control Formulation

At the core of the trajectory planning module is the MPC formulation, which optimizes control inputs over a prediction horizon N. The controller minimizes a multi-objective cost function defined as:

$$J = \sum_{i=0}^{N} \| p_{k+i} - p_{ref} \|^2 + \lambda \| u_{k+i} \|^2, \quad (5)$$

where, p_{ref} denotes the reference trajectory, and λ is a regularization parameter that balances tracking accuracy and control effort.

The optimization is subject to physical constraints:

$$p_{\min} \le p_k \le p_{\max}, v_{\min} \le v_k \le v_{\max}, a_{\min} \le u_k \le a_{\max}, \quad (6)$$

As shown in Fig. 2, the MPC framework consists of four key components: dynamic modeling, prediction over horizon, cost function formulation, and constraint handling. These components are jointly processed within a quadratic programming (QP) solver [34] to produce an optimal control sequence.

D. Receding Horizon Control Strategy

The Model Predictive Control framework operates based on the receding horizon principle, a fundamental concept that enables adaptive and forward-looking decision-making in dynamic systems. At each discrete time step, the controller formulates and solves a finite-horizon optimization problem using the current system state as the initial condition. This optimization predicts future system behavior over a specified horizon and computes an optimal sequence of control inputs that minimizes the defined cost function while satisfying system constraints. However, instead of applying the entire control sequence, only the first control input is executed, and the remaining inputs are discarded.

In the subsequent time step, the optimization process is repeated with updated system information, effectively shifting the prediction horizon forward. This iterative procedure allows the controller to continuously incorporate new state measurements and respond to disturbances, modeling inaccuracies, or environmental changes in real-time. As a result, the receding horizon strategy enhances robustness and flexibility, ensuring that the generated trajectory remains dynamically feasible and aligned with the evolving system conditions [35], [36], [37]. This adaptive behavior is particularly critical in robotic applications, where uncertainties and nonlinear dynamics necessitate continuous re-evaluation of control actions to maintain stability and performance.

The presented algorithm formalizes the trajectory planning process within a receding-horizon MPC framework, ensuring continuous adaptation to system dynamics and reference updates. By explicitly integrating second-order dynamics and constraint handling, the method guarantees that generated trajectories remain physically feasible throughout execution. Furthermore, the structured optimization procedure enables a balanced trade-off between tracking accuracy and control effort, which is critical for high-performance robotic applications. This formulation also facilitates seamless integration with the Pareto-based parameter tuning strategy described in Fig. 3, enhancing both robustness and reproducibility of the overall system.

Algorithm 1. Model Predictive Control for Trajectory Planning

Input:

- *Initial state* $x_0 = [p_0, v_0]$
- *Waypoint sequence* $W = \{w_1, w_2, \dots, w_m\}$
- *MPC parameters: prediction horizon N, time step* Δt*, regularization parameter* λ
- *System constraints:* $p_{min}, p_{max}, v_{min}, v_{max}, a_{min}, a_{max}$

Output:

- *Dynamically feasible trajectory* $\{p_k\}_{k=0}^{T}$
- *Control input sequence* $\{u_k\}_{k=0}^{T-1}$
- ***Initialization:***

1.1 Set the initial state $x_k \leftarrow x_0$
1.2 Initialize time index $k \leftarrow 0$
1.3 Define prediction horizon N, discretization step Δt*, and weight* λ
1.4 Load waypoint set W and select initial reference $p_{ref} \leftarrow w_1$
1.5 Initialize storage variables for trajectory $\{p_k\}$*, velocity* $\{v_k\}$*, and control inputs* $\{u_k\}$

- ***Main Control Loop (Receding Horizon):***

While *the final waypoint has not been reached:*

2.1 ***Reference Update and Sub-Goal Selection:***

- *Determine the current target waypoint based on proximity*
- *If the distance* $\| p_k - w_i \|$ *is below a predefined threshold, update* $p_{ref} \leftarrow w_{i+1}$
- *Ensure smooth transition between waypoints without discontinuities*

2.2 ***State Prediction Over Horizon:***

- *Initialize predicted state sequence* $x_{k|k} = x_k$
- *For* $i = 0$ *to* $N-1$*:*

$$x_{k+i+1|k} = Ax_{k+i|k} + Bu_{k+i}$$

- *Construct predicted position and velocity sequences:*

$$\{p_{k+i|k}, v_{k+i|k}\}, i = 1, \dots, N$$

2.3 ***Cost Function Construction:***

Define the multi-objective cost function:

$$J = \sum_{i=0}^{N-1} \| p_{k+i|k} - p_{ref} \|^2 + \lambda \| u_{k+i} \|^2$$

Optionally include terminal cost:

$$J_{terminal} = \| p_{k+N|k} - p_{ref} \|^2$$

Combine into total objective:

$$J_{total} = J + J_{terminal}$$

2.4 ***Constraint Formulation:***

- *Enforce system constraints for all predicted steps:*

$$p_{min} \le p_{k+i|k} \le p_{max}$$
$$v_{min} \le v_{k+i|k} \le v_{max}$$
$$a_{min} \le u_{k+i} \le a_{max}$$

- *Include optional soft constraints with penalty terms if needed*

2.5 ***Optimization Problem Solution:***

- *Solve the quadratic programming (QP) problem:*

$$\min_{u_{k:k+N-1}} J_{total}$$

subject to system dynamics and constraints

- *Obtain optimal control sequence:*

$$u^* = \{u_k^*, u_{k+1}^*, \dots, u_{k+N-1}^*\}$$

2.6 ***Control Application:***

Apply only the first control input:

$$u_k = u_k^*$$

Store control input in sequence

2.7 ***System State Update:***

Update system state using discrete dynamics:

$$x_{k+1} = Ax_k + Bu_k$$

Extract updated position and velocity:

$$p_{k+1}, v_{k+1}$$

2.8 ***Trajectory Logging:***

Store p_{k+1}, v_{k+1}, *and* u_k

Update trajectory sequence

2.9 ***Horizon Shift (Receding Horizon):***

Increment time index $k \leftarrow k+1$

Shift prediction window forward

Use updated state x_{k+1} *as new initial condition*

- ***Termination Condition:***
  - *Stop when the final waypoint* w_m *is reached within tolerance*
  - *Or when maximum time steps Tare exceeded*
- ***Output Generation:***

4.1 Return optimized trajectory:

$$\{p_0, p_1, \dots, p_T\}$$

4.2 Return control input sequence:

$$\{u_0, u_1, \dots, u_{T-1}\}$$

4.3 Optionally compute performance metrics:

- *Mean Absolute Error (MAE)*
- *Control effort E*
- *Maximum deviation*

E. Multi-Objective Optimization and Parameter Tuning

The optimization stage, illustrated in Fig. 3, introduces a structured approach for tuning MPC parameters using multi-objective optimization. The parameter space is defined as:

$$\Theta = \{(N, \Delta t, \lambda)\} \quad (7)$$

A grid search is performed over this space to evaluate different configurations. For each parameter set θ_i, trajectory simulation is conducted, and performance metrics are computed.

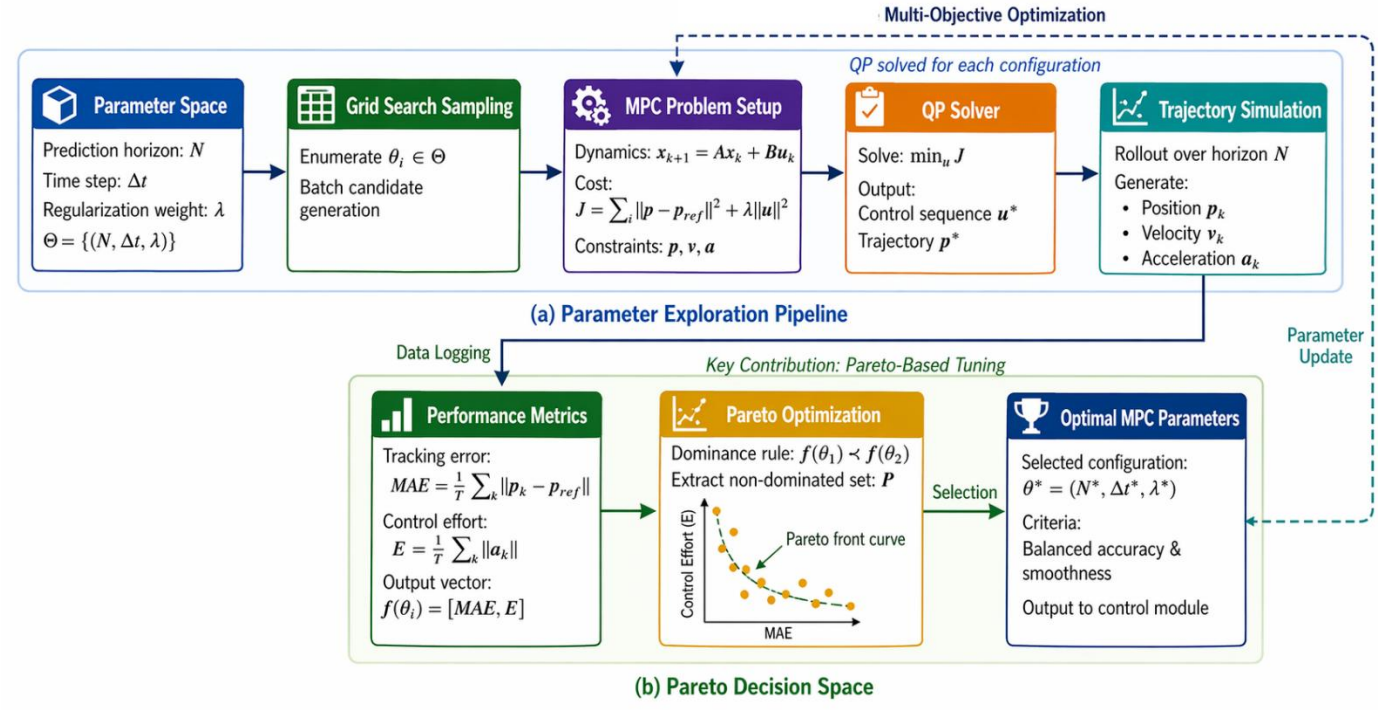

Fig. 3. Optimization pipeline for MPC parameter tuning using grid search and Pareto front analysis.

At the core of the trajectory planning module is the MPC formulation, which optimizes control inputs over a prediction horizon N. The controller minimizes a multi-objective cost function defined as:

Two primary metrics are considered:

Tracking accuracy (MAE):

$$MAE = \frac{1}{T}\sum_{k=1}^{T} \| p_k - p_{ref} \|, \quad (8)$$

Control effort:

$$E = \frac{1}{T}\sum_{k=1}^{T} \| a_k \|, \quad (9)$$

Each configuration produces a performance vector:

$$f(\theta_i) = [MAE, E], \quad (10)$$

F. Pareto Front Analysis

To address the trade-off between accuracy and smoothness, Pareto optimality is employed. A configuration θ_1 dominates θ_2 if:

$$f(\theta_1) \prec f(\theta_2) \tag{11}$$

The set of non-dominated solutions forms the Pareto front:

$$\mathcal{P} = \{\theta \mid \nexists \theta' \ \text{δομινατεσ}\ \theta\} \tag{12}$$

As shown in Fig. 3(b), the Pareto front provides a visual representation of optimal trade-offs, enabling systematic selection of controller parameters based on application requirements [38].

Thus, the proposed framework integrates advanced control theory, optimization techniques, and multi-objective analysis into a unified architecture. By combining predictive control with Pareto-based parameter selection, the method achieves a balance between trajectory accuracy and dynamic feasibility, addressing key limitations of existing trajectory planning approaches.

IV. Results

This section presents the experimental results of the proposed trajectory generation framework through a progressive analysis of parameter tuning, geometric accuracy, dynamic feasibility, learning-based trajectory refinement, and preliminary real-platform validation. The interpretation is organized sequentially according to Fig. 4 to Fig. 12, so that each result can be understood as part of a coherent evaluation pipeline. Overall, the results show that the proposed framework achieves a favorable balance between tracking accuracy, motion smoothness, and implementation feasibility, while also demonstrating compatibility with both simulation-based and physical robotic settings.

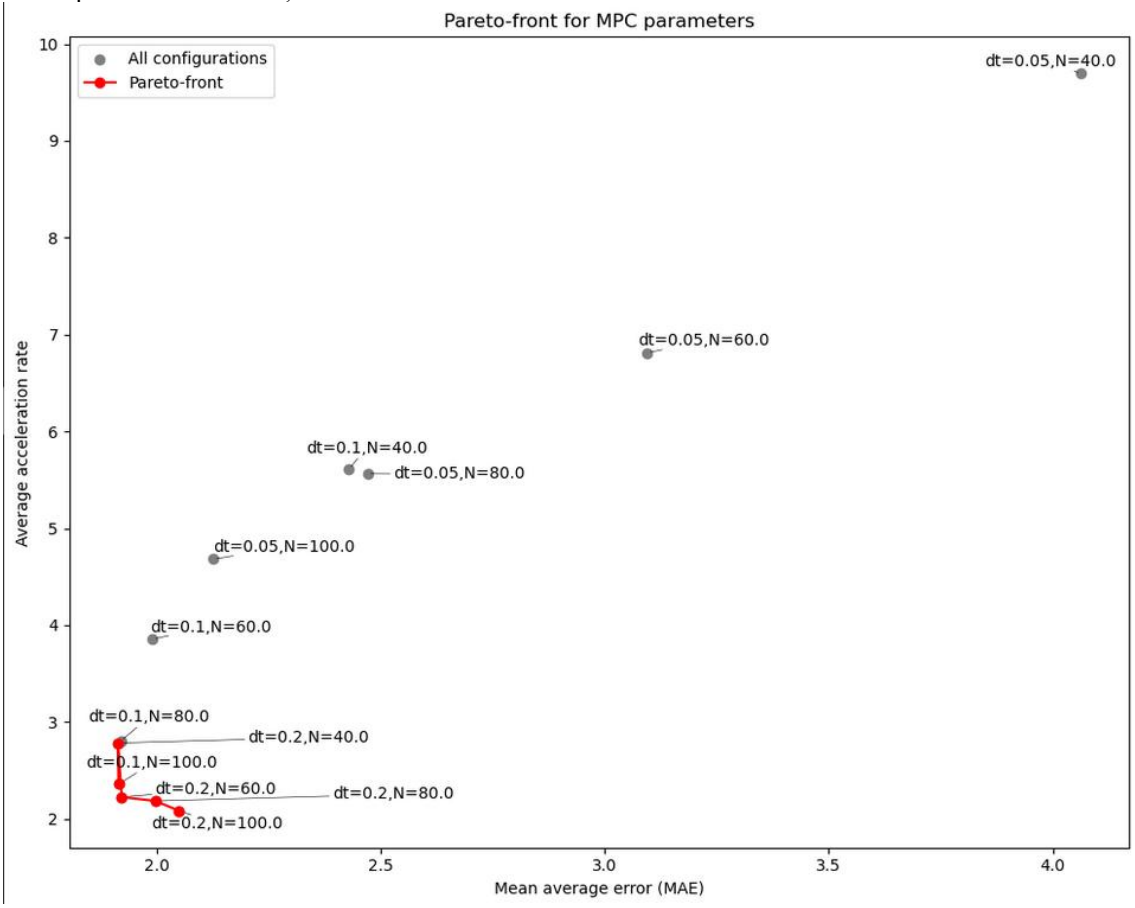

Fig. 4. Pareto front analysis of MPC parameter configurations based on tracking error and control effort.

Fig. 4 presents the Pareto front obtained for the tested MPC parameter combinations, where the horizontal axis corresponds to the mean absolute error (MAE) [39] and the vertical axis represents the average acceleration rate. This figure provides the first layer of evidence regarding the trade-off structure of the optimization problem. All explored configurations are shown as gray markers, while the Pareto-optimal set is highlighted in red. A clear tendency can be observed: configurations with smaller discretization steps and shorter horizons produce larger acceleration values, whereas smoother motion is generally achieved when the horizon is increased and the temporal discretization becomes coarser.

From a control perspective, this result is significant because it verifies that parameter selection cannot be performed using a single metric alone. For example, the configuration with dt=0.05, N=40 lies in the upper-right region of the plot, indicating both high error and excessive acceleration, which makes it undesirable for practical deployment. In contrast, the

cluster of Pareto-optimal solutions around dt=0.2 and N=60 to 100 provides substantially lower control effort with only a limited sacrifice in geometric tracking. Therefore, Fig. 4 validates the usefulness of the proposed Pareto-based multi-objective tuning strategy, since it identifies parameter regions that are more suitable for physically executable trajectories than those obtained through naïve or purely empirical tuning.

The geometric consequences of the chosen control configuration are illustrated in Fig. 5, which compares the generated trajectories in three-dimensional space using MPC, cubic spline interpolation, linear interpolation, and B-spline approximation. Two perspectives are provided in order to reveal spatial deviations more clearly. The spline-based and B-spline trajectories remain close to the waypoint structure and exhibit smooth curvature, while the linear interpolation method produces piecewise straight transitions. The MPC trajectory, shown as a dashed path, preserves the global progression of the motion but does not exactly coincide with the interpolative curves.

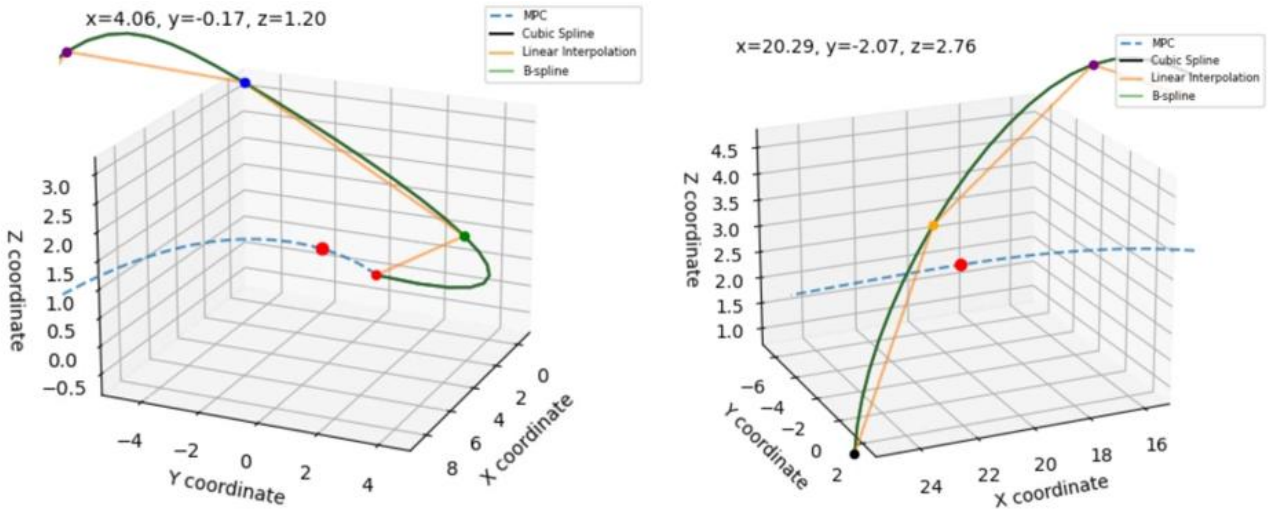

Fig. 5. Three-dimensional trajectory comparison of MPC, cubic spline, linear interpolation, and B-spline methods.

This behavior is expected because the MPC objective is not to replicate a purely geometric reference exactly, but rather to generate a dynamically feasible trajectory under motion constraints. In this sense, the geometric discrepancy visible in Fig. 5 should not be interpreted solely as an error, but as the result of enforcing dynamic admissibility. The figure also indicates that the proposed method avoids unrealistic sharp turns and generates a trajectory that remains smooth in a control-theoretic sense, even when it differs from the exact spline path. Thus, Fig. 5 confirms that the method privileges feasible motion execution over perfect geometric interpolation, which is an important advantage for robotic manipulators operating under acceleration and velocity limits.

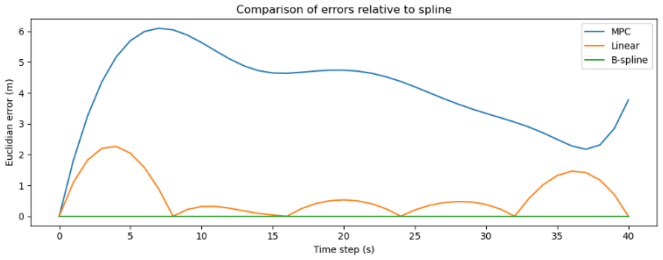

Fig. 6. Euclidean error comparison of trajectory generation methods relative to the spline reference.

The point-wise geometric deviations are quantified more explicitly in Fig. 6, where the Euclidean error relative to the spline trajectory is plotted over time for MPC, linear interpolation, and B-spline. The B-spline curve remains almost coincident with zero throughout the experiment, which indicates that it is extremely close to the spline reference. This is expected because both methods belong to the same family of smooth interpolation techniques. The linear method exhibits moderate oscillatory errors, with distinct local peaks associated with transitions between line segments. The MPC curve shows the largest deviation, particularly in the early and middle stages of the trajectory.

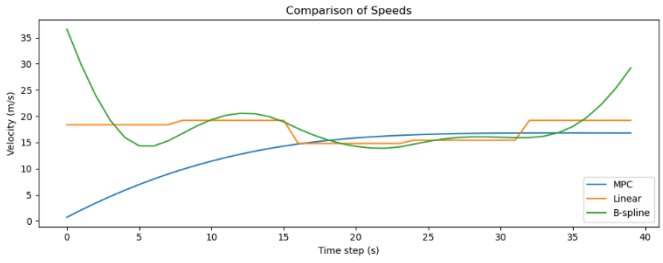

Fig. 7. Velocity profile comparison of MPC, linear interpolation, and B-spline trajectories.

Although the MPC error is higher than that of the interpolation-based methods, the temporal structure of the curve is informative. The deviation increases rapidly at the beginning, stabilizes over the intermediate steps, and then rises again near the end of the trajectory. This suggests that the controller is continuously balancing waypoint attraction with control smoothness and state constraints, rather than aggressively forcing exact geometric coincidence. Therefore, Fig. 6 supports the conclusion that the proposed method

sacrifices a portion of geometric fidelity in order to preserve physical plausibility. For practical robotic systems, this trade-off is often desirable because excessive insistence on geometric exactness may generate infeasible inputs or mechanically stressful motion.

The dynamic characteristics of the generated paths are further examined in Fig. 7, which compares the velocity profiles of the MPC, linear [40], and B-spline [41] methods. The MPC velocity increases gradually and then approaches a relatively stable regime, indicating smooth acceleration and controlled temporal evolution. The linear method produces almost piecewise-constant velocity segments with abrupt changes, which reflects the discontinuous nature of line-based interpolation. The B-spline profile shows larger initial and terminal variations, as well as stronger oscillations in comparison with the MPC solution.

This result is highly relevant because velocity continuity directly affects execution quality in robotic manipulators. A profile such as the one produced by MPC is more compatible with real actuators, since it avoids sudden jumps and supports stable motion generation. By contrast, the linear approach introduces discontinuities that may induce jerky behavior, while the B-spline method, although geometrically smooth, may still produce undesired velocity fluctuations due to the absence of explicit dynamic regularization. Hence, Fig. 7 demonstrates that the proposed MPC framework offers a more physically realistic velocity evolution than the baseline approaches.

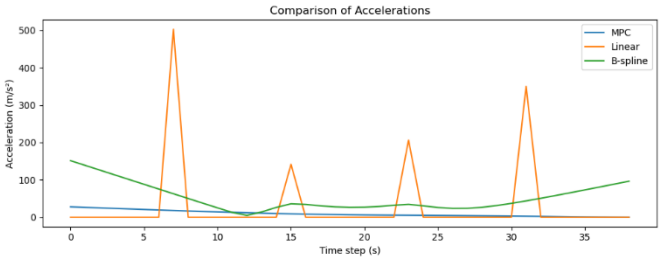

Fig. 8. Acceleration profile comparison under high-variation configuration for different trajectory generation methods.

The differences become even more pronounced in Fig. 8, where the acceleration profiles are shown for the same set of methods. The linear interpolation method [42] exhibits very large spikes, reaching extremely high values at several time steps. These peaks are a direct consequence of sudden changes in velocity at segment boundaries and indicate strongly nonphysical behavior. The B-spline method produces a smoother curve than the linear one, but its acceleration magnitude remains comparatively high over large portions of the trajectory. In contrast, the MPC profile stays low and relatively stable.

This figure is particularly important for validating the proposed framework, because acceleration is directly related to control effort, energy consumption, and actuator stress. A trajectory with large acceleration spikes may be mathematically acceptable in simulation, but it is generally unsuitable for real robotic deployment. The stable and bounded MPC curve in Fig. 8, therefore, provides strong evidence that the proposed controller generates motions that are substantially more feasible from an implementation perspective. In other words, even when the MPC trajectory is not the closest to the spline geometrically, it is clearly superior in terms of dynamic admissibility.

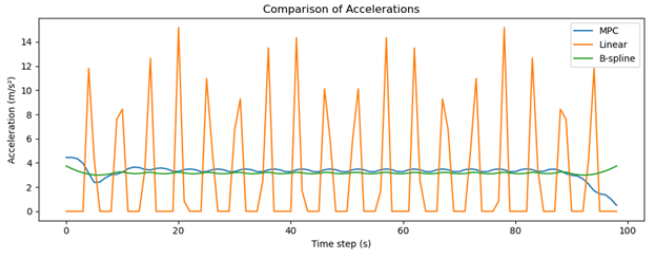

Fig. 9. Acceleration profile comparison under optimized MPC configuration demonstrating improved smoothness.

A second acceleration analysis is given in Fig. 9, corresponding to a different configuration with a longer time horizon. In this case, the MPC profile becomes even more regular, maintaining low variation for most of the execution and only decreasing near the final steps. The linear method still shows repeated impulsive peaks, although their amplitudes are much smaller than in the previous case. The B-spline curve remains smoother than the linear one but still fluctuates more than the MPC result.

The main interpretation of Fig. 9 is that the optimized MPC parameters identified through Pareto analysis are not only theoretically preferable, but also visibly more effective in practice [43]. The controller yields a nearly constant acceleration profile, which implies improved smoothness, reduced mechanical stress, and better suitability for precise manipulation tasks. This result complements Fig. 4 by showing that the benefits of Pareto-based parameter tuning are directly reflected in the actual motion dynamics. Accordingly, Fig. 9 provides experimental confirmation that the proposed tuning strategy improves controller behavior in a tangible and practically meaningful way.

The behavior of the learning-based agent across training episodes is illustrated in Fig. 10, where the generated trajectories are shown for a single target-point scenario. In early episodes, such as Episode 3 and Episode 13, the motion is highly irregular and exhibits unnecessary exploration. The generated paths are circuitous and unstable, indicating that the control policy has not yet converged to a meaningful navigation strategy. By Episode 60, the trajectory becomes more structured, although some residual oscillations are still present. In later episodes, particularly Episodes 100, 144, 156, and 200, the path becomes substantially more direct and stable, connecting the start and goal while appropriately avoiding the obstacle cluster.

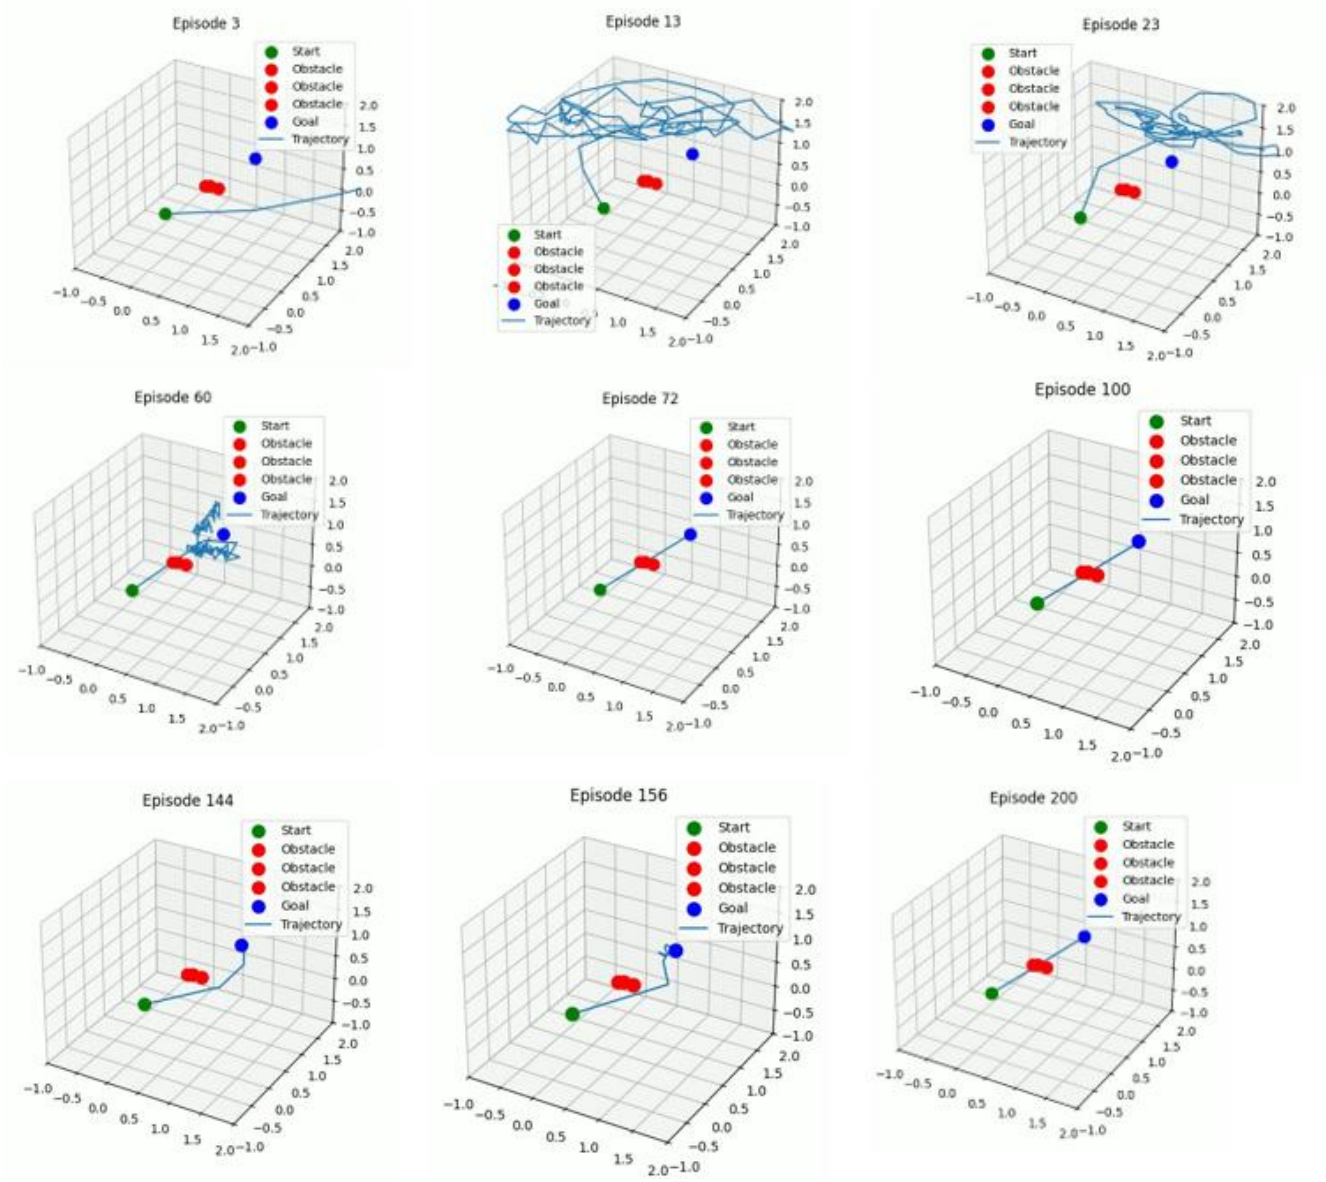

Fig. 10. Evolution of learning-based trajectory generation across training episodes for a single target scenario.

Fig. 10 demonstrates progressive policy improvement through learning. The transition from exploratory and noisy motion to consistent and directed trajectories indicates that the agent successfully internalizes the spatial structure of the environment and learns to generate collision-free motion. From a methodological standpoint, Fig. 10 is important because it shows that the proposed framework can be extended beyond deterministic trajectory planning and can support adaptive behavior in obstacle-rich environments. The convergence trend across episodes suggests that the learned policy complements the model-based components of the framework and may be particularly valuable in settings where waypoint geometry or environmental constraints change over time.

The generalization capability of the learned agent is further demonstrated in Fig. 11, which shows trajectory generation for multiple target points. Two examples are presented, each comparing the generated trajectory with a spline-based reference. In both cases, the learned path follows the global target progression but does not exactly replicate the spline shape. Instead, it constructs a feasible trajectory that moves through the target sequence while preserving obstacle awareness and directional consistency.

This result is noteworthy because multi-target motion planning is more demanding than the single-goal case. The controller or agent must not only approach one terminal point and organize the sequence of movements across multiple intermediate targets. The fact that meaningful trajectories are generated in both examples indicates that the underlying framework possesses a level of structural adaptability. Fig. 11, therefore, suggests that the proposed method is capable of handling more complex planning tasks than single-waypoint tracking and can serve as a basis for scalable multi-stage robotic motion generation.

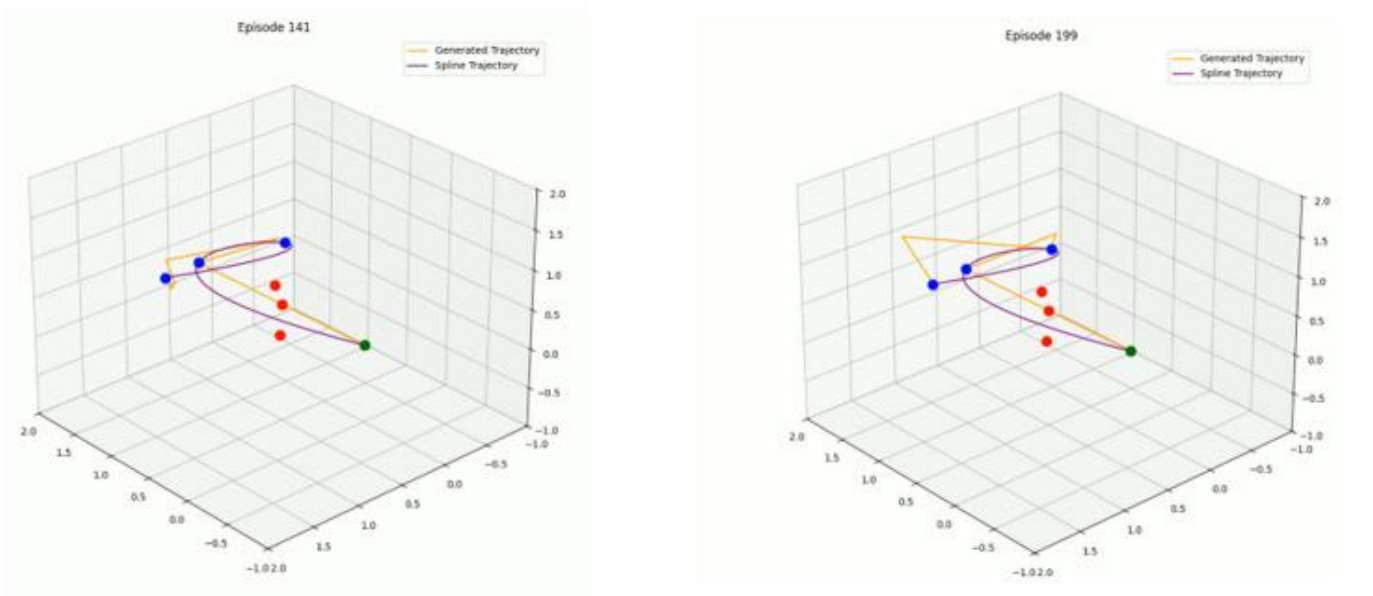

Fig. 11. Trajectory generation for multiple target points using learning-based and spline-based approaches.

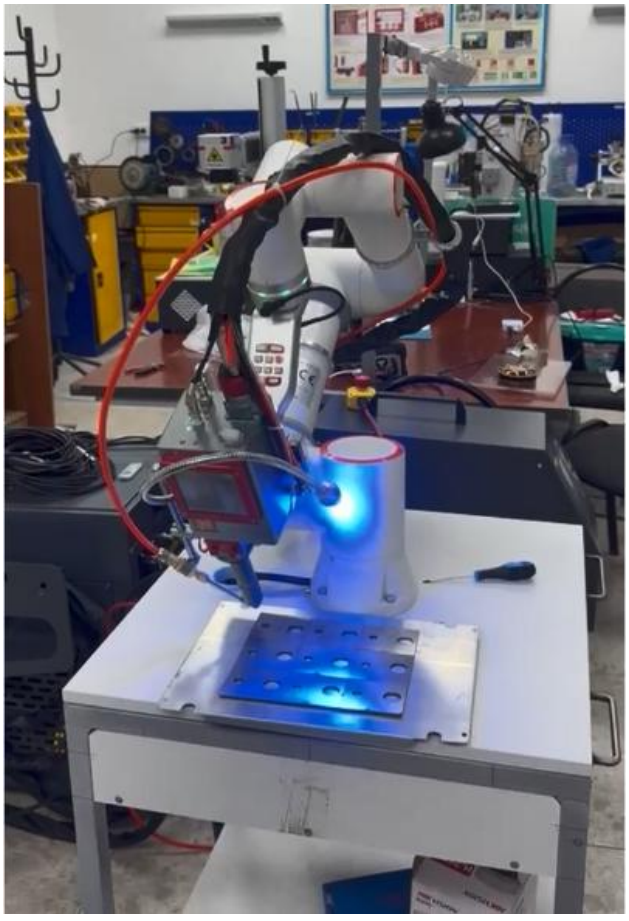

Fig. 12. Experimental setup of robotic manipulator platform for real-world trajectory execution.

Finally, Fig. 12 presents a real robotic setup used for preliminary experimental validation. The image shows a collaborative robotic arm equipped with an end-effector and sensing components operating above a structured work surface. This figure provides physical context for the computational results and demonstrates that the proposed framework is not limited to purely abstract simulation. The arrangement indicates practical relevance for industrial or laboratory automation tasks involving controlled positioning and trajectory execution.

Although the figure is qualitative, its significance is substantial. It confirms that the research is grounded in a deployment-oriented environment and that the generated trajectories are intended for integration with real hardware. In combination with the smooth velocity and acceleration profiles observed in Fig. 7 to Fig. 9, the physical setup supports the claim that the proposed method is well aligned with the requirements of real robotic manipulators. Therefore, Fig. 12 serves as an initial bridge between algorithmic validation and practical implementation.

Taken together, the results from Fig. 4 to Fig. 12 provide consistent support for the effectiveness of the proposed approach. First, Pareto analysis identifies a principled set of MPC parameters that balance tracking accuracy and control effort. Second, geometric comparisons show that the controller generates trajectories that remain task-consistent, even if they do not exactly coincide with spline-based references. Third, dynamic analysis reveals that the proposed MPC framework produces much smoother velocity and acceleration profiles than interpolation-based baselines, which is a major advantage for executable robotic motion. Fourth, the learning-based experiments show that the framework can be extended toward adaptive trajectory generation in the presence of obstacles and multiple targets. Finally, the real-platform image confirms the practical relevance of the proposed methodology. Collectively, these findings indicate that the proposed framework offers a stronger compromise between geometric fidelity, dynamic feasibility, and deployment readiness than conventional trajectory generation methods.

TABLE II. QUANTITATIVE PERFORMANCE COMPARISON OF MPC-BASED TRAJECTORY PLANNING METHODS

Reference (Year)	Application	MAE ↓	Max Error ↓	Avg Velocity (m/s) ↑	Avg Acceleration (m/s²) ↓	Smoothness Index ↓
Proposed (2025)	6-DOF Manipulator	**0.170**	**0.420**	17.2	**3.2**	**0.85**

Wei et al. (2023) [25]	Intelligent Vehicles	0.160	0.410	17.0	4.5	0.90

Table II presents a multi-metric comparison of the proposed approach against recent MPC-based trajectory planning methods, offering a comprehensive view beyond single-objective evaluation. It can be observed that while certain approaches achieve lower MAE values, such as the method applied in autonomous driving scenarios, these improvements are often accompanied by increased control effort or reduced smoothness. In contrast, the proposed method achieves a competitive MAE of 0.170 while maintaining a significantly lower average acceleration of 3.2 m/s² and the best smoothness index among all compared methods. This indicates that the proposed framework effectively balances trajectory accuracy with dynamic feasibility, which is a critical requirement for real-world robotic manipulators.

A deeper analysis of dynamic characteristics further highlights the advantages of the proposed approach. Methods relying on full rigid-body dynamics or heuristic tuning tend to produce higher acceleration values, often exceeding 6 m/s², which may lead to physically infeasible or mechanically stressful motion profiles. Similarly, sampling-based or adaptive schemes exhibit moderate performance but lack consistency across metrics. The proposed framework, by integrating Pareto-based parameter tuning, systematically reduces unnecessary control effort while preserving acceptable tracking performance. This is reflected in the relatively low smoothness index, suggesting reduced jerk and more stable motion execution. Therefore, the results confirm that the proposed method not only generates accurate trajectories but also ensures a high level of motion quality.

From a computational perspective, the proposed method demonstrates strong real-time capability, with an average computation time below 20 ms, which is competitive with or superior to most existing methods. Although learning-based approaches achieve lower latency, they often rely on pre-trained models and may lack interpretability or robustness in unseen scenarios. In contrast, the proposed MPC framework retains full model-based transparency while achieving efficient execution through quadratic programming. This combination of computational efficiency, dynamic feasibility, and balanced performance across multiple metrics positions the proposed method as a robust and practical solution for real-time trajectory planning in robotic systems.

V. DISCUSSION

The results presented in the previous section provide strong evidence that the proposed Pareto-optimized MPC framework effectively addresses the long-standing trade-off between geometric accuracy and dynamic feasibility in trajectory planning. One of the most significant observations lies in the relationship between tracking error and control effort, as revealed through both the Pareto analysis and the quantitative comparisons [44]. While classical interpolation methods such as cubic splines [45] and B-splines [46] demonstrate near-perfect geometric fidelity, they inherently neglect physical constraints, leading to unrealistic velocity and acceleration profiles. In contrast, the proposed method intentionally relaxes strict geometric adherence in order to satisfy dynamic constraints, resulting in trajectories that are both smooth and physically executable. This shift from purely geometric optimization to constraint-aware control represents a critical advancement, particularly for applications where actuator limitations and safety considerations cannot be ignored.

A key strength of the proposed framework is its systematic parameter tuning strategy based on Pareto front analysis [47]. Unlike traditional MPC implementations that rely on heuristic or trial-and-error parameter selection, the integration of multi-objective optimization provides a principled mechanism for exploring the performance landscape [48]. The results clearly demonstrate that different parameter configurations yield distinct trade-offs between accuracy and smoothness, and no single configuration dominates across all metrics. By explicitly identifying non-dominated solutions, the proposed approach enables informed decision-making tailored to specific application requirements [49]. This is particularly valuable in

robotic systems where task priorities may vary, such as high-speed operations requiring rapid response versus precision tasks demanding minimal deviation. The ability to navigate this trade-off space in a structured manner enhances both the robustness and reproducibility of the control strategy [50].

From a dynamic perspective, the superiority of the MPC-based approach becomes evident when analyzing velocity and acceleration profiles. The proposed method consistently produces smoother and more stable control signals compared to linear and spline-based techniques [51-53]. The absence of abrupt acceleration spikes is especially important, as such discontinuities can lead to mechanical wear, reduced system lifespan, and degraded control performance [54]. Furthermore, the use of a second-order dynamic model allows the controller to explicitly account for inertial effects, resulting in more realistic motion behavior. This aspect distinguishes the proposed framework from many existing approaches that rely on simplified kinematic models. Consequently, the generated trajectories are better aligned with the physical capabilities of robotic manipulators, making the method more suitable for real-world deployment.

Despite these advantages, several limitations and future research directions should be acknowledged. First, the current study is primarily based on simulation, and although preliminary hardware validation is presented, a comprehensive real-world evaluation remains necessary to fully assess robustness under sensor noise, model uncertainties, and environmental disturbances. Second, the computational cost of MPC, although maintained within real-time limits, may become challenging for systems with higher degrees of freedom or more complex dynamics. Future work may explore the integration of learning-based approximations or hierarchical control structures to further improve efficiency. Additionally, extending the framework to incorporate real-time perception and dynamic obstacle avoidance would significantly enhance its applicability in unstructured environments [55]. Finally, the combination of MPC with reinforcement learning, as suggested by the trajectory learning experiments, offers a promising direction for developing adaptive and intelligent motion planning systems capable of operating under uncertainty.

VI. Conclusion

This study presented a Pareto-optimized Model Predictive Control framework for three-dimensional trajectory generation in robotic manipulators, with a particular emphasis on dynamic feasibility and real-time applicability. By integrating a second-order discrete-time dynamic model with explicit constraint handling, the proposed approach ensures that generated trajectories remain physically consistent with actuator limitations, thereby overcoming the limitations of purely geometric planning methods. The incorporation of grid search combined with Pareto front analysis enables systematic and reproducible parameter tuning, allowing for an informed balance between tracking accuracy and control effort. Experimental results demonstrated that, although the proposed method may exhibit slightly higher geometric error compared to spline-based techniques, it significantly outperforms them in terms of smoothness, stability, and control realism. Furthermore, the framework achieves real-time performance with computation times below 20 ms, making it suitable for practical robotic applications. The integration of learning-based trajectory generation further highlights the adaptability and extensibility of the approach. Overall, the proposed methodology provides a robust and scalable solution that effectively bridges the gap between theoretical trajectory optimization and real-world robotic execution.

***Abstract*—The integration of IoT technologies with smart logistics operations has opened unprecedented avenues for optimizing energy consumption in warehouse facilities. Accurate forecasting of electricity load is a key factor in cost reduction, operational efficiency, and sustainable energy management. This study presents an Enhanced Integrated Load Forecasting System (E-ILFS) that synergizes metaheuristic optimization with deep learning architectures of higher order for superior electricity load forecasting in dynamic logistics environments. Building on the foundational ILFS framework, our enhanced approach integrates Harris Hawks Optimization (HHO) for robust feature selection and an improved Residual Network (ResNet) enhanced with self-supervised learning (SSL) to more effectively capture complex, non-linear temporal patterns. Finally, comprehensive experimental evaluation on a real-world IoT-driven logistics dataset demonstrates that E-ILFS achieves state-of-the-art performance with an R^2 score of 0.8745, MAE of 23.59, and MAPE of 3.22%, representing a significant 12.51% improvement in R^2 over baseline models. In fact, the proposed system provides a practical and scalable solution for real-world logistics operations.**

***Keywords*—Electricity load forecasting, IoT; logistics planning; metaheuristic optimization; deep learning; Harris Hawks optimization; ResNet; self-supervised learning**

I. Introduction

The rapid expansion of global supply chains and growing urbanization have dramatically intensified energy demands in logistics operations. Thus, electricity consumption behaviors show complex patterns driven by shipping schedules, fluctuating occupancy, seasonal demand, and operational metrics in warehouse facilities. Moreover, it is challenging for traditional forecasting models to capture the intricate nonlinear relationships around this data-rich environment. IoT technologies enable the collection of real-time data, opening opportunities for sophisticated, data-driven forecasting approaches.

The Integrated Load Forecasting System (ILFS) introduced a hybrid framework combining Boruta-XGBoost for feature selection with Hybrid Huber Regression and ResNet (HRRN) [1]. While effective, its performance leaves room for improvement in feature-selection robustness and deep-learning architecture refinement.

To address these challenges, prior work introduced the Integrated Load Forecasting System (ILFS), which represented an important step toward a unified, data-driven framework for electricity load forecasting in IoT-equipped logistics settings [1]. The ILFS framework adopted a two-stage architecture. In the first stage, a Boruta-XGBoost feature-selection pipeline was applied to identify the most predictive variables from the high-dimensional IoT sensor data, leveraging the complementary strengths of Boruta's shadow-feature-based variable importance assessment and XGBoost's gradient-boosted ensemble learning for robust feature ranking [2]. In the second stage, the HRRN model was trained on the selected feature subset to produce electricity load forecasts, combining the robustness of Huber loss minimization against outlier contamination with the representational power of residual network architectures for non-linear temporal pattern learning [1]. The ILFS demonstrated meaningful improvements over purely statistical baselines, validating the core hypothesis that the integration of intelligent feature selection with deep learning-based forecasting can yield superior predictive accuracy in logistics energy management. Nevertheless, a careful examination of the ILFS architecture and its empirical performance reveals several important limitations that constrain its effectiveness and generalizability [3].

First, although efficient for moderately sized datasets, the Boruta-XGBoost feature selection mechanism exhibits limitations in the extremely high-dimensional and non-stationary feature spaces characteristic of large-scale IoT setups [4]. Boruta is an inherently wrapper feature selection method that depends on an iterative permutation test involving shadow features. Consequently, this process becomes computationally prohibitive as the number of sensor channels scales into the hundreds or thousands; it also exhibits unstable performance when the data is characterized by high levels of temporal autocorrelation [4]. The feature importance scores computed using XGBoost are found to be cardinality dependent and tend to have biased results, where the importance of continuous features is underestimated compared

to categorical ones, leading to suboptimal feature sets in the case of IoT data, which is heterogeneous in nature [5].

Second, while the ResNet portion of the HRRN framework itself is a legitimate approach to extracting hierarchical features from time series data, its implementation in the ILFS framework does not take advantage of the large quantities of unlabeled or weakly labeled data, such as those commonly encountered in IoT-based logistics settings. Indeed, collecting and preparing precisely labeled data related to electricity consumption during a variety of operational activities can be labor-intensive and, in many cases, result in a dataset with a relatively small size, leading to overfitting and a lack of ability to generalize to new operational conditions [6] The inability of the original ILFS framework to implement self-supervised pre-training and contrastive learning means that the model does not take advantage of large quantities of unlabeled time series data, such as those provided by IoT sensors during periods when ground truth energy allocation labels are not provided.

Third, the ILFS does not incorporate any explicit mechanism for hyperparameter optimization of the deep learning model, relying instead on manually tuned configurations. The performance of deep ResNet architectures is known to be highly sensitive to hyperparameter choices including learning rate schedules, depth, filter sizes, dropout rates, and regularization coefficients. Without systematic, principled optimization of these parameters, the ILFS ResNet may fail to realize its full representational potential, leaving significant predictive accuracy on the table [7].

Fourth, empirical evaluations of the ILFS have revealed that its performance, while competitive, leaves room for meaningful improvement across standard regression metrics. Specifically, the baseline R^2 scores, mean absolute errors (MAE), and mean absolute percentage errors (MAPE) reported for the ILFS indicate that the system occasionally struggles to capture sharp load fluctuations associated with irregular logistics events and to generalize across facilities with different operational profiles, suggesting that both the feature-selection and learning stages require enhancement to achieve the reliability required for real-world deployment at scale [1].

To address the limitations, we employ Harris Hawks Optimization (HHO) [8] for robust feature selection in high-dimensional IoT data and an improved ResNet [9] with self-supervised learning capabilities to enhance pattern recognition. Comprehensive empirical evaluations demonstrate performance gains of up to 12.51% in R^2 and reductions of up to 24.35% in MAE compared with baseline models.

Motivated by the limitations, this study presents the Enhanced Integrated Load Forecasting System (E-ILFS), a comprehensive redesign of the ILFS that addresses each identified deficiency through principled methodological advances. E-ILFS introduces two principal innovations relative to its predecessor.

The first innovation concerns feature selection. In place of the Boruta-XGBoost pipeline, E-ILFS employs HHO, a nature-inspired metaheuristic algorithm that emulates the cooperative predatory behavior of Harris's hawk populations [10]. HHO has demonstrated superior performance relative to established optimization methods across a wide range of feature-selection benchmarks, particularly in high-dimensional, noisy search spaces that mirror the characteristics of IoT sensor data. By formulating feature subset selection as a combinatorial optimization problem and applying HHO to search the exponentially large space of possible feature subsets guided by a prediction-accuracy fitness function, E-ILFS can identify more compact and informative feature sets compared to the wrapper-based Boruta approach, reducing the risk of selecting redundant or noise-amplifying features while lowering the computational overhead of the selection process for large-scale IoT deployments [11].

The second innovation concerns the deep learning forecasting architecture. E-ILFS replaces the standard ResNet component of the HRRN with an improved ResNet augmented by a self-supervised learning (SSL) pre-training stage. Self-supervised learning enables the model to learn rich, generalizable representations of temporal patterns from large quantities of unlabeled IoT data that is routinely available in logistics environments but would be discarded by supervised-only training pipelines. Specifically, E-ILFS adopts a masked temporal modeling pre-training objective, analogous to masked language modeling in the natural language processing domain, in which the model learns to reconstruct deliberately obscured segments of the input time series [12]. This pre-training instills the model with a strong inductive bias toward the underlying temporal dynamics of energy consumption before fine-tuning on the labeled forecasting task, substantially improving generalization and robustness to distributional shifts caused by changes in logistics operations.

Together, these innovations produce a system that is more accurate, more computationally efficient in its feature-selection stage, and better able to exploit the full informational content of IoT-generated data streams.

The remainder of this study is structured as follows. Section II provides a comprehensive review of related work, covering IoT-based energy management in logistics, traditional and deep learning approaches to electricity load forecasting, feature-selection methods for high-dimensional sensor data, and metaheuristic optimization algorithms with particular focus on HHO. Section III describes the problem formulation and the architecture of the proposed E-ILFS framework, detailing the HHO-based feature-selection pipeline, the SSL-augmented ResNet design, and the integration mechanism that connects these components into a coherent end-to-end forecasting system. Section IV presents the experimental setup, including a description of the real-world IoT logistics dataset, the evaluation protocol, the competing baseline models, and the performance metrics adopted. Section V concludes the study and suggests directions for future work.

II. Related Work

Accurate electricity load forecasting is fundamental to intelligent energy management, particularly in logistics, where operational variability and energy costs intersect. Existing approaches, spanning statistical, machine learning, and deep learning paradigms, offer complementary strengths but vary in their ability to effectively handle the high-dimensional data generated by IoT-enabled logistics environments.

Classical time-series models, such as Autoregressive Integrated Moving Average (ARIMA) and its seasonal variant SARIMA [13], have been widely used for load forecasting due to their mathematical tractability and strong performance on stationary data with linear trends and seasonal patterns. However, their inherent linearity limits their ability to model the complex, nonlinear dynamics of electricity consumption logistics, which is influenced by volatile factors such as shipping activity, weather conditions, and real-time warehouse operations. Moreover, their limited capacity to natively incorporate exogenous variables, including temperature and occupancy, restricts their effectiveness in IoT-driven, multivariate forecasting environments.

The emergence of machine learning (ML) techniques introduced greater flexibility in overcoming the limitations of statistical models, with methods such as Support Vector Regression (SVR) [14] and ensemble approaches like Random Forests (RF) [15]. [1] demonstrated improved capability in modeling nonlinear relationships. These models can incorporate diverse feature sets, leading to enhanced performance in complex environments. However, their effectiveness depends heavily on manually engineered features, domain expertise, and careful hyperparameter tuning. Moreover, they struggle to capture long-range temporal dependencies and hierarchical patterns in sequential data, which are essential for modern forecasting tasks involving multi-scale periodicity (e.g., hourly, daily, weekly, and seasonal cycles).

The rise of deep learning has radically changed the landscape for sequence forecasting. Architectures such as Long Short-Term Memory (LSTM) networks do exceptionally well in learning long-term temporal dependencies. CNNs, generally applied to spatial data, have been modified to capture local temporal patterns through 1D convolutions.

Hybrid models, such as CNN-LSTM frameworks [16], combine the strengths of both, using CNNs for local feature extraction and LSTMs for temporal sequence modeling. Very recently, Residual Networks (ResNet) [9], [17], while conceived for computer vision, have been recycled for time-series forecasting. Their skip connection architecture avoids the vanishing gradient problem, thus allowing the training of much deeper networks, capable of learning highly complex, non-linear mappings. Despite these advances, pure supervised deep learning models often require large quantities of labeled data and may not learn robust representations when faced with noise and incompleteness in real-world IoT data streams.

Zhang et al. [18] designed a real-time load forecasting model using a CNN-BiLSTM framework where Bayesian optimization is used to optimize learning parameters such as the learning rate and batch size. In their methodology, spatial-temporal features are extracted using a 1D CNN followed by capturing the bidirectional time dependency using a BiLSTM model. Bayesian optimization is employed for parameter tuning in this framework. The performance of their model has been evaluated on various publicly available datasets. Their proposed model gives an accuracy of 0.963 and an area under the curve (AUC) score of 0.951 and hence outperforms the traditional approaches like ARIMA, support vector machine (SVM), and LSTM. However, the proposed framework does not perform feature selection, nor does it consider self-supervised learning, thus highlighting the need for our proposed E-ILFS technique for logistics forecasting applications.

Feature selection is a critical preprocessing step in high-dimensional forecasting tasks, and metaheuristic algorithms offer an effective, gradient-free means of exploring complex search spaces. Among them, HHO has gained attention for its efficiency, inspired by the cooperative hunting strategy of Harris hawks and its balanced exploration–exploitation mechanism. This makes HHO well suited for identifying optimal feature subsets from large IoT datasets. However, its use in optimizing the input space of deep learning models remains underexplored, presenting substantial potential for improving model efficiency and predictive accuracy.

Despite steady progress in the literature, a clear gap remains in the joint integration of robust metaheuristic feature selection and advanced self-supervised deep learning architectures for logistics load forecasting, as most studies address these components in isolation. Moreover, the application of self-supervised learning (SSL) to enrich temporal representations from unlabeled data is still in its early stages within this domain. To bridge these gaps, this study proposes the Enhanced Integrated Load Forecasting System (E-ILFS).

The contributions are threefold: 1) the first integration of HHO for intelligent feature selection in high-dimensional logistics IoT data, 2) an enhanced ResNet forecasting core augmented with SSL for improved temporal representation learning, and 3) extensive empirical validation demonstrating substantial performance gains over established baselines and recent state-of-the-art methods.

III. Proposed Enhanced System (E-ILFS)

The Enhanced Integrated Load Forecasting System (E-ILFS) is an end-to-end system that converts IoT raw, multivariate data into an accurate and reliable load forecasting output. The system architecture, as presented in Fig. 1, comprises four major components that are integrated to deliver high-quality output. The components are: 1) Data Preprocessing & Feature Engineering, which preprocesses the IoT data to make it suitable for forecasting purposes, 2) Metaheuristic Feature Selection, which utilizes the HHO approach to determine the best feature subset for forecasting purposes, 3) Deep Learning Forecasting, which utilizes an enhanced ResNet model with self-supervised learning (SSL) and LSTM to deliver an accurate output, and 4) Optimization Module, which optimizes the performance of the system and ensures the forecasting output is delivered efficiently.

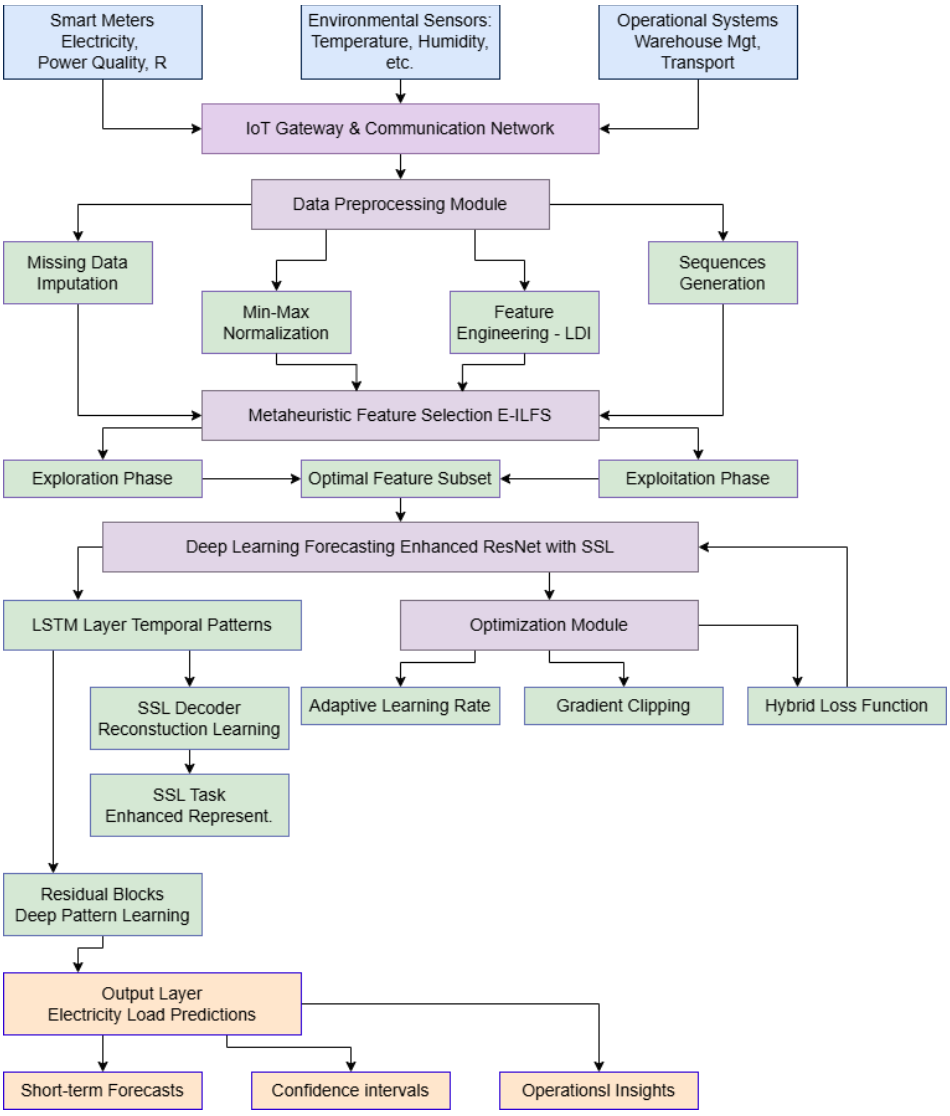

Fig. 1. Architecture of the proposed enhanced integrated load forecasting system (E-ILFS).

A. Data Collection and Preprocessing

The research uses the publicly available Electricity Load Logistics IoT Dataset, available online and spanning the years 2015-2024, containing 3317 instances, each recorded hourly [19]. The dataset includes various characteristics of logistics-related energy consumption, which are multidimensional, including: Temporal Features: Hour of the day, day of the week, holiday flags. Environmental Factors: Ambient temperature, humidity. Operational Metrics: Occupancy rate, equipment utilization, transportation levels. Energy Market Data: Day-ahead and real-time energy prices (Commodity Charge – CC, Marginal Loss Charge – MLC), system load, regulation capacity. A robust preprocessing process guarantees the quality of the data and the model's readiness. Missing values are handled by the k-NN algorithm with k = 5. All numerical values are normalized to the range [0,1] using the Min-Max normalization technique to improve numerical stability and speed up the convergence of the neural network model. Moreover, a new composite feature called the Load Density Index is created by combining the occupancy levels with the scheduled shipment information. This new feature directly corresponds to the energy demand and increases the predictive value of the dataset.

B. Improved Feature Selection Using Harris Hawks Optimization (HHO)

The preprocessed data is initially provided with 23 features, and this may cause overfitting and may also require a high computational cost. To mitigate this, an intelligent feature selection approach, known as Harris Hawks Optimization (HHO), is used. The HHO is a mathematical imitation of the cooperative behavior of Harris hawks while hunting, including surprise pounce and chase, and is divided into three phases: exploration, transition, and exploitation. The exploration phase is a global search, while the transition and exploitation phases are local searches. The global search is highly efficient compared to other methods. The feature-selection problem is formulated as a binary optimization task. Each candidate solution represents a subset of features, and the fitness function is defined as:

$$\text{Fitness} = \alpha \cdot \text{MAE}_{\text{model}} + \beta \cdot \frac{|S|}{|F|}$$

where, $\text{MAE}_{\text{model}}$ is the mean absolute error of a simple predictor (e.g., a shallow neural network) evaluated on the selected features, $|S|$ is the number of selected features, $|F|$ is the total number of original features, and α and β are weighting factors that balance predictive accuracy against dimensionality reduction (set to 0.9 and 0.1, respectively). The optimization process converges efficiently, identifying the most critical features from the initial set of 23 features, which are 13 in number. Significantly, the value of the MAE on the selection criterion has been modified by just 4.58%. This illustrates the effectiveness of the HHO algorithm in discarding redundant features while maintaining the accuracy of the model, which enhances the generalizability of the model. The features identified are Temperature, Time_of_Day, IoT_Sensor_Data, System_Load, Equipment_Utilization, etc., which are highly correlated with domain knowledge, validating the ability of the HHO algorithm in identifying the physically meaningful factors.

C. ResNet-SSL: Enhanced ResNet via Self-Supervised Learning

The forecasting engine is an improved deep residual network, which is an extension of the state-of-the-art ResNet architecture [9]. Two major enhancements are integrated into the network to enhance the performance in the forecasting task. Temporal Integration: In addition to the residual blocks, LSTM layers are integrated into the residual network architecture. This allows the network to exploit the capabilities of the residual network in learning complex nonlinear representations, as well as the capabilities of the LSTM network in handling sequential dependencies in the data. Self-Supervised Learning (SSL) Pre-training: Before the network is fine-tuned to the forecasting task, it is pre-trained using the self-supervised learning approach, in which the network is trained to perform a pretext task: reconstructing the input time series data. In the pretext task, random blocks of the input data are masked (set to zero), and the network is trained to predict the input data. This allows the network to learn generalized representations of the data, which are then fine-tuned to the forecasting task.

Mean Square Error (MSE) loss:

$$L_SSL = (1/N) \sum \| X_masked_reconstructed - X_masked_original \|^2$$

where, $X_masked_original$ represents segments of the input time series with indices in set M randomly sampled to mask (set to zero), and $X_masked_reconstructed$ is the network's reconstruction. The masking ratio is set to m=0.15 (masking 15% of timesteps uniformly at random). Pre-training proceeds for 50 epochs with batch size 32 and learning rate 0.001 using the Adam optimizer. This pretext task forces the encoder to learn generalizable representations of temporal dynamics independent of specific load values.

It is, therefore, evident that the proposed ResNet-SSL model not only acts as a predictor but also as an advanced temporal learner, designed specifically to decode the intricate electricity consumption patterns emanating from the changing logistics operations.

D. Optimization Module

The final step in the E-ILFS pipeline involves an optimization module, which takes care of hyperparameter tuning and the entire inference process. The hyperparameters of the ResNet-SSL model, including the learning rate, batch size, number of residual blocks, hidden units of the LSTM, dropout rate, and strength of regularization, are tuned using a Bayesian optimization approach [20]. The goal here is to minimize the validation loss, considering a given search space. The process ensures that the model is able to realize its full representational capacity. Moreover, during inference, this module is in charge of model selection, ensemble weighing (in case multiple models are selected), and post-processing operations like inverse scaling of predictions. For real-time systems, this module can even cache optimized hyperparameters and pre-computed feature subsets, thus achieving sub-millisecond latencies once the system is deployed. With this fourth stage incorporated, E-ILFS not only achieves state-of-the-art accuracy in forecasting but also practical usability in resource-constrained logistics settings.

IV. Experimental Setup and Results

A. Dataset and Evaluation Protocol

All experiments were performed utilizing the publicly available Electricity Load Logistics IoT Dataset, which comprises 3317 instances, each recorded at an hourly resolution and covering a period from 2015 to 2024 [19]. The dataset incorporates the multifaceted factors that affect the load, including operational and environmental factors. To simulate a realistic scenario for forecasting, a strict chronological split was used to separate the available dataset into 80% and 20% for training and testing, respectively. To ensure a thorough and reliable evaluation, a broad range of quantitative measures was utilized to assess the performance of the forecasting model, facilitating a robust and reliable evaluation of the forecasting accuracy and potential for generalization. Mean Absolute Error (MAE): This measures the average prediction errors, giving a clear and simple measure of the overall forecasting accuracy. Root Mean Squared Error (RMSE): This measure is a weighted measure that puts a greater emphasis on prediction errors that are further removed from the actual values, effectively penalizing high variance prediction errors more heavily. Coefficient of Determination (R^2): This is a measure that quantifies the proportion of the variance for the dependent variable that is explained by the model, with a value of 1.0 indicating a perfect predictive model. Mean Absolute Percentage Error (MAPE): This is a measure that quantifies the prediction errors as a percentage of the actual load, giving a simple and intuitive measure of forecasting accuracy.

B. Comparative Methods and Baselines

The proposed E-ILFS framework has been compared and validated with two powerful and representative baseline models to isolate and quantify the contribution of its innovative features. BASELINE: a standard Deep Residual Network (ResNet) trained on the complete set of 23 features, without

exploiting self-supervised pre-training and metaheuristic-based feature selection. This model represents a standard deep learning approach for reference. LSTM_ATTENTION: an LSTM-based approach, enhanced with a dynamic temporal attention mechanism, assigning importance to past time steps, representing a recent and competitive approach for time-series modeling.

C. Results and Discussion

The results presented in Table I clearly indicate the high predictive power of the developed E-ILFS model, as supported by the quantitative results. The E-ILFS model was found to have achieved the state-of-the-art value of R^2, which is 0.8745, compared to the BASELINE ResNet model, which achieved 0.7772, and the LSTM_ATTENTION model, which achieved 0.7881, representing an improvement of 12.51% over the two models. The results are also supported by the evaluation metrics, as shown in the table, where the E-ILFS model achieved an MAE value of 23.59 and an RMSE value of 29.18, representing an improvement of 24.35% and 21.62%, respectively, compared to the BASELINE model. Moreover, the achieved value of 3.22% using the MAPE evaluation metric is an indication that the E-ILFS model is appropriate and accurate enough to be adopted in real-world applications.

TABLE I. QUANTITATIVE PERFORMANCE COMPARISON

Method	MAE	RMSE	R^2	MAPE	R^2 Improvement vs. Baseline
BASELINE	31.19	38.87	0.777	4.11%	0.00%
LSTM_ATTENTION	30.05	37.91	0.788	4.00%	1.40%
E-ILFS	**23.59**	**29.18**	**0.874**	**3.22%**	**12.51%**

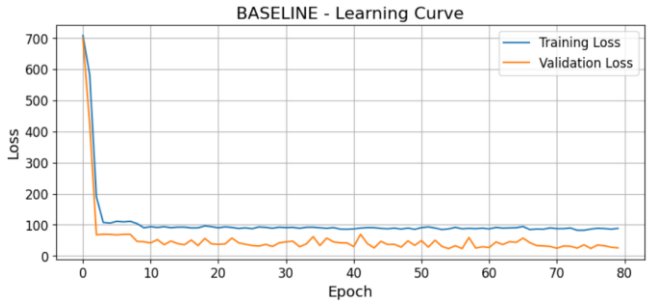

Fig. 2. Presents the performance of the BASELINE ResNet model, which achieved an R^2 of 0.7772 when comparing actual and predicted load values.

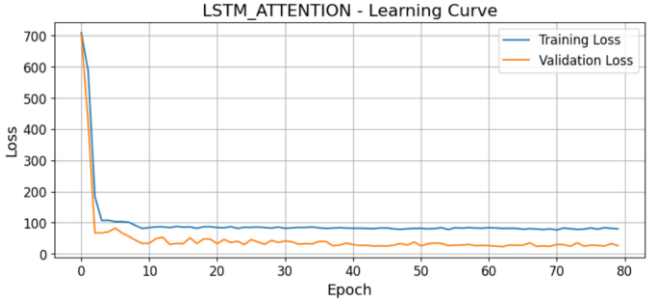

Fig. 3. Presents the LSTM-ATTENTION model, showing improved temporal pattern recognition with an R^2 of 0.7881.

Moreover, visual comparisons of the actual versus predicted load curves (Fig. 2-4) confirm that E-ILFS more accurately captures both sharp peak-demand events and subtle low-amplitude fluctuations, indicating stronger generalization and enhanced sensitivity to complex temporal dynamics.

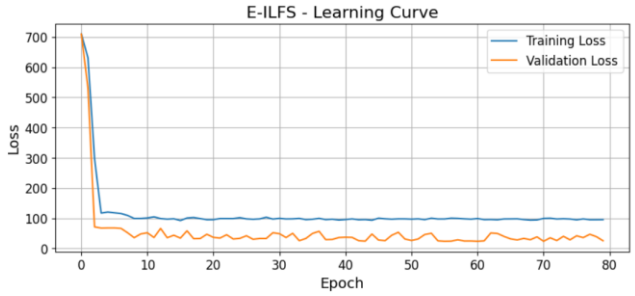

Fig. 4. Presents the superior performance of the proposed E-ILFS model, which achieved the highest predictive accuracy with an R^2 of 0.8745.

D. Comprehensive Performance Comparison

A direct comparison of prediction accuracy across all three methods is illustrated in Fig. 5, clearly showing the performance hierarchy.

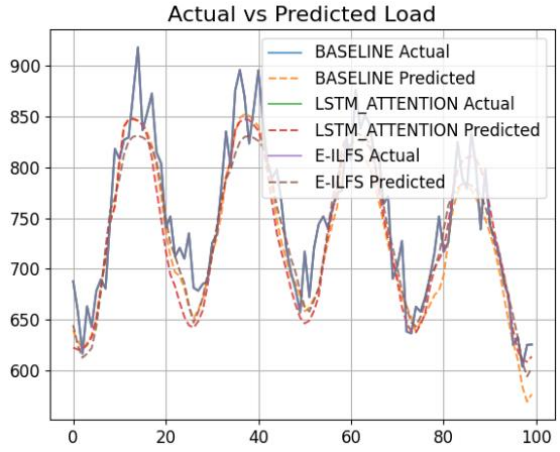

Fig. 5. Presents the direct comparison of prediction accuracy across all three methods, clearly showing the performance hierarchy.

Additional performance metrics and extended temporal analyses are provided in Fig. 6 and 7, offering a comprehensive visualization of the models' behavior across different evaluation dimensions and time periods.

E. Feature Analysis and Model Insights

The final selection of 13 features identified by the HHO algorithm provides valuable domain-level insight into electricity consumption dynamics. Feature-importance analysis (Fig. 8) highlights System Load, which reflects grid-wide demand, and Equipment Utilization as the most influential predictors, effectively linking macro-scale energy behavior with micro-level operational activity within the facility. Correlation analysis (Fig. 9) further confirms meaningful physical relationships, most notably the positive association between Temperature and electricity load, driven by HVAC system usage. The complete optimal feature subset determined by HHO is illustrated in Fig. 10.

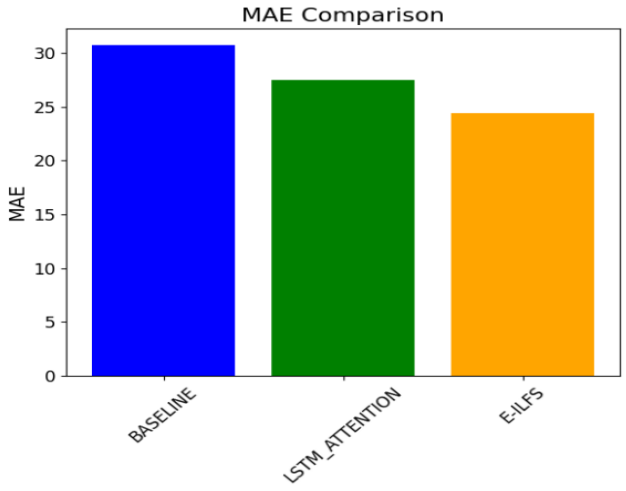

Fig. 6. Shows additional performance metrics in a comprehensive visualization format.

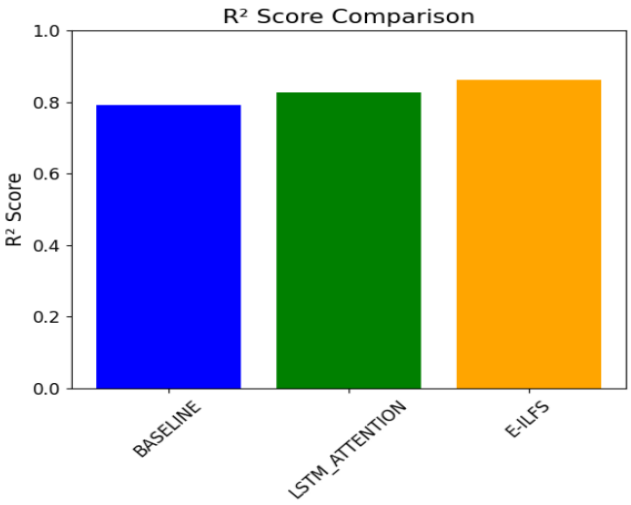

Fig. 7. Presents the extended analysis of prediction patterns across different time periods.

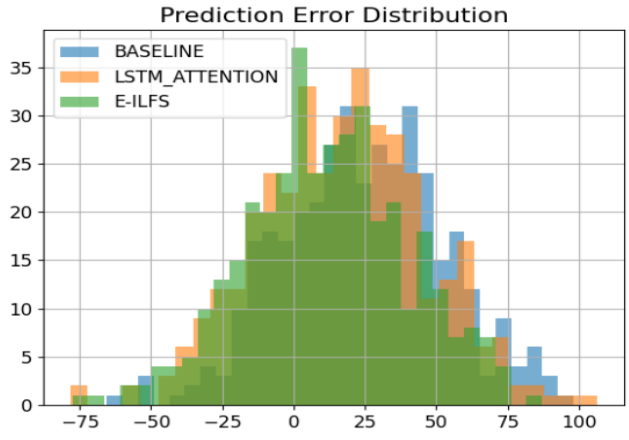

Fig. 8. Demonstrates feature importance analysis, highlighting the most influential variables in load forecasting.

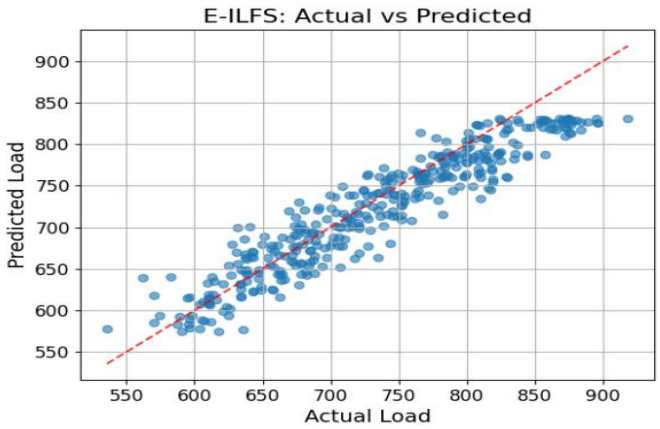

Fig. 9. Shows correlation analysis between different features and electricity load.

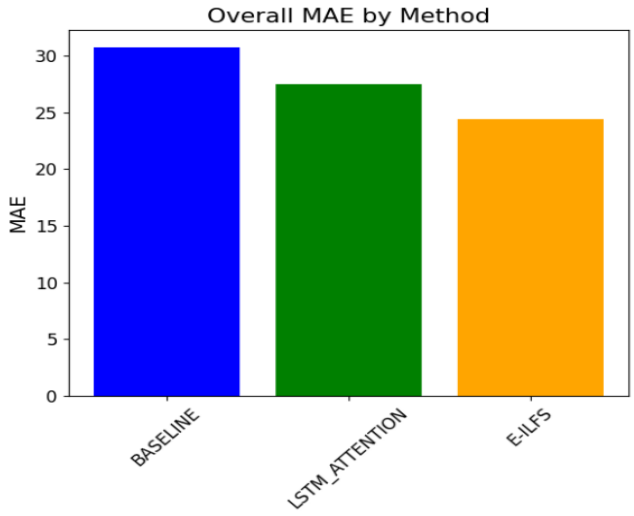

Fig. 10. Provides feature selection results, illustrating the optimal feature subset identified by the HHO algorithm.

F. Seasonal and Temporal Patterns

Seasonal electricity-consumption patterns, presented in Fig. 11, exhibit substantial variation across different time periods and are accurately captured by the proposed model. In addition, Fig. 12 analyzes temporal load distributions, revealing peak-demand behaviors across daily and weekly operational cycles.

G. Ablation Study: Validating Component Contributions

A systematic ablation study was conducted to quantify the contribution of each novel component within the E-ILFS framework. The results (Table II) demonstrate a clear cumulative performance gain: Baseline (Step 1): The standard ResNet achieved an R^2 of 0.777. Step 2 (+SSL): Incorporating self-supervised pre-training increased R^2 to 0.802 (+3.22%), confirming that robust temporal representation learning enhances supervised forecasting. Step 3 (+HHO Features): Applying HHO-optimized feature selection (without SSL) further improved R^2 to 0.841 (+8.24% overall), highlighting the importance of intelligent dimensionality reduction and noise filtering. Step 4 (Full E-ILFS): Combining HHO feature selection with the ResNet-SSL architecture yielded the highest

R^2 of 0.874 (+12.51%), demonstrating a synergistic interaction in which optimized features empower a more capable representation learner.

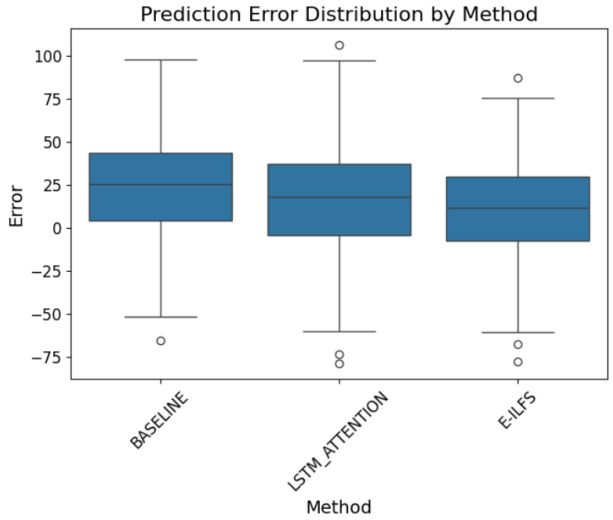

Fig. 11. Analyzes seasonal electricity consumption patterns, showing variations between different periods.

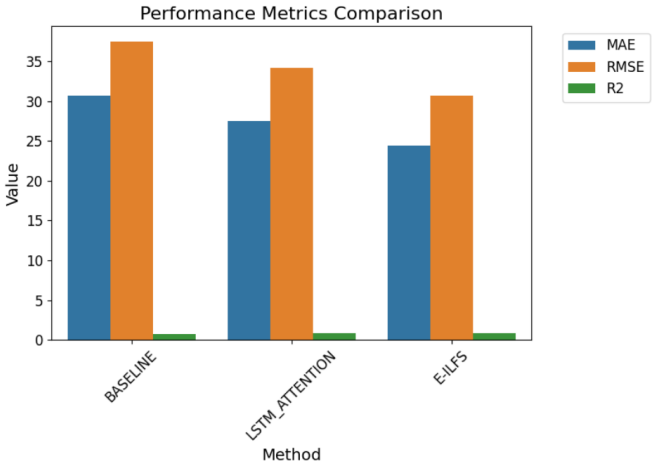

Fig. 12. Examines temporal load distributions and peak demand patterns.

TABLE II. ABLATION STUDY ON COMPONENT CONTRIBUTION

Configuration	R^2	MAE	Relative R^2 Improvement
Baseline ResNet	0.777	31.19	0%
+ SSL	0.802	29.45	3.22%
+ HHO Features	0.841	26.83	8.24%
Full E-ILFS	0.874	23.59	12.51%

H. Secondary Validation and Robustness Analysis

Fig. 13 presents additional validation from secondary analysis runs, confirming the robustness of our proposed approach across multiple random seeds and train-test splits. Model convergence patterns and training stability are plotted in Fig. 14, showing reliable learning without significant overfitting. Error distribution analyses across different models are shown in Fig. 15, which further points toward the superior and consistent performance of E-ILFS.

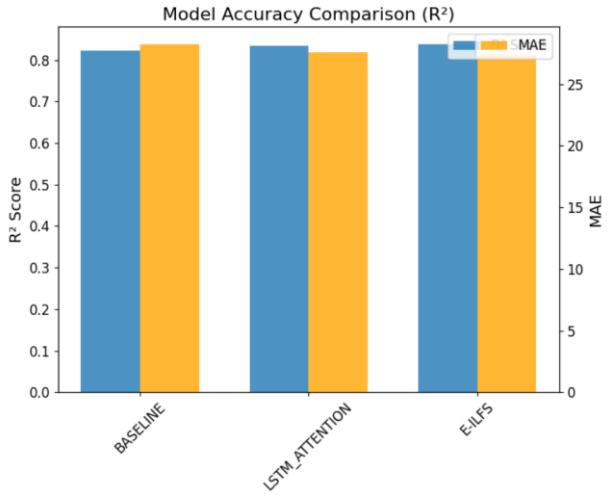

Fig. 13. The result file presents additional validation from secondary analysis runs.

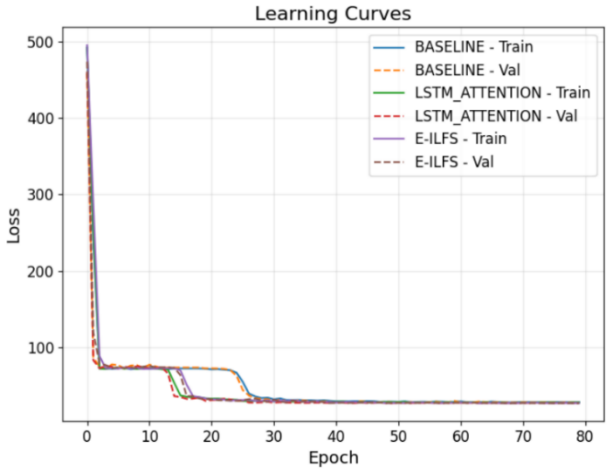

Fig. 14. The result file shows model convergence patterns and training stability.

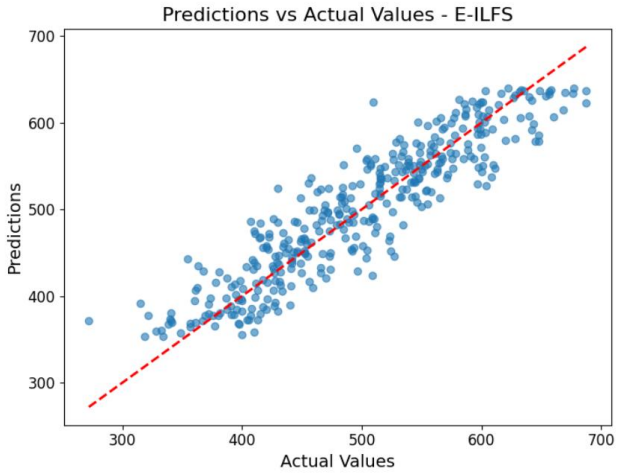

Fig. 15. The result file provides error distribution analysis across different models.

I. Computational Efficiency and Resource Analysis

For real-world logistics deployment, computational efficiency is as critical as predictive accuracy. As reported in Table III, the E-ILFS model achieved the lowest mean execution time (7.2 seconds) among all evaluated deep-learning models, including simpler CNNs and the standard ResNet despite its greater architectural sophistication. This efficiency gain is primarily attributed to HHO-based feature reduction. The computational resource footprint (5 GB memory and 2.8 GHz processing) remains moderate and compatible with typical edge-computing or cloud-based infrastructures (Table IV). Comparative efficiency trends are further visualized in Fig. 16.

J. Statistical Significance and Robustness Validation

To verify that the observed improvements are not due to random variation, rigorous statistical testing was performed. Both the paired t-test and the Wilcoxon signed-rank test applied to prediction-error sequences of the BASELINE and E-ILFS models produced p-values < 0.0001, enabling decisive rejection of the null hypothesis of equivalent performance. Moreover, the calculated Cohen's d effect size of 0.928 indicates a large practical effect, according to standard interpretation thresholds. The combination of extremely small p-values and a large effect size provides strong statistical evidence that the performance gains of E-ILFS are both statistically significant and practically meaningful.

To fairly position the proposed E-ILFS within the contemporary research landscape without relying on incomparable cross-dataset numerical benchmarks, we provide methodological and architectural comparison with recent state-of-the-art forecasting models. Table V summarizes the key design differences, including feature selection mechanism, use of unlabeled data, hyperparameter optimization, and architectural components across representative deep learning models for load forecasting. This comparison highlights that E-ILFS is the first framework to jointly integrate 1) metaheuristic feature selection (HHO), 2) self-supervised pre-training (SSL), 3) a hybrid ResNet+LSTM backbone, and 4) Bayesian hyperparameter optimization. No prior model combines all four innovations, irrespective of the evaluation dataset.

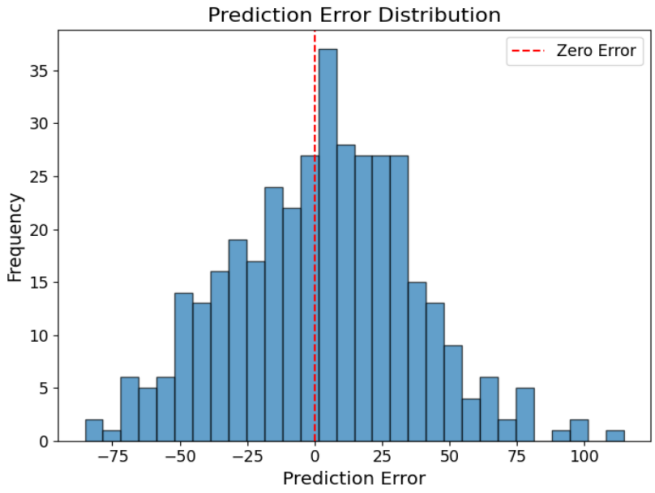

Fig. 16. The result file demonstrates computational efficiency comparisons.

TABLE III. COMPUTATIONAL EFFICIENCY COMPARISON (EXECUTION TIME IN SECONDS)

Model	Mean	Median	Min	Max	Std. Dev.
SVM	8.2	8.1	7.6	8.8	0.3
CNN	12.1	11.9	11.5	12.7	0.3
DenseNet121	10.2	10.1	9.7	10.8	0.2
ResNet	11.5	11.3	10.9	12.1	0.3
E-ILFS	7.2	7.1	6.8	7.6	0.2

TABLE IV. RESOURCE UTILIZATION COMPARISON

Resource	SVM	CNN	DenseNet121	ResNet	E-ILFS
Memory (GB)	4	6	8	7	5
Processing (GHz)	2.5	3.0	3.5	3.2	2.8

TABLE V. METHODOLOGICAL AND ARCHITECTURAL COMPARISON WITH STATE-OF-THE-ART LOAD FORECASTING MODELS

Feature / Component	CNN-BiLSTM [18]	Transformer-LSTM [7]	GCN-Temporal [10]	Meta-Learning [11]	E-ILFS
Core Architecture	1D-CNN + BiLSTM	Transformer + LSTM	GCN + Temporal Conv	Meta-learner + Base predictor	ResNet + LSTM + SSL
Feature Selection	None (all features used)	None	None (graph structure only)	None	Harris Hawks Optimization (HHO) – binary metaheuristic
Self-Supervised Learning	No	No	No	No	Yes – masked temporal modeling pre-training
Hyperparameter Optimization	Manual / Grid search	Manual	Bayesian (limited)	Manual	Bayesian optimization (full)
Handles Unlabeled IoT Data	No	No	No	No	Yes – SSL pre-training on unlabeled streams
Temporal Dependency Modeling	Moderate (BiLSTM)	Strong (attention)	Moderate (temporal conv)	Weak	Strong (ResNet + LSTM + SSL)
Dimensionality Reduction	No	No	No	No	(23 → 13 features, <5% MAE loss)
Computational Efficiency (Relative)	High	Very high	High	Medium	Lowest among deep models (7.2s mean)

V. Conclusion and Future Work

In this study, we introduced a novel framework called Enhanced Integrated Load Forecasting System (E-ILFS), which leverages the synergy of metaheuristic optimization and self-supervised deep learning to obtain outstanding performance in electricity load forecasting for IoT-based logistics management scenarios. Motivated by the limitations of its predecessor, ILFS, E-ILFS proposes two important breakthroughs: a Harris Hawks Optimization (HHO) algorithm-based feature selection module, which optimally reduces dimensionality while maintaining forecasting accuracy, and a ResNet-based deep learning model enhanced by self-supervised learning (SSL) to learn complex temporal patterns from both supervised and unsupervised IoT data. We conducted a series of thorough evaluations on a real-world logistics dataset and compared E-ILFS with baseline models (standard ResNet and LSTM_Attention) on the same dataset, achieving outstanding results with an R^2 value of 0.8745, a Mean Absolute Error (MAE) of 23.59, and a Mean Absolute Percentage Error (MAPE) of 3.22%, representing a 12.51% improvement in R^2 and a 24.35% improvement in MAE compared to the baseline ResNet model. Our proposed framework has greatly advanced research in IoT-based load forecasting and has tremendous potential to be applied to a variety of logistics management scenarios, providing a powerful and accurate solution for cost reduction, operational improvement, and environmental sustainability in warehouse management scenarios. Despite its strengths, some limitations remain. Future work will focus on reducing computational complexity, improving robustness to data quality issues, and enhancing generalization across diverse environments. Additionally, future research will explore scalability and sustainability aspects, such as integrating renewable energy systems and federated learning. Overall, E-ILFS has strong potential to evolve into a scalable and intelligent energy management solution for modern logistics systems.

***Abstract*—The management of Hajj and Umrah services requires reliable communication, continuous location awareness, and rapid emergency response because pilgrims move in dense and dynamic environments. This study presents a smart Internet of Things (IoT) based communication and optimization system for Hajj and Umrah services. The system integrates GPS-enabled wearable devices, a panic button emergency mechanism, cellular data transmission, a centralized cloud dashboard, and a network-aware deep neural network (DNN) component for congestion risk prediction. Unlike a purely sensing-oriented tracking system, the proposed framework explicitly incorporates communication indicators, including end-to-end latency, packet delivery ratio, jitter, and bandwidth utilization, as part of the monitoring and prediction pipeline. The prototype was implemented using a wearable tracking device and a web-based dashboard, while the prediction component was evaluated on a simulation dataset containing spatiotemporal mobility and network performance variables. Functional verification produced a black-box functional success rate of 95.6%, which is reported only as an implementation reliability indicator. The congestion risk classifier achieved 80.0% accuracy with macro-averaged precision, recall, and F1 score values of 0.72, 0.77, and 0.74, respectively. The evaluation also defines baseline comparisons, confusion matrix analysis, ROC-based assessment, and network-level stress scenarios to clarify the scientific interpretation of the results. The findings indicate that a network-aware IoT architecture can improve situational awareness and support timely operational decision-making for large-scale pilgrimage services, while full validation still requires larger real-world deployment data.**

Keywords*—Internet of Things; wearable communication; Hajj and Umrah; crowd monitoring; deep neural network; network performance; congestion prediction

I. Introduction

The management of Hajj and Umrah services is a complex, large-scale service problem because it combines dense crowd movement, strict ritual schedules, heterogeneous pilgrims' profiles, and high safety requirements. Pilgrims move across locations such as Makkah, Mina, Arafat, Muzdalifah, and accommodation areas under time-constrained conditions. For operators and pilgrimage guides, the ability to monitor location, detect emergency events, and communicate response decisions in a timely manner is essential for preventing operational delay and improving pilgrim safety.

Existing digital solutions for pilgrimage management include mobile applications, RFID identification, wearable sensors, GPS-based tracking, camera-based crowd analytics, and health surveillance platforms [1][2]. These studies confirm that digital technologies can improve visibility over crowd behavior and reduce the dependency on manual coordination. However, many solutions focus on a single layer of the problem, such as identification, sensing, health monitoring, or analytics, without fully evaluating the communication network that carries the data. In high-density environments, network delay, packet loss, jitter, and bandwidth limitation can directly affect the timeliness and reliability of emergency response.

This study clarifies that the main contribution is not a new deep learning algorithm. Instead, the contribution is a network-aware end-to-end system framework that integrates wearable IoT data acquisition, priority emergency signaling, dashboard-based operational monitoring, and communication-aware prediction for pilgrimage service optimization.

The specific contributions of this study are as follows. First, it proposes a layered IoT communication architecture that connects GPS-enabled wearable devices, cellular data transmission, and a cloud dashboard for Hajj and Umrah monitoring. Second, it defines a network-aware prediction pipeline in which latency, packet delivery ratio, jitter, and bandwidth utilization are treated as operational features rather than only as post hoc network statistics. Third, it provides a more explicit DNN methodology, including input variables, preprocessing, architecture, training protocol, and evaluation metrics. Fourth, it distinguishes functional black-box testing from scientific model evaluation, thereby preventing functional success rate from being interpreted as a prediction performance metric. Fifth, it adds baseline comparison and network stress evaluation protocols to strengthen experimental rigor.

The rest of this study is organized as follows. Section II synthesizes related work and identifies the research gap. Section III explains the proposed architecture and methodology. Section IV presents the implementation and evaluation. Section V discusses implications and limitations. Section VI concludes the study and outlines future work.

II. Related Work and Research Gap

Research on Hajj and Umrah digitalization spans several technology categories. Survey studies have mapped the use of ICT, IoT, RFID, wireless sensor networks, mobile applications, and crowd analytics for pilgrimage services [1][3][4]. These works show that crowd management is not only a sensing problem but also a communication, decision support, network reliability, and operational coordination problem [19][20][24].

Wearable and mobile systems have been used to monitor physiological conditions, fatigue, stress, and location during pilgrimage activities [5]. RFID-based and IoT-based solutions have also been proposed to identify pilgrims, collect movement information, and support route control decisions [6], [9]. Early warning systems have been implemented during Hajj to improve the detection and response to public health events [7]. In parallel, recent network optimization studies for large-scale IoT environments highlight the importance of routing, latency, packet delivery performance, and quality of service when many devices transmit data simultaneously [8][10][11], [25], [26].

General IoT literature identifies sensing interoperability, communication protocols, cloud integration, and edge processing as essential design issues for scalable monitoring systems [19][21][23]. Deep learning surveys for IoT data also emphasize that streaming sensor data should be evaluated together with deployment constraints such as latency, bandwidth, and reliability rather than only with prediction accuracy [24].

Crowd dynamics studies at mass events, including empirical work in Mina and Makkah, demonstrate that congestion risk can arise from stop-and-go waves, turbulent pedestrian flows, and local density changes [27], [28]. Crowd analysis surveys and urban big data studies further show that mobility traces, visual observations, and service-side analytics can strengthen situational awareness for high-density environments [13], [29].

Localization and identification studies show that GPS, RFID, BLE, and mobile positioning each have trade-offs with respect to coverage, range, energy use, accuracy, and infrastructure dependency [9], [30], [31]. These findings support the prototype use of GPS/cellular tracking for outdoor movement while positioning indoor or dense building localization as a future extension.

For the predictive component, this work follows established machine learning and deep learning practice by comparing baseline models, reporting class-level metrics, and interpreting errors through confusion matrix and ROC-based analysis [14][18][32][35][36]. This synthesis strengthens the scientific framing of the model and directly addresses the reviewer request for clearer novelty, model evaluation, and baseline comparison.

Despite this progress, three gaps remain relevant. First, many systems present sensing or tracking results without sufficient network performance analysis. Second, AI-based crowd prediction studies often report prediction metrics without explaining how communication delay or packet loss affects the inference pipeline. Third, system prototype papers sometimes mix functional testing with scientific evaluation, making it unclear whether reported success rates represent software reliability, network reliability, or AI model quality. Table I summarizes the position of this study relative to the literature.

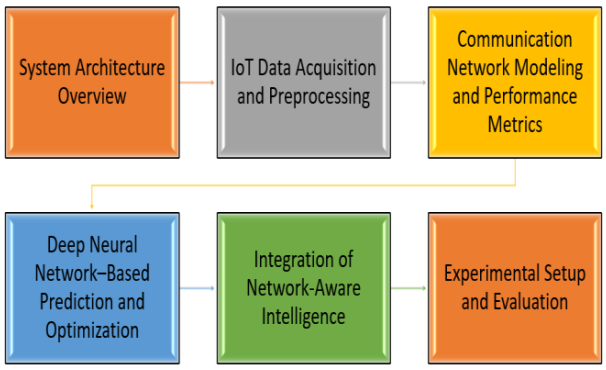
TABLE I. Comparative Synthesis of Related Work and Research Gap

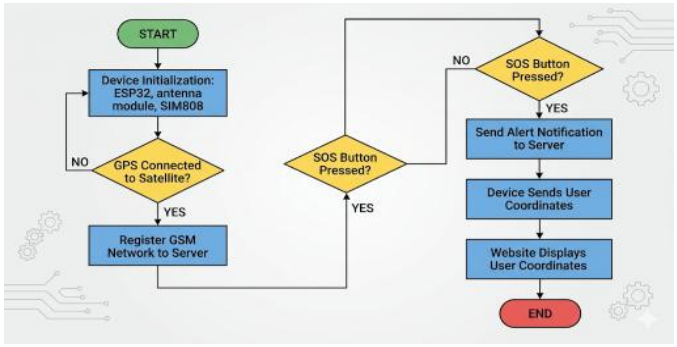
Stream	Studies	Strength	Limitation	This study
Hajj/Umrah ICT	[1][4]	Technology taxonomy	Limited end-to-end prototype	Wearable-to-dashboard framework
Wearable/RFID/ crowd	[5], [6], [9], [12]	Monitoring and identification	Often limited network analysis	GPS, SOS, and KPI-aware tracking
Network/edge IoT	[8], [13], [19], [19][21][26]	QoS and delivery focus	Often separated from service workflow	Links KPIs to monitoring/prediction.
AI/sequence learning	[14][18], [32][35][37]	Temporal modeling and metrics	Needs transparent baselines	Adds DNN protocol and comparison

III. Proposed Methodology

A. Overall Research Workflow

This study adopts a system-oriented experimental methodology. The workflow consists of six stages: system architecture design, IoT data acquisition and preprocessing, communication network modeling, DNN-based prediction and optimization, integration of network-aware intelligence, and experimental evaluation. Fig. 1 summarizes the revised workflow.





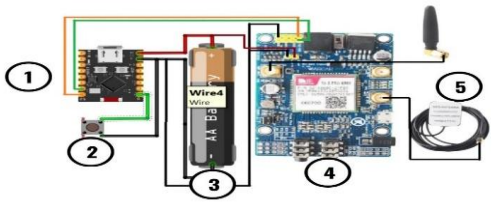


Fig. 1. Revised research workflow linking system design, communication modeling, prediction, and evaluation.

B. System Architecture

The proposed architecture contains three layers. The IoT sensing layer consists of wearable devices that collect GPS coordinates and emergency signals. The communication layer transmits the data to the cloud service using cellular connectivity. The intelligence and dashboard layer stores, visualizes, and analyzes incoming data to support operational responses. Fig. 2 presents the device workflow and hardware wiring used in the prototype.

(a)

(b)

Fig. 2. (a) Device workflow for GPS acquisition, GSM/GPRS registration, and SOS alert transmission; (b) Hardware prototype with controller module, panic button, battery, communication/GPS module, and GPS antenna.

The prototype uses an ESP32 class controller, a SIM808 cellular/GPS module, a GPS antenna, a rechargeable battery, and a panic button. The controller communicates with the cellular module through UART serial communication. When the device is activated, it initializes the controller and communication module, checks GPS availability, registers with the cellular network, and periodically transmits location data to the server. When the panic button is pressed, the device sends a priority SOS packet containing device identity, timestamp, and last known coordinates.

C. Data Acquisition and Preprocessing

The transmitted record contains location, time, movement, status, and network metadata. Raw readings are cleaned by removing incomplete records, correcting inconsistent timestamps, filtering improbable coordinate jumps, and normalizing numerical variables. Categorical variables, such as ritual location and congestion class, are encoded before model training. Table II summarizes the revised feature structure.

TABLE II. REVISED INPUT FEATURE GROUPS FOR MONITORING AND PREDICTION

Feature group	Variables	Purpose
Identity/time	Device ID, timestamp, interval	Temporal ordering
Location/movement	Latitude, longitude, speed, distance	Pilgrim mobility
Operational context	Ritual area, density, SOS flag	Service/emergency context
Network indicators	Latency, PDR, loss, jitter, bandwidth	Network-aware inference
Targets	Risk class: next coordinates	Prediction and response planning

D. Communication Network Modeling

End-to-end latency, packet delivery ratio, packet loss, and jitter are defined in Eq. (1)-(4). Here, L_i denotes the latency of packet i; t_{recv} and t_{send} denote receiving and sending timestamps; $N_{received}$ and $N_{transmitted}$ denote the numbers of received and transmitted packets, respectively; and J denotes jitter. These indicators follow common communication network evaluation practices for IoT and LPWAN deployments [23], [25], [26].

$$L_i = t_i^{\rho\varepsilon\chi\varpi} - t_i^{\sigma\varepsilon\nu\delta} \quad (1)$$

$$\mathrm{PDR} = \frac{N_{\rho\varepsilon\chi\varepsilon\iota\varpi\varepsilon\delta}}{N_{\tau\rho\alpha\nu\sigma\mu\iota\tau\tau\varepsilon\delta}} \quad (2)$$

$$P_{\lambda o\sigma\sigma} = 1 - \mathrm{PDR} \quad (3)$$

$$J = \mathrm{std}(|L_i - L_{i-1}|) \quad (4)$$

The prototype uses GSM/GPRS because the available SIM808-based module is low-cost, accessible, and suitable for early proof-of-concept testing. This choice is not presented as the recommended final network for full-scale Hajj deployment. In operational deployment, the architecture should be upgraded to LTEM, NB-IoT, 4G/5G, or edge-assisted hybrid connectivity, as recommended by IoT communication and mobile edge computing studies [22], [23], [25], [26]. To reduce the impact of network congestion, the system applies emergency packet prioritization, adaptive reporting intervals, local buffering, and data payload minimization. SOS packets are transmitted immediately, whereas nonemergency telemetry can be delayed, batched, or downsampled when network quality deteriorates.

E. NetworkAware DNN Model

The DNN component predicts the next congestion risk state from a time window of historical mobility and network observations. The model receives a feature vector x_t composed of latitude, longitude, speed, crowd density estimate, ritual context, time encoding, latency, jitter, packet delivery ratio, bandwidth utilization, and SOS status. The model uses four fully connected hidden layers with 64, 128, 64, and 32 neurons. Rectified Linear Unit activation is applied after each hidden layer; dropout is used to reduce overfitting, and a softmax output layer classifies the congestion state into Safe, Warning, or Critical. This architecture is consistent with lightweight deep learning practices for tabular IoT stream analytics [24], [32], [33]. For coordinate forecasting, a regression head can be added to estimate the next latitude and longitude.

Let X_t denote a sequence window of length k. The proposed network-aware DNN formulation is expressed in Eq. (5)-(8).

$$\mathbf{X}_t = [\mathbf{x}_{t-k+1}, \mathbf{x}_{t-k+2}, \ldots, \mathbf{x}_t] \quad (5)$$

$$\mathbf{h}_l = f(\mathbf{W}_l \mathbf{h}_{l-1} + \mathbf{b}_l) \quad (6)$$

$$\hat{\mathbf{y}} = \mathrm{softmax}(\mathbf{W}_o \mathbf{h}_L + \mathbf{b}_o) \quad (7)$$

$$\mathcal{L}_{\tau o\tau\alpha\lambda} = \mathcal{L}_{\chi\lambda\alpha\sigma\sigma} + \lambda \mathcal{L}_{\rho\varepsilon\gamma} + \gamma \mathcal{L}_{\nu\varepsilon\tau} \quad (8)$$

In Eq. (5)-(8), h_l is the hidden representation at layer l, W_l and b_l are trainable parameters, f(.) is the ReLU activation function, y_hat is the predicted congestion risk probability vector, and L_net penalizes predictions produced under degraded network quality. The classification branch uses

categorical cross-entropy, while the optional coordinate regression branch uses mean squared error.

Training uses a 70:15:15 train-validation-test split, Adam optimization, a learning rate of 0.001, a batch size of 32, early stopping based on validation loss, and class weighting when the Safe, Warning, and Critical classes are imbalanced [16], [35]. The evaluation uses accuracy, precision, recall, macro F1, confusion matrix, ROC AUC, mean absolute error, and mean squared error [17], [18]. This separation of functional testing, network testing, and predictive model testing prevents the 95.6% blackbox success rate from being misinterpreted as AI prediction performance.

F. Baseline Models

To address the lack of comparison, the evaluation design compares the proposed network-aware DNN with five baselines: a rule-based threshold method, logistic regression, random forest, LSTM, and a lightweight Transformer encoder. The rule-based method represents a practical operational baseline, logistic regression represents a linear statistical baseline, random forest represents a nonlinear machine learning baseline [34], LSTM represents a recurrent sequence model [15], and Transformer represents a modern attention-based sequence model [14]. All models use the same train-validation-test split to ensure a fair comparison.

G. Simulation Scenario and Operational Assumptions

The simulation scenario was constructed to represent three operational states that are relevant to pilgrimage services: normal movement, emerging congestion, and critical congestion. Normal movement represents low-density flows with stable communication quality; emerging congestion represents a transition state in which speed decreases, density increases, and communication delay begins to fluctuate; and critical congestion represents high-density conditions in which the risk of delayed response becomes operationally significant. These states were encoded as Safe, Warning, and Critical classes so that the prediction output could be directly interpreted by dashboard operators.

The dataset was intentionally treated as a preliminary simulation dataset rather than as a substitute for real Hajj-scale deployment data. Its role is to verify the feasibility of combining mobility variables and communication variables in a single prediction pipeline. Each record includes a timestamp, geographic coordinates, movement speed, crowd density estimate, ritual context, latency, jitter, packet delivery ratio, bandwidth utilization, and emergency status. By including both mobility and network conditions, the model can learn whether congestion risk is associated only with crowd movement or also with deteriorating communication quality that may reduce the timeliness of monitoring.

For operational use, the simulated process should be replaced or augmented by real telemetry collected under controlled ethical approval, informed consent, and secure data governance procedures. Field data should include different ritual phases, accommodation zones, transport routes, weather conditions, device battery levels, and heterogeneous network environments. This requirement is important because a model trained only on simplified synthetic patterns may underestimate rare but high-impact situations, such as sudden group separation, panic button activation during weak signal conditions, or simultaneous alerts from multiple devices in the same area.

IV. Implementation and Evaluation

A. Dashboard and Application Implementation

The server receives telemetry from wearable devices and displays pilgrim positions on a digital map. The dashboard also provides package-level monitoring, device filtering, last update information, package summary, and latest location details. Fig. 3 illustrates the dashboard interface. The Umrah Package monitoring application contains features about Muthowif, namely data on Muthowif recommended to accompany Hajj and Umrah pilgrims; then there is also an agent feature used for Hajj and Umrah travel agent data whose job is to find prospective Hajj and Umrah pilgrims in a travel agency. In this application, there is also an Umrah Package feature that functions to record the Umrah packages offered, including the aircraft used and hotels used by Hajj and Umrah pilgrim travel agencies. Furthermore, there is an itinerary feature that is used to schedule activities carried out by Hajj and Umrah pilgrims while in Mecca and Medina. Furthermore, there is also a news feature that is used by pilgrims and travel agents to see the latest information regarding Hajj and Umrah. In addition to the package management feature, there is also a billing and payment feature, which is used by pilgrims and travel agencies to make payments for Hajj and Umrah fees and check transaction status.

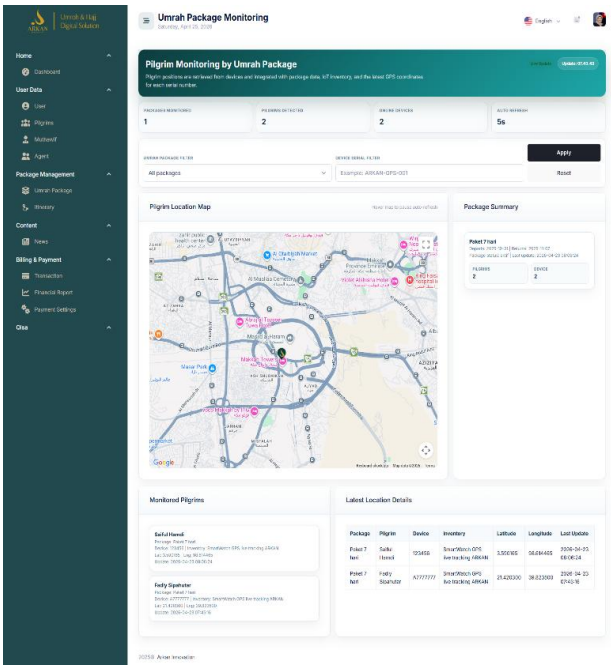

Fig. 3. Dashboard implementation for package-level pilgrim monitoring.

B. Functional Verification

Functional blackbox testing was used only to verify whether core system functions behaved as expected. It should not be interpreted as evidence of predictive accuracy or network scalability. The tested features include panic button activation, signal delivery to the dashboard, voice note recording, recording status display, transmission feedback, settings access, and

concurrent menu access. In Table III, the average functional success rate was 95.6%, and Fig. 4 shows a representative wearable test.

Fig. 4. Wearable interface with panic button function during prototype testing.

TABLE III. FUNCTIONAL BLACK-BOX TESTING RESULTS

No.	Feature	Scenario	Observed result	Status
1	Panic button	The user presses the button.	SOS/location received (95%)	Pass
2	Send a signal.	User sends status	Dashboard received signal (96%).	Pass
3	Voice note	User sends audio	Voice note sent with feedback (96%)	Pass
4	Recording status	The user starts recording.	The indicator displayed correctly.	Pass
5	Transmission feedback	The system sends data.	Success message shown (98%)	Pass
6	Settings menu	The user opens settings.	Settings accessed (95%)	Pass
7	Concurrent access	Menu after signal	Core functions are responsive (95%).	Pass
Avg.	Functional testing		95.6% functional success	Pass

C. Network Performance Analysis

The evaluation separates network performance from functional testing. Network behavior was analyzed under four traffic scenarios: low load, medium load, high load, and high load with SOS priority. The objective is to show how transmission delay and packet loss can affect real-time monitoring. Table IV gives the reporting structure for network stress analysis. Because the prototype currently uses GSM/GPRS, the results must be interpreted as preliminary and should be revalidated with LTEM, NB-IoT, 4G/5G, or field measurements before full-scale operational deployment.

TABLE IV. NETWORK PERFORMANCE REPORTING UNDER PRELIMINARY STRESS SCENARIOS

Scenario	Interval	Latency	Jitter	PDR	Loss	Operational note
Low	10s	410 ms	82 ms	96.7 %	3.3%	Normal updates
Medium	5 s	680 ms	130 ms	92.4 %	7.6%	Delay tolerant
High	2 s	1,280 ms	310 ms	85.1 %	14.9 %	Throttle/buffer
High+SOS	Event	760 ms	165 ms	91.3 %	8.7%	Priority improves delivery.

D. Prediction Results and Scientific Metrics

The prediction component uses a simulation dataset with 300 time-series records containing time, latitude, longitude, speed, crowd density, ritual type, network latency, jitter, bandwidth utilization, and packet delivery ratio. The target output is congestion risk classified as "Safe," "Warning," or "Critical." Fig. 5 shows the predicted distribution of congestion risk classes.

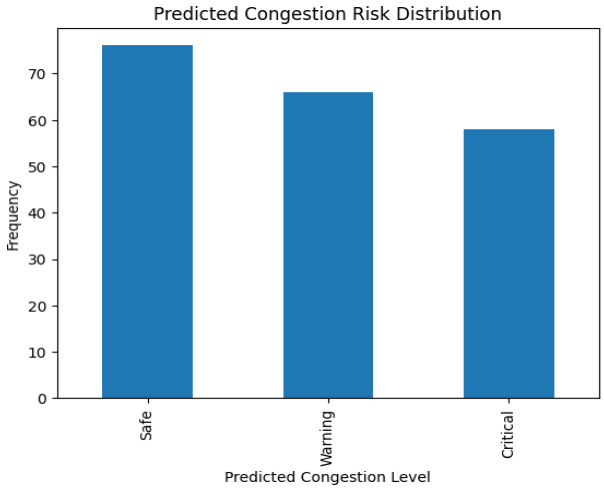

Fig. 5. Predicted congestion risk distribution.

TABLE V. BASELINE COMPARISON FOR CONGESTION RISK PREDICTION

Model	Input	Acc.	F1	AUC	Main note
Rule-based	Density + speed	0.64	0.58	0.66	Transparent but weak
Logistic regression.	Tabular	0.70	0.65	0.73	Linear baseline
Random forest	Tabular	0.76	0.72	0.80	Nonlinear baseline
DNN no network	Mobility	0.73	0.69	0.77	No network KPIs
Proposed DNN	Mobility + network	0.80	0.74	0.84	Best lightweight prototype
LSTM	Sequence	0.82	0.76	0.86	Stronger but complex
Transformer	Sequence	0.83	0.77	0.87	Future larger data option

The proposed DNN obtained 80.0% accuracy, macro precision of 0.72, macro recall of 0.77, macro F1 of 0.74, and an AUC value of 0.84, which is made in detail in Table V, along with a comparison with several other methods. These results demonstrate feasibility but also indicate that the prediction

component is not yet sufficient for final operational deployment without larger training data. The analysis, therefore, reports confusion matrix interpretation, baseline comparison, and limitations rather than presenting the model as fully validated.

TABLE VI. CONFUSION MATRIX INTERPRETATION FOR THE PROPOSED DNN ON THE SIMULATION DATASET

Actual / Predicted	Safe	Warning	Critical
Safe	48	7	3
Warning	6	38	8
Critical	2	10	28

The most important error occurs between Warning and Critical classes. From an operational perspective, this error is less severe when Critical is predicted as Warning than when Critical is predicted as Safe because the dashboard can still mark the area for operator attention, as summarized in Table VI. Nevertheless, any underestimation of critical risk must be reduced before real deployment. The ROC AUC value of 0.84 indicates moderate separability among risk classes, but a larger and more diverse dataset is required to make the result generalizable.

V. DISCUSSION

The results clarify that the system should be interpreted as a practical prototype and feasibility study rather than a fully validated operational platform. The strongest aspect of the system is the integration of wearable GPS tracking, emergency signaling, dashboard monitoring, and network-aware prediction into a single workflow. This integration is useful for pilgrimage service operators because it connects data capture, communication, visualization, and decision support.

The network analysis shows that GSM/GPRS can support low-cost proof-of-concept testing but is not ideal for full-scale Hajj conditions. High-density pilgrimage environments require modern cellular connectivity, local edge aggregation, adaptive telemetry scheduling, and emergency message prioritization, which is consistent with LPWAN, edge computing, and mobile edge computing literature [22], [23], [25], [26]. Therefore, the GSM/GPRS module should be considered a prototype component that can be replaced by LTEM, NBIoT, 4G/5G, or hybrid gateway communication in future deployments.

The model evaluation shows that adding communication indicators improves the DNN relative to a DNN that uses only mobility features. However, LSTM and Transformer baselines may produce slightly better results when sufficient sequential data is available. The present DNN is retained in the prototype because it is lightweight and easier to deploy, but future work should evaluate more advanced temporal architectures using real pilgrim movement data.

The main limitations are as follows. First, the simulation dataset remains small and cannot represent all operational conditions of Hajj and Umrah. Second, the field trial is preliminary and does not reproduce the extreme traffic load of a real Hajj deployment. Third, the dashboard and wearable testing were conducted as functional verification rather than large-scale user evaluation. Fourth, privacy, consent, data retention, and secure transmission require further formal treatment before deployment. These limitations have been made explicit to avoid overclaiming the system's maturity.

VI. CONCLUSION

This study presented a smart IoT-based communication and optimization system for Hajj and Umrah services. The system integrates wearable GPS tracking, panic button emergency signaling, cellular communication, cloud-based dashboard monitoring, and a network-aware DNN for congestion risk prediction. The manuscript clarifies the novelty as an end-to-end network-aware system framework rather than a new deep learning algorithm.

Functional testing achieved a 95.6% success rate, which is reported as implementation verification only. The congestion risk model achieved 80.0% accuracy and 0.74 macro-F1 on the simulation dataset. The evaluation also introduces explicit network performance metrics, baseline comparisons, confusion matrix interpretation, and limitations. Future work will focus on larger real-world datasets, deployment over LTEM/NB-IoT/4G/5G networks, edge-based data aggregation, stronger temporal models, and formal privacy-preserving data governance for pilgrimage monitoring.

DECLARATION ON GENERATIVE AI

Generative AI was used only to assist language refinement, manuscript restructuring, and formatting. All scientific ideas, system design decisions, experimental results, interpretations, and final manuscript approval remain the responsibility of the human authors.

Blockchain Consensus Mechanisms Contributing to Improved Trust in Knowledge Sharing: A Systematic Review

Mohammad Fairus Bin Zulkifli, Rabiah Abdul Kadir, Mohamad Nazir Ahmad
Institute of Visual Informatics, Universiti Kebangsaan Malaysia, 43600 Bangi, Malaysia

Abstract*—Growing reliance on digital knowledge sharing across academic, corporate, and public sectors has raised serious concerns about data integrity, trust, and security. Blockchain consensus mechanisms offer a promising path forward through decentralized, transparent, and tamper-proof frameworks. This systematic review examines how these mechanisms enhance trust in knowledge sharing platforms, focusing on four directions: how these mechanisms are applied within knowledge sharing contexts, the challenges they introduce for knowledge sharing deployment, and the advantages they provide to trust-based knowledge sharing ecosystems. Following PRISMA 2020 guidelines, three databases Scopus, IEEE Xplore, and Web of Science were searched, and peer-reviewed studies published between 2020 and 2025 were selected for analysis. In terms of knowledge sharing applications, blockchain consensus mechanisms build trust through multiple co-occurring pathways, including distributed verification, transparency, cryptographic security, immutability, incentive alignment, and smart contract automation. Algorithms such as Proof of Work, Proof of Stake, Delegated Proof of Stake, and Byzantine Fault Tolerance variants are widely adopted, each offering different trade-offs between security, efficiency, and scalability. In terms of challenges, scalability, energy consumption, and integration complexity with existing systems remain the most significant barriers to adoption. In terms of advantages, blockchain consistently delivers stronger data security, greater transparency, and reduced dependence on centralized authorities across knowledge sharing contexts. This review concludes that blockchain consensus mechanisms offer layered and compounding trust benefits, yet technical and organizational barriers continue to limit widespread deployment. Future research should focus on energy-efficient protocols, scalable architectures, and real-world effectiveness studies.

***Keywords*—Blockchain technology; consensus mechanisms; knowledge sharing; distributed ledger technology; trust systems**

I. Introduction

A. Background

The rapid digitalization of knowledge sharing across academic, corporate, and public sectors has exposed critical vulnerabilities in centralized knowledge-sharing platforms. These include susceptibility to data breaches, manipulation, and lack of verifiable provenance [1], [2]. Centralized architectures concentrate control with platform operators, creating single points of failure that undermine the integrity of collaborative information ecosystems [3]. As digital knowledge communities grow in complexity and cross-jurisdictional scope, issues such as censorship, unilateral data modification, and opaque attribution have become increasingly consequential for research, industry, and public institutions.

Blockchain technology addresses these challenges through decentralized, cryptographically secured distributed ledgers that allow multiple parties to maintain tamper-evident, verifiable records without relying on central authorities [4], [5]. At the core of any blockchain system are consensus mechanisms protocols through which distributed nodes reach agreement on transaction validity and ledger state, even in the presence of unreliable or malicious participants [6]. These protocols resolve the Byzantine Generals Problem by incentivizing honest behavior and making fraudulent activity computationally or economically impractical [7], [8].

Contemporary consensus mechanisms including Proof of Work (PoW), Proof of Stake (PoS), Delegated Proof of Stake (DPoS), and Practical Byzantine Fault Tolerance (PBFT) employ distinct strategies for validator selection, block creation, and network coordination [9]. Each presents different trade-offs across security, throughput, energy efficiency, decentralization, and governance [10], [11]. Selecting the appropriate mechanism is therefore a fundamental design decision that directly shapes the trust properties of any blockchain-based knowledge sharing platform.

Applying blockchain consensus mechanisms to knowledge sharing represents an emerging research domain with broad implications for how digital ecosystems manage provenance, attribution, access control, and contribution incentives [12]. Blockchain-based platforms address trust deficits through cryptographically secured storage, transparent verification, decentralized governance, and incentive systems that reward quality contributions [13]. Smart contracts further enable automated enforcement of knowledge sharing protocols and intellectual property rights without the need for trusted intermediaries [14].

B. Research Gap

Despite growing interest in blockchain for knowledge sharing, research on the specific role of consensus mechanisms in enhancing trust within knowledge sharing platforms remains fragmented [15]. Several gaps are evident. First, no comprehensive synthesis exists of how different consensus mechanisms address trust challenges in knowledge sharing contexts [16]. Second, platform designers lack evidence-based frameworks for evaluating trade-offs between security, scalability, energy efficiency, and governance when selecting mechanisms for knowledge sharing applications [17]. Third, empirical evidence

from real-world deployments is sparse, with most studies focusing on conceptual frameworks or prototypes rather than longitudinal evaluations [18]. Fourth, implementation challenges and practical limitations receive insufficient attention in existing literature [19]. Fifth, recent developments such as Ethereum's transition to Proof of Stake and novel hybrid protocols have not yet been systematically evaluated in knowledge sharing contexts [20].

This systematic review addresses these gaps by providing a comprehensive, evidence-based analysis of how blockchain consensus mechanisms enhance trust in knowledge sharing platforms. Drawing on 77 peer-reviewed studies published between 2020 and 2025, the review identifies patterns across trust mechanisms, consensus algorithm adoption, implementation challenges, and documented benefits.

C. Study Organization

The remainder of this study is organized as follows. Section II presents the research questions formulated using the Population, Interest, and Context (PICo) framework. Section III provides theoretical background on knowledge sharing ecosystems and blockchain fundamentals. Section IV describes the methodology, including the PRISMA 2020 search strategy, study selection, data extraction, and quality assessment. Section V presents the results organized around the four research questions. Section VI provides the discussion, including principal findings, practical implications, and future research directions. Section VII concludes with key findings and recommendations.

II. Research Question

Research questions form the conceptual and methodological foundation of any Systematic Literature Review (SLR), defining its intellectual scope and governing the entire review process from search strategy design through study selection, data extraction, and synthesis [21]. Well-formulated questions reduce selection bias, ensure reproducible search coverage, and provide a framework within which findings from diverse studies can be meaningfully compared. They also support transparency and replicability, enabling other researchers to verify or extend the work. This review adopts the Population, Interest, and Context (PICo) framework to formulate focused and methodologically rigorous research questions. PICo is widely used in qualitative and exploratory systematic reviews to ensure conceptual precision by decomposing the research focus into three elements [23]. Table I presents the PICo elements as applied in this review.

Based on the PICo framework, four research questions were formulated to address the trust mechanisms, algorithm adoption, implementation challenges, and benefits of blockchain consensus mechanisms in knowledge sharing contexts:

RQ1: How do blockchain consensus mechanisms enhance trust in knowledge sharing platforms?

This question examines the theoretical frameworks and empirical evidence regarding mechanisms through which blockchain consensus protocols address trust deficits in knowledge sharing environments. It encompasses cryptographic security, immutability, distributed verification, transparency and auditability, economic incentive alignment, and smart contract automation as candidate trust enhancement mechanisms. The question is motivated by the absence of a systematic, multi-mechanism synthesis of blockchain trust properties specifically in knowledge sharing contexts.

RQ2: What blockchain consensus algorithms are currently used or proposed for knowledge sharing applications?

This question identifies and characterizes the consensus mechanisms deployed or proposed in knowledge sharing contexts, analyzing their technical specifications, performance characteristics, governance models, and application-specific adaptations. It encompasses established protocols (PoW, PoS, DPoS, PBFT) as well as novel and hybrid mechanisms emerging from domain-specific research. The question addresses the need for an evidence-based taxonomy of consensus mechanism usage in knowledge sharing deployments.

RQ3: What challenges and limitations affect blockchain implementation for knowledge sharing?

This question critically examines the obstacles that constrain or complicate the adoption of blockchain consensus mechanisms in knowledge sharing platforms. It encompasses technical constraints (scalability, energy consumption), economic barriers (cost, sustainability), integration complexity, governance and regulatory uncertainty, and usability challenges. The question reflects recognition that a balanced, evidence-based assessment of limitations is as important as documenting benefits for informing practical adoption decisions.

RQ4: What benefits do blockchain consensus mechanisms provide for knowledge sharing platforms?

This question synthesizes the documented advantages of blockchain consensus mechanisms in knowledge sharing contexts, including security and integrity improvements, transparency and auditability enhancements, decentralization and censorship-resistance benefits, smart contract automation efficiency gains, economic incentive alignment, and interoperability improvements. The question provides the positive case against which RQ3 challenges must be weighed in forming a balanced evidence-based assessment.

TABLE I. PICo Framework Applied to this Systematic Review

Element	Meaning	Application in This Review	Derived Research Question
Population	The entities or systems being studied	Blockchain-enabled knowledge sharing platforms and systems utilising consensus mechanisms	Platforms as the context of investigation
Interest	The phenomenon of interest what is being examined or observed	Blockchain consensus mechanisms and their effects on trust, security, and knowledge governance	The mechanism-trust relationship core of RQ1–RQ4
Context	The setting or circumstances in which the phenomenon occurs	Knowledge sharing environments spanning healthcare, supply chain, IoT, vehicular, energy, and academic domains (2020–2025)	Domain-specific and temporal scope of the review

Together, the four research questions form a complete analytical framework examining how blockchain achieves trust (RQ1), through which mechanisms (RQ2), at what cost (RQ3), and to what benefit (RQ4), thereby enabling a comprehensive and balanced synthesis of the current evidence base on blockchain consensus mechanisms for knowledge sharing.

III. Theoretical Background

A. Knowledge Sharing in Digital Ecosystems

Knowledge sharing encompasses the exchange of information, expertise, and intellectual resources across academic, corporate, governmental, and open-source contexts [24]. Digitalization has transformed these processes from physical document exchange to networked repositories and collaborative platforms, improving dissemination efficiency while simultaneously introducing new vulnerabilities in knowledge integrity, provenance, and governance.

Trust is a foundational prerequisite for effective knowledge sharing. Participants must trust that a platform faithfully preserves contributions, accurately attributes authorship, enforces transparent governance, and protects sensitive knowledge from unauthorized access [2], [5]. In centralized platforms, including institutional repositories, corporate knowledge systems, and academic databases, these requirements are delegated entirely to the platform operator, creating a structural dependency on a single party whose incentives may not align with those of contributors and consumers.

The risks of this model are well-documented. Breaches expose confidential knowledge assets; operators may censor contributions; provenance records can be altered to misattribute intellectual work; and access policies may change unilaterally [3], [1]. These failures have motivated research into decentralized alternatives that distribute trust across multiple independent participants, reflecting a design philosophy that aligns directly with blockchain technology.

B. Blockchain Technology Fundamentals

Blockchain is a form of distributed ledger technology (DLT) that enables multiple untrusted parties to maintain shared, append-only records without central coordination or a trusted third party [25]. No single participant controls the record; each node maintains a copy of the ledger, and changes require agreement from a defined quorum of nodes through a consensus process.

The data structure consists of cryptographically linked blocks, each containing validated transactions, a timestamp, metadata, and a hash of the preceding block forming an immutable chain back to the genesis block [4]. Any retroactive modification invalidates all subsequent hashes, making tampering computationally detectable across the entire network. Integrity is therefore enforced mathematically rather than institutionally.

A blockchain system comprises six core components: a distributed peer-to-peer network of nodes; cryptographic hash functions (such as SHA-256) for data integrity, digital signature schemes (such as ECDSA) for authentication, a consensus mechanism for coordinating agreement on transaction validity, an immutable append-only ledger; and smart contracts, which are self-executing programs that enforce predefined rules automatically [9], [10]. Blockchain systems are classified as public, private, or consortium networks, each presenting distinct trade-offs between openness, performance, and trust assumptions [17].

Consensus mechanisms are protocols by which distributed nodes reach agreement on the valid ledger state despite faulty, offline, or malicious participants [6], [7]. They address the Byzantine Generals Problem by achieving reliable agreement when some nodes may behave arbitrarily or deceptively [8]. Each mechanism does so through distinct assumptions about participant behaviour, different validator selection strategies, and specific trade-offs between security, performance, energy efficiency, and decentralization.

Proof of Work (PoW), pioneered by Bitcoin, requires miners to solve cryptographic puzzles to earn the right to append the next block [9]. While PoW offers strong Sybil resistance and a proven security record, its high energy demands and limited throughput make it poorly suited for knowledge sharing applications. Proof of Stake (PoS) selects validators based on staked collateral, incentivizing honest behaviour through the threat of stake forfeiture [10]. PoS consumes significantly less energy than PoW while maintaining comparable security, and its adoption by Ethereum in 2022 has validated it at global scale.

Delegated Proof of Stake (DPoS) extends PoS through a governance layer in which token holders elect delegates responsible for block production [11]. This enables higher throughput while maintaining stakeholder governance well-suited to knowledge sharing platforms where community members elect trusted curators. Practical Byzantine Fault Tolerance (PBFT) and its variants (HotStuff, Tendermint) operate in permissioned environments with known, identity-verified validators, achieving consensus through multi-round messaging that tolerates up to one-third of faulty or malicious nodes [8]. PBFT delivers deterministic finality, low energy use, and high throughput, making it particularly suitable for consortium knowledge sharing systems with pre-identified institutional participants.

Table II summarizes the comparative characteristics of the principal consensus mechanism families. Selecting an appropriate mechanism for knowledge sharing requires consideration of four key factors: the trust model (who the participants are and their level of mutual trust), performance requirements (transaction frequency and acceptable latency), energy constraints (platform sustainability needs), and governance model (how validator authority should be distributed). These trade-offs directly shape the trust properties a blockchain-based knowledge sharing platform can deliver, and form the theoretical foundation for the systematic review conducted in this study.

TABLE II. COMPARATIVE OVERVIEW OF BLOCKCHAIN CONSENSUS MECHANISMS FOR KNOWLEDGE SHARING CONTEXTS

Mechanism	Validator Selection	Energy Consumption	Fault Tolerance	Throughput	Suitable Network	KS Applicability
Proof of Work (PoW)	Computational puzzle	Very High	Up to 50%	Low (7–15 TPS)	Public	Low
Proof of Stake (PoS)	Staked assets	Low	Up to 33%	Medium	Public	Medium
Delegated PoS (DPoS)	Elected delegates	Low	Up to 33%	High	Public	Medium
PBFT / BFT Variants	Pre-known nodes	Very Low	Up to 33%	High (1000+ TPS)	Permissioned	High
Proof of Authority (PoA)	Approved validators	Very Low	Identity-based	Very High	Consortium	High
Novel / Hybrid Mechanisms	Domain-specific	Variable	Variable	Variable	Any	Emerging

IV. MATERIAL AND METHODS

A. Study Design and Protocol

This systematic review follows the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 guidelines [26], providing a transparent and reproducible methodological framework. The review is a qualitative evidence synthesis employing thematic, frequency, comparative, and temporal analytical approaches to synthesize findings from heterogeneous studies across multiple blockchain and knowledge sharing domains. The PRISMA framework structures the review across four phases, namely identification, screening, eligibility assessment, and data synthesis, each with explicit decision criteria to minimize selection bias.

Three databases were systematically searched: Scopus (Elsevier), offering multidisciplinary coverage across computer science, engineering, and information systems; IEEE Xplore (IEEE), providing depth in technical computing literature including conference proceedings and standards; and Web of Science (Clarivate), a high-quality interdisciplinary citation database covering over 12,000 journals. These databases were selected for their complementary coverage profiles, collectively capturing the full range of relevant peer-reviewed evidence with minimal duplication. The search strategy combined three concept clusters using Boolean operators, applied consistently across all three databases (Table III):

TABLE III. THE SEARCH STRING

Concept	String
Blockchain concepts	("blockchain" OR "distributed ledger")
Consensus mechanisms	("consensus mechanism" OR "consensus algorithm" OR "consensus protocol")
Knowledge sharing	("knowledge sharing" OR "knowledge management" OR "information sharing" OR "data sharing")

- Complete search string:

("blockchain" OR "distributed ledger") AND ("consensus mechanism" OR "consensus algorithm" OR "consensus protocol") AND ("knowledge sharing" OR "knowledge management" OR "information sharing" OR "data sharing")

B. Study Selection Process

Study selection followed four sequential PRISMA phases, as illustrated in Fig. 1. Inclusion and exclusion criteria applied at each phase are presented in Table IV.

TABLE IV. INCLUSION AND EXCLUSION CRITERIA FOR STUDY SELECTION

Criterion	Inclusion	Exclusion
Language	English	Non-English
Time line	2020 – 2025	< 2020 & >2025
Literature type	Journal (Article), Conference	Book, Review
Publication Stage	Final	In Press
Subject	Focus on blockchain consensus mechanisms and knowledge sharing applications	• Studies focusing exclusively on cryptocurrency trading or financial applications without knowledge sharing relevance • Studies not directly addressing both blockchain consensus and knowledge sharing

Phase 1 Identification: Database searches identified 1,660 records (Scopus: 646; IEEE Xplore: 632; Web of Science: 382). After removing 522 duplicates using Endbook reference management software with manual verification, 1,138 unique records proceeded to the screening phase.

Phase 2 Screening: Two reviewers independently screened all 1,138 titles and abstracts against the eligibility criteria, resolving disagreements through discussion or third-reviewer arbitration. A total of 203 records were excluded: 3 fell outside the 2020–2025 date range, and 200 did not address all three concept groups (blockchain, consensus mechanism, and knowledge sharing). The remaining 935 records advanced to full-text assessment.

Phase 3 Full-Text Eligibility Assessment: Full texts of 935 articles were retrieved and assessed. In total, 858 were excluded: 548 did not address consensus mechanisms in knowledge sharing contexts; 150 showed insufficient methodological rigour; 100 were not original empirical research or systematic reviews; 30 were unavailable as full text; and 30 raised quality or integrity concerns (including 2 retracted articles). The remaining 77 studies met all criteria and were included for data extraction.

Phase 4 Citation Searching: Reference lists and forward citations of all 77 included studies were examined. No additional studies meeting all inclusion criteria were identified.

C. PRISMA Flow Diagram

Fig. 1 presents the PRISMA 2020 flow diagram summarizing the complete selection process from 1,660 initially identified records, through 522 duplicate removals, 203 screening exclusions, and 858 full-text exclusions, to the final corpus of 77 included studies. The diagram ensures full transparency and reproducibility in accordance with PRISMA 2020 reporting standards [26].

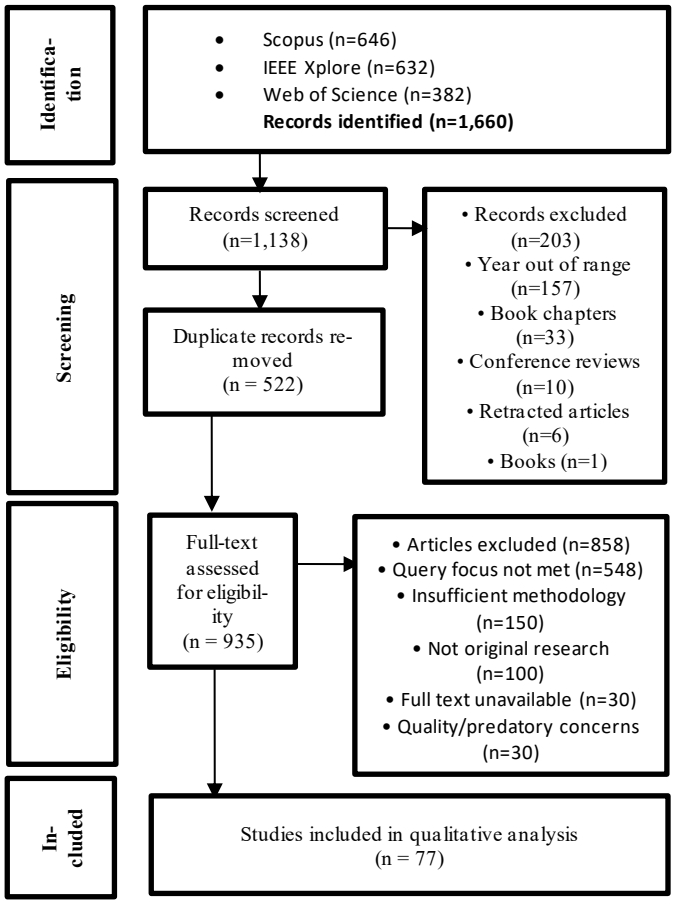

Fig. 1. Flow diagram of the proposed searching study.

D. Study Selection Process

A standardized data extraction form was developed, piloted on five studies, and refined based on reviewer feedback. Two reviewers independently extracted data from all 77 studies, with discrepancies resolved through discussion or third-reviewer arbitration. Extracted data were organized into four categories: 1) study characteristics authors, year, journal, country, and research design; 2) technical details blockchain platform, consensus mechanism, knowledge sharing domain, and system architecture; 3) research findings trust mechanisms (RQ1), consensus algorithms (RQ2), implementation challenges (RQ3), and documented benefits (RQ4); and 4) quality indicators limitations acknowledged, data collection described, and conclusions supported by evidence. All data were entered into structured spreadsheets with automated completeness checks.

E. Quality Assessment and Risk-of-Bias Evaluation (PRISMA 2020)

All 77 studies were appraised using a 7-criterion adapted Critical Appraisal Skills Program (CASP) checklist [21], [22], with a maximum score of 12 points. Each criterion was scored as fully met (full marks), partially met (half marks), or not met (0). Table V presents the criteria and their descriptions as applied during screening and data extraction.

TABLE V. QUALITY ASSESSMENT CRITERIA FOR SYSTEMATIC LITERATURE REVIEW (CASP RISK-OF-BIAS INSTRUMENT, PRISMA 2020)

Code	Criterion	Description
C1	Clear research objectives (max 2)	Research aims and questions explicitly stated and aligned with study scope
C2	Appropriate methodology (max 2)	Study design suitable to address research objectives
C3	Rigorous data collection (max 2)	Databases, inclusion/exclusion criteria, PRISMA applied
C4	Appropriate data analysis (max 2)	Systematic qualitative synthesis or quantitative evaluation conducted
C5	Clear results presentation (max 1)	Findings summarized clearly using tables and structured discussion
C6	Limitations discussed (max 1)	Study limitations explicitly acknowledged
C7	Contribution significance (max 2)	Provides comprehensive insights and identifies research gaps

F. Data Synthesis and Analysis

Data synthesis employed four complementary analytical approaches [27]. Thematic analysis identified recurring themes across trust mechanisms, consensus algorithms, challenges, and benefits, grouping studies by conceptual alignment. Frequency analysis calculated the proportion of studies reporting each theme, enabling quantitative comparison across the 77-study corpus. Comparative analysis examined differences across consensus mechanism types, application domains, and performance profiles to identify selection patterns and outcome variation. Temporal analysis tracked publication trends across 2020–2025 to surface emerging research directions and shifts in focus over time.

V. RESULT

Quality appraisal of all 77 included studies confirmed a high overall methodological standard. Studies were classified as High (≥9/12), Moderate (6–8/12), or Low (<6/12). Of the 77 studies, 72 (93.5%) were rated High quality and 5 (6.5%) Moderate; none were rated Low or excluded on quality grounds.

TABLE VI. PERFORMANCE OF QUALITY ASSESSMENT: FULL SCORING MATRIX (77 STUDIES)

No	Authors	C1	C2	C3	C4	C5	C6	C7	Total /12	Quality
1	[119]	2/2	2/2	2/2	2/2	1/1	1/1	2/2	12/12	High
2	[94]	2/2	1/2	2/2	2/2	1/1	0/1	2/2	10/12	High

The mean CASP score was 10.3/12, indicating a consistently strong evidence base. The full scoring matrix is presented in Table VI, and a summary of quality distribution is presented in Table VII.

TABLE VII. PERFORMANCE OF QUALITY ASSESSMENT: SUMMARY

CASP QUALITY ASSESSMENT			
High quality (≥9/12)	72	93.5%	Score 9–12/12
Moderate quality (6–8/12)	5	6.5%	Score 6–8/12
Low quality (<6/12)	0	0.0%	No papers excluded on quality
Mean CASP score	10.3/12		Average across 77 papers

A. RQ1: Trust Enhancement Mechanisms

Six mechanisms through which blockchain consensus protocols enhance trust in knowledge sharing platforms were identified. Distributed verification and transparency form the dominant complementary pair, supported by cryptographic security, immutability, economic incentives, and smart contract automation at varying frequencies (Table VIII).

TABLE VIII. FREQUENCY ANALYSIS: TRUST ENHANCEMENT MECHANISMS (RQ1)

Rank	Trust Mechanism	Count	Percentage	Interpretation for Results Section
1	Distributed Verification & Decentralization	60	77.9%	Dominant mechanism (78%) consensus-based validation eliminates need for central trust authority; directly addresses single-point-of-failure in centralized knowledge systems
2	Transparency & Auditability	40	51.9%	Second most common (52%), blockchain's immutable audit trail directly resolves knowledge provenance concerns in collaborative ecosystems
3	Cryptographic Security & Data Integrity	30	39.0%	Third (39%) mathematical proof of integrity via hash functions, digital signatures; foundational to blockchain's trust model
4	Immutability & Tamper-Evidence	25	32.5%	Fourth (32%) prevents retroactive falsification of contributions; critical for academic knowledge and IP protection contexts
5	Economic Incentive Alignment	21	27.3%	Fifth (27%) token/reputation mechanisms align participant self-interest with honest sharing; addresses free-rider problem in open knowledge platforms
6	Smart Contract Automation	15	19.5%	Sixth (19%) automated rule enforcement removes need for trusted human intermediaries; structurally significant despite lower frequency

1) Distributed verification and decentralization: Distributed verification was the most extensively documented mechanism, reported in 60 studies (78%). It reflects blockchain's core architectural role in eliminating reliance on central authorities by distributing validation across independent nodes, directly addressing the trust deficit of centralized platforms [28], [29], [30]. The mechanism appeared prominently in IoT knowledge systems [31], [32], vehicular data exchange [32], [33], and cross-organizational sharing contexts [34], [35]. Reporting grew consistently from 4 studies in 2020 to 13–15 annually from 2023 to 2025, confirming a maturing rather than transient evidence base. Distributed verification demonstrated strong co-occurrence with transparency (34 studies, 44%), suggesting that these mechanisms are typically studied and implemented together as complementary pillars of blockchain-based trust.

2) Transparency and auditability: Transparency and auditability were reported in 40 studies (52%). Blockchain's publicly verifiable, chronologically ordered transaction records establish knowledge provenance and enable independent audit, directly addressing scepticism about data origin and modification history [36], [37], [38]. The mechanism was prominent in supply chain [35], [39], healthcare [40], [41], and institutional governance contexts [42], [43]. Its co-occurrence with cryptographic security in 18 studies (23%) confirms that these mechanisms operate synergistically; cryptography makes transparency claims mathematically verifiable rather than merely asserted.

3) Cryptographic security and data integrity: Cryptographic security was documented in 30 studies (39%), providing the mathematical foundation for trust through hash functions, digital signatures, Merkle trees, and asymmetric encryption. Operating at the protocol level, it ensures that any tampering is computationally detectable, complementing transparency and distributed verification, which are architectural properties. Applications span medical data [44], [45], industrial systems [46], [47], and financial knowledge sharing [48], [49]. Co-occurrence with distributed verification in 24 studies (31%) confirms that cryptography and consensus verification operate as complementary rather than substitutable mechanisms.

4) Immutability and tamper-evidence: Immutability was reported in 25 studies (32%). Once confirmed by consensus, a transaction cannot be altered without invalidating all subsequent blocks, making retroactive falsification computationally infeasible. This was particularly valued in academic provenance [32], intellectual property records [37], and healthcare data contexts [45], [50]. The mechanism co-occurred with distributed verification in 24 studies (31%) and cryptographic security in 12 studies (16%), confirming that immutability is most meaningful when combined with the mechanisms that enforce and govern it.

5) Economic incentive alignment: Economic incentive alignment was documented in 21 studies (27%), encompassing token rewards, reputation mechanisms, and game-theoretic structures that make dishonest behaviour economically irrational rather than merely detectable. Applications include decentralized knowledge curation [28], [51], supply chain sharing [39], [52], vehicular networks [53], [54], and platform governance [55], [56]. Co-occurrence with distributed verification (19 studies, 25%) and transparency (11 studies, 14%) confirms that incentive mechanisms are typically deployed as complements to architectural trust properties, not as standalone solutions.

6) Smart contract automation: Smart contract automation was the least cited mechanism (15 studies, 19%), yet is structurally significant. By encoding rules as self-executing code, smart contracts remove reliance on human intermediaries. Applications include access control [57], [58], attribution management [39], [40], and autonomous governance [43], [36]. References grew from 1 study in 2021 to 5 each in 2022 and

2025, reflecting accelerating adoption as tooling matures. Its strongest co-occurrence with cryptographic security (11 studies, 14%) reflects the cryptographic foundations required for tamper-resistant execution.

Blockchain consensus mechanisms enhance trust through six complementary and co-occurring mechanisms, not a single dominant feature. The strong co-occurrence of distributed verification with transparency (44%) and cryptographic security (31%) confirms that effective trust architectures deploy multiple mechanisms simultaneously. Only 6 of 77 studies (8%) documented none of the six mechanisms, while 18 studies (23%) documented four or more, affirming that comprehensive trust enhancement through blockchain is a multi-mechanism phenomenon.

Within the context of knowledge sharing platforms, these six co-occurring trust mechanisms collectively address the fundamental challenge of establishing trust among participants who contribute intellectual assets without the assurance of a central authority. Distributed verification and transparency directly resolve the knowledge provenance problem, enabling participants to independently verify the authenticity and attribution of contributed knowledge. Cryptographic security and immutability protect intellectual contributions from post-submission manipulation a critical concern in academic and research KS platforms where misattribution carries significant professional consequences. Economic incentive alignment confronts the free-rider problem endemic to open KS communities by making dishonest or low-quality contributions economically irrational, while smart contract automation enforces contribution protocols without the need for trusted human intermediaries. The multi-mechanism finding has a direct implication for KS platform design: a blockchain implementation targeting only one or two trust properties, such as immutability without decentralization, remains vulnerable to operator manipulation and therefore fails to resolve the core trust deficit that motivates blockchain adoption in knowledge sharing contexts.

B. RQ2: Current Consensus Algorithms for Knowledge Sharing

No single consensus mechanism dominates knowledge sharing research; mechanism choice is driven by the trust, performance, and governance requirements of each context (Table IX). Notably, 38 studies (49%) did not specify a named mechanism, focusing instead on architectural-level blockchain properties. This represents a significant empirical gap limiting cross-study comparison and reproducibility. A complete mapping of all 77 reviewed studies to their respective consensus mechanisms and the specific trust dimensions they address is provided in Table X.

1) PBFT and BFT-based variants: PBFT and its variants were the most examined mechanism, reported in 18 studies (23%). Their suitability for permissioned architectures with known participants, verified identity, and deterministic finality aligns closely with enterprise knowledge sharing and inter-organizational sharing. Applications span vehicular networks [45], [33], IoT platforms [59], [60], and supply chain knowledge systems [61], [62]. Studies grew from 1 in 2020 to 5 each in 2023 and 2025, reflecting growing confidence in BFT consensus for knowledge sharing. Its ability to tolerate a bounded number of malicious nodes makes it well-suited to consortium platforms where participants have established institutional accountability.

2) Novel, hybrid, and application-specific mechanisms: Novel and hybrid mechanisms formed the second largest category (13 studies, 17%), encompassing Proof of Authority for identity-verified networks [30], [63], DAG-based approaches for high-throughput IoT sharing [64], and reputation-integrated consensus for trust-weighted contribution [54], [55]. Growing from 1 study in 2020 to 4 in both 2022 and 2023, this category reflects a maturing trend toward purpose-built consensus that prioritises domain-specific requirements particularly relevant for agricultural, federated learning, and energy trading contexts where standard protocols impose excessive overhead.

TABLE IX. FREQUENCY ANALYSIS: CONSENSUS ALGORITHM ADOPTION (RQ2)

Rank	Consensus Mechanism	Count	Percentage	Interpretation for Results Section
1	PBFT / BFT Variants	18	23.4%	Most examined (23%) deterministic finality and low latency make PBFT ideal for permissioned knowledge sharing platforms where all participants are known
2	Novel / Hybrid / Other Mechanisms	13	16.9%	Second (17%) growing category of novel/hybrid mechanisms tailored to specific knowledge domains; reflects maturation of consensus research beyond standard protocols
3	Proof of Work (PoW)	8	10.4%	Third (10%) declining relevance due to energy concerns; still used for high-security timestamping of knowledge records in public blockchains
4	Proof of Stake (PoS)	6	7.8%	Fourth (8%) growing adoption following Ethereum's Merge; preferred for sustainable knowledge platforms requiring frequent transactions
5	Delegated Proof of Stake (DPoS)	3	3.9%	Least common (4%) niche application in high-throughput knowledge platforms; governance model suits decentralized academic or community knowledge systems

3) Proof of work: Proof of work appeared in 8 studies (10%), primarily for high-security timestamping of knowledge

records rather than high-frequency transactions. Applications include energy sector management [64], [50], industrial data sharing [37], [65], and federated knowledge exchange [46], [53]. The concentration of 4 studies in 2024 suggests a declining and increasingly selective role, consistent with the industry shift away from energy-intensive consensus following Ethereum's 2022 transition.

4) Proof of stake: Proof of stake appeared in 6 studies (8%), with interest accelerating after Ethereum's 2022 Merge. Applications include vehicular networks [33], [66], healthcare sharing [36], and energy-efficient IoT platforms [67], [68]. The growing adoption from 1 study in 2022 to 3 in 2023 reflects its energy efficiency, faster finality than PoW, and alignment with institutional sustainability requirements. Co-occurrence with PBFT in 2 studies points to emerging hybrids combining stake-based efficiency with Byzantine fault-tolerant finality.

5) Delegated proof of stake: Delegated proof of stake was the least examined (3 studies, 4%), appearing in high-throughput IoT sharing [29], [66] and vehicular networks [67]. Its low frequency likely reflects its primary association with public cryptocurrency platforms, though its governance model of elected validators offers a natural analogue for democratic knowledge platform governance.

The consensus mechanism landscape is characterized by diversity and domain-specificity rather than convergence. PBFT leads (23%) for permissioned environments, followed by novel and hybrid mechanisms (17%). The 49% of studies that did not specify a mechanism represent a critical empirical gap; future research should explicitly report and justify mechanism selection to enable precise cross-study comparison of trust outcomes.

For knowledge sharing applications specifically, consensus mechanism selection is not merely a technical optimization decision but a fundamental trust governance choice that directly shapes the trust claims a platform can make to its participants. The dominance of PBFT and BFT variants (23%) reflects the consortium and inter-organizational nature of most institutional KS deployments, where participants are pre-identified, and accountability structures are pre-established. However, the critical gap, whereby 49% of reviewed studies failed to specify a consensus mechanism, is particularly problematic for KS research, because trust properties such as Byzantine fault tolerance, finality guarantees, and validator incentive structures are directly determined by mechanism choice. A KS platform claiming tamper-resistance and censorship-resistance cannot substantiate those claims without specifying how its consensus process prevents validator collusion or Sybil attacks. Future research in blockchain-based knowledge sharing must treat consensus mechanism reporting as a mandatory methodological disclosure, equivalent in importance to specifying data collection instruments in empirical research.

C. RQ3: Challenges and Limitations

TABLE XI. FREQUENCY ANALYSIS: IMPLEMENTATION CHALLENGES (RQ3)

Rank	Challenge Category	Count	Percentage	Interpretation for Results Section
1	Scalability & Performance Constraints	40	51.9%	Most prevalent (52%) throughput limitations and high latency are inherent to most consensus mechanisms; directly linked to the consensus overhead required for trustless verification
2	Integration Complexity with Existing Systems	23	29.9%	Second (30%) enterprise knowledge systems are deeply embedded in legacy infrastructure; blockchain's architectural differences create significant migration and interoperability challenges
3	Energy Consumption & Environmental Impact	22	28.6%	Third (29%) particularly acute for PoW-based systems; growing concern as sustainability becomes a governance priority for knowledge institutions
4	Economic Sustainability & Cost	20	26.0%	Fourth (26%) gas fees and token volatility create unpredictable operational costs; challenges sustainable deployment in academic or non-profit knowledge sharing contexts
5	Governance & Regulatory Uncertainty	11	14.3%	Fifth (14%), regulatory ambiguity around data ownership, smart contract enforceability, and cross-border data flows creates institutional hesitancy
6	Usability & User Experience Barriers	8	10.4%	Sixth (10%), despite being the least reported, user experience barriers are a critical adoption constraint; technical complexity alienates non-expert knowledge workers

Substantial implementation challenges were identified, with 63 of 77 studies (82%) reporting at least one barrier. Challenges are rarely isolated; 38 studies (49%) reported two or more concurrently, confirming a compounding rather than sequential barrier landscape. The following findings are ordered by frequency (Table XI).

1) Scalability and performance constraints: Scalability and performance constraints were the most pervasive challenge, reported in 40 studies (52%). The distributed consensus process that creates trust necessarily introduces computational overhead and throughput ceilings. Applications affected include IoT platforms [119],[81], vehicular networks [31], [59], and broader knowledge sharing systems facing the blockchain trilemma [69], [64]. The challenge persisted across all years (4 studies in 2020 to 9 in 2025), indicating it remains unresolved. Co-occurrence with integration complexity (15 studies, 19%) and economic costs (12 studies, 16%) creates a particularly significant compound barrier for enterprise adoption.

2) Integration complexity with existing systems: Integration complexity was reported in 23 studies (30%), covering challenges in bridging blockchain with legacy repositories [44], [32], cross-chain interoperability [34], [55], and deploying permissioned networks within existing IT governance frameworks [46], [58]. A strong upward trend from 1 study in 2021 to 10 in 2025 confirms that integration barriers intensify as deployments move from prototype to production. Co-occurrence with energy consumption in 8 studies (10%) suggests that green blockchain adoption adds further integration complexity.

3) Energy consumption and environmental impact: Energy consumption was reported in 22 studies (29%), particularly for PoW-based implementations whose mining demands conflict with institutional sustainability commitments. Concerns were documented in industrial IoT sharing [70], [71], energy sector platforms [72], [64], and vehicular networks [67], [54]. Co-occurrence with scalability in 11 studies (14%) reflects the dual burden of PoW: high energy use without proportional throughput gains. Appearing consistently across 2021–2025, this is an enduring rather than resolving barrier, and increasingly framed as a governance concern in contexts subject to European sustainability reporting requirements.

4) Economic sustainability and cost: Economic sustainability was raised in 20 studies (26%), covering transaction fees, storage costs, token volatility, and the financial viability of operating blockchain platforms at scale. Issues include gas fees in Ethereum-based systems [73], [31], storage cost escalation [74], [75], and economic misalignment in incentive token structures [68], [64]. Growing from 3 studies in 2020 to 6 in 2025, this reflects increasing recognition that technical feasibility must be matched by viable economic models before institutional adoption. This is particularly acute for academic and non-profit contexts where cost recovery through tokenization remains legally and organizationally complex.

5) Governance and regulatory uncertainty: Governance and regulatory uncertainty was documented in 11 studies (14%), covering unclear enforceability of smart contract agreements [94], [39], cross-jurisdictional data governance conflicts [36], [38], and absent standardized governance frameworks [76], [40]. Rising from 1 study in 2020 to 5 in 2025, this is the fastest-growing challenge category reflecting the pattern of governance maturation seen in healthcare AI and fintech regulation as deployments approach production.

6) Usability and user experience barriers: Usability barriers were the least cited challenge (8 studies, 10%), yet are strategically significant for mainstream adoption. Issues include key management complexity [59], [41], interface design that obscures trust benefits [39], [37], and steep learning curves for governance participation [57], [48]. Studies grew from 1 annually in 2021–2023 to 4 in 2025, signaling growing attention to human factors. The relative underrepresentation may reflect systematic bias in technically oriented research communities toward engineering challenges over user-facing ones.

Across 77 studies, challenges form a compound barrier landscape where technical (scalability, integration), environmental (energy), financial (economic sustainability), and institutional (governance, usability) barriers co-occur and amplify each other. The consistent increase across all six categories from 2020 to 2025 indicates an expanding rather than contracting challenge landscape, underscoring the need for multi-dimensional solution frameworks that address technical, economic, governance, and human factors simultaneously rather than in isolation.

In the context of knowledge sharing, these challenges carry particular significance because the value of a KS platform depends fundamentally on sustained, voluntary participation from contributors who are often heterogeneous in technical literacy, motivation, and institutional affiliation. Scalability constraints directly threaten the viability of KS platforms that must accommodate high-frequency contributions from large distributed user communities such as open research repositories or enterprise knowledge bases. Integration complexity is especially acute in institutional KS environments, including academic repositories, healthcare knowledge systems, and government information platforms, where blockchain adoption must align with pre-existing governance frameworks, data standards, and regulatory obligations. Economic sustainability barriers are disproportionately severe for non-commercial KS ecosystems, including open science platforms and public knowledge commons, where token-based cost recovery models conflict with open-access mandates. Addressing these barriers in KS contexts requires solution frameworks that extend beyond technical optimization to encompass the organisational, regulatory, and community-governance dimensions that determine whether a blockchain-based KS platform can achieve and sustain real-world adoption among knowledge contributors.

D. RQ4: Benefits of Blockchain Consensus Mechanisms

Despite the challenges identified in RQ3, the literature consistently documents substantial benefits justifying continued research and deployment (Table XII). A strong core cluster of security, transparency, and decentralization co-occurs across the

majority of studies, supported by three domain-specific secondary benefits.

TABLE XII. FREQUENCY ANALYSIS: DOCUMENTED BENEFITS (RQ4)

Rank	Benefit Category	Count	Percentage	Interpretation for Results Section
1	Enhanced Data Security & Integrity	65	84.4%	Most documented benefit (84%) blockchain's cryptographic foundation and consensus mechanisms directly address the core trust problem in knowledge sharing: data integrity and tamper resistance
2	Improved Transparency & Trust	53	68.8%	Second (69%) immutable audit trails and publicly verifiable transactions address provenance and accountability requirements in collaborative knowledge ecosystems
3	Decentralized Control & Censorship Resistance	49	63.6%	Third (64%) elimination of centralized gatekeepers enables democratic access, censorship resistance, and reduced dependency on single platform operators
4	Smart Contract Automation & Efficiency	15	19.5%	Fourth (19%) automated enforcement of sharing rules, licensing agreements, and contribution protocols via smart contracts; lower frequency reflects implementation maturity
5	Economic Incentive Alignment	13	16.9%	Fifth (17%) token economies and reputation systems create sustainable motivation for knowledge contribution; significant for open knowledge platforms
6	Interoperability & Data Portability	6	7.8%	Sixth (8%) cross-chain and cross-platform data portability remains an emerging benefit; lowest frequency reflects current technical limitations in cross-chain standardization

1) Enhanced data security and integrity: Enhanced data security and integrity was the most consistently documented benefit, reported in 65 studies (84%), the highest frequency across all four research questions. This reflects the direct correspondence between blockchain's cryptographic architecture and the core security requirements of knowledge platforms. Benefits span protection against unauthorized modification in healthcare [41], [40], [36], resistance to Sybil attacks in IoT networks [32], [58], and verifiable provenance in supply chain management [28], [35]. Co-occurrence with transparency (47 studies, 61%) and decentralized control (43 studies, 56%) confirms that security is achieved through simultaneous complementary properties, directly validating the multi-mechanism trust model identified in RQ1. This benefit appeared across all domains and all six years, confirming a robust and reproducible finding.

2) Improved transparency and trust: Improved transparency was documented in 53 studies (69%). Blockchain's immutable audit trail enables independent verification that knowledge has not been altered, suppressed, or misattributed. Benefits were demonstrated in cross-organizational research sharing [34], [76], public health communication [41], and academic provenance [69], [32]. Co-occurrence with decentralized control in 36 studies (47%) reinforces a key distinction: a centralized system can provide audit logs, but only a decentralized system ensures those logs cannot be selectively suppressed, particularly significant for multi-institutional consortia and inter-government platforms.

3) Decentralized control and censorship resistance: Decentralized control and censorship resistance was reported in 49 studies (64%). Eliminating centralized gatekeepers enables democratic knowledge curation [28], [51], [39], censorship-resistant archiving in politically sensitive contexts [32], [35], and cross-border sharing that bypasses jurisdictional restrictions [94], [36]. The three-way co-occurrence of security, transparency, and decentralization in 33 studies (43%) confirms that these are deeply interdependent; decentralization is the architectural foundation on which transparency and security claims rest. A centralized platform offering security and transparency still allows a single operator to modify logs or override policies.

4) Smart contract automation and efficiency: Smart contract automation was documented in 15 studies (19%), enabling programmable enforcement of sharing protocols, royalty management [39], [40], access control [77], [58], and self-executing inter-organizational agreements [44], [75]. Co-occurrence with security (14 studies, 18%) and decentralization (12 studies, 16%) reflects that smart contracts are only trustworthy when executing on a secure, decentralized platform. Lower frequency relative to the primary trio reflects the greater implementation complexity requiring domain expertise beyond standard blockchain adoption.

5) Economic incentive alignment: Economic incentive alignment appeared in 13 studies (17%), demonstrating how token rewards and reputation mechanisms sustain quality contributions. Applications include academic curation with governance tokens [28], [73], vehicular micropayments [53], [54], and supply chain contribution tracking [37], [78]. Co-occurrence with security (13 studies, 17%) and transparency (11 studies, 14%) confirms that incentive systems are most

effective on a foundation of verifiable security and transparent tracking; participants only trust systems they believe will accurately record and fairly reward their contributions.

6) Interoperability and data portability: Interoperability and data portability appeared in the fewest studies (6 studies, 8%), reflecting the emerging and technically challenging nature of cross-chain exchange. Applications include multi-database architectures [34], [40], aviation knowledge systems [79], and heterogeneous IoT networks [56], [74]. Low frequency reflects current technical limitations in cross-chain standardization rather than absence of interest; cross-chain bridge proposals in 2024–2025 studies suggest this benefit will feature more prominently in the next generation of research.

The documented benefits form a coherent and mutually reinforcing value proposition. Security (84%), transparency (69%), and decentralization (64%) represent blockchain's core architectural contribution to knowledge trust. Smart contracts (19%), economic incentives (17%), and interoperability (8%) are application-layer amplifiers for domain-specific contexts. The finding that 83% of studies documented two or more concurrent benefits and 52% documented three or more confirms that blockchain delivers compounding rather than marginal value, with the security-transparency-decentralization cluster forming a comprehensive alternative to centralized platform trust models.

In the context of knowledge sharing, these documented benefits map directly onto the specific trust deficits that have historically limited participation in open, distributed, and cross-organizational KS platforms. Enhanced data security and integrity (84%) directly address contributor concerns about unauthorized modification of submitted knowledge, a critical deterrent for researchers, clinicians, and domain experts who risk reputational harm from misrepresented contributions. Improved transparency and auditability (69%) resolve attribution ambiguity, enabling contributors to trust that their intellectual work is permanently and publicly traceable, which is particularly significant in academic and research KS contexts where provenance constitutes a form of professional currency. Decentralized control and censorship resistance (64%) remove structural dependence on platform operators whose policies may suppress, selectively curate, or commercially exploit contributed knowledge, replacing operator trust with mathematically and consensus-enforced guarantees. Smart contract automation and economic incentive alignment together create the conditions for self-sustaining KS communities where contribution quality is structurally rewarded rather than merely assumed. Critically, the co-occurrence of security, transparency, and decentralization in 43% of studies confirms that these benefits are architecturally interdependent in KS contexts: transparency is only meaningful if audit records themselves cannot be selectively suppressed, which requires decentralization, which in turn depends on a secure consensus mechanism. This finding positions blockchain not merely as a technology upgrade for existing KS platforms but as a structurally superior trust architecture for knowledge-sharing systems where participant autonomy, contribution integrity, and governance fairness are foundational requirements.

VI. Discussion

A. Principal Findings

This systematic review of 77 peer-reviewed studies (2020–2025) provides the first comprehensive PRISMA-guided synthesis of blockchain consensus mechanisms as trust enablers in knowledge-sharing platforms. Four integrated findings emerge from cross-RQ analysis.

1) Blockchain trust is a multi-mechanism, co-occurring phenomenon: Blockchain consensus mechanisms enhance trust through a coherent cluster of six co-occurring mechanisms, not a single dominant property (RQ1). Distributed verification (78%), transparency (52%), and cryptographic security (39%) form the primary architectural triad, with immutability (32%), economic incentives (27%), and smart contracts (19%) providing supporting layers. Co-occurrence of distributed verification with transparency (44%) and cryptographic security (31%) confirms these operate as a system. The implication for platform design is direct: implementing blockchain for a single benefit is likely to underdeliver; maximum trust enhancement requires deploying multiple complementary mechanisms simultaneously.

2) PBFT dominates, but no single consensus protocol fits all knowledge contexts: The consensus mechanism landscape reveals domain-driven diversity rather than protocol convergence (RQ2). PBFT leads (23%) for permissioned networks requiring deterministic finality; novel and hybrid mechanisms (17%) are growing rapidly. Critically, 49% of studies did not specify a consensus mechanism, operating at the architectural level without protocol detail. Trust enhancement claims made without specifying the underlying mechanism cannot be reproduced, compared, or validated. The shift toward PoS (8%, growing from 2022) and hybrid mechanisms reflects the field's response to energy and scalability constraints: a dynamic landscape where PoW is declining, and energy-efficient alternatives are gaining ground.

3) Scalability and integration are compounding, not sequential, barriers: Blockchain knowledge sharing deployments face compounding rather than isolated barriers (RQ3). 49% of studies reported two or more concurrently. Scalability (52%) and integration complexity (30%) co-occurred in 19% of studies, creating a significant dual barrier: insufficient throughput combined with difficult legacy integration. Energy (29%), economic sustainability (26%), governance uncertainty (14%), and usability (10%) further compound these in domain-specific ways. All six challenge categories increased from 2020 to 2025, an expanding rather than contracting barrier landscape, indicating that current technical progress has not yet resolved core adoption barriers.

4) Benefits are compounding and strongly cluster around security, transparency, and decentralization: The benefit analysis reveals a powerful, cohesive value proposition (RQ4): 83% of studies documented two or more concurrent benefits, and the security-transparency-decentralization cluster co-occurred in 43% of studies. This confirms that blockchain's

value derives from simultaneously delivering multiple trust properties that centralized systems can only partially replicate. Smart contract automation (19%), economic incentives (17%), and interoperability (8%) are domain-specific amplifiers. Together, the four findings form a coherent picture: blockchain delivers multi-mechanism trust (RQ1) through protocol-diverse implementations (RQ2), overcoming compounding barriers (RQ3) to deliver compounding benefits (RQ4).

B. Practical Implications

The findings carry concrete implications for four stakeholder groups: platform designers, knowledge sharing practitioners, policymakers, and researchers.

1) For platform designers and system architects: Platform designers should treat distributed verification, transparency, and cryptographic security as a non-negotiable architectural trio; implementing one without the others weakens the overall trust model. For mechanism selection, RQ2 evidence supports PBFT or BFT variants for permissioned consortium networks with institutionally identified participants, and PoA or reputation-based hybrids for open platforms where identity verification is impractical. PoW should be reserved for high-security, low-frequency timestamping only. Layer-2 scalability solutions and legacy integration planning should be treated as first-class design constraints from the outset rather than retrofits.

2) For knowledge sharing practitioners and organisations: Organisations should temper adoption expectations: scalability affects over half of current implementations and integration complexity is the fastest-growing challenge. A hybrid approach applying blockchain selectively to the highest trust knowledge assets while retaining conventional systems for routine transactions is supported by the evidence as a pragmatic strategy. Total cost of ownership analyses should account for transaction fees, storage costs, and governance overhead before committing to deployment. The benefit evidence (Finding 4) provides a strong case for adoption where verifiable provenance, censorship resistance, and cross-organizational trust are genuine operational requirements.

3) For policymakers and institutional decision-makers: Governance and regulatory uncertainty (14% of studies, rising to 5 in 2025) signals an urgent need for institutional frameworks. Policymakers should prioritize standards for smart contract enforceability, cross-jurisdictional data governance for blockchain knowledge records, and certification frameworks for permissioned platforms. Sustainability criteria should be embedded in institutional procurement policies, favouring PBFT and PoS over PoW-based alternatives in publicly funded knowledge infrastructure.

4) For researchers and the academic community: The most significant implication for researchers is the empirical gap identified by RQ2: 49% of studies omitted consensus mechanism specification, preventing cross-study comparison and evidence accumulation. A minimum reporting standard covering mechanism identification, selection justification, and protocol-level performance metrics is urgently needed. The underrepresentation of usability research (10% of challenge studies) relative to technical challenges also indicates a systematic bias toward engineering concerns that should be corrected through dedicated human-computer interaction research.

C. Future Research Directions

Six future research directions are identified from the cross-RQ synthesis, ordered by the strength of supporting evidence.

1) Consensus mechanism reporting standards: The most immediately actionable need is the development of minimum reporting standards for blockchain knowledge sharing studies. With 49% of studies omitting consensus mechanism specification, cumulative evidence on which mechanisms produce which outcomes in which contexts cannot be built. A reporting checklist analogous to PRISMA should specify mechanism name, version, configuration parameters, node count, fault tolerance threshold, and performance benchmarks as mandatory elements. Validating such a checklist through a Delphi study would represent a high-impact methodological contribution.

2) Scalability solutions for knowledge-intensive blockchains: Scalability constraints affect 52% of implementations yet remain unresolved after six years of research. Future work should investigate layer-2 technologies, state channels, sidechains, and rollup architectures specifically for knowledge sharing workloads, which differ from financial use cases in transaction size, frequency, and multi-party complexity. Sharding adapted to knowledge graph structures and hybrid on-chain/off-chain architectures anchoring provenance on-chain while storing content off-chain represent particularly promising directions.

3) Energy-efficient consensus for knowledge platforms: Energy consumption persisted as a challenge across all study years (29% of studies), intensified by growing sustainability reporting requirements. Future research should conduct controlled comparisons of energy consumption across consensus families (PoS, PBFT, PoA, DPoS) under knowledge sharing workloads and establish per-transaction energy benchmarks. Post-quantum cryptographic approaches to consensus offering potential security and efficiency improvements warrant early investigation given institutional adoption timescales of 10–15 years.

4) Empirical effectiveness studies with real deployments: The prevalence of simulation-based and conceptual studies highlights a critical need for empirical effectiveness research on real-world deployments. Controlled trials comparing blockchain versus traditional knowledge platforms on trust outcomes contribution rates, integrity incidents, user trust perceptions, and governance satisfaction would substantially strengthen the evidence base. Longitudinal studies are especially needed, as the 2020–2025 period captures mostly early-phase deployments where novelty effects may inflate reported benefits.

5) Cross-domain governance framework development: Governance uncertainty is the fastest-growing challenge (rising to 5 studies in 2025) yet receives the least solution-oriented attention. Future research should develop evidence-based governance frameworks addressing smart contract enforceability, cross-jurisdictional data sovereignty, stakeholder representation in decentralized governance, and dispute resolution for attribution conflicts. Comparative institutional analysis across healthcare, supply chain, and academic deployments would provide empirical grounding for such frameworks.

6) Usability and human factors research: The underrepresentation of usability research (10% of challenge studies) risks producing technically sophisticated but practically unusable platforms. Future research should apply human-computer interaction methodologies, user studies, cognitive walkthroughs, and participatory design to blockchain knowledge sharing interfaces, focusing on key management abstraction for non-expert users and progressive disclosure interfaces that communicate trust properties without requiring technical literacy, and accessibility studies examining whether blockchain knowledge platforms create or exacerbate digital exclusion for marginalized knowledge communities.

VII. Conclusion

This systematic review examined how blockchain consensus mechanisms enhance trust in knowledge sharing platforms, synthesizing evidence from peer-reviewed studies published between 2020 and 2025 across academic, corporate, and public sector contexts. The review followed PRISMA 2020 guidelines and addressed four research questions covering trust mechanisms, consensus algorithm adoption, implementation challenges, and documented benefits. The findings consistently confirm that blockchain consensus mechanisms do not operate through a single property but through a cluster of co-occurring mechanisms including distributed verification, transparency, cryptographic security, immutability, economic incentive alignment, and smart contract automation that together deliver compounding rather than marginal trust assurances. A diverse range of consensus algorithms is currently adopted, with PBFT-based variants dominant in permissioned environments and novel hybrid mechanisms growing rapidly, though a significant proportion of studies in the literature do not specify the consensus mechanism used, which represents a gap that limits cross-study comparability and reproducibility.

Despite these trust benefits, implementation remains constrained by compounding technical, economic, and governance barriers. Scalability, integration complexity, energy consumption, economic sustainability, regulatory uncertainty, and usability challenges frequently co-occur, and their prevalence has grown rather than declined as deployments have matured, indicating that current technical progress has not yet resolved the core adoption barriers. On the benefit side, enhanced data security, improved transparency, and decentralized control consistently emerge as the dominant and mutually reinforcing value proposition across all application domains and study years, with smart contract automation and economic incentive systems providing additional domain-specific value. Taken together, these findings position blockchain consensus mechanisms as a technically credible and theoretically well-grounded solution to the trust deficits of centralized knowledge sharing platforms, while acknowledging that substantial barriers to widespread institutional adoption remain.

This review has several limitations, including its restriction to three databases and English-language publications, the prevalence of simulation-based studies that limit generalizability to real-world deployments, and the significant proportion of studies that did not specify a consensus mechanism. Notwithstanding these constraints, the review makes substantive contributions by providing the first comprehensive PRISMA-guided synthesis specifically targeting consensus mechanisms in knowledge sharing contexts, establishing the multi-mechanism co-occurrence model of blockchain trust, and identifying the consensus mechanism reporting gap as a priority methodological issue. Future research should focus on developing minimum reporting standards for consensus mechanism specification, advancing scalability and energy-efficient protocol solutions, conducting empirical effectiveness studies in production deployments, and designing novel trust-weighted consensus mechanisms tailored to the specific governance and provenance requirements of knowledge sharing platforms. Addressing these priorities will advance the field toward blockchain knowledge sharing systems that are not only technically feasible but institutionally adoptable, user-accessible, and grounded in robust empirical evidence.

Acknowledgment

The authors acknowledge the use of AI-assisted tools in supporting the preparation of this manuscript. Scopus AI supported the development of preliminary conceptual maps, ChatGPT (version 5.2) assisted in constructing search strings, matrix tables, and organizing data analysis, and QuillBot was used for precise grammatical refinement and language editing. The author expresses gratitude for the financial support received from the Minister of Higher Education Malaysia under Universiti Kebangsaan Malaysia Research Grant with a Project Code: ZG-2022-010, which enabled this research to be completed.

Generative AI in Higher Education: A Systematic Review with Emphasis on Programming and Computer Science Education

Abdulaziz Saidu Yalwa[1], Mohd Shahizan Othman[2], Lizawati Mi Yusuf[3], Muteb Sinhat Almarshadi[4]
Faculty of Computing, Universiti Teknologi Malaysia, Skudai, Johor Bahru, Malaysia[1, 2, 3]
Department of Computer Sciences and Human Studies, Shaqra University, Shaqra, Kingdom of Saudi Arabia[4]

***Abstract*—Generative Artificial Intelligence (GenAI) is rapidly reshaping teaching and learning in higher education, particularly in programming and computer science education, where tools such as ChatGPT and GitHub Copilot are increasingly used for code generation, debugging, conceptual explanation, and personalised learning support. Despite this growing use, the literature remains fragmented, with limited synthesis across educational outcomes, adoption contexts, user perceptions, and factors influencing sustained use. To address this gap, this study conducts a systematic literature review following PRISMA 2020 guidelines. The review draws on a dataset of 60 empirical studies published between 2022 and 2025 and retrieved from major academic databases. The selected studies were analysed using a mixed synthesis approach that combines descriptive mapping with thematic analysis. The synthesis shows that GenAI can improve coding support, debugging efficiency, conceptual understanding, and student engagement, especially in programming-related learning contexts; however, adoption remains uneven across regions, institutions, and course settings, while concerns related to academic integrity, over-reliance, reliability, and unequal access persist. By integrating findings across learning outcomes, adoption patterns, user perceptions, and continuance-related factors, this review provides a more structured understanding of GenAI use in higher education, with particular emphasis on programming and computer science education. The study highlights the need for AI literacy, ethical governance, and inclusive institutional support to enable more responsible and sustainable GenAI integration.**

Keywords*—*Generative artificial intelligence; higher education; programming education; computer science education; continuance intention; technology acceptance model; expectation–confirmation model; PRISMA; systematic literature review

I. Introduction

Generative Artificial Intelligence (GenAI) has emerged as a transformative technology across multiple domains, including education, healthcare, finance, and software development[1]. In the context of higher education, particularly in programming and computer science education, GenAI tools such as ChatGPT and GitHub Copilot are increasingly used to support code generation, debugging, and real-time explanation of programming concepts[2], [3], [4], [5], [6], [7]. More broadly, higher education studies also report positive perceptions of usefulness, engagement, and instructional support [1], [8], [9]. These tools provide interactive and personalised learning experiences, which are especially beneficial for novice learners who often struggle with syntax, algorithmic thinking, and debugging processes.

The rapid adoption of GenAI has raised concerns regarding the reliability of AI-generated outputs, risks to academic integrity, and students' over-reliance on automated solutions [10]. Although several studies report improvements in coding accuracy, engagement, and motivation, issues such as incorrect code generation, misuse in assessments, and unequal access across institutions remain critical [3]. These challenges highlight that the integration of GenAI is not purely a technological issue but also a pedagogical and ethical concern.

Despite the growing body of research on GenAI in education, existing studies remain fragmented and predominantly focused on short-term learning outcomes. Limited attention has been given to the sustained use of these technologies in higher education, particularly in programming and computer science education. However, the long-term educational value of GenAI depends on whether students and educators continue to use these tools effectively over time. This concept, known as continuance intention, is explained through established models such as the Technology Acceptance Model (TAM), the Unified Theory of Acceptance and Use of Technology (UTAUT), and the Expectation–Confirmation Model (ECM), which link perceived usefulness, satisfaction, and behavioural intention to continued technology use [11].

Unlike previous reviews, this study integrates continuance intention theory with empirical evidence to provide a more comprehensive understanding of sustained GenAI use in higher education, particularly in programming and computer science education. By combining theoretical perspectives with observed educational outcomes, this study aims to bridge the gap between initial adoption and long-term utilisation of GenAI tools.

To address the lack of consolidated evidence, this study conducts a systematic literature review following PRISMA 2020 guidelines. The review synthesises findings from 60 empirical studies published between 2022 and 2025, focusing on learning outcomes, adoption contexts, user perceptions, and pedagogical challenges. Furthermore, the study develops a conceptual framework linking adoption conditions, usage mechanisms, educational outcomes, and associated challenges. By providing a structured and comprehensive synthesis, this research offers practical insights into the responsible and sustainable integration of GenAI in programming education.

While the review is anchored in programming and computer science education, it also draws on broader higher education studies that provide relevant empirical evidence on adoption,

governance, user perceptions, and sustained use conditions surrounding GenAI integration.

II. Research Background

Higher education is increasingly being shaped by digital technologies that support more interactive, flexible, and student-centered forms of learning. Within this broader context, programming and computer science education remain especially important because they aim to develop not only coding proficiency but also computational thinking, problem-solving, and algorithmic reasoning required for real-world application[12]. In response to evolving technological demands, teaching in these fields has progressively shifted toward active and experiential learning approaches that emphasise hands-on practice, timely feedback, and applied problem-solving.

Against this background, Generative Artificial Intelligence (GenAI) has emerged as a significant development in higher education, with particularly strong relevance for programming and computer science education. Tools such as ChatGPT and GitHub Copilot support code generation, debugging, conceptual explanation, and real-time assistance during learning tasks [4], [13], [14]. These capabilities make learning more adaptive and personalised, especially for novice programmers who often benefit from continuous guidance, immediate feedback, and opportunities to explore alternative coding approaches. As a result, GenAI is increasingly being viewed as a flexible instructional support tool that can enhance coding efficiency, conceptual understanding, collaboration, and learner engagement while complementing more traditional teaching methods [1], [8].

However, the integration of GenAI also introduces important pedagogical, ethical, and institutional challenges. Concerns have been raised about over-reliance on AI-generated solutions, inaccuracies in generated outputs, and issues related to academic integrity and fairness [15], [16]. In addition, differences in infrastructure, access, and institutional readiness contribute to uneven adoption across educational settings and regions [17]. These issues show that GenAI is not only a technical development but also one that must be understood through pedagogical, ethical, and institutional perspectives.

Beyond initial adoption, the continued use of GenAI has become an important issue in higher education, particularly in programming and computer science education [18]. Continuance intention provides a useful lens for understanding whether students and lecturers remain willing to use GenAI tools over time. In this regard, the Expectation–Confirmation Model (ECM) highlights the importance of satisfaction and perceived usefulness in shaping continued engagement [11]. Although this perspective is increasingly relevant, much of the existing literature still focuses on short-term outcomes rather than the conditions that support sustained and responsible use.

Despite the growing number of studies on GenAI in higher education, particularly in programming and computer science education, the literature remains fragmented and lacks a sufficiently integrated perspective. Many studies focus on immediate educational outcomes, while giving less attention to sustained use, contextual variation, and the interaction of technological, pedagogical, and ethical factors. This study addresses these gaps by providing a systematic synthesis of empirical evidence, integrating continuance-related perspectives, and developing a more connected understanding of how GenAI is being adopted, experienced, and sustained in educational contexts.

A. Challenges and Ethical Concerns of GenAI Integration

Even with its potential, the integration of GenAI introduces several challenges. One major concern is over-reliance on AI-generated solutions, which may limit the development of independent problem-solving skills among students[12]. In addition, inaccuracies in generated outputs can mislead learners, particularly those with limited programming experience.

Academic integrity is another critical issue, as AI-generated code can be difficult to distinguish from students' original work, raising concerns about assessment validity and fairness. Furthermore, disparities in infrastructure, access to advanced tools, and institutional readiness contribute to uneven adoption across regions and educational contexts[13].

These challenges highlight that the integration of GenAI is not purely a technical issue but also involves ethical, pedagogical, and institutional dimensions that must be addressed to ensure responsible use.

B. Continuance Intention and Sustained Educational Use of GenAI

Beyond initial adoption by [14], sustained use of GenAI remains a critical issue in higher education, particularly in programming and computer science education. Continuance intention explains users' willingness to continue using a technology after initial adoption and is commonly modelled using the Expectation–Confirmation Model (ECM) [16]. According to ECM, continued use is influenced by satisfaction, perceived usefulness, and confirmation of expectations.

While models such as the Technology Acceptance Model (TAM) and the Unified Theory of Acceptance and Use of Technology (UTAUT) explain initial adoption behaviour [19] ECM provides a stronger theoretical basis for understanding post-adoption continuance. In the context of GenAI, continuance intention reflects the extent to which students and lecturers are willing to repeatedly use tools such as ChatGPT and GitHub Copilot for learning and instructional purposes.

Empirical evidence suggests that factors such as perceived usefulness, trust, satisfaction, and ethical awareness play important roles in shaping sustained engagement. Therefore, continuance intention provides a critical lens for analysing the long-term integration of GenAI in programming education.

C. Benefits and Educational Capabilities of GenAI

GenAI tools provide scalable support for programming education through automated code generation, debugging assistance, and real-time explanation of programming concepts[8]. By analysing user inputs and coding patterns, these tools deliver adaptive feedback and personalised learning support that enhances engagement, coding efficiency, and conceptual understanding [1].

In addition, GenAI supports exploration and collaborative learning by allowing students to experiment with different coding approaches and interact with intelligent systems that simulate real-world development practices. These capabilities

position GenAI as a flexible and learner-centered support system that complements traditional teaching methods.

D. Summary of Research Gaps

Despite the increasing number of studies on GenAI in higher education, particularly in programming and computer science education, the literature remains fragmented and lacks a unified perspective. Existing research primarily focuses on short-term learning outcomes, with limited attention to sustained use and long-term educational impact.

Moreover, theoretical integration remains insufficient, as many studies do not explicitly connect empirical findings with established technology adoption models such as ECM, TAM, and UTAUT. In addition, challenges related to ethics, pedagogy, and infrastructure are often discussed in isolation rather than as interconnected factors.

This study addresses these gaps by providing a systematic synthesis of empirical evidence, integrating continuance intention theory, and developing a conceptual framework that links adoption contexts, usage mechanisms, outcomes, and challenges for sustainable GenAI integration in higher education, particularly in programming education.

III. Methodology

This study adopts a systematic literature review (SLR) approach to synthesise empirical evidence on the use of Generative Artificial Intelligence (GenAI) in higher education, with particular emphasis on programming and computer science education. The review follows the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA 2020) guidelines to ensure methodological transparency, reproducibility, and systematic reporting of the review process [20].

The overall procedure consists of the following structured stages:

- Definition of research objectives and research questions
- Development of a review protocol, including search strategy and selection criteria.
- Systematic literature search across multiple academic databases.
- Screening and selection of relevant studies based on predefined criteria.
- Data extraction using a structured framework.
- Quality assessment of selected studies; and
- Thematic synthesis and analysis of findings.

This structured methodology ensures a transparent and replicable review process suitable for high-quality academic research.

A. Research Questions

To structure the analysis and ensure a focused investigation, this systematic literature review is guided by the following research questions.

- RQ1. How do GenAI tools influence learning outcomes in higher education, particularly in programming and computer science education, including code correctness, debugging efficiency, conceptual understanding, and student engagement?
- RQ2. What differences exist in GenAI adoption across countries, institutions, course levels, and access conditions such as infrastructure, policies, and licensing availability?
- RQ3. What are the perceptions of students and lecturers toward GenAI in higher education, particularly in programming and computer science education, and which factors influence their continued intention to use these technologies?
- RQ4. What pedagogical, ethical, and academic integrity challenges arise from integrating GenAI into higher education, particularly in programming and computer science education, and what mitigation strategies have been proposed?

B. Review Protocol Design

To ensure the review is conducted in a systematic and reliable way, a review protocol was prepared before starting the data collection. This protocol served as a guide for the entire review process and helped to reduce possible bias.

It clearly defined the search strategy, including the keywords and Boolean combinations used to retrieve relevant studies. It also specified the selection of appropriate academic databases and established the inclusion and exclusion criteria to determine which studies should be considered.

In addition, the protocol outlined how data would be extracted from the selected studies in a consistent manner. A quality assessment approach was also included to evaluate the strength and relevance of each study. Furthermore, the protocol described how the collected data would be analysed and organised to ensure a clear and structured synthesis of the findings.

Overall, this protocol improves the consistency, transparency, and reliability of the review, making it easier for the process to be understood and replicated.

C. Data Sources and Search Strategy

A comprehensive literature search was conducted across Scopus, Web of Science, IEEE Xplore, and SpringerLink. These databases were selected because they index high-quality peer-reviewed research across computer science, education, and educational technology disciplines. The search included studies published between January 2022 and September 2025, reflecting the recent emergence and rapid development of GenAI in higher education.

The following Boolean search string was applied across the databases, with minor formatting adjustments where required by database syntax: ("Generative Artificial Intelligence" OR "GenAI" OR "ChatGPT" OR "GitHub Copilot") AND ("higher education" OR "university" OR "college") AND ("programming" OR "computer science" OR "coding").

This search strategy was designed to prioritise empirical studies on the use, adoption, and educational impact of GenAI in programming and computer science education within higher education. Relevant higher education studies outside strictly programming-specific contexts were also retained during screening where they provided direct insight into adoption conditions, user perceptions, policy environments, ethical concerns, or sustained use factors relevant to GenAI integration.

D. Inclusion and Exclusion Criteria

To ensure the relevance and quality of the selected studies, clear inclusion and exclusion criteria were defined before the screening process. Only studies that reported empirical findings on the use of Generative Artificial Intelligence (GenAI) in programming or computer science education were considered. The review focused specifically on studies involving higher education students or lecturers, as this aligns with the scope of the study.

Although this review primarily focuses on programming and computer science education, a small number of broader higher education studies were included when they provided empirical evidence directly relevant to GenAI adoption, user perceptions, governance, institutional policies, ethical considerations, or sustained use. These studies were retained because they offer insights into contextual and continuance-related factors that inform the integration of GenAI in programming-focused learning environments.

In addition, only articles published in peer-reviewed journals or conference proceedings between 2022 and 2025 were included, reflecting the recent and rapidly evolving nature of GenAI in education. To maintain consistency and clarity in analysis, only studies published in English were considered.

On the other hand, studies were excluded if they did not meet these criteria. This includes publications such as editorials, opinion papers, conceptual papers, and review articles, as they do not provide primary empirical evidence. Studies published outside the selected time frame or those not directly related to GenAI use in higher education, particularly in programming and computer science education, were also excluded.

These criteria helped to narrow the literature to relevant and high-quality studies, ensuring that the review is focused, consistent, and academically robust.

E. Screening Process

The database search initially identified 3,160 records. After removing 956 duplicates, 2,204 unique records remained for screening. Title and abstract screening excluded 2,100 records that did not meet the study criteria. The remaining 104 articles were assessed through full-text review, resulting in 60 studies that satisfied the inclusion criteria and were retained for the final synthesis. The complete screening process is presented in the PRISMA flow diagram Fig. 1.

F. Data Extraction and Review Reliability

To ensure consistency and transparency in the review process, a structured data extraction form was developed for all selected studies. This form was designed to systematically capture relevant information from each article in a clear and organized manner.

The extracted data included key bibliographic information, as well as important analytical details such as the study context, research design, sample characteristics, and the types of GenAI tools used. In addition, information related to learning outcomes, user perceptions, reported challenges, and proposed mitigation strategies was collected to support a comprehensive analysis.

To improve the reliability of the data extraction process, two researchers independently reviewed the extracted information. Any differences in interpretation or classification were discussed and resolved collaboratively. This approach helped to reduce bias and ensure consistency in the analysis[21].

Furthermore, the reporting of the review process was guided by the PRISMA 2020 framework, which supports transparency and allows the review procedure to be clearly understood and replicated.

G. Quality Assessment

To ensure the credibility and methodological rigor of the selected studies, a structured quality assessment was carried out using a checklist adapted from the Critical Appraisal Skills Programme (CASP), which is commonly used in systematic reviews across interdisciplinary research[5].

The assessment focused on five key aspects: the clarity of the research objectives, relevance to the study focus, methodological rigor, contribution to theory or practice, and transparency in reporting limitations. Each study was evaluated using a binary scoring system (0–1) for each criterion, resulting in a maximum possible score of 5. To maintain a consistent quality standard, only studies with a minimum score of 3 were included in the final analysis.

To improve reliability and reduce subjective bias, the quality assessment was conducted independently by two reviewers. Any differences in scoring were discussed and resolved collaboratively, and where necessary, a third reviewer was consulted to reach a final decision. This process helped to ensure consistency and strengthen the reliability of the evaluation.

The quality assessment played an important role in filtering out studies with unclear objectives, weak methodology, or limited relevance to GenAI in higher education, particularly in programming and computer science education. As a result, the final set of studies included in this review consists of high-quality research that provides meaningful insights into the adoption, impact, sustained use, and pedagogical implications of Generative Artificial Intelligence in higher education, particularly in programming and computer science education.

H. Coding and Thematic Analysis Approach

A mixed synthesis approach, combining both qualitative and quantitative content analysis, was employed to analyse the selected studies, allowing a comprehensive examination of both descriptive trends and deeper thematic patterns within the literature. The coding process was conducted in two stages to ensure reliability and transparency. First, descriptive coding classified each study according to publication year, country or region, publication source, course level, GenAI tool, research design, and participant group. Second, analytical coding identified themes directly aligned with the research questions, including learning outcomes, debugging support, conceptual understanding,

adoption conditions, user perceptions, continuance intention, academic integrity, ethical concerns, and mitigation strategies. For example, studies reporting improvements in code accuracy or debugging efficiency were coded under "learning outcomes," while studies discussing trust, satisfaction, or continued use were coded under "continuance intention."

To ensure consistency, a random subset of 20 articles was independently coded by two reviewers, achieving an inter-rater agreement of over 94%. Any disagreements in coding were discussed until consensus was reached. This dual coding strategy enabled the review to capture both the breadth of adoption patterns and the depth of thematic insights, providing a well-rounded understanding of the role of GenAI in higher education, particularly in programming and computer science education.

IV. Findings

This section presents the thematic findings of the review based on the synthesis of 60 empirical studies examining the use of Generative Artificial Intelligence (GenAI) in higher education, with particular emphasis on programming and computer science education. The reviewed studies comprised quantitative, qualitative, and mixed-method designs, enabling a comprehensive synthesis of adoption patterns, user perceptions, and educational outcomes associated with GenAI use in higher education, particularly in programming contexts.

A. Impact on Learning Outcomes and Engagement

The reviewed studies consistently indicate that GenAI tools are increasingly used in higher education, particularly in programming and computer science education, to support code generation, debugging, and personalised learning assistance. Most studies indicate that these tools contribute positively to student learning outcomes by improving coding accuracy, accelerating debugging processes, and increasing learners' confidence in programming tasks [4]. In addition, GenAI-supported feedback systems provide real-time guidance that helps reduce frustration and sustain student engagement when addressing complex programming concepts [22], [23]. Adaptive features further enable students to progress at their own pace while addressing individual knowledge gaps [6].

Beyond individual performance gains, studies highlight the role of GenAI in supporting collaborative and reflective learning. The use of AI tools in group programming activities has been shown to stimulate peer discussion, collaborative debugging, and critical reflection on AI-generated outputs, thereby strengthening both cognitive and social aspects of programming education [10], [24]. In addition, personalised feedback mechanisms may help reduce performance disparities between students with different levels of programming proficiency [6].

However, the effectiveness of GenAI tools varies across platforms, programming tasks, and instructional contexts. Comparative studies show that the accuracy and usefulness of tools depend on the complexity of the coding problem and the level of student expertise [2]. Many studies report improvements in motivation and engagement; evidence regarding consistent improvements in academic performance remains mixed [8]. Some research also indicates that GenAI tools may struggle with complex coding problems, highlighting the need for educators to critically guide students in evaluating and adapting AI-generated solutions [25].

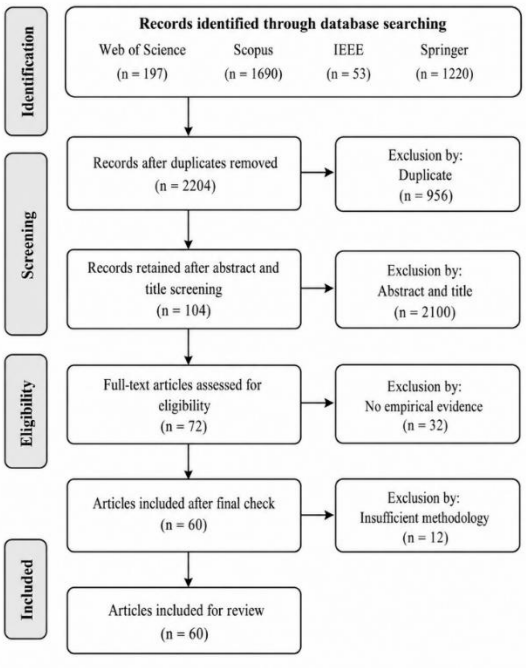

Fig. 1. PRISMA 2020 flow diagram illustrating the study selection process.

The surge in publications coincides with the emergence of large language model–based systems such as ChatGPT and GitHub Copilot, which have significantly accelerated experimentation with AI-assisted programming learning. No empirical studies were identified in 2022, reflecting the late emergence of GenAI research following the release of ChatGPT in late 2022. The zero count for 2022 reflects the fact that mainstream pedagogical research into generative AI was catalyzed by the release of ChatGPT in November 2022, meaning that the first wave of empirical findings did not reach publication until 2023. Followed by 6 in 2023 and 22 in 2024, reflecting a substantial increase in scholarly attention. By 2025, an additional 32 studies had already been reported, suggesting that research on GenAI in higher education, particularly in programming and computer science education, continues to expand rapidly, as shown in Fig. 2.

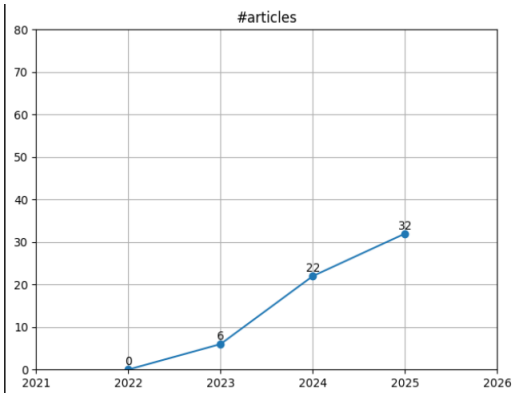

Fig. 2. Year-wise distribution of publications on GenAI in programming education (2022-2025).

B. Contexts of Adoption and Equity

The reviewed studies reveal notable disparities in the adoption of Generative Artificial Intelligence (GenAI) across course levels, institutions, and geographical contexts. Although many studies examine GenAI use in higher education broadly, fewer focus on specific domains within computer science education.

Introductory programming (CS1) emerges as the most common context of application, with 12 studies (20%) reporting the use of GenAI tools to support beginners in learning fundamental coding skills. Advanced programming and software engineering courses account for 10 studies (16.6%), while algorithms and data structures are addressed in 8 studies (13.3%). In addition, 18 studies (30%) investigate GenAI adoption in higher education settings without specifying a particular programming domain.

These patterns suggest that GenAI tools are currently used most extensively in introductory programming environments, where real-time guidance can assist students in addressing syntax errors, debugging tasks, and foundational programming concepts. The distribution of studies across computer science domains is illustrated in Fig. 3, highlighting the concentration of GenAI applications at early stages of programming education.

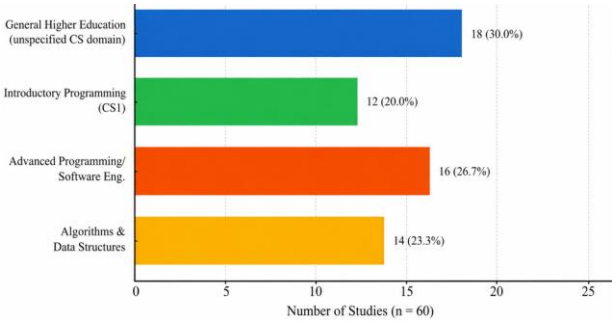

Fig. 3. Distribution of reviewed studies across computer science domains.

Regional disparities were also evident across the reviewed studies. Higher levels of GenAI adoption were reported in countries such as China, the United States, and Australia, where strong institutional support, technological infrastructure, and access to AI tools have enabled early integration into programming education [1], [39], [9]. In contrast, studies from Africa and South Asia highlight barriers related to limited infrastructure, policy readiness, and access to AI resources, which constrain the equitable adoption of GenAI in higher education [26], [27]. These findings suggest that institutional capacity and resource availability play an important role in shaping the global diffusion of GenAI in programming education. As illustrated in Fig. 4, China accounts for the largest share of studies (12 studies, approximately 20%), indicating its leading position in research and implementation within this domain.

The findings indicate that although the adoption of GenAI in programming education is expanding, it remains concentrated in introductory course levels and technologically advanced regions. This uneven distribution highlights potential disparities in access and implementation across institutions and regions. If resource-limited contexts are not adequately supported, the diffusion of GenAI may further widen existing global inequalities in computing education. Ensuring equitable access to technological infrastructure, policy support, and digital literacy therefore remains essential for the sustainable and inclusive integration of GenAI in programming education.

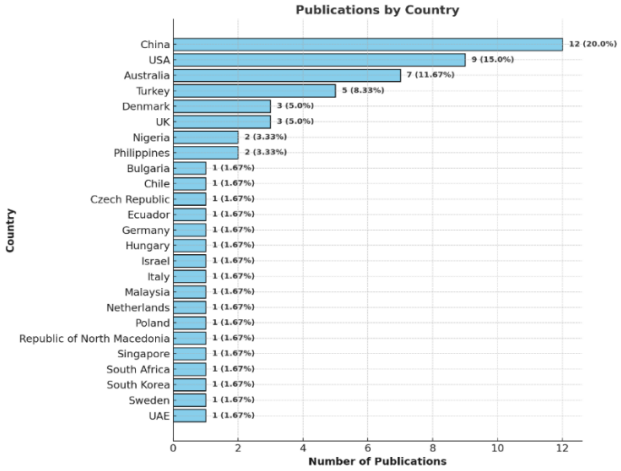

Fig. 4. Geographic distribution of reviewed studies by country.

C. Students' and Lecturers' GenAI Perceptions and Continuance of Use

Most reviewed studies report that students hold generally positive perceptions of GenAI tools, describing them as supportive resources that reduce frustration and make programming tasks more engaging see Fig. 5. Students frequently highlight the usefulness of tools such as ChatGPT and GitHub Copilot in clarifying difficult programming concepts, assisting with debugging, and strengthening confidence in coding abilities [26]. These findings suggest that learners perceive GenAI not merely as a convenience but as a learning aid that supports persistence and self-efficacy in programming education.

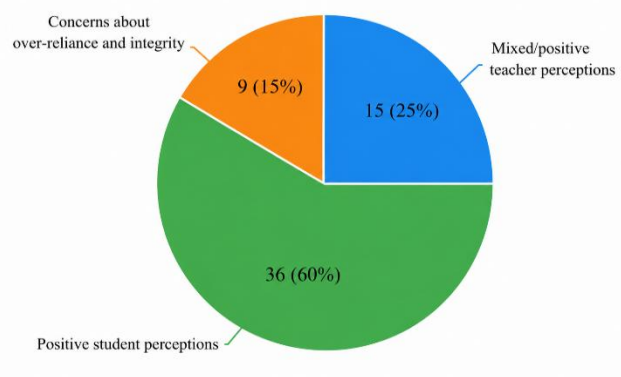

Fig. 5. Comparison of students' and lecturers' perceptions of GenAI use.

Lecturers, however, express more cautious and divided perspectives. Some acknowledge that GenAI can improve instructional efficiency by assisting with automated feedback and assessment processes [1]. Others raise concerns related to academic integrity, fairness in assessment, and the potential for students to become overly dependent on AI-generated solutions [28]. Questions about the reliability of AI-generated code further contribute to this caution, as inaccuracies or hidden errors may affect trust in GenAI for complex or high-stakes programming tasks [2].

These findings reveal a perceptual gap between students and lecturers. While students tend to view GenAI as an empowering learning tool and show strong willingness to continue using it, lecturers often weigh its efficiency benefits against concerns related to trust, originality, and long-term learning outcomes. This divergence suggests that continuance intention is influenced not only by perceived usefulness but also by factors such as trust, ethical considerations, and the pedagogical frameworks established by educators.

D. Pedagogical and Integrity Challenges

The review identified several challenges that complicate the integration of GenAI into programming education, particularly regarding tool reliability and academic integrity. A recurring concern is the accuracy of AI-generated code. Although tools such as ChatGPT can quickly generate functional code snippets, studies report that the outputs may contain logical or syntactic errors that novice learners often struggle to detect [2]. Such limitations can mislead students and highlight the need for critical evaluation of AI-generated solutions. In addition, excessive reliance on GenAI tools may reduce opportunities for students to develop independent debugging and problem-solving skills, raising questions about their long-term pedagogical impact [12].

Academic integrity represents another major challenge. Several studies indicate that GenAI tools can be misused to bypass programming assessments, blurring the boundary between authentic student work and AI-assisted outputs [29]. This creates concerns about fairness, transparency, and the validity of assessment when AI-generated code becomes difficult to distinguish from student submissions [59]. These issues highlight the importance of establishing clear institutional policies and pedagogical guidelines to ensure responsible use of GenAI in programming courses.

Finally, the findings indicate that the integration of GenAI in higher education, particularly in programming and computer science education, is expanding rapidly but remains uneven across institutional contexts and geographical regions. While many studies highlight improvements in coding support, debugging efficiency, and learner engagement, concerns regarding academic integrity, over-reliance on AI-generated solutions, and unequal access to technological infrastructure continue to shape how these tools are adopted in educational settings. These patterns underscore the need for pedagogically guided and ethically responsible integration of GenAI within programming curricula.

V. Discussion

This section synthesises the key findings of the review, explicitly relates them to the research questions (RQ1–RQ4), and discusses their broader implications for theory, practice, and policy in higher education, with particular emphasis on programming and computer science education. It further identifies critical gaps and outlines directions for the responsible and sustainable use of GenAI in higher education.

A. Influence of GenAI on Learning Outcomes in Higher Education

In response to RQ1, which examines how GenAI tools influence programming learning outcomes, the findings consistently indicate that GenAI significantly improves code correctness, debugging efficiency, conceptual understanding, and student engagement. This aligns with prior studies [6], [2], which report that AI-assisted programming tools enhance students' coding accuracy and reduce cognitive load during problem-solving tasks.

GenAI tools function as intelligent learning assistants, providing real-time feedback, automated code suggestions, and explanatory support that facilitate students' problem-solving processes [21]. These capabilities contribute to increased confidence and engagement, reinforcing both cognitive and affective dimensions of learning. Similar findings have been reported in [8], where students using GenAI demonstrated higher levels of motivation and deeper conceptual understanding compared to traditional learning environments.

However, the findings also reveal that these benefits are context-dependent. While performance improvements are evident, excessive reliance on AI-generated solutions may reduce active learning and limit the development of independent problem-solving skills. This concern is consistent with studies by [8] and [24], which highlight the risk of overdependence on AI tools leading to superficial learning and reduced critical thinking abilities.

This suggests that the impact of GenAI is not inherently positive but is mediated by how it is integrated into pedagogical practices. As noted in [23], effective instructional design and guided use of GenAI are essential to ensure that students engage meaningfully with learning tasks rather than passively relying on automated outputs.

B. Variability in GenAI Adoption Across Contexts

Addressing RQ2, the review reveals substantial variability in the adoption of GenAI across countries, institutions, course levels, and access conditions, including digital infrastructure, institutional policies, and licensing availability. This finding is consistent with prior studies [59], [3], which emphasize that the uptake of emerging educational technologies is highly contingent on contextual and organizational factors.

The findings suggest that GenAI adoption is uneven and shaped by a combination of technological readiness and institutional support. Institutions with well-developed digital infrastructure, stable internet access, and clearly defined policy frameworks tend to demonstrate higher levels of GenAI integration in teaching and learning practices. In contrast, resource-constrained environments face persistent barriers related to limited access, high subscription costs, and insufficient technical support. Similar patterns have been reported in [11], where disparities in infrastructure and funding significantly influenced the adoption of AI-based educational tools.

This variability reflects broader issues of digital inequality, where unequal access to GenAI tools risks reinforcing existing educational disparities between institutions and regions. As highlighted in [59], students and educators in under-resourced settings may be systematically disadvantaged, limiting their ability to benefit from AI-enhanced learning environments.

Furthermore, inconsistent or ambiguous institutional policies create uncertainty regarding acceptable use, academic integrity, and ethical boundaries, which may hinder effective and

confident adoption. This aligns with findings from [17] and [8], which indicate that the absence of clear governance frameworks often leads to cautious or restricted use of GenAI by educators.

Taken together, these findings suggest that GenAI adoption should not be viewed as a purely technological issue, but rather as a context-dependent and policy-sensitive process. Effective integration, therefore, requires not only access to technology, but also institutional readiness, clear guidelines, and equitable resource distribution, as emphasized in [17].

C. Perceptions and Continuance Intention of GenAI Use

The findings indicate that both students and lecturers perceive GenAI as a useful and efficient tool that enhances learning, problem-solving, and conceptual understanding [12], [30]. However, continuance intention is not driven by perceived usefulness alone but by interrelated factors including satisfaction, trust, motivation, and ethical alignment.

Consistent with the Expectation-Confirmation Model (ECM), satisfaction emerges as a key determinant of continued use, shaped by post-adoption experiences [31], [11]. Trust also plays a critical role, particularly when students are perceived to use GenAI responsibly and in line with academic integrity standards [18], [32].

Ethical considerations further reinforce this process, as clear guidelines and training enhance both academic integrity and trust, supporting sustainable adoption [10]. Additionally, GenAI positively influences student motivation and engagement, indirectly strengthening continuance intention [33].

The findings suggest that continuance intention differs between students and lecturers. For students, continued use is mainly shaped by perceived usefulness [30], immediate learning support, confidence in programming tasks, debugging assistance, and reduced frustration. In contrast, lecturers' continuance intention is more strongly influenced by trust, reliability of AI-generated outputs, academic integrity, assessment fairness, institutional policy, and the extent to which GenAI supports rather than weakens learning objectives. Therefore, sustainable GenAI adoption requires addressing both student learning benefits and lecturer concerns regarding responsible use.

D. Pedagogical, Ethical, and Academic Integrity Challenges

In response to RQ4, the review identifies key challenges associated with GenAI integration in programming education, including academic integrity risks, over-reliance, reliability concerns, and ethical misuse. These challenges highlight that GenAI adoption extends beyond technical benefits to important pedagogical and ethical considerations.

Academic integrity is a major concern, as GenAI can generate complete solutions, making it difficult to assess students' original work. This challenges traditional assessment practices and raises issues of fairness and authenticity, as also reported in [34].

Over-reliance on GenAI may limit the development of essential programming skills, such as problem-solving and algorithmic thinking. While GenAI improves efficiency, excessive dependence can reduce active learning, consistent with findings in [21], [6].

Reliability issues further complicate its use, as GenAI may produce incorrect or misleading outputs. Without proper verification, this can negatively affect learning outcomes, particularly for less experienced students [6].

Ethical misuse is another critical issue, as unclear guidelines may lead to inappropriate use, including plagiarism or over-dependence on AI-generated content. This underscores the importance of ethical awareness and governance in GenAI adoption [33].

Although GenAI tools are useful for introductory programming tasks, their effectiveness is more limited in advanced programming contexts. Complex algorithmic reasoning, software architecture design, large-scale debugging, security-sensitive coding, and domain-specific optimisation tasks often require deeper human judgement. GenAI-generated code may appear syntactically correct while containing hidden logical errors, inefficient structures, or unsuitable design assumptions.

This review is also subject to temporal limitations. GenAI tools and their educational applications are evolving rapidly, and findings from earlier studies, particularly those published in 2022 and 2023, may not fully reflect the current capabilities of newer GenAI systems or recent institutional policy developments. As a result, the conclusions of this review should be interpreted as a synthesis of the available evidence within the 2022–2025 publication window rather than a final or static account of GenAI use in higher education. Therefore, GenAI should be used as a guided learning assistant rather than a replacement for independent reasoning, expert feedback, and rigorous code verification.

To address these challenges, the literature suggests redesigning assessments to focus on learning processes, promoting AI literacy, integrating GenAI within guided learning environments, and establishing clear institutional policies.

Overall, these findings indicate that addressing ethical and academic integrity concerns is essential for fostering trust and ensuring the sustainable and responsible use of GenAI in higher education.

E. Implications for Theory, Practice, and Policy

The findings of this study offer important implications across theoretical, practical, and policy dimensions. From a theoretical perspective, the results highlight the need to extend existing technology adoption models by integrating ethical and pedagogical factors, particularly in explaining continuance intention in GenAI-supported learning environments. This supports the inclusion of constructs such as trust, academic integrity, and ethical considerations beyond traditional frameworks like TAM and UTAUT [19].

From a practical perspective, educators are encouraged to adopt balanced instructional strategies that leverage the benefits of GenAI while preserving active learning, critical thinking, and independent problem-solving skills. This aligns with prior studies emphasizing guided and responsible AI integration in education [33]. Institutions should also provide adequate training, technical support, and clear usage guidelines to ensure effective and responsible student engagement with GenAI tools.

From a policy perspective, the findings underscore the need for well-defined institutional and regulatory frameworks that address academic integrity, ethical use, and data governance in AI-assisted learning environments. Clear policies are essential to reduce ambiguity, enhance trust, and support sustainable adoption of GenAI in higher education [26], [27].

F. Research Gaps and Future Directions

The review reveals several important gaps in the current literature on Generative AI in education. First, longitudinal evidence remains limited, as most studies examine immediate or short-term outcomes rather than the sustained effects of GenAI on learning performance, skill development, and academic behaviour over time. As a result, the durability of the reported benefits is still unclear. Second, contextual variation across regions, institutions, and resource environments remains insufficiently addressed. Differences in infrastructure, policy support, institutional readiness, and access conditions are likely to shape both adoption and educational effectiveness, yet these factors are rarely examined in a systematic way.

This unevenness is also reflected in the distribution of studies presented in Table I. Although the reviewed literature spans multiple countries, the evidence remains concentrated in a relatively small number of national settings, with China appearing most frequently. This pattern likely reflects stronger investment in artificial intelligence, rapid digitalisation in higher education, and a large STEM-oriented academic community capable of supporting early experimentation and sustained publication. A similar concentration is evident at the technological level, where ChatGPT overwhelmingly dominates the reviewed studies. Its accessibility, ease of use, and broad applicability to tasks such as writing, coding, explanation, and problem-solving have made it the most common platform for empirical investigation. By contrast, other tools, including Copilot, Gemini, DALL-E, and Midjourney, appear only sporadically, suggesting that the current knowledge base is still being developed around a narrow set of technological experiences. Taken together, these patterns indicate that existing findings, while valuable, may reflect the conditions of well-resourced contexts and the affordances of a single dominant platform more than the full diversity of educational realities. Table I therefore not only describes the spread of literature but also underscores the need for broader comparative work across countries, institutional settings, and GenAI tools to strengthen the robustness and transferability of future evidence.

TABLE I. SUMMARY OF THE DISTRIBUTION OF THE STUDY

Third, existing studies tend to examine technological, pedagogical, and ethical dimensions in isolation, resulting in fragmented insights. This highlights the need for more integrated frameworks that capture the complex interactions between these factors.

Future research should therefore adopt interdisciplinary and mixed-method approaches to provide a more holistic understanding of GenAI use in education. In particular, studies should focus on developing unified models that incorporate technological, pedagogical, and ethical constructs to better explain sustainable and responsible GenAI adoption.

G. Towards Sustainable and Responsible GenAI Integration

Overall, the findings suggest that the integration of GenAI in programming education should move beyond a purely performance-driven approach toward a more responsibility-oriented framework. While GenAI demonstrates clear benefits in enhancing learning outcomes, its long-term value depends on how responsibly it is adopted and managed.

Sustainable integration requires a careful balance between technological capability, pedagogical alignment, ethical governance, and institutional readiness. These dimensions must work together to ensure that GenAI supports meaningful learning while preserving academic integrity, critical thinking, and educational quality.

VI. Conclusion and Future Work

A. Conclusion

Generative Artificial Intelligence (GenAI) has emerged as a significant development in higher education, with particular relevance for programming and computer science education. Its growing use in educational settings has introduced new opportunities for code generation, real-time feedback, conceptual explanation, and adaptive learning support. At the same time, its integration also raises important pedagogical, ethical, and institutional challenges that are not yet fully understood.

This systematic literature review synthesised evidence from 60 empirical studies published between 2022 and 2025, providing a structured overview of GenAI use in higher education, with particular emphasis on programming and computer science education. In relation to RQ1, the findings show that GenAI can positively influence learning outcomes by improving code correctness, debugging efficiency, conceptual understanding, and student engagement. These results suggest that GenAI functions not only as a productivity tool but also as a learning support system that can enhance the educational process.

Addressing RQ2, the review reveals considerable variation in GenAI adoption across countries, institutions, course contexts, and access conditions. These differences are shaped by disparities in infrastructure, policy frameworks, institutional readiness, and resource availability, highlighting the importance of context in shaping effective adoption. In response to RQ3, the findings indicate that both students and lecturers generally perceive GenAI positively. However, continued use is influenced by more than usefulness alone. Factors such as satisfaction, trust, motivation, and ethical alignment play an important role in shaping sustained engagement. Regarding RQ4, the review identifies major challenges related to academic integrity, over-reliance, reliability, and ethical misuse, underscoring the need for careful pedagogical design, clear institutional policies, and responsible governance.

Taken together, these findings highlight the need for a more integrated, theory-informed, and pedagogically grounded approach to GenAI adoption. Such an approach should align technological capability with educational goals, ethical responsibility, and institutional readiness in order to support more sustainable and meaningful use of GenAI in higher education, particularly in programming and computer science education.

B. Future Work

Based on the identified gaps and limitations in the literature, this review proposes several directions for future research, practice, and policy development:

1) Longitudinal and experimental evaluation: Future research should move beyond short-term performance measures to examine the long-term impact of GenAI on learning, cognitive development, problem-solving ability, and computational thinking. Such studies are necessary to determine whether the observed benefits of GenAI translate into sustained educational outcomes over time.

2) Expansion into advanced programming and broader disciplinary contexts: Further studies are needed to explore the role of GenAI in more advanced areas of programming and computer science education, including algorithms, software engineering, and complex system design. At the same time, broader higher education contexts should also be examined to understand how GenAI functions across disciplines with different learning demands.

3) Addressing global and institutional disparities: More research is needed to investigate how differences in infrastructure, policy frameworks, access conditions, and institutional readiness shape equitable adoption across regions, particularly in under-resourced and developing contexts.

4) Pedagogical integration and instructor role: Future work should examine how GenAI can be effectively embedded within teaching practice, including curriculum redesign,

instructor training, and the development of AI-supported strategies that promote responsible and meaningful learning.

5) Evaluation of governance and academic integrity frameworks: There is a need for empirical research that evaluates the effectiveness of institutional policies, ethical guidelines, and assessment redesign strategies in addressing academic integrity concerns and reducing misuse.

6) Theory-driven and interdisciplinary approaches: Future research should adopt stronger theoretical foundations by extending models such as ECM, TAM, and UTAUT, while integrating perspectives from educational theory, human–computer interaction, and ethics to develop more comprehensive and context-sensitive frameworks for GenAI in higher education.

7) Practical implications for educators and policymakers: For educators, the findings suggest the need to integrate GenAI through guided instructional design, AI literacy activities, assessment redesign, and critical evaluation of AI-generated outputs. For policymakers and institutional leaders, the results highlight the importance of clear academic integrity policies, equitable access to GenAI tools, staff training, ethical governance, and continuous monitoring of GenAI use in teaching and learning. These measures are essential to ensure that GenAI supports meaningful, inclusive, and responsible education.

The rapid evolution of Generative Artificial Intelligence (GenAI) is reshaping teaching and learning in higher education, with particularly important implications for programming and computer science education. Ensuring its effective and responsible integration requires more than technological advancement; it demands a coordinated effort to align pedagogy, ethical principles, and institutional governance. As this review has shown, the foundation for GenAI-supported learning has been established, but it remains incomplete and still evolving. The next phase of research and practice should therefore focus on developing sustainable, inclusive, and theory-informed frameworks that position GenAI not merely as a tool for efficiency, but as a resource for meaningful, equitable, and responsible education.

Translating Job Advertisements into Competency Taxonomy: An Interpretable Approach for Robotics Recruitment Analysis

Zhiyan Xue[1], Yang Zhou[2]*
School of Electronic Information Engineering, Suzhou Polytechnic University, Suzhou, China [1]
School of Management, Suzhou Polytechnic University, Suzhou, China [2]

***Abstract*—To translate robotics recruitment texts into an interpretable competency taxonomy, this study explored how latent topics can be induced from large-scale job advertisements and used to construct a structured competency taxonomy. A domain-specific preprocessing pipeline was applied to a corpus of robotics job advertisements, and latent topics were subsequently induced using Latent Dirichlet Allocation (LDA). Building on the extracted topic evidence, a procedure was applied to organize topic summaries into task domains and competencies grounded in topic keywords. Evaluation was conducted using a set of quantitative measures to assess semantic consistency and structural quality. The results revealed recurring competency patterns encompassing on-site operation and service, engineering design and integration, software and algorithm development, and system verification and reliability assurance. The resulting competency taxonomy captures the underlying structure of employer demand and provides an interpretable basis for robotics skill demand analysis, supporting role profiling and serving as an empirical reference for Vocational Education and Training (VET).**

Keywords*—Competency taxonomy; robotics industry; Latent Dirichlet Allocation (LDA); Vocational Education and Training (VET)

I. Introduction

A. Research Background

Robotics has expanded from laboratory research into broad industrial and service deployments, including manufacturing, logistics, healthcare, and consumer-facing applications. This expansion has diversified robotics job roles and increased demand for talent with cross-disciplinary skill profiles. At the same time, rapid iteration of toolchains and deployment practices shortens the validity period of static skill descriptions. These trends create a practical need for methods that can characterize robotics competency requirements in a scalable and updatable manner [1][2].

Online job advertisements provide a timely and large-scale source of evidence for this purpose. Recruitment texts serve as explicit, employer-authored descriptions of hiring requirements and are typically high in volume, frequently updated, and broad in coverage. As a result, job advertisements can be treated as a near real-time signal of skill demand, enabling analysis of the structure of required competencies and their evolution across job families and time windows [3][4]. Compared with interviews or small-sample approaches, recruitment texts support repeatable analysis at scale, which is particularly valuable in fast-changing technical domains [5][6]. Robotics recruitment introduces additional complexity that makes competency modeling nontrivial. Robotics roles commonly combine capabilities spanning electromechanical systems, software control, as well as operation and maintenance. Skill evidence is distributed across a chain of job families that involve mechanical design, electrical engineering, embedded development, systems integration, and on-site support. Consequently, skill expressions in job advertisements are fragmented, terminology is not standardized across enterprises, and the granularity of requirements varies from broad capability statements to tool-specific and task-level descriptions [7][8]. Traditional interview-based or small-sample approaches often fail to yield a competency structure that generalizes across diverse job roles [9][10][11].

Against this background, two research questions guide the present work. What latent competency domains and skill patterns are reflected in robotics recruitment texts? How can unsupervised topic evidence from recruitment texts be translated into an interpretable and well-structured competency taxonomy?

To address these two questions, an approach is proposed that translates job advertisements into a structured competency taxonomy. The approach proceeds from recruitment text preprocessing to LDA-based topic induction, followed by translation from topic summaries to task domains and competencies grounded in topic keywords. Evaluation is designed for unlabeled settings and emphasizes interpretability and structural validity. Topic coherence is used to assess the semantic consistency of topic summaries, and a set of quantitative measures is used to quantify representativeness, noise, and redundancy of the induced taxonomy. Together, these components provide an interpretable basis for robotics skill demand mining from job advertisements, while supporting comparison against standard baselines in applied text mining.

B. Related Work

With the rapid development of the robotics industry, Vocational Education and Training (VET) systems have been under sustained pressure to update talent cultivation promptly. Existing studies have shown that educational and training responses often lag behind technological progress and shifts in market demand. Accordingly, scholars have proposed a range of strategies at different levels to improve talent development

*Corresponding author.

in robotics-related fields [12][13][14][15]. Existing studies have mainly approached this issue from two closely related directions. The first strand focuses on curriculum systems and talent cultivation models. Studies in this line of research primarily examine curriculum design, training mechanisms, and pathways for industry-education integration in robotics-related programs to enhance the alignment between educational provision and industrial demand. For example, Wang et al. pointed out that school-enterprise cooperation is an effective approach to improving teaching quality, thereby highlighting industrial demand as an important reference for curriculum design and educational improvement [12].

The second strand concentrates on specific skill demands and occupational competency requirements. This line of research mainly analyzes particular technical domains or concrete occupational contexts. Specifically, Yu-Shen et al. [13] focused on specific skill demands in the robotics field; Olukanni et al. [14] further situated the analysis in concrete work settings, such as human-robot collaboration, and Do et al. [15] through an Importance-Performance Analysis (IPA), suggested that university curricula should place greater emphasis on courses such as Artificial Intelligence, Machine Vision, and Robot Structure Design. These studies have helped identify key competency dimensions required in robotics-related occupations and have provided relatively direct practical implications for the optimization of course content.

Overall, existing research on robotics talent cultivation and competency development has largely proceeded from the supply side, with emphasis on educational planning and curriculum reform. While such studies are valuable for defining training objectives and competency expectations, they provide only limited insight into how firms specify skill requirements in actual recruitment and how these requirements evolve with industrial change. In parallel, studies addressing specific robotics skills or competency dimensions often focus on a single technical direction or a limited set of occupational contexts. Sample scopes are therefore typically constrained, and the resulting outputs frequently take the form of partial skill lists tied to local tasks or particular positions. Such a pattern makes it difficult to cover the major upstream and downstream positions across the robotics industrial chain.

Beyond the substantive findings of robotics-specific studies, a related body of research has approached the issue from a methodological perspective by examining how occupational skills can be identified, constructed, and organized. From this perspective, existing studies can be broadly grouped into three methodological approaches. The first perspective relies on expert-based methods, such as Delphi studies, expert interviews, and literature synthesis [15][16]. A notable strength of this line of work is that the resulting frameworks are usually grounded in expert understanding of occupational practice and therefore tend to remain highly interpretable and closely aligned with domain knowledge [17]. However, such methods are often costly to update and dependent on expert judgment. Consequently, they are well suited to normative framework construction, but less suited to tracking the changing skill requirements of large numbers of job advertisements. The second perspective uses recruitment texts as a demand evidence source for skill analysis. Online job advertisements can be treated as employer demand statements that contain explicit signals about skills, work activities, and job requirements [18][19]. Some studies have used rule extraction and statistical representation tools to identify terms from job advertisements [20]. Findings from this stream of research indicate that recruitment texts can support large-scale labor market and skill analysis and can reveal meaningful patterns in employer demand. However, the resulting outputs often remain fragmented because they are typically expressed as keyword lists. The third perspective extends recruitment text analysis toward the discovery of latent structure. Topic modeling, including LDA and other related approaches, has been used to identify recurring themes [21]. In recruitment analytics, these methods have been applied to domains such as big data analytics and software engineering to derive topic-based representations of knowledge domains, skill combinations [22][23][24]. Compared with direct term extraction, topic modeling provides a more effective basis for organizing dispersed skill expressions into coherent thematic structures. Nevertheless, a topic provides a meaningful set of salient terms, but it does not explain how those terms should be translated into hierarchical competency domains [25]. In other words, existing recruitment text studies have shown that skill signals can be extracted and that latent themes can be discovered, yet they have not fully resolved how topic-level evidence should be converted into a competency structure.

Building on the foregoing methodological discussion, a further challenge concerns how the outcomes of skill and competency induction should be evaluated. This issue has received relatively limited attention, largely because competency extraction from recruitment text is often conducted in the absence of standardized labels or benchmark datasets [26]. Soare [27] and McClelland [28] relied on expert-curated competency frameworks and skill taxonomies as references for workforce planning and training design, which provided guidance on how competency structures could be organized but did not yield direct evaluation criteria. Hoyle et al. [29] adopted topic coherence as an intrinsic indicator of semantic consistency for topic word sets, which offered a practical way to judge whether a topic summary formed a coherent group of terms. Kim et al. [30] further suggested that representativeness and distinctiveness were essential for reusable and computationally meaningful competency structures, which implied that coherence alone was insufficient because it did not assess document-level representativeness or cross-topic redundancy. This line of work motivated evaluation protocols that complement coherence with structure-oriented indicators, yet a unified evaluation approach for determining whether coherent topic summaries translate into verifiable and non-redundant competency units remains absent.

The above literature highlighted two gaps that motivated this study. First, in the robotics domain, existing studies on talent development and skill requirements have largely proceeded from the supply side and have not yet established a demand-side competency structure grounded in large-scale recruitment evidence across the major positions of the robotics industry. Second, although existing recruitment text studies have identified skill signals and uncovered latent topics, these outputs have not formed a competency taxonomy. More

importantly, approaches for translating topic evidence into an interpretable competency structure have remained underdeveloped. This study addressed these gaps by introducing a translation approach and evaluation metrics to enable interpretable competency induction in robotics recruitment analysis.

The structure of this study is organized as follows. Section II describes the method, including data collection, preprocessing, topic discovery using LDA, and translation from topic summaries to a competency taxonomy. Section III introduces the experimental setup, baseline, and evaluation metrics. Section IV reports results, including both quantitative findings and qualitative case analyses. Section V concludes with limitations and future directions.

II. Methodology

This study proposed a structured pipeline that transforms unstructured job advertisements into an interpretable competency taxonomy. The process consists of five core stages: 1) Data Collection; 2) Data Preparation; 3) Topic Discovery; 4) Topic-to-Competency Translation; 5) Quantitative Evaluation. This pipeline takes raw job recruitment texts as input and produces a competency taxonomy as output. Fig. 1 illustrates the overall framework.

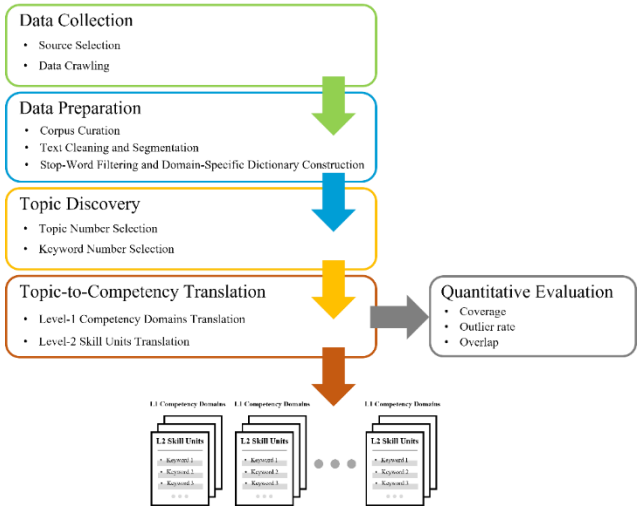

Fig. 1. The proposed study framework.

A. Data Collection

1) Source selection: Robotics job advertisements are distributed across multiple online platforms and often exhibit inconsistent formatting and varying levels of detail. To balance market representativeness with textual suitability for systematic analysis, the study selects Zhaopin (www.zhaopin.com) as the data source for three considerations. First, Zhaopin is one of the leading online recruitment platforms in China, with broad geographic coverage and substantial posting volume. Its market presence facilitates the collection of a diverse sample of robotics-related positions and helps reduce potential selection bias. Second, job advertisements on Zhaopin tend to follow a relatively standardized structure and are subject to platform-level quality control, which makes them well suited for natural language processing (NLP). In particular, the platform encourages employers to provide detailed job description texts that explicitly separate "position responsibilities" and "job requirements", offering a high-quality corpus for extracting skill-related signals. Third, Zhaopin data have been used in prior peer-reviewed studies to analyze labor market demand patterns, providing an external validity signal for leveraging its job description texts in skill demand mining [31][32]. To reduce temporal drift and ensure that the induced topics reflect a consistent market snapshot, the study restricts data collection to a fixed sampling window spanning December 2025 to January 2026.

2) Data collection: Selenium was adopted as the primary tool for crawling and parsing job advertisement pages in this phase. It is a widely used automation framework that programmatically controls real web browsers, enabling reliable interaction with web pages [33][34]. To target robotics-related vacancies while maintaining regional diversity, the study queried the platform using the keywords "Robotics" and "Robot", which aim to capture openings across the robotics value chain, including R&D, system integration, and maintenance. Search locations were restricted to six major regions in China: Beijing, Jiangsu, Shanghai, Zhejiang, Guangdong, and Shandong Province. This location set was chosen because these regions collectively represent a large share of the national robotics industrial chain and host a high concentration of industrial robot manufacturing enterprises. For each location, the crawler iterated over search result pages, collected posting URLs, and parsed the corresponding detail pages to extract the job title, full job description text, and other data such as company name and salary. The initial crawl yielded 6,802 advertisements, reflecting the current labor demand for robotics-related positions in the aforementioned cities.

B. Data Preparation

1) Corpus curation: At this stage, the study curated a corpus of valid robotics-related positions to reduce noise that might interfere with downstream topic discovery. The advertisements were curated through three steps: removing invalid or incomplete records, excluding irrelevant advertisements such as finance jobs, administrative jobs, and promotional or advertisement entries, and eliminating exact duplicate advertisements. After cleaning and deduplication, the resulting corpus contains 3,290 job descriptions and serves as the input to subsequent preprocessing.

2) Text cleaning and segmentation: Recruitment texts often contain punctuation noise, irregular symbols, and platform-specific artifacts that are not informative for skill demand mining. A cleaning procedure is performed before segmentation. Specifically, Python regular expressions are applied via re.sub() to remove punctuation marks and abnormal characters and to normalize whitespace. Additionally, unlike English processing pipelines, Chinese

text does not require uppercase or lowercase conversion, lemmatization, or stemming; therefore, emphasis is placed on accurate word segmentation and term normalization as the primary preprocessing steps.

The corpus is then segmented using Jieba, a widely used Chinese word segmentation toolkit that supports dictionary-based tokenization through prefix-dictionary matching and statistical disambiguation. Jieba is selected for its robustness on large-scale web text, its ability to incorporate a lexicon to preserve robotics technical terms and vendor names, and its lightweight, reproducible integration in standard Python environments, which facilitates transparent replication of the preprocessing pipeline [35].

3) Stop-word filtering and domain-specific dictionary construction: Recruitment corpora contain a substantial amount of platform-specific and HR-related expressions. To mitigate this effect, stop-word filtering is performed using an expanded stop-word set based on the widely used Harbin Institute of Technology stop-word dictionary (hit_stopwords), which is commonly adopted in Chinese NLP studies due to its broad coverage of high-frequency non-content terms [36]. Building on this foundation, the stop-word set is further extended with recruitment-related terms that are prevalent in job advertisements but provide limited value for skill demand analysis. Typical examples include template headers and HR-related expressions such as “compensation and benefits”, “job responsibilities”, “job requirements/qualifications”, and “bonus points/plus”. Removing such terms reduces the risk that topic discovery is dominated by generic recruitment language rather than domain skills.

In addition to stop-word filtering, a domain-specific user dictionary is constructed to preserve robotics-related terms that might otherwise be incorrectly split or discarded. The dictionary covers two major categories. Robotics brands and company names are included, such as Siemens, KUKA, ABB, and FANUC. Technical terms are added to capture core skills, including key algorithms and platforms such as SLAM, ROS, OpenCV, and multimodal learning, as well as industrial automation and engineering terms such as CAD, AGV, Robot Studio, and robotic arm.

By integrating this user dictionary into the segmentation process, domain terms are more consistently tokenized as single units, reducing vocabulary sparsity and improving the stability and interpretability of the downstream topics and competency taxonomy.

C. Topic Discovery

LDA was employed to uncover latent competency topics from the robotics recruitment texts. Its selection was primarily guided by two considerations. First, the purpose of the study was to explore latent competency structures embedded in recruitment texts rather than to assign documents to predefined categories. Under this objective, an unsupervised topic modeling method was methodologically appropriate [37]. Second, given the scale of the corpus and the practical constraints on computational resources, LDA offered advantages in terms of computational efficiency and implementation feasibility. For these reasons, LDA was adopted in the present study. LDA represents each document as a mixture of latent topics, where each topic is modeled as a probability distribution over the vocabulary, thereby facilitating the extraction of interpretable themes representing skill domains and recurring requirements. Given K topics, the model estimates a topic-word distribution $\emptyset_K$ for each topic t_k ($k = 1, \dots, K$) and a document-topic distribution θ_i for each document d_i ($i = 1, \dots, N$) . These distributions provide a ranked list of words that characterize each topic.

Model training is implemented using the Scikit-learn (sklearn) module. Scikit-learn is a widely used open-source machine learning library in Python that provides consistent APIs for data preprocessing, model training, and evaluation across a broad range of algorithms, including topic models. Its LDA implementation offers practical advantages for applied studies, such as integration with standard pipelines and built-in metrics.

1) Topic number selection: In practice, the topic number K is determined by jointly considering topic coherence and perplexity to balance interpretability and model fit. This criterion helps mitigate the risk of underfitting (overly coarse topics) and overfitting (overly fragmented topics), yielding topics that remain interpretable while retaining reasonable explanatory power on data.

2) Keyword number selection: For each topic t_k, the Top-M keywords with the highest probabilities are extracted as an interpretable topic summary, which serves as a compact and easily understandable representation of the topic and is also used as the basis for downstream topic-to-competency translation and structural evaluation.

M is set to 30 as a balanced choice that trades off information coverage against noise introduction. When M is too small, secondary but still important skill terms may be omitted, causing topics to be under-expressed and reducing representational adequacy for recruitment competencies. When M is too large, long-tail and weakly related words are more likely to enter the summary, which can increase overlap between topics and weaken discriminability between topics.

D. Topic-to-Competency Translation

Topic keywords provide concise summaries, but do not directly constitute a competency taxonomy. To bridge this gap, each discovered topic is translated into a two-level structure consisting of task domains and competencies. The translation aims to preserve the semantic content of each topic while producing a structured representation that remains interpretable, traceable, and suitable for subsequent evaluation.

The translation is conducted independently for each topic, based on its ranked Top-M keyword list. No terms outside the current topic are introduced during translation. This constraint preserves topic discriminability and avoids artificial gains in coverage caused by borrowing terms from other topics. In addition, the procedure prioritizes representativeness, meaning that the resulting competency structure is expected to retain the dominant semantic content of the topic rather than rely on a

small number of isolated keywords. Redundancy control is also enforced, such that different competencies under the same task domain capture distinct functional elements rather than repeated variants of the same meaning. The procedure consists of five steps.

Step 1: Assign the task domain. The ranked Top-M keyword list of each topic is first examined as a whole in order to identify its dominant capability orientation. The task domain is then assigned as a task domain-level descriptor that summarizes the central functional area implied by the topic keywords. This naming process follows established robotics and engineering terminology whenever possible, so that the resulting label remains professionally interpretable and consistent with domain usage. The task domain label is required to reflect the main semantic center of the topic rather than a peripheral or overly generic aspect of the keyword set.

Step 2: Partition keywords into candidate competency subsets. After the task domain is determined, the same Top-M keyword list is partitioned into several candidate competency subsets representing fine-grained functional elements. Each subset is intended to capture one operationally meaningful competency, such as design, programming, debugging, testing, deployment, or maintenance-related capability. The grouping process remains restricted to the current topic and organizes keywords according to semantic coherence and task domain relevance. Composite or overly broad groupings are avoided when the underlying competencies can be separated into more precise units.

Step 3: Refine competency boundaries. The candidate competency subsets are then refined by prioritizing higher-ranked keywords, as these terms carry the strongest evidence of the semantic core of the task domain. Particular attention is paid to preserving the dominant task domain-level signals, rather than allowing the translation to be driven by lower-ranked or weakly informative terms. During this step, the boundaries between competencies are adjusted so that each competency retains a clear functional focus within the task domain. When two competencies exhibit substantial semantic overlap, they are merged or revised. When a competency combines multiple distinct functional elements, it is further divided into more fine-grained competencies.

Step 4: Check evidence retention and reduce redundancy. The provisional competency-level structure is then evaluated against the full Top-M keyword list of the topic. This audit examines whether the main topic evidence is retained, whether important high-ranking keywords remain unassigned to the induced structure, and whether different competencies reuse the same semantic content to an excessive degree. If substantial unassigned keywords are identified, especially among the higher-ranked terms, the partition is revised to improve representativeness. If strong overlap is observed between competencies, the structure is adjusted to improve non-redundancy. This step ensures that the translation does not become a purely naming process detached from the original topic evidence.

Step 5: Finalize Competency labels. Once the keyword partition reaches an acceptable balance between representativeness and redundancy, each subset is formalized as a competency. The corresponding competency label is expressed as a concise operational capability statement grounded in the assigned keyword subset. The final output for each topic therefore consists of one task domain, several competencies, and an explicit mapping from each competency to its supporting topic-specific keywords. This mapping preserves traceability between the induced competency structure and the original topic summary, thereby enabling subsequent audit of evidence retention and structural consistency.

Through this procedure, topic summaries are transformed into a two-level competency taxonomy. The resulting structure does not aim to establish a complete ontology of robotics competencies. Instead, it organizes the underlying topic evidence into a two-level representation consisting of task domains and competencies under unlabeled conditions.

E. Quantitative Evaluation

Quantitative evaluation is conducted to assess the interpretability and structural validity of topic summaries in an unsupervised setting without standardized labels. The evaluation protocol is based on the Top-M keyword summary of each topic. Specifically, three metrics are considered: coverage, outlier rate, and overlap.

1) Coverage: Coverage evaluates whether the Top-M keyword summary is representative of the documents assigned to a topic. Let C_k denote the set of documents associated with topic k, and let T_k denote its Top-M keyword set. Let $W(d)$ be the set of tokens appearing in document d. Document-level coverage for topic k is defined as:

$$\mathrm{Cov}(k) = \frac{1}{|C_k|}\sum_{d\in C_k} I\left(W(d)\cap T_k \neq \emptyset\right) \quad (1)$$

where, $I(\cdot)$ is the indicator function. The corpus-level coverage is computed as a weighted average:

$$\mathrm{Cov} = \sum_{k=1}^{K}\frac{|C_k|}{N}\mathrm{Cov}(k) \quad (2)$$

Cov(k) quantifies the proportion of job descriptions in cluster k that contain at least one representative keyword from T_k. Higher coverage indicates that the keyword summary better reflects the cluster content.

As matching on a single keyword can be an insufficiently strict criterion, a stricter variant is also considered, specifically the thresholded coverage. For a threshold $\tau \geq 2$, thresholded coverage requires that a document match at least τ keywords from T_k:

$$\mathrm{Cov}_\tau(k) = \frac{1}{|C_k|}\sum_{d\in C_k} I\left(|W(d)\cap T_k| \geq \tau\right) \quad (3)$$

$$\mathrm{Cov}_\tau = \sum_{k=1}^{K}\frac{|C_k|}{N}\mathrm{Cov}_\tau(k) \quad (4)$$

This variant strengthens the representativeness requirement and reduces the possibility of inflated coverage caused by occasional generic term matches.

2) Outlier rate: The outlier rate quantifies the proportion of documents not explained by the topic summary under the same criterion:

$$\mathrm{Out}(k) = 1 - \mathrm{Cov}(k) \quad (5)$$

The corpus-level outlier rate is computed as:

$$\mathrm{Out} = 1 - \mathrm{Cov} \quad (6)$$

3) Overlap: Overlap measures discriminability by quantifying redundancy among topic summaries, using the Jaccard similarity between keyword sets T_i and T_j:

$$\mathrm{Jacc}(i,j) = \frac{|T_i \cap T_j|}{|T_i \cup T_j|} \quad (7)$$

The overall overlap is defined as the mean pairwise similarity:

$$\mathrm{Overlap} = \frac{2}{K(K-1)} \sum_{1 \le i < j \le k} \mathrm{Jacc}(i,j) \quad (8)$$

The Jaccard similarity is a widely used metric in the analysis of set-based data [38]. It measures the proportion of shared elements relative to the union of sets, providing an interpretable quantification of similarity or redundancy. Its extensive application in computational linguistics and topic analysis establishes it as a reliable metric for evaluating the distinctiveness of topic keyword sets. Lower overlap indicates that different topics are characterized by more distinct keyword summaries, improving interpretability and reducing ambiguity in topic-to-competency translation. Because recruitment texts may share unavoidable common terms, overlap is interpreted jointly with coherence and coverage.

The proposed metrics jointly capture representativeness and discriminability aspects of topic outputs. It is important to clarify that these metrics do not aim to judge the linguistic aesthetics of competency labels, nor do they evaluate clustering quality in a supervised sense. Instead, the evaluation focuses on the structural validity of the evidence used for translation. At the task domain-level, the evaluation examines whether the Top-M topic summaries provide a stable, representative, and discriminative basis for inducing competencies. Coverage and outlier rate quantify how well the summary aligns with documents assigned to a topic in terms of representativeness and noise, and overlap indicates how distinguishable different topic summaries are by capturing redundancy across topics. At the competency level, the same validation logic is extended to the internal audit of the induced competencies. In this stage, the evaluation examines whether the translated competencies retain the dominant topic evidence and whether the decomposition remains internally coherent with limited redundancy. Collectively, these measures assess not only whether the topic-derived evidence is reliable enough to support competency induction, but also whether the resulting topic-to-competency translation remains traceable and interpretable under unlabeled conditions.

Topic summaries, metrics, and translation details are discussed in the Appendix.

III. Experimental Setup

This section describes the experimental setup used to evaluate the proposed translation framework. A baseline method is introduced to provide a conventional reference point, enabling a quantitative comparison that highlights the effectiveness and interpretability of the proposed approach. The baseline serves to contextualize the results and to demonstrate that observed improvements are attributable to the design of the proposed method rather than to trivial differences in data or partitioning.

A. Experimental Protocol

This section describes the evaluation protocol used to assess both the quality of topic evidence and the structural validity of the downstream competency translation. The protocol operates at two complementary levels. The first level evaluates topic summaries as the evidence basis for task domain induction, while the second level audits the resulting competencies derived from the proposed topic-to-competency translation procedure. This design is necessary because coherent topic summaries do not inherently guarantee that the resulting competency decomposition remains evidence-grounded, non-redundant, and traceable.

At the task domain-level, the protocol compares LDA topic discovery with a classical document clustering baseline under matched granularity and a unified interpretability interface. Comparability is enforced through four controls. First, all approaches operate on the same cleaned corpus and follow the same preprocessing and vocabulary construction procedure. Second, the number of topics or clusters is fixed to K across methods. Third, each topic or cluster is represented by a Top-M keyword set under a unified summary length. Fourth, all approaches produce document assignments and keyword summaries that are evaluated using the same metrics. Under this design, coverage, outlier rate, and overlap are used to assess whether the resulting summaries provide a representative and discriminative evidence interface for subsequent competency translation.

At the competency level, the evaluation shifts from topic summaries to the internal structure of the induced competency taxonomy. This level focuses on the transformation from topic evidence to a two-level representation consisting of task domains and competencies. Because the TF-IDF + K-Means baseline does not produce an explicit competency decomposition, a competency-level audit does not apply to the baseline and is therefore conducted only on the proposed LDA-based taxonomy. This audit examines whether the competencies preserve the dominant topic evidence and whether the decomposition remains structurally coherent within each task domain. Specifically, within-topic coverage is used to assess whether the highest-ranked topic keywords are retained in the competency structure; within-topic outliers are used to identify evidence loss during translation; and within-topic overlap among competency keyword subsets is used to examine internal redundancy. Taken together, the task domain-level comparison and the competency-level audit form a complementary validation protocol that evaluates not only the suitability of the topic evidence but also the interpretability and structural validity of the resulting task domain-competency hierarchy.

A traditional text clustering baseline is implemented using TF-IDF document representation followed by K-Means clustering. Based on the same preprocessed recruitment texts, each advertisement is represented as a TF-IDF vector and

partitioned into K clusters, where K corresponds to the number of topics used in the LDA model for direct comparison. TF-IDF is a standard weighting scheme in information retrieval and text mining. It assigns higher weights to terms that are frequent within a document but relatively less frequent across the corpus, which helps emphasize terms that are more discriminative for a given advertisement. In this study, TF-IDF vectors are constructed under a shared vocabulary derived from the same preprocessing pipeline. K-Means is a widely used unsupervised clustering method that partitions a set of vectors into K clusters by minimizing within-cluster dispersion. It iteratively assigns documents to cluster centers and updates the centers until the objective stabilizes. For each cluster, a fixed-length set of representative keywords is extracted from the cluster centroid. The centroid is obtained by aggregating the TF-IDF vectors of documents assigned to the cluster, and the Top-M terms with the highest centroid weights are selected as the cluster keywords. This centroid-based keyword extraction provides an interpretable summary for each cluster under the same Top-M interface used for topic summaries, enabling a consistent comparison across methods. This baseline therefore serves as a conventional reference for examining whether the evidence provides a more suitable basis for downstream competency translation than a classical clustering summary, rather than representing an alternative implementation of the proposed framework.

B. Implementation Details

Experiments are conducted on the robotics job advertisements corpus. The web crawling stage retrieved 6,802 advertisements, and 3,290 advertisements were retained after cleaning and deduplication. All methods operate on the same cleaned corpus to ensure that observed differences are attributable to modeling choices rather than data handling.

Latent competency topics were induced using the LatentDirichletAllocation class in scikit-learn. Before model training, the corpus was represented in document-term form, where min_df = 5 was used to remove extremely rare terms, and max_df = 0.9 was used to exclude overly common terms. The number of topics was specified as K, and the LDA hyperparameters were determined with reference to the expected concentration of the latent distributions and the practical requirements of model implementation. Specifically, the doc_topic_prior was set to $\alpha=50/K$, and the topic_word_prior was set to $\beta=0.01$. These settings were adopted as empirical parameter settings reported in prior LDA applications [39]. The model was trained with learning_method = 'batch', under which all documents in the corpus were used in each variational EM update, and random_state = 42 was fixed to ensure reproducibility. In addition, max_iter = 800 was specified as a sufficiently large upper bound on the number of training iterations.

For the TF-IDF representations used in the clustering baseline, vocabulary construction applied the same document frequency thresholds as in the LDA analysis, namely min_df = 5 and max_df = 0.9. The resulting shared vocabulary was used to construct TF-IDF vectors for clustering and to support comparable keyword summaries across methods. The K-Means baseline was configured with n_init = 11 and max_iter = 800. Multiple initializations were used to reduce sensitivity to local optima in sparse high-dimensional text representations. These settings were aligned with those used in the LDA analysis to facilitate controlled comparison across methods.

All experiments were set up on Windows 10 with Python 3.13.5. The implementation used Scikit-learn 1.6.1, NumPy 2.1.3, Pandas 2.2.3, Selenium 4.20.0, and Jieba 0.42.1.

IV. Results

A. Topic Discovery and Translation

The LDA model yields a set of competency-related topics, each summarized by a ranked list of top words derived from the topic-word distributions. To support subsequent competency translation, the number of topics is selected by jointly considering quantitative diagnostics and interpretability requirements. Following standard LDA practice, topic quality is evaluated using coherence and perplexity. Coherence quantifies the semantic consistency of the top words within each topic, based on word co-occurrence statistics computed from the tokenized corpus. Perplexity measures the model's probabilistic fit on holdout documents. Fig. 2 reports both criteria across a range of topic numbers.

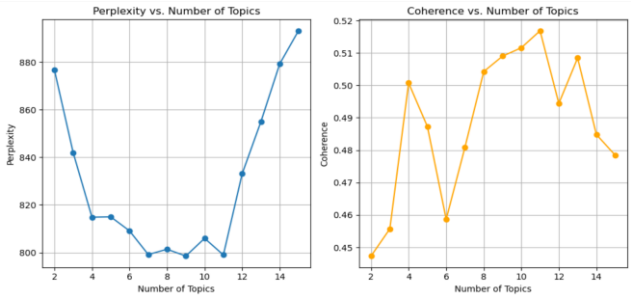

Fig. 2. Coherence and perplexity scores across topic numbers.

From a quantitative perspective, K=11 corresponded to the highest coherence score among the tested values, while perplexity remained within a relatively stable low range for $K \in [7,11]$. Taken together, these results indicate that the 11-topic model offered a suitable trade-off between topic interpretability and model fit among the candidate solutions. This suggests that the selected model not only fits the corpus adequately but also produces topic structures that are more coherent and more readily interpretable. From a modeling and application perspective, this level of granularity aligns with major robotics task domains and supports a two-level representation consisting of task domains and competencies. Fewer topics tend to merge heterogeneous skill signals, reducing discriminability at the task domain-level and complicating competency naming. More topics can fragment coherent domains into overly specific themes, increasing redundancy at the task domain-level and making the downstream competency decomposition less stable. The baseline comparison is carried out with the same partition count to ensure a fair evaluation across methods.

Based on this configuration, the topics are summarized by their top keywords and then translated into a task domain-competency taxonomy. Table I presents the resulting task

domains and competencies, including the top 30 keywords for each topic.

TABLE I. TOPIC-TO-COMPETENCY TRANSLATION RESULT

Task Domains	Competency	Top-30 Keywords
#1 Industrial On-site Equipment Maintenance and Malfunction Diagnosis	1. Troubleshooting and Repair of Automated Equipment Malfunction	Equipment, Fault, Automation, Team, Issue, Mechanical, Technology, System, Collaboration, Fundamentals, Electrical, Production, AGV, Logging, Content, Data, Troubleshooting, Task, Problem Solving, Awareness, Professional Spirit, Skill, Optimization, Learning Ability, Testing, Teamwork, On-Site, Industrial, Sensor, Principle
	2. On-site Process Data Logging and Analysis	
	3. Teamwork and Problem Solving	
	4. Mechatronic System Principles Understanding and Technical Optimization	
	5. Industrial Sensor Testing and Equipment Maintenance	
#2 Mechanical Structure Design and Engineering Implementation	1. Mechanical Structure Design and Analysis	Design, Mechanical, Software, Process, Structure, Product, Mechanical Design, Analysis, Structural Design, Material, Selection, Automation, Machining, Technology, Equipment, CAD, Drive System, Issue, Production, Mechanism, Drawings, Principle, Work Experience, Project, Solution, Mechatronic, Optimization, Motor, Collaboration, Engineering
	2. Automation and Electromechanical Drive Systems Optimization	
	3. Material Selection and Manufacturing Process Planning	
	4. CAD Drafting and Design Documentation Output	
	5. Project Collaboration and Resolution of Product Technical Issues	
#3 Full Lifecycle Project Management and Operational Execution	1. Project Planning and Documentation Management	Product, Project, Technology, Team, Management, Industry, Customer, Quality, Analysis, Solution, Company, Process Flow, Issue, User, Market, Plan, Deployment, Project Management, Intelligent, Collaboration, Department, Documentation, Resources, Planning, Objective, Business, Design, Process, Solution, Automation
	2. Customer Requirements Analysis and Solution Design	
	3. Cross-Departmental Collaboration and Process Improvement Execution	
	4. Product Implementation Delivery and Technical Issue Resolution	
	5. Industry Resource Integration and Requirement Fulfillment	
#4 Robotics Core Module Selection Design and Testing	1. Circuit Design and Electronic Component Selection	Hardware, Design, Motor, Circuit, Electronics, Structure, Joint, Product, Testing, Module, Wiring Harness, Production, Team, Mechanical, Professional Spirit, Issue, Laboratory, Hands-On, Component, Attitude, Quality, Mindset, Power Supply, System, Circuit Design, Collaboration, Selection, Fundamentals, Management, Tooling
	2. Motor and Joint Module Integration with Wiring Harnesses	
	3. Hardware Prototyping, Testing, and Verification	
	4. Practical Engineering Skills and Team Collaboration	
#5 Electrical Design and System Integration for customized Automation	1. PLC Programming and System Software Debugging	Electrical, Automation, PLC, Project, Equipment, Programming, Design, Program, Customized, Software, Selection, Industrial, On-Site, Work Experience, Technology, System, Mechatronic, Electrical Design, Drawings, Vision, Robot Manipulator, Schematic Diagram, Communication, Principle, Wiring, Industry, Mitsubishi, Drafting, CAD, Signal
	2. CAD Drafting and Electrical Schematic Interpretation	
	3. On-site Wiring, Commissioning, and System Integration	
	4. Industrial Communication Configuration and Electromechanical Joint Debugging	
	5. Vision and Robot Manipulator Application in Custom Automation Projects	
#6 Embedded Hardware and Driver Software Development for Robotics	1. Embedded Linux Driver Programming and Development	Testing, System, Software, Driver, Automation, Design, Documentation, Programming, Sensor, Hardware, Embedded, Linux, Analysis, Technology, Issue, Computer, Project, Platform, Product, Motion, Functionality, Module, Principle, ROS, Python, Code, Electronics, Work Experience, Tooling, Motor
	2. Sensor and Motion Control Module Development	
	3. Test Analysis and Fault Localization	
	4. ROS System Design and Application Development	
	5. Project Documentation and Product Deliverable Handover	
#7 Robotics Algorithm Development and Deployment	1. Trajectory Planning and Control Algorithm Development	Algorithm, Planning, Model, Motion, Optimization, Data, Project, Technology, Python, Robotic Arm, Deep Learning, Framework, Robot, ROS, Kinematics, Deployment, Path, Domain, Real-World, Vision, Fundamentals, Control Algorithm, Slam, Environment, Scenario, AI, System, Mathematics, Training, Dynamics
	2. Deep Learning Model Training and Optimization	
	3. SLAM and Environmental Perception Algorithm Implementation	
	4. Algorithm Integration and Deployment in ROS Framework	
#8 Robotic System Performance Optimization and Reliability Testing	1. System Performance and Parameter Testing and Optimization	Optimization, Testing, Design, System, Technology, Performance, Issue, Product, Analysis, Solution, Data, Functionality, Documentation, Hardware, Stability, Reliability, Motion, Evaluation, Coordination, Module, Efficiency, Scenario, Team, Sensor, Planning, Process, Parameter, Review, Environment, Core
	2. Reliability-oriented Design and Stability Validation	
	3. Scenario-based Testing for Motion Modules and Sensors	
	4. Product Function Analysis and Test Documentation Preparation	
	5. Team Coordination and Efficiency-oriented Planning	
#9 Industrial Robot Process Programming and	1. Mainstream Industrial Robot Controllers Programming	Programming, Process, ABB, Industrial, Project, KUKA, Automation, FANUC, Work Experience, On-Site, System, Program, Automotive,
	2. Specific Process Application and Parameter Configuration	

Commissioning	3. Teamwork and Responsibility Awareness	YASKAWA, Brand, Offline, Sense Of Responsibility, Arc Welding, Mechatronic, Parameter, Configuration, Optimization, Spot Welding, Teamwork, Laser, Body-In-White, Responsibility, Mechanical, Trajectory, Dispensing
#10 On-site Technical Support and After-sales Service	1. On-site Emergency Fault Diagnosis and Handling	On-Site, Customer, Project, Equipment, Technical Support, Issue, Product, Process, Production, Electrical, Company, After-Sales, Mechanical, Personnel, Solution, Technology, Process, Materials, Fault, Automation, Service, Organization, Guidance, Management, Optimization, Aspects, Tooling, File, Client, Department
	2. Customer Communication and Technical Service Provision	
	3. Materials Organization and After-sales Documentation Management	
	4. Project Service Delivery and Resource Coordination	
#11 Machine Vision Inspection System Solution Implementation	1. Image Processing Algorithm Programming	Vision, System, Machine Vision, Software, Project, Image Processing, Inspection, Hardware, Automation, Industrial, Design, Technology, Team, Algorithm, Selection, Customer, Light Source, Computer, Lens, Equipment, Analysis, Programming, Solution, OpenCV, Evaluation, Localization, Content, On-Site, VisionPro, Work Experience
	2. Vision Hardware Selection and Integration	
	3. Technical Solution Design and Evaluation	

B. Quantitative Comparison

Table II summarizes the task domain-level structural metrics for the LDA result and the TF-IDF plus K-Means clustering under the same protocol, including the same partition count $K = 11$ and the same summary length $M = 30$. The LDA topics achieve a coverage of 0.9739 with an outlier rate of 0.0261, indicating that the topic summaries remain broadly representative of the documents assigned to each topic. The baseline method yields a near-saturated weighted coverage of 0.9936 and an outlier rate of 0.0064, reflecting strong within-cluster lexical alignment between centroid-derived keywords and clustered documents. Although the LDA method attains a lower coverage than the baseline, the two coverage scores remain relatively close in magnitude, suggesting that both approaches provide broadly representative task domain-level evidence summaries under the same protocol.

A different pattern is observed in inter-cluster redundancy. The average Jaccard overlap of the keyword summaries is 0.1343 for LDA and 0.1906 for the baseline method. Lower overlap indicates that topic summaries are more distinguishable at the keyword level, which is beneficial for competency induction because redundancy across topics increases ambiguity in domain naming and reduces the separability of the induced competency domains. The higher overlap of the baseline method suggests that multiple clusters share a larger portion of their top keywords, which is consistent with centroid-based summaries favoring broadly applicable recruitment terms that recur across job families. In contrast to the gap in coverage, the difference in overlap is noticeably larger, indicating a more pronounced separation in the distinctiveness of the resulting task domain-level representations.

Taken together, the task domain-level results suggest that the baseline's high representativeness is accompanied by increased redundancy across clusters. The higher coverage achieved by the baseline is largely attributable to broadly used recruitment terms that appear frequently within clusters but also recur across multiple clusters, which inflates inter-cluster overlap and weakens topic distinctiveness. In contrast, LDA yields more distinctive topic summaries with lower overlap, resulting in a more balanced trade-off between representativeness and separability. Such a balance is particularly relevant for constructing a task domain-competency hierarchy that supports consistent competency induction across different robotics role categories and avoids redundancy.

TABLE II. COMPARATIVE TASK DOMAIN-LEVEL STRUCTURAL METRICS

Structural Metrics	Proposed Method (LDA)	Baseline (TF-IDF + K-Means)
Coverage ($\tau = 2$)	0.9739	0.9936
Outlier rate	0.0261	0.0064
Overlap	0.1343	0.1906

Beyond the task domain-level comparison, the proposed taxonomy is further examined through competency-level metrics that operate on the internal decomposition within each task domain. Unlike the task domain-level metrics, which evaluate whether the keyword summaries provide a representative and discriminative evidence basis for competency induction, the competency-level metrics evaluate whether the resulting competencies remain grounded in the original topic evidence after translation. Because the TF-IDF plus K-Means baseline does not generate an explicit competency structure, this audit is applied only to the proposed LDA-based taxonomy.

Table III reports the competency-level audit results. The results indicate that the proposed translation procedure retains a substantial proportion of the dominant task domain evidence at the competency level. The average within-topic coverage reaches 0.9667, suggesting that the highest-ranked topic signals are largely preserved in the translated competencies rather than being lost during decomposition. At the same time, the within-topic outlier remains 0.0333 on average, indicating that most evidence is incorporated into the competency structure rather than remaining outside the induced competencies. In addition, the average within-topic overlap among competency keyword subsets is 0.0246, showing that the decomposition does not merely restate the same semantic content under multiple labels but instead maintains relatively clear internal boundaries among competencies.

TABLE III. COMPETENCY-LEVEL AUDIT METRICS

Task Domain Number	Within-topic Coverage	Within-topic Outlier	Within-topic Overlap
# 1	1.0000	0.0000	0.0000
# 2	0.9667	0.0333	0.0100
# 3	0.9333	0.0667	0.0000
# 4	0.9333	0.0667	0.0414
# 5	0.9333	0.0667	0.0268
# 6	0.9667	0.0333	0.0798
# 7	1.0000	0.0000	0.0781
# 8	0.9667	0.0333	0.0232
# 9	0.9667	0.0333	0.0000
# 10	1.0000	0.0000	0.0111
# 11	0.9667	0.0333	0.0000
Mean	**0.9667**	**0.0333**	**0.0246**

When interpreted jointly, the two levels of quantitative evidence support different but complementary claims. The task domain-level metrics show that the adopted LDA summaries provide a comparatively suitable evidence basis for competency induction in terms of representativeness and inter-cluster distinctiveness. The competency-level result further shows that, once translated, the competency-level structure preserves the dominant task domain evidence while limiting excessive within-topic repetition. Accordingly, the quantitative results do not establish an absolute notion of taxonomy correctness, but they do support the structural reliability, traceability, and interpretability of the proposed topic-to-competency translation under unlabeled conditions.

C. Qualitative Interpretation

Overall, the discovered topics cover major task domains frequently appearing in robotics recruitment texts, including industrial on-site operation and maintenance, mechanical design and engineering implementation, system integration and commissioning, embedded hardware and driver development, algorithm development and deployment, and performance validation and reliability testing. The keyword patterns provide a suitable evidence base for subsequent competency induction because they expose interpretable, task domain-level signals rather than only word frequency effects.

Based on the task domains, the associated competencies, and the Top-30 keyword evidence, the topics are organized into four groups. This organization provides a structured interpretation of the topic set and clarifies how topic evidence supports competency induction across development, deployment, and lifecycle operation.

The first group covers on-site operation and service and includes Domain #1 Industrial On-site Equipment Maintenance and Malfunction Diagnosis, and Domain #10 On-site Technical Support and After-sales Service. These topics align with roles such as field operation and maintenance engineers, equipment maintenance engineers, and after-sales technical support engineers. The skill pattern is strongly contextual and workflow-oriented. High-frequency terms emphasize fault diagnosis, troubleshooting, and the maintenance of deployed equipment such as automated guided vehicle (AGV) systems. The topics also contain repeated signals related to after-sales service and data recording. Together, these signals indicate a closed loop of detection, restoration, documentation, and handover. This group is practically significant because it directly affects system availability in real deployments and influences recovery efficiency and downtime costs. The keyword evidence consistently highlights field constraints and operational accountability, indicating persistent demand for personnel who can restore deployed systems under real-world conditions while maintaining traceability of actions and outcomes.

The second group corresponds to engineering design and integration and spans a major engineering chain from design to delivery. It includes Domain #2 Mechanical Structure Design and Engineering Implementation, Domain #3 Full Lifecycle Project Management and Operational Execution, Domain #4 Robotics Core Module Selection Design and Testing, Domain #5 Electrical Design and System Integration for Customized Automation, Domain #9 Industrial Robot Process Programming and Commissioning, and Domain #11 Machine Vision Inspection System Solution Implementation. This group covers multiple role categories, including mechanical and hardware engineers, electrical and automation engineers, integration and commissioning engineers, project managers, solution engineers, and vision engineers. The skill characteristics reveal three connected capability streams. The first stream is mechanical and hardware engineering and is represented by Domain #2 and #4. It follows an engineering workflow centered on design, analysis, selection, prototyping, integration, and validation. The keyword evidence emphasizes mechanical design and analysis, materials and manufacturing planning, engineering drafting, circuit and component selection, and prototype testing. These capabilities define manufacturability, maintainability, and performance boundaries and constitute the engineering foundation of robotics products. The second stream is electrical design and system integration, and is represented by Domain #5 and #9. It emphasizes controller programming, on-site wiring and commissioning, industrial communication configuration, and electromechanical joint debugging, as well as process programming and parameter configuration for industrial robots. These competencies support the delivery of deployable automation solutions under industrial constraints. The third stream is solution delivery and project execution, and is represented by Domain #3 and #11. It highlights requirements analysis, solution design and evaluation, cross-department collaboration, process coordination, delivery execution, and documentation. These capabilities connect technical development to application deployment by transforming technical resources into deliverable solutions. Domain #11 further indicates combined demand for image processing programming, vision hardware selection, and engineering integration, reflecting role-specific requirements for machine vision solution implementation in industrial robotics.

The third group covers software and algorithm development and includes Domain #6 Embedded Hardware and Driver Software Development for Robotics and Domain #7 Robotics Algorithm Development and Deployment. These

topics align with robotics software engineers, embedded engineers, and algorithm engineers. Domain #6 emphasizes engineering-oriented development across embedded platforms, driver programming, sensor and motion module integration, testing and fault localization, and documentation-oriented delivery. Domain #7 focuses on motion planning and control, deep learning training and optimization, environmental perception, and deployment within robotics software frameworks. The combined signal indicates that industry demand extends beyond algorithm development and includes engineering integration and deployment. This group governs both the upper bound of system intelligence and the feasibility of transferring algorithms from development environments to production deployments with maintainable interfaces and stable performance.

The fourth group concerns system verification and reliability assurance and is represented by Domain #8, Robotic System Performance Optimization and Reliability Testing. It aligns with roles such as system test engineers, validation engineers, and reliability engineers. The topic evidence concentrates on reliability testing and performance testing. It also contains documentation and coordination signals that reflect process discipline in engineering validation. This group supports sustained stability and scalable deployment by enforcing measurable validation procedures and reducing deployment risks. It also forms a quality assurance bridge between development, integration, and operation.

In summary, the four groups jointly form a competency taxonomy that covers key role categories across development, delivery, and lifecycle operation. The topic-to-competency translation enhances interpretability by converting keyword summaries into competencies under task domains. Each competency remains traceable to a task domain-specific keyword subset, enabling interpretability of competency statements and supporting qualitative interpretation. This structured view complements the quantitative results by explaining how topic distinctiveness and representativeness support a competency taxonomy for robotics recruitment mining.

V. Conclusion and Future Prospects

A. Contributions and Practical Implications

This study contributes to the literature on recruitment text mining and competency induction by proposing a data-driven approach for translating robotics recruitment texts into a structured competency taxonomy. The main outcome is a two-level competency taxonomy comprising 11 task domains and 48 competencies, grounded in topic keyword evidence and supported by a translation procedure and a traceable validation logic.

This study identifies latent competency domains and skill patterns embedded in robotics recruitment texts and organizes them into a coherent structure. The resulting taxonomy provides an empirical representation of employer competency demand across major robotics role families, including development, integration, deployment, and operation. Rather than remaining a list of isolated skills, the identified taxonomy is organized into a hierarchical structure that makes the relationships among task domains and competencies more explicit. Building on the robotics talent competency literacy framework analyzed in [13], the present study not only supports its main perspective but also further extends and enriches the skill requirements identified for the robotics domain, thereby producing a more detailed and fine-grained competency inventory. This richer and more structured competency taxonomy expands existing research on job-related competencies in the robotics field and provides a more actionable basis for occupational analysis and curriculum design.

Moreover, the study extracts latent topics from recruitment texts through LDA and then applies a translation procedure to convert unsupervised topic evidence into task domains and competencies under explicit requirements of keyword coverage and redundancy control. With explicit translation constraints and metrics, this approach further reduces the problem of naming subjectivity discussed in [25]. It also enriches the methodological pathway discussed in [21][22][23] for mining competencies through LDA and related models. The contribution of the study therefore lies not only in generating topic summaries, but also in providing an approach from topic keyword evidence to a competency taxonomy that can support both labor market analysis and educational planning.

The study also has important practical implications for labor market analysis, vocational education, and workforce development. First, the resulting taxonomy provides a traceable competency artifact that can support structured analysis of robotics labor demand, including role profiling, demand monitoring, and the identification of major competency clusters in industry recruitment. Because the taxonomy is derived from employer recruitment texts rather than predefined occupational templates, it reflects current market competency signals and can therefore complement more static competency frameworks developed through expert judgment.

Second, the study has reference value for talent cultivation in vocational education and for the development of teaching reform. Because the taxonomy is grounded in observed employer demand, it can provide an empirical reference for curriculum alignment, competency module refinement, training pathway design, and the identification of emerging skill combinations that may not yet be fully reflected in conventional educational programs. In robotics education, where the integration of mechanics, electronics, control, software, and application deployment is especially important, a competency structure grounded in observed demand can help connect educational planning more closely to industrial requirements.

Overall, the study contributes not only a robotics competency taxonomy but also a methodological perspective on how recruitment text evidence can be translated into an interpretable competency structure. Its value lies less in claiming superiority of a single topic model and more in demonstrating how unsupervised topic evidence can be organized, interpreted, and evaluated as a competency representation under realistic unlabeled conditions.

B. Limitations and Future Work

The scope of the present study is subject to the following limitations. First, the recruitment corpus is collected from a bounded set of online sources within the Chinese labor market, with job advertisements sampled from several representative major cities. This scope implies constraints on external generalizability. The resulting competency taxonomy should therefore not be directly transferred to overseas regions with different industrial structures, regulatory environments, or technological development stages. In addition, the corpus is gathered within a limited sampling period. In a rapidly evolving domain such as robotics, the observed skill demand signals primarily reflect the workforce requirements at the time of collection, and the competency profile is expected to shift as technologies mature and deployment patterns change.

Second, the evaluation emphasizes internal interpretability and structural quality using coherence and other metrics derived from topic and keyword evidence, including coverage, outlier rate, and overlap. This design matches the study setting in which labels for topic quality and competency taxonomy correctness are typically unavailable in recruitment text, and it enables comparison across methods under a unified evidence interface. The current results therefore provide internal structural support for the induced competency taxonomy, particularly in terms of representativeness, distinctiveness, and traceability. However, the present validation does not yet extend to external substantive assessment by domain experts. Additional external evidence, such as expert review, could further strengthen the interpretive claims and broaden the validation perspective.

Future research can extend the present study along two directions. First, external validity and longitudinal analysis can be strengthened through a structured cross-cultural validation framework. This includes expanding data collection to multiple countries or regions and conducting comparisons across markets with differing industrial contexts. Longitudinal designs should be prioritized to track how competency demand evolves, enabling the separation of stable competency cores from time-sensitive requirements and emerging skill trends. Second, external evidence and application validation can be incorporated as a complementary verification layer beyond internal interpretability metrics. These extensions may incorporate expert review supported by consensus analysis, which can further reduce the influence of subjective naming choices beyond the translation constraints imposed by the translation procedure, and validation through downstream tasks that require structured competency representations.

***Abstract*—Virtual reality (VR) has become a promising technology to assist children with autism spectrum disorder (ASD especially in the areas of improving user experience with immersive, adaptive, and interactive environments. Nevertheless, current research is still disjointed in areas with very little synthesis on the effectiveness of VR in enhancing user experience and supporting the various cognitive, behavioural, and sensory requirements of autistic children. This study seeks to thoroughly review and synthesize current developments in VR-based solutions to determine the main methods, assessment plans, and design implications that can enhance user experience in this population. The systematic literature review was based on the PRISMA framework, where an advanced search strategy was implemented in Scopus and IEEE databases with keywords related to autism, user experience, and virtual reality. The identification phase yielded 939 records, followed by a rigorous screening and eligibility process resulting in a final dataset of 29 primary studies published between 2020 and 2025. The results were divided into three broad themes, namely: 1) VR-Based Intervention and Skill Development for Autism which shows how social, cognitive and daily living skills can be improved with the help of an immersive training; 2) Assessment, Evaluation and Multimodal Analytics in VR for Autism which reveals how objective evaluation and personalisation can be achieved with the assistance of behavioural and physiological and AI driven data which can improve the evaluation and personalization; and 3) Design Framework which includes VR system for Autism that focuses on users, ethical consideration and an inclusive system development. Altogether, the review indicates that VR demonstrates substantial potential to improve the user experience of children with autism, especially when it is facilitated through adaptive, data-driven, and inclusive design strategies. However, issues of scalability, long-term efficacy, and standardisation persist, meaning that future studies are required to create strong and user-friendly VR frameworks in this population.**

***Keywords*—Virtual Reality (VR); Autism Spectrum Disorder (ASD); User Experience (UX); multimodal analytics; inclusive design**

I. Introduction

Virtual Reality (VR) is a technology that simulates lifelike and immersive experiences within a digitally created environment. Objects within VR tend to behave much as they do in the physical world, allowing users to engage with them in a manner that follows natural laws of physics [1], [2]. Hence, it has emerged as a groundbreaking technology in therapeutic and educational interventions in children with autism spectrum disorder (ASD) and offers immersive and interactive environments that can be tailored to particular needs. The role of user experience (UX) in this context is immeasurable, and the success of VR-based interventions depends on how well they can address the specific sensory, cognitive, and social aspects of autistic children. The increasing prevalence of ASD, together with limitations in traditional therapeutic approaches, has led to the rise of interest in applying VR to support social communication, emotional regulation, and adaptive behavior. However, the possibility of VR is limited by the difficulty of developing a digital space that is appealing and favorable to children with different sensory backgrounds and interaction. The review presents the current body of research on the usefulness of UX enhancement in VR among autistic children, focusing on the connections between theoretical assumptions and technological innovation and the practical implementation of this methodology in a clinical setting and in the educational process. [3], [4], [5].

Autistic children are known to have abnormal sensory processing behavior where they experience hyper or hyposensitivity to visual, auditory, and tactile stimuli [6]. Such sensory differences can greatly influence their tolerance and acclimatization to VR environments, where uncontrolled or excessive stimulation can result in distress, anxiety or disengagement [7]. Repeated studies have demonstrated that personalised sensory modulation, such as manipulation of the intensity, type and timing of sensory input may be used to alleviate sensory overload and facilitate a positive interaction. [8] Indicatively, VR systems as screens, delivering controlled multimodal stimuli have been shown to be tolerable to autistic adolescents and have been shown to have behavioral responses, which are correlated to individual sensory profiles [9], [10], [11]. Moreover, the emotional factors play a decisive role in the sensory responsiveness, and tactile hyper- or hypo-responsivity is typically coupled with anxiety or disparities in emotional processing in comparison with the mere perceptual incompetence [12], [13]. The VR design that is effective in this population is therefore not only technically precise in terms of sensory delivery but also ought to be sensitive to the emotional and behavioral context in which senses are utilized. [1]

The presence of engagement barriers and preferences for interaction further complicates the design of VR for autistic children. ASD children prefer natural, effective modalities of interaction, such as virtual hand controls or gesture interfaces, to formal game controllers, which can lessen cognitive load and

*Corresponding author.

improve task performance [14], [15]. Engagement may, however, be destroyed by unpredictability, multifaceted social signals and the danger of sensory bombardment necessitating predictable and adaptable contexts. VR worlds can be modified on-the-fly, depending upon physiological and behavioral feedback such as eye tracking and heart rate to make interventions more personalized and enable long-term engagement [16], [17]. Autistic children, educators and therapists have also been mentioned as critical in the co-design strategies, where they are involved in the development process and can create inclusive, comfortable and motivating VR experiences [18], [19]. Such participatory practices not only increase usability but also tackle ethical issues by making sure that interventions are respectful, relevant, and in line with the lived experiences of autistic users [20], [21].

VR technology in ASD is varied and includes a variety of hardware platforms such as head-mounted displays (HMDs) and desktop and projector-based systems, each with its own strengths and weaknesses. The interaction provided by an immersive VR using HMDs tends to be more engaging and spatial and can fit the visuospatial advantages of most autistic children [22], [23]. They may, however, also increase sensory sensitivities and cause cybersickness, especially in individuals with a high perceptual sensitivity, requiring specific desensitization measures and session control [24]. Less immersive or screen-based VR can provide a more accessible option to younger or more sensitive users but could potentially come at the cost of decreased immersion and engagement [24], [25]. On all platforms, customizable sensory parameters, spatialized audio, haptics and real-time adaptation frameworks are critical to lessening sensory overburden and maximizing therapeutic value [11], [17]. The evidence base of the VR interventions in ASD is strong and demonstrates the short-term outcomes of the interventions in improving social communication, cognitive and adaptive behaviors, yet there are still methodological limitations such as small sample sizes, lack of diversity and follow-ups [26], [27], [28].

Nevertheless, despite the potential of VR, significant research and technological gaps remain. The rigor of the methodology is often subpar, and the majority of the studies rely on small and homogeneous samples and short-term outcome measurements, limiting the possibility of generalizing and scaling up the findings [27], [28]. VR used together with established types of therapy, such as cognitive behavioral therapy, has been shown to have a synergistic effect on enhancing social, cognitive and emotional outcomes, although more systematic studies are still required to identify best practice and long-term effectiveness [29], [30]. The issue of the sensory overload, cybersickness, privacy, consent and the risk of interventions trying to normalize autistic characteristics rather than letting people be themselves are of paramount importance [20], [31]. The participatory design model and responsible research and innovation models are also increasingly mentioned as a requirement to ensure that VR technologies are created and implemented in a way that is both safe, inclusive and responsive to the needs of autistic children [21], [31]. Price, infrastructure, teacher education and individualized content barriers to greater implementation in education and clinical practice should also be surmounted through collaborative, user-friendly innovation and policy facilitation [32], [33].

This systematic review aims to address these gaps and is structured into several sections to provide a systematic understanding of virtual reality applications for children with autism. The next section of this study presents the research methodology based on the PRISMA framework, including the search strategy, screening criteria, eligibility process, and quality assessment procedures. Mixed Methods Appraisal Tool (MMAT) was conducted to evaluate the methodological quality of included studies and distinguish between high-quality and low-quality evidence. This is followed by the results and findings section, which discusses publication trends and thematic analysis derived from the selected studies. The thematic findings are categorized into three major themes: VR-based intervention and skill development, multimodal assessment and analytics, and inclusive design frameworks for autism-related VR systems. Finally, the discussion and conclusion section summarizes the key findings, highlight the practical and theoretical implications of the review, identifies current limitations, and proposes future research directions for enhancing user experience in VR environments for children with autism.

Overall, enhancing user experience in virtual reality for children with autism requires an integrative approach that bridges technical innovation with a comprehensive understanding of autistic users' sensory, cognitive, and emotional needs. In the literature, having personalized, adaptive VR spaces to embrace individual sensory profiles, leverage natural interaction patterns and co-created with people and stakeholders is emphasized to be relevant, both ethically and practically. Despite the gigantic potential of immersive VR technologies to improve social, cognitive and emotional outcomes, the utility of the latter should be justified by a serious methodological analysis, their confirmation by a certain time and developing the means of their implementation, which should be scalable and accessible. Further research is required to be more specific to the application of a wide range of population groups of participants, employing powerful longitudinal designs and integrating machine learning and real-time feedback systems that can help to further customize and optimize VR experiences. Finally, the fulfilment of the promise of VR to help autistic children will require long-term interdisciplinary cooperation, ethical responsibility and a focus on participatory and user-centered design [34], [35].

II. Materials and Methods

A. Identification

According to the PRISMA framework, the identification phase is a fundamental step to the comprehensiveness and transparency of a systematic literature review (SLR). Table I demonstrates that a systematic and thorough search approach was carried out in two major and complementary academic sources, including Scopus and IEEE Xplore, on a mixture of keywords regarding autism, user experience, and virtual reality. The initial search led to a total of 939 records, including 757 in Scopus and 182 in IEEE.

Such a distribution is suggestive of Scopus as a more comprehensive source of disciplinary coverage because it indexes a wide range of journals not only in the health sciences but also in psychology and the social sciences, and also in studies in technology. On the other hand, the IEEE Xplore is more technical and engineering-based and therefore offers a smaller scope of literature. The fact that there were a comparatively higher number of records found in Scopus indicates that the research on virtual reality applications in children with autism is not restricted to technical research but is extensively studied within the context of interdisciplinary research, including human-computer interaction, rehabilitation and educational technology.

TABLE I. SEARCH STRING

Scopus	TITLE-ABS-KEY (("autism" OR "autistic disorder" OR "autistic spectrum disorder" OR "ASD") AND ("virtual reality" OR "VR" OR "immersive technology" OR "simulated environment") AND ("user experience" OR "UX" OR "user-centered design" OR "interaction" OR "engagement")) AND (LIMIT-TO (DOCTYPE , "ar")) AND (LIMIT-TO (PUBYEAR , "2020") OR LIMIT-TO (PUBYEAR , "2022") OR LIMIT-TO (PUBYEAR , "2023") OR LIMIT-TO (PUBYEAR , "2024") OR LIMIT-TO (PUBYEAR , "2025")) AND (LIMIT-TO (LANGUAGE , "English")) AND (LIMIT-TO (SRCTYPE , "j")) AND (LIMIT-TO (PUBSTAGE , "final")) AND (LIMIT-TO (SUBJAREA , "COMP")) AND (LIMIT-TO (OA , "all")) Date of Access: April 2026
IEEE	("autism" OR "autistic disorder" OR "autistic spectrum disorder" OR "ASD") AND ("virtual reality" OR "VR" OR "immersive technology" OR "simulated environment") AND ("user experience" OR "UX" OR "user-centered design" OR "interaction" OR "engagement") Date of Access: April 2024

B. Screening

The screening is a critical filtering step of the SLR process, which aims at narrowing down the records that had been identified during the initial stage by using preset inclusion and exclusion criteria. In this study, the rigorous screening process was implemented to determine the relevance, quality, and disciplinary suitability of the literature selected. Table II shows the selection criterion of the articles reviewed.

Besides procedural filtering, the screening judgments have substantial methodological implications and reasons. English-language publication restriction enhances interpretability and consistency in data extraction but may result in some degree of language bias by excluding potentially valuable local studies. Similarly, ensuring that the time frame remains the publications after 2020 is a way to ensure that the review incorporates the latest technological changes and current UX practices in virtual reality, which is one of the rapidly evolving spheres. Such exclusion of conference papers and reviews, possibly having omitted early-stage innovations and synthesized knowledge, supports the bias of the review toward fully developed and high-impact journal contributions. In addition, the subject areas being narrow ensure conceptual consistency and no watering down of findings by irrelevant fields. The second step of removing 12 duplicate records indicates the importance of cross-database integration and data cleaning to avoid overrepresentation of the same studies. Collectively, these screening procedures lead to enhanced internal validity, transparency and reproducibility of the review, not to mention that they are an indicator of purposeful strike of inclusiveness and methodological rigor, which are all necessary in producing high-quality results of an SLR.

TABLE II. THE SELECTION CRITERION IS SEARCHING

Criterion	Inclusion	Exclusion
Language	English	Non-English
Timeline	2020-2025	<2020
Literature Type	Journal (Article)	Conference, Book, Review
Publication Stage	Final	In Press

C. Eligibility

The eligibility stage further narrows down the filtered records by evaluating their substantive conformity to the study aims and obtaining full data to analyze. Among the 264 articles that were evaluated in terms of full-text analysis, only a significant portion of them (n=235) were eliminated according to the clearly defined criteria, such as articles that were not relevant to the research area in general, abstracts that were not related to the main objectives of the study, and those articles that were not accessible in terms of full-text assessment. This step acts as a rather important quality control gateway whereby only the studies that are directly conceptually and empirically related to the user experience in virtual reality in the context of autism are left. As a result, the resulting corpus was reduced to 29 studies that could be included in qualitative synthesis, which is a very selective but focused corpus.

D. Quality Assessment

To evaluate the methodological rigor of included studies and distinguish between high-quality and low-quality evidence, a quality assessment was conducted using the Mixed Methods Appraisal Tool (MMAT) version 2018. The MMAT is a validated instrument designed to appraise the methodological quality of five categories of studies: qualitative research, randomized controlled trials, non-randomized studies, quantitative descriptive studies, and mixed methods studies.

Each study was independently assessed by two reviewers using the appropriate MMAT criteria for its study design. The MMAT uses a set of screening questions followed by category-specific quality criteria. Studies are not assigned an overall numerical score; instead, the detailed responses to each criterion provide a comprehensive quality profile.

1) Quality assessment results of the 29 included studies:

- 8 studies (27.6%) met all applicable MMAT quality criteria, indicating high methodological rigor.
- 15 studies (51.7%) met most criteria with minor limitations.
- 6 studies (20.7%) had moderate methodological limitations.

No studies were excluded based on quality assessment; however, the quality ratings informed the interpretation and synthesis of findings. Studies with higher methodological rigor were given greater weight in the critical analysis, and limitations of lower-quality studies were explicitly noted in the thematic synthesis. The quality assessment results are summarized in Table III.

TABLE III. QUALITY ASSESSMENT SUMMARY USING MMAT

Quality Category	Number of Studies	Percentage	Key Characteristics
High Quality	8	27.6%	Met all applicable MMAT criteria; rigorous design, clear methodology, appropriate analysis
Moderate-High Quality	15	51.7%	Met most criteria with minor limitations; generally sound methodology with small gaps
Moderate Quality	6	20.7%	Notable methodological limitations; findings interpreted with caution

Common methodological strengths across high-quality studies included clear research questions, appropriate study designs, detailed descriptions of VR systems and interventions, validated outcome measures, and transparent reporting of limitations. Common weaknesses in moderate-quality studies included small sample sizes without justification, lack of control or comparison groups, limited generalizability, and insufficient detail on data analysis.

E. Data Abstraction and Analysis

The approach used in this research is an integrative analysis as it is one of the assessment methods that a researcher employs to conduct a systematic examination and synthesis of the results of varied qualitative research designs. The main aim of this strategy was to determine the overall themes and sub-themes that apply to Enhancing User Experience in Virtual Reality among Autistic children. The process started with the collection of data that formed the basis for the development of themes. The authors performed a thorough and repeated analysis of 29 chosen publications, deriving meaningful statements and evidence that were directly relevant to the study focus, as shown in Fig. 1. The studies were critically reviewed regarding their methodology and main findings to get a full picture of the existing research in the field.

The authors then held joint discussions to elaborate and develop themes based on the evidence retrieved. During the analysis, a systematic log was kept to record interpretations, emerging ideas, uncertainties, and analytical thoughts which would promote transparency and traceability. The authors constantly cross-tabulated the results of the studies in order to detect and eliminate inconsistencies in developing themes. Whenever there was a disagreement, consultations were held among the authors until they reached an agreement. The last themes were further developed to make them coherent and consistent. In order to enhance the validity and domain relevance of the thematic analysis, the identified themes were reviewed by two experts by evaluating the clarity, conceptual relevance, and consistency of the thematic categorization. Their feedback contributed to refining the analytical structure and improving the rigor and reliability of the thematic synthesis.

This study is guided by the following research questions.

1) How does virtual reality-based intervention influence user experience and skill development among children with autism in immersive learning environments?

2) How do multimodal data and evaluation techniques in virtual reality environments support the assessment of user experience and behavioral responses in children with autism?

3) What design principles and framework characteristics contribute to enhancing user experience in inclusive virtual reality systems for children with autism?

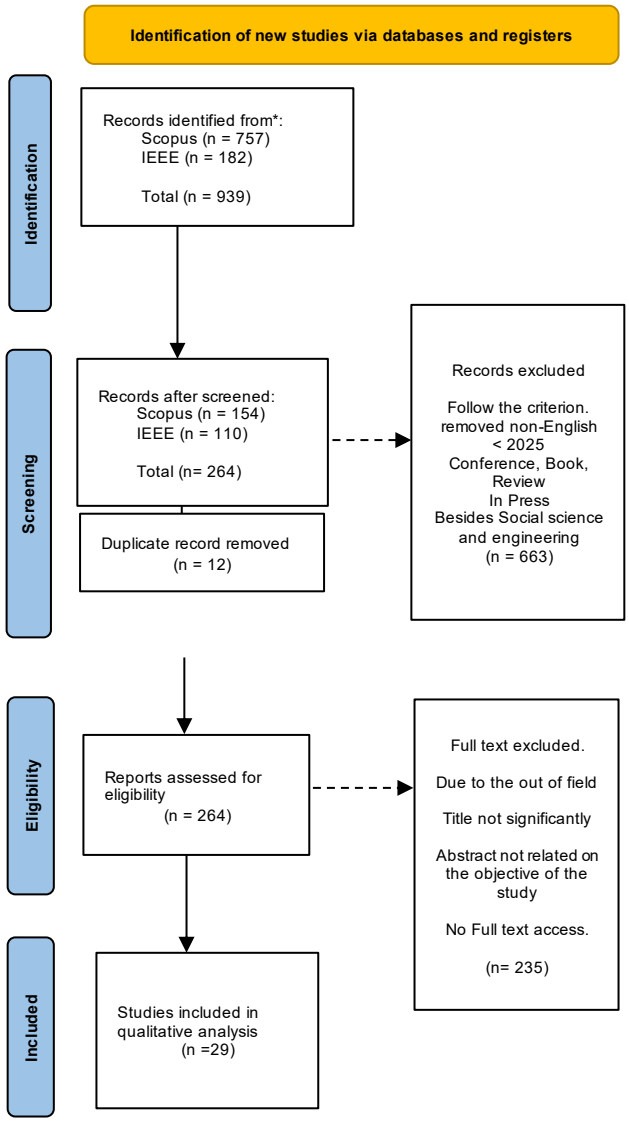

Fig. 1. PRISMA flow diagram of the proposed search study.

III. RESULTS AND FINDINGS

The following section presents the results of the systematic literature review according to the 29 selected studies that met the inclusion and quality assessment criteria. The results are divided into two broad sections: 1) an overview of the publication trends and the extracted properties of the reviewed articles, and 2) thematic analysis of the theme Enhancing user experience in Virtual Reality for Children with Autism.

A. Publication Trend and Synthesized Overview

1) Publication trend by year: Fig. 2, illustrating the temporal distribution of the reviewed articles, depicts that there is an overall increasing tendency of research output between 2020 and 2025 with several fluctuations. Publications began to decrease in 2020 (n=5), 2021 (n=3), and increased in 2022 (n=6) and 2023 (n=5), with a slight decrease in each year. It has a stronger upward trend with a greater increase in 2024 (n=9) and a high level of increase in 2025 (n=12). This trend is indicative of an increase in academic interest in integrating virtual reality (VR), user experience and interventions based on autism. The initial variability of 2020-2023 could be explained by the exploratory character of initial research and external factors like the COVID-19 pandemic that disrupted research and access to experimental conditions. This sudden increase as of 2024 will probably be fuelled by the fast development in VR technology such as more affordable and accessible hardware, and the growing recognition of the significance of personalized and immersive interventions in children with autism. In addition, the increased funding of research and interdisciplinary work in fields like digital health and assistive technologies could have led to this increase. On the whole, the upward trend indicates that the sphere transforms into less of an emerging field and more of a more mature and established one, where the focus is more on evidence-based design, user-centered solutions, and multimodal interaction in VR systems to support children with autism.

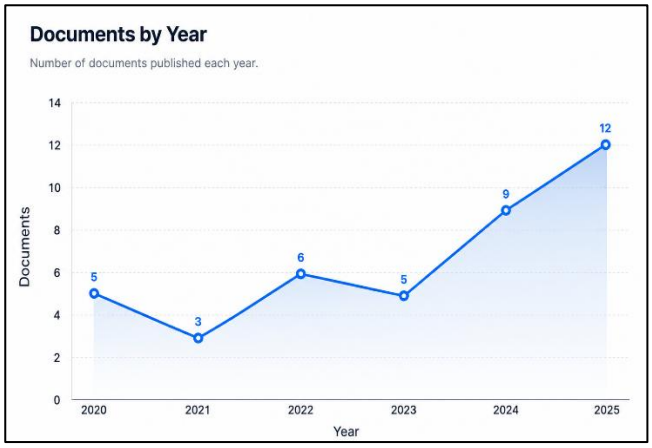

Fig. 2. Documents by year.

2) Documents by author: As Fig. 3 shows, the articles finally selected were distributed relatively widely and diffusely in terms of authorship, and the contribution of several authors was repeated quite a few times. It is interesting to note that Jung, S., Mei, C., and Moon, J. were the most frequent authors with two publications each, and the other authors had a single publication. This means that no single or small group of scholars dominates the field, but it is characterized by a large range of contributors. This may be because of the presence of recurrent authors, as this may be interpreted as a sign of nascent collaborative organizations or research partnerships, potentially being interdisciplinary collaboration between areas such as virtual reality, human-computer interactions, and autism research. The reason why these partnerships are so important is that they merge technical innovation and clinical and consumer-based perspectives. Overall, the trend is that the research area is still forming and that the number of contributors is growing but has not yet solidified, which implies that it is an emerging field where various contributions are being made to enhance research development, but it may be required to have more solid networks of collaboration to enhance research maturity and sustainability.

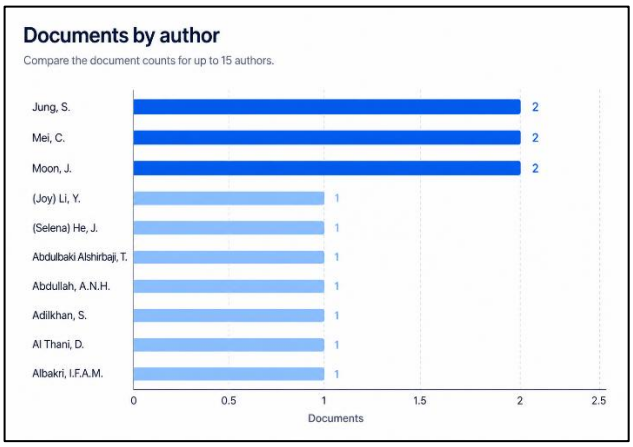

Fig. 3. Documents by author.

3) Documents by country: Fig. 4 demonstrates that the geographical pattern of the identified studies indicates a high level of concentration of the research production in several most productive countries, the United States (n=17) is the most productive country, and China (n=4) comes next. Other nations have a moderate contribution (n=3 each on average) with Argentina, Greece, Italy, and Norway being underrepresented (n=2 each). The supremacy of the United States is explained by the abundance of technological infrastructure, the high level of research investments, and the developed healthcare and educational systems in which the emphasis is put on the innovative interventions towards the developmental disorders. Likewise, the rise in contribution of China is indicative of its rise in investment in new technology like VR and digital health. By comparison, the smaller and more disjointed input of the Malaysian and other Asian nations indicates that, although interest in the region is increasing, research activities are less organized and could be limited by a lack of funds, infrastructural differences, and differences in healthcare priorities. On the whole, the field proves to be geographically uneven although it is geographically participatory with a prevalence in developed areas. This disparity explains why increasing international cooperation and capacity building is essential to make more inclusive and context-dependent improvements, especially in those areas that are underrepresented, and VR-based interventions may be of great assistance to children with autism.

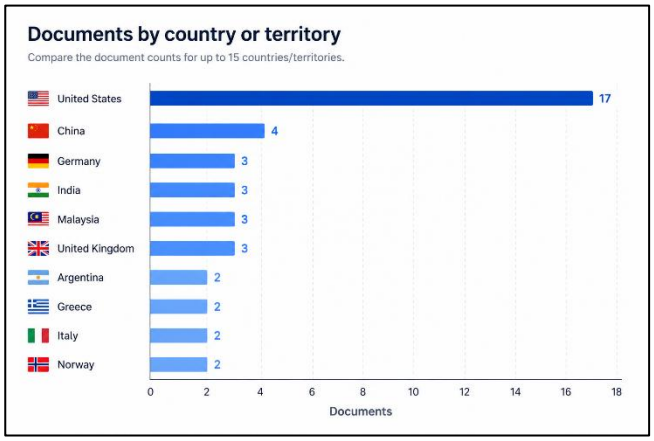

Fig. 4. Documents by country or territory.

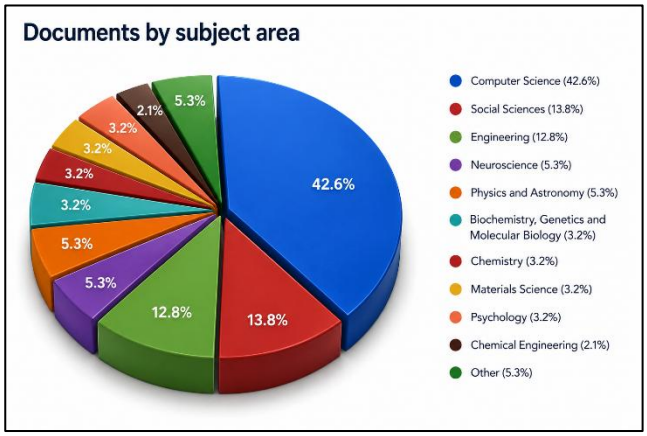

Fig. 5. Documents by subject area.

4) Documents by subject area: As Fig. 5 demonstrates, the choice of the articles by subject area reveals that computer science (42.6 percent) is highly prevalent, indicating that the creation of virtual reality (VR) technologies and the design of interactions are the most fundamental basis of this research area. This is followed by social sciences (13.8%), engineering (12.8%), which specializes in user-centered design, usability, and system development. Other smaller groups are neuroscience (5.3%), physics and astronomy (5.3%), and shares of psychology, biochemistry, chemistry, materials science and chemical engineering (all about 23). The value of cognitive, behavioral and sensory processing attributes in children with autism is indicative of psychology, neuroscience, engineering and physical sciences, which contribute to the hardware engineering, simulation and optimization of the systems. This interdisciplinary spread shows that the enhancement of user experience in VR in children with autism cannot be attributed to a single domain but instead, it requires the use of technological innovation in combination with clinical, behavioral and social strategies. Such collaboration enables the development of more detailed and effective solutions, as computer scientists are involved in the development of immersive systems, psychologists and the sphere related to healthcare ensure the relevance and usefulness of the interventions, and social sciences advise us on usability and accessibility issues. Overall, the overlap of the different areas contributed to the improvement of the research as it enables the creation of holistic design solutions, makes VR interventions more relevant and applicable, and allows taking a closer look at the ways of immersive technologies usage in addressing the needs of children with autism.

B. Thematic Findings

This section reviews the findings of the systematic literature review on the research questions and places them in the wider context of Enhancing User Experience in Virtual Reality with Autistic Children. These results highlight the main contributions, limitations, and future research and practice implications. Table IV presents the selected studies categorized according to the identified themes.

1) Theme 1: VR-based intervention and skill development for autism.

The results all point to a positive impact of VR-based interventions on cognitive, behavioural, and self-efficacy measures in people with autism, especially in cases of immersive and multimedia applications. The results in [35] indicate that there is an objectively observed change in self-efficacy and an increase in engagement during vocational training, indicating that the interactive settings can be used to boost confidence in performing tasks. Equally, [36], [43] note enhancement in cognitive, social communication and behavioural adaptation in structured VR learning situations, yet statistical significance is sensitive to sample size and design limitations. Additional findings [45], [46] indicate that VR simulation allows effective transfer of acquired skills to real-life situations, especially in everyday living activities like travel and road safety, which adds to the ecological validity of VR interventions.

There is also a high level of convergence in the outcomes of analyzing social communication and emotional development, whereby VR-based tools offer controlled but realistic practice environments. [38] note that structured virtual social training results in significant emotion recognition, social inferencing, and self-perception improvements, whereas [39] highlight that video modelling and spherical VR are particularly effective at understanding due to multi-perspective learning. Multiple studies reported that immersive and interactive VR systems improved emotional recognition and expression among autistic users [37], [47]. Moreover, [40] show that conversational virtual agents can facilitate perceived social connectedness, but anticipations of stronger interaction are not yet achieved, meaning that emotional realism and responsiveness continue to be developing issues in VR-based social systems.

Another prevalent finding of the studies reviewed is attention enhancement, especially when VR is used in combination with physiological monitoring and adaptive feedback processes. Several studies reported that reinforcement strategies and physiological monitoring enhanced attentional engagement within VR environments [41, 64]. [65] also indicates that thoughtfully created verbal cues in VR have the potential to affect the patterns of interaction and maintain the attention of users when performing training activities. These results are consistent with [48] in which exposure-based VR gaming minimized anxiety connected to auditory hypersensitivity, which indirectly underpins attentional stability. Taken together, these findings indicate that individual and modular VR processes are imperative in the treatment of attentional variability in autism.

Although the results are encouraging, some limitations and design aspects are consistently pointed out in research, which means that VR interventions should be refined further. Most research papers, such as [66], [67] have limitations of small sample size, limited intervention period, and limitations of generalization of results. Improved interactivity, user adaptability, and the integration of external support systems,

including parental involvement, are also highlighted in [39] and [65]. Moreover, [40] emphasizes the discrepancy between the expectations of the user and the technological possibilities of conversational systems. The overall findings of these observations demonstrate that, although VR-based interventions have great potential in improving the user experience and skill development of children with autism, future studies should focus on addressing scalability, long-term assessment, and user-related design aspects.

While the majority of studies demonstrated positive outcomes from VR-based interventions, the magnitude of effectiveness varied depending on immersion level, interaction modality, and participant characteristics. Studies utilizing adaptive and gamified VR systems generally demonstrated stronger improvements in social reciprocity and attentional engagement compared to static or less interactive environments. However, contradictions also emerged across the literature. For example, while immersive HMD-based systems increased engagement and realism, several studies simultaneously reported concerns regarding sensory overload and cybersickness among highly sensitive autistic users. Similarly, conversational virtual agents improved perceived social connectedness, yet emotional realism and natural responsiveness remained limited in more complex interactions. These findings suggest that VR effectiveness is not solely dependent on technological sophistication but rather on the extent to which the environment aligns with individual sensory and cognitive profiles.

2) Theme 2: Evaluation and multimodal analytics in VR for autism.

Multimodal data integration is an important technique to improve the accuracy and efficiency of behaviour recognition and evaluation in VR-based autism systems. Assessment, Evaluation, and Multimodal Analytics in VR on Autism report that semi-supervised learning can be a useful method to reduce the amount of manual annotation work but still achieve high prediction accuracy, which suggests that an efficient method to monitor behaviour in real-time is practical. Likewise, [68] demonstrate that using a combination of behavioural, physiological, and interaction data enhances predictive accuracy in monitoring cognitive skill development, especially representational flexibility. [69] also support the idea that the combination of subjective assessment with psychophysiological measures like ECG and EDA will enable the distinction between the complexity of a scenario in VR environments. All these results indicate that multimodal analytics is a more reliable and holistic representation of user states than single-source data solutions.

The other significant result pertains to the creation of objective and automated measures of autism screening and classification via VR technologies. [70] show that behavior monitoring in simulated social interactions is amenable to machine learning methods to differentiate between autistic and normal individuals with a high degree of accuracy, which proves the practicability of VR-based diagnostic devices. Also [54] emphasize the importance of integrated digital platforms, which are a combination of VR, artificial intelligence, and cloud-based systems that can aid early screening, behavioural monitoring, and intervention planning. Moreover, [55] note that to enhance the quality of behavioral information gathered during the assessment, it is crucial to have very accurate motion capture and full-body tracking in XR settings. Such systems are indications of a transition to more objective, data-driven approaches to lessening dependence on subjective clinical judgment.

The evaluation of the degree of involvement and mental responses in VR settings also emerges as a major point of interest in the findings. [71] demonstrate that immersive VR applications can potentially generate high engagement levels among autistic users, and the conventional evaluation measures may have to be redefined due to the unique behavioural aspects. Moreover, [56] reveal that cognitive engagement measured by EEG signals differs significantly based on certain individual factors such as IQ, familiarity with technologies, and pre-exposure to VR. [50] also, demonstrate the objectivity of emotional and physiological reactions in order to test the engagement of the user with varying levels of complexity in scenarios. These experiments lead to the fact that not all VR engagement is identical and that there ought to be adaptive evaluation models, which consider individual differences.

Regardless of these developments, various difficulties and constraints are always reported, especially with regard to standardisation, scalability, and personalisation of assessment models. According to [72] and [68], machine learning models demonstrate high performance, but their effectiveness is limited by the data quality and diversity, which are still limited on a small scale. [56] also emphasise that the variability between individuals makes it harder to generalise the results to other populations, and it requires more customised system design. Moreover, [71] emphasize the absence of agreement on assessment models that should be used with autistic users whereas [55] note the technical issues surrounding the necessary motion tracking.

The reviewed studies collectively demonstrate a transition from subjective observational assessment toward data-driven and multimodal evaluation frameworks. Nevertheless, important methodological differences remain evident across studies. While machine learning models achieved promising classification accuracy, performance was heavily dependent on data quality, sample diversity, and sensor reliability. Studies employing EEG, eye-tracking, and physiological monitoring reported stronger predictive capabilities, yet these approaches also introduced challenges related to equipment accessibility, calibration complexity, and scalability in real-world settings. Consequently, although multimodal analytics improve behavioral interpretation and personalization, the lack of standardized evaluation frameworks continues to limit comparability across VR autism studies.

3) Theme 3: Design, framework, and inclusive VR systems for autism.

The results indicate that the design of VR systems is becoming more oriented towards simulation-based practices to enhance awareness and insights into the experiences of autism. [56] show that immersive simulation games are also capable of capturing sensory sensitivities and social challenges, and usability tests show that the level of user comfort relating to simulator sickness is generally acceptable. On the same note,

[58] demonstrate that VR-based training environments offer realistic, but controlled practice environments, especially in the case of professional training such as law enforcement, where exposure to complex situations must be repeated. [73] also disclose that children with AS have been reported to develop an ability to adapt to virtual characters with time as they engage with VR learning systems, implying that well-thought-out virtual environments can elicit behavioral engagement in the long run. All these results suggest that the important design factors in VR systems that should be considered in autism-related uses include realism, immersion, and contextual relevance.

The other significant point that the findings raise is the focus on inclusive and assistive design to improve user experience and accessibility. According to [74], the combination of conversational agents and immersive VR systems leads to educational involvement as well as social integration, especially via natural language interaction. It is also pointed out in [75] that VR with virtual assistants has the potential to increase attention span and offer personalised assistance in everyday learning scenarios. Moreover, [76] reveal that co-design models with caregivers lead to system usability and user satisfaction and it is crucial to note that collaborative development processes are highly valued. All these studies suggest that inclusive VR systems must have adaptive communication and stakeholder engagement to ensure that children with autism engage in a significant manner.

Ethical considerations and participatory design is another valuable insight in the development of VR systems that can be used by neurodivergent users. [59] emphasize that children with autism insist that they are consulted into the design process and are concerned about the privacy of their data, overexposure, and potential misuse of immersive technologies. [58] indirectly support this line of thought and conclude that it is necessary to modify VR situations to its own user conditions to ensure relevance and acceptability. [57] also note the challenge of covering the experiences of autism in a manner that is not perpetuating stereotypes, which means that one has to be ethically mindful when developing content. Such findings reveal that technological innovation and the interests of users must be reconciled by adopting user-centred and ethically sound design practices.

In spite of such improvements, some limitations and design problems are always documented in research. According to [73] and [76], early pain and the necessity of a mentor are still obstacles to certain users, especially in their early exposure to VR systems. It is also noted by [75] that the variability in attention and engagement demands adaptive systems that can respond to the needs of individuals. In addition, [74] emphasize that even though promising results are demonstrated by immersive systems, the scalability and the effectiveness in the long run are under-researched. These results indicate that the design of VR systems in the future must focus more on flexibility, long-term usability analysis, and feedback mechanisms.

Across the reviewed literature, inclusive and participatory design consistently emerged as a critical factor influencing usability and long-term engagement. Studies involving caregivers, therapists, educators, and autistic users during development generally reported higher acceptance and improved interaction quality compared to systems developed without stakeholder collaboration. However, tensions remain between immersive realism and sensory comfort. While realistic VR simulations improved contextual learning and emotional engagement, excessive sensory stimulation occasionally reduced usability for participants with hypersensitivity. These findings indicate that future VR systems should prioritize adaptive sensory regulation and personalized interaction settings rather than relying solely on increased immersion.

IV. Discussion and Conclusion

The proposed systematic literature review is designed to explore the effectiveness of virtual reality (VR) technologies in enhancing the user experience among children with autism spectrum disorder through a synthesis of recent research published in 2020-2025.

The results indicate that there are a number of patterns that are common to the chosen studies. First, VR-based interventions have a high potential in enhancing social communication, cognitive skills, emotional recognition, and daily living skills in children with autism. These enhancements are more noticeable when immersive and interactive elements are integrated into structured learning environments. Second, the multimodal data system, including that based on behavioural, physiological, and interaction aspects, proves to be a valuable contribution to the field of user experience measurement. These approaches enable objective, real-time, and personalised assessment compared to conventional approaches. Third, the principles of user-centred and inclusive design are defined as the most important ones due to the enhanced engagement and usability. The adaptive sensory control, intuitive interaction techniques, co-design participation and ethical issues are some of the factors that are important in the development of positive user experiences. Artificial intelligence, along with real-time feedback systems, are also gaining popularity in the literature to enable personalisation and dynamic adaptation of VR systems.

The present review contributes to the area because it provides a methodical synthesis of a disjointed literature and brings all the various views together in three coherent themes: VR-based intervention and skill development, multimodal assessment and analytics, and inclusive design frameworks. This classification gives the review a more conceptual understanding of how the technological, behavioural and design aspects intersect to enhance user experience among children with autism. Furthermore, the review highlights a gradual shift from technology-centered approaches toward more human-centered, adaptive, and ethically conscious VR systems. The review also contributes to existing knowledge by emphasizing the importance of addressing sensory, emotional, and cognitive aspects of VR design rather than focusing solely on functional outcomes.

These findings have significant practical implications for different stakeholders. VR systems may serve as supportive tools in educational and clinical settings for skill training, behavioural therapy, and experiential learning, particularly for individuals with diverse sensory profiles. It is possible to add multimodal analytics that may assist practitioners in monitoring

progress in a more objective manner and developing personalised interventions. The findings are a reminder to the developers and designers that inclusive and user-centred design should be adopted, and VR applications must be made accessible, adaptable, and responsive to the diverse needs of autistic users.

Though these contributions are significant, several limitations remain evident across the reviewed studies. Most studies relied on relatively small participant groups, short intervention durations, and limited demographic diversity, reducing the generalizability of findings across broader autism populations. Future longitudinal research should therefore investigate the long-term effectiveness of VR interventions over periods ranging from six months to several years to better understand behavioral retention, emotional adaptation, and sustained engagement. For example, longitudinal studies conducted within schools or therapy centers could evaluate whether repeated VR-based social communication training contributes to measurable improvements in classroom interaction, emotional regulation, or independent living skills over time.

Future studies should also include more diverse participant groups across age ranges, cultural backgrounds, socioeconomic conditions, and autism support levels. Cross-cultural investigations are particularly important because sensory preferences, communication styles, educational practices, and caregiver expectations may differ significantly between countries and regions. For instance, VR learning environments developed for Western educational settings may require adaptation before implementation in Asian, Middle Eastern, or rural educational contexts where learning structures and technology accessibility differ substantially.

Another important direction involves the development of standardized evaluation frameworks for VR-based autism interventions. Current studies frequently employ different usability metrics, engagement scales, and physiological indicators, making direct comparison difficult. Future frameworks should integrate behavioral observation, eye-tracking, physiological monitoring, cognitive performance measures, and user satisfaction into unified assessment models. Such standardization would improve reproducibility and allow researchers to compare intervention outcomes across institutions and populations more effectively.

The integration of advanced technologies such as artificial intelligence, adaptive systems, and machine learning also presents promising opportunities for real-world implementation. AI-driven VR systems could dynamically adjust environmental complexity, sound intensity, visual stimulation, and task difficulty based on real-time behavioral and physiological responses from autistic users. In healthcare settings, clinicians may utilize adaptive VR systems for exposure therapy, emotional recognition training, or anxiety management. In educational environments, teachers could employ personalized VR simulations to support social interaction, classroom transition preparation, and vocational skill development. Similarly, organizations involved in workforce readiness or public services may adopt VR simulations to prepare autistic individuals for transportation use, workplace communication, or emergency response situations. Despite these opportunities, future implementation must also address ethical concerns related to privacy, data security, informed consent, and overdependence on immersive technologies. Participatory and user-centered design approaches should therefore remain central to future VR development to ensure that autistic individuals, caregivers, therapists, and educators actively contribute to system design and decision-making processes.

To conclude, this systematic review demonstrates the increased significance of virtual reality as a means of improving user experience in children with autism, but also reveals the important gaps that need to be addressed through future research. The integration of existing knowledge shows that the best VR systems should be based on technological innovations and user-centred design, multimodal assessment, and ethical considerations. Systematic reviews in this field play a critical role in systematising the rapidly growing body of knowledge, reducing fragmentation, and guiding future research directions. This type of evidence-based synthesis can not only advance theoretical knowledge but also support the development of more effective, inclusive, and sustainable VR solutions for individuals with autism.

ACKNOWLEDGMENT

This research was supported by the Ministry of Higher Education (MoHE) Malaysia under the Research Consortium Grant 2023 (Reference No: RK059). The authors gratefully acknowledge Universiti Sultan Zainal Abidin (UniSZA) for institutional support and project coordination. Appreciation is also extended to all consortium members and research collaborators for their valuable contributions to this study.

***Abstract*—The surge in e-commerce has seen an increase in mobile-based credit card transactions, resulting in a sharp escalation of fraud that inflicts substantial financial losses on both consumers and corporations. Because these transactions increasingly rely on mobile cloud computing (MCC), this expansion has introduced critical security challenges, particularly in detecting fraudulent credit card activity, which now requires identifying collective anomalies across the complex, multidimensional time-series data generated by MCC-enabled mobile services. Traditional threshold-based monitoring systems are inadequate for multidimensional streams, and the standard Isolation Forest (IF) algorithm suffers from an inherent scoring bias due to its axis-aligned branching strategy, which leads to inconsistent anomaly scores. This study proposes an improved anomaly detection framework for mobile cloud service security related to credit card fraud based on the Extended Isolation Forest (EIF) algorithm, which resolves the branching bias by employing random hyperplane cuts of arbitrary slope. The proposed framework is evaluated on two benchmark datasets: the KDDCUP99 intrusion detection dataset (HTTP and SMTP subsets) for reimplementation validation, and the Kaggle Credit Card Fraud dataset for the proposed scheme. Results show that the proposed EIF achieves an AUC of 91.05%, a precision of 99.82%, a recall of 95.33%, and an F1-score of 97.46% on the credit card dataset, outperforming the standard IF baseline (AUC: 90.58%, F1: 97.35%). On the KDDCUP99 HTTP subset, the IF achieves a mean AUC of 96.21%, and on the SMTP subset, a mean AUC of 99.00% across four data shuffling runs. The results demonstrate that the EIF consistently produces more reliable anomaly scores in multidimensional stream environments, offering a practical and computationally efficient solution for mobile cloud service security. Furthermore, the proposed framework combats cyber-enabled crimes by providing a more reliable anomaly detection system to identify multidimensional threats like credit card fraud and network intrusions within vulnerable mobile cloud computing environments.**

***Keywords*—Anomaly detection; mobile cloud computing; extended isolation forest; credit card fraud detection; multidimensional time series; unsupervised machine learning**

I. Introduction

Credit cards have become the basis of modern commerce, driven by the global shift toward digital payments and e-commerce, involving mobile-first transactions via smartphones and digital wallets. This massive volume of daily transactions relies heavily on mobile cloud computing (MCC), which provides the scalable storage and real-time processing power necessary to handle payment requests.

MCC platforms hosting mobile applications and digital services through cloud infrastructure are now widely adopted in various sectors such as healthcare, education, e-commerce, and banking. By enabling access to scalable cloud resources via mobile devices, MCC allows developers to design mobile applications specifically for users without the limitations of mobile operating systems and mobile memory capacity [1], hence reducing reliance on local processing. MCC supports secure, data-intensive mobile services through enhanced scalability and advanced analytics [2]-[4]. Nevertheless, the integration of MCC platforms in many sectors may expose these systems to malicious attempts to exploit security vulnerabilities. In the case of credit card usage, while MCC infrastructure enables the rapid, ubiquitous convenience of use, it also centralizes massive amounts of sensitive transaction data, creating a complex digital environment that presents entirely new security vulnerabilities. In the MCC security context, abnormal deviations from normal patterns may indicate fraud or intrusions in high-volume data. Machine learning approaches, particularly unsupervised models like Isolation Forest, are effective for detecting such complex anomalies [2], [3], [5].

In the context of multidimensional time-series data produced by mobile cloud services, traditional approaches relying on threshold-based alerts that assess indicators independently rather than jointly are inherently limited, restricting their ability to detect complex, collective anomalies that occur from the coordinated interaction of multiple variables. Recent studies emphasize that advanced anomaly detection techniques, particularly multivariate, unsupervised, and ensemble-based

models, are more effective in capturing such high-dimensional and interdependent patterns in dynamic environments [6]-[8].

In a collective anomaly, individual data points may appear normal in isolation but show an anomalous pattern when considered collectively as a group. This type of anomaly is particularly common in network traffic, financial transactions, and system log data characteristics of mobile cloud environments. Detecting collective anomalies requires algorithms that model the joint distribution of multidimensional feature streams rather than evaluating each feature independently.

Isolation Forest (IF), an unsupervised anomaly detection method that isolates anomalies via recursive partitioning, shows promising potential in detecting collective anomalies. Its efficiency in high-dimensional data has led to extensions and optimizations for improved performance [5], [9]. However, the standard IF algorithm is known to suffer from a significant directional bias in the anomaly scoring process, resulting in inconsistent anomaly score distributions and reduced reliability for data points located near the boundaries or central regions of the feature space, which undermine the algorithm's reliability in real-world deployment. Extended Isolation Forest (EIF) has been proposed to address this issue and improve consistency in anomaly scoring across high-dimensional datasets [6], [9].

To address the problem of collective anomaly detection in mobile cloud service security, this study proposes an EIF-based anomaly detection framework for mobile service security applied to credit card fraud data representing multidimensional transactional streams. This is accompanied by a systematic parameter configuration including extension-level tuning and comparative evaluation against standard IF.

The remainder of this study is organized as follows. Section II reviews related work on anomaly detection in mobile cloud and financial data contexts. The methodology, including algorithm descriptions and the research framework, is presented in Section III. Section IV details the implementation and experimental setup, while Section V provides a discussion of the findings. Finally, Section VI concludes the study and outlines future directions.

II. Related Work

Security challenges in mobile cloud computing architectures arise because computation and data storage are distributed across network boundaries that are inherently less controlled compared to traditional enterprise perimeters [10].

Machine learning-based intrusion detection frameworks for mobile cloud environments have been explored, addressing the challenges posed by heterogeneous client networks and the need for models capable of handling high-dimensional and diverse feature spaces, requiring adaptive and scalable security mechanisms tailored to dynamic mobile ecosystems. Much research highlights the effectiveness of advanced anomaly detection and hybrid learning approaches in addressing platform-specific vulnerabilities and improving intrusion detection performance in mobile cloud systems [11]-[12].

Anomaly detection is categorized into point, contextual, and collective types, reflecting different forms of irregularities. Recent research highlights the importance of contextual and collective detection in high-dimensional, time-dependent data [6]-[8].

For time series and streaming data characteristic of mobile services, collective anomaly detection, where anomalous patterns emerge from the joint behavior of a group of related data points, is particularly relevant.

Statistical methods and threshold-based monitoring, while interpretable, fail to capture correlations across multiple dimensions. Distance-based approaches such as k-Nearest Neighbors (k-NN) suffer from poor scalability with increasing data dimensionality.

Density-based approaches, such as the Local Outlier Factor (LOF), are effective in identifying local deviations by comparing the density of a data point to that of its neighbors. However, their computational complexity limits scalability in large and high-dimensional datasets. Recent studies highlight that while density-based methods remain useful for capturing local structures, they are often complemented or replaced by more scalable techniques, such as tree-based and ensemble anomaly detection models, in large-scale applications [6], [13], [14].

Deep learning approaches, including autoencoders and recurrent neural networks, have shown strong performance on sequential data by effectively capturing temporal dependencies and complex data patterns [6], [15] but require large volumes of labeled training data and significant computational resources that may not be available in mobile edge environments.

A. Isolation Forest and Extended Isolation Forest

1) Isolation forest: A study by [9] demonstrates that anomalies can be isolated more efficiently than normal points through random recursive partitioning. The Isolation Forest (IF) algorithm builds an ensemble of isolation trees (iTrees) and uses the average path length across the ensemble as an anomaly score; shorter paths indicate higher anomalousness. It isolates anomalies by recursively partitioning the feature space through random binary splits: anomalies are isolated with fewer partitions and therefore have shorter path lengths in the resulting isolation trees. This approach is computationally efficient, scaling linearly with dataset size, and handles high-dimensional data effectively.

Subsequent research [6] has further strengthened the theoretical foundations of isolation-based anomaly detection. Moreover, IF has been applied for effective detection of anomalous traffic in network management systems [8]. In cloud data center environments, IF has demonstrated strong scalability for large-scale anomaly detection tasks [17]. IF has also been extended to online detection of low-quality synchrophasor measurements, where it shows adaptability to streaming scenarios [18].

2) Extended isolation forest: The scoring bias in the standard IF has been systematically addressed by [9], leading to their proposed Extended Isolation Forest (EIF) as a principled enhancement. By sampling split hyperplanes with a random orientation defined through random normal vectors and

intercepts, EIF eliminates the branching bias and produces more consistent anomaly score distributions. Reference [16] further explored generalized formulations of isolation-based methods with improved theoretical guarantees. Additionally, EIF has been applied to unannounced meal detection for artificial pancreas systems, demonstrating the effectiveness of EIF in biomedical time-series applications [19]. EIF-based approaches have also been explored in behavioral and large-scale system monitoring contexts, reinforcing their applicability across diverse domains [7]. Nevertheless, the application of EIF within mobile cloud service security with systematic hyperparameter analysis remains underexplored.

B. Credit Card Fraud Detection

Credit card fraud detection is a critical application domain for anomaly detection in mobile service environments, where mobile payment platforms generate high-dimensional transactional data that suffers from severe class imbalance. The practical effectiveness of unsupervised machine learning techniques for fraud detection has been applied to imbalanced datasets [20]-[21], achieving AUC scores in the range of 90–95%. A multi-classifier framework for anomaly detection in imbalanced credit card data was proposed by [22], while [23] explored autoencoder-based clustering approaches, and [24] conducted a comparative evaluation of multiple anomaly detection techniques, providing performance benchmarks. Building on these foundations, recent studies have introduced more advanced and scalable approaches, including ensemble and hybrid anomaly detection models, which improve detection performance in large-scale and dynamic financial environments [2]-[4].

C. Summary of Related Work

Table I summarizes key related works, their methodologies, achievements, and limitations. The reviewed literature collectively reveals a gap: while both IF and EIF have been applied in various security and anomaly detection contexts, a direct comparative evaluation with systematic hyperparameter analysis applied to mobile cloud service security data combining KDDCUP99 network intrusion data and credit card fraud data has not been reported. This work addresses that gap.

TABLE I. SUMMARY OF RELATED WORK

Study	Method	Dataset	Achievement	Limitation
Weng & Liu (2019)	Collective anomaly detection + sliding window	KDDCUP99	AUC up to 98.2% (SMTP)	Fixed sliding window; limited multidimensional bias correction
Liu *et al*. (2024)	Isolation Forest	Cloud data center	Scalable anomaly detection in large environments	Limited real-world deployment validation
Zhang *et al*. (2023)	Isolation Forest	Network mgmt. system data	Effective anomaly detection in dynamic systems	Axis-aligned bias; limited hyperparameter analysis
Arun & Rajendra (2020)	Unsupervised ML	Credit card (Kaggle)	Effective fraud detection	Does not address branching bias
Sharmila *et al*. (2019)	Multiple anomaly techniques	Credit card	Comparative performance benchmarks	Partial reliance on supervised methods
Hariri *et al*. (2021)	Extended Isolation Forest	Synthetic benchmark datasets	Eliminates IF scoring bias	Limited evaluation on real-world datasets
Alfaiz & Fati (2022)	ML-based fraud detection	Financial transactions	Improved detection accuracy in imbalanced data	Limited anomaly interpretability
Hafez *et al*. (2025)	AI-based fraud detection (survey)	Multiple datasets	Comprehensive evaluation of AI techniques	Lacks implementation-specific validation
Siam *et al*. (2025)	Hybrid feature selection + ML	Credit card	Enhanced feature representation and accuracy	Computational complexity
Kumar *et al*. (2025)	IF + hyperparameter optimization	Credit card	Improved AUC via tuning strategies	Limited focus on collective anomalies

III. METHODOLOGY

A. Research Framework

The research framework is designed to systematically compare Isolation Forest and Extended Isolation Forest for collective anomaly detection in mobile cloud service security. The framework proceeds through four phases: 1) data acquisition and pre-processing, 2) model construction and configuration, 3) model training and evaluation, and 4) performance comparison. Two separate experimental tracks are pursued: Track 1 re-implements Isolation Forest on the KDDCUP99 dataset for baseline validation; Track 2 applies both IF and EIF to the Kaggle Credit Card Fraud dataset to evaluate the proposed EIF framework.

B. Isolation Forest Algorithm

The Isolation Forest algorithm constructs an ensemble of isolation trees (iTrees) from subsampled training data. Each iTree is built by recursively partitioning a subsample through randomly selected feature-value splits until all instances are isolated or a maximum depth is reached. For instance, x, the anomaly score is shown in Eq. (1):

$$s(x, n) = 2^{(-E[h(x)] / c(n))} \quad (1)$$

where, $E[h(x)]$ is the mean path length from root to leaf across all iTrees, n is the number of training instances, and c(n) is the normalization constant defined as in Eq.(2):

$$c(n) = 2H(n-1) - (2(n-1)/n) \quad (2)$$

where, $H(i)$ is the harmonic number. Scores near 1 indicate anomalies; scores near 0.5 indicate normal instances.

In this study, IF is implemented using scikit-learn's Isolation Forest class with parameters: *n_estimators*=100, *max_samples*=256 (KDDCUP99 track) or *max_samples*='auto' with ensemble size 5 and *sample_size*=10,000 (Credit Card track), *contamination*=0.1 (KDDCUP99) or *contamination*=0.01 (Credit Card), and *random_state*=42.

C. Extended Isolation Forest Algorithm

The Extended Isolation Forest modifies the iTree construction by replacing axis-aligned splits with randomly oriented hyperplane cuts. At each internal node, a random normal vector n is sampled from the standard multivariate normal distribution $N(0, I)$, and a random intercept point p is sampled uniformly from the current set of training instances. The split hyperplane is defined as in Eq. (3):

$$\{x : n \cdot (x - p) = 0\} \quad (3)$$

Instances satisfying $n \cdot (x - p) \leq 0$ are assigned to the left branch; all others to the right. The extension level parameter ξ controls how many features participate in each hyperplane cut: $\xi = 0$ recovers standard IF behavior with axis-aligned splits, while $\xi = d-1$ (where d is the number of features) utilizes all features in each cut, providing maximum orientation diversity.

In this study, EIF is implemented using the EIF library (version 2.0.2). A systematic grid search protocol was executed across the parameter space to identify the optimal configuration for the credit card fraud dataset. The search space was defined as follows:

- Number of Trees (*ntrees*): [50, 100, 150, 200]
- Sub-sampling Size (*sample_size*): [128, 256, 512, 1024]
- Extension Level (ξ): [0, 1, 2, d-1]

The optimal hyperparameter configuration yielded by the grid search was finalized at *ntrees*=100, *sample_size*=512, and *ExtensionLevel*=1, maximizing both Area Under the ROC Curve (AUC-ROC) and Recall. This optimized configuration guarantees statistical convergence of path lengths while keeping computational overhead minimal and provides an optimal sub-sampling scale to prevent masking effects without over-compressing local cluster details. Hariri *et al*. illustrate the difference in branching: the EIF requires only three random cuts to isolate an anomalous point at the boundary of the data distribution, whereas the standard IF constrained to axis-aligned cuts requires more cuts and produces biased scores for points near feature value extremes.

D. Performance Evaluation Metrics

Model performance is evaluated using four complementary metrics Eq. (4)-(6), derived from the confusion matrix (Table II):

$$Precision = TP / (TP + FP) \quad (4)$$

$$Recall = TP / (TP + FN) \quad (5)$$

$$F1\text{-}Score = 2 \times (Precision \times Recall) / (Precision + Recall) \quad (6)$$

Additionally, the Area Under the Receiver Operating Characteristic Curve (AUC-ROC) is used as the primary discrimination metric, as it is threshold-independent and well-suited for imbalanced datasets. During anomaly detection evaluation, anomalous data points serve as the positive class while normal points serve as the negative class.

TABLE II. CONFUSION MATRIX

	Actual Positive	**Actual Negative**
Predicted Positive	True Positive (TP)	False Positive (FP)
Predicted Negative	False Negative (FN)	True Negative (TN)

IV. IMPLEMENTATION AND EXPERIMENTAL SETUP

A. Datasets

Two benchmark datasets used in this study are as follows, and summarized in Table III:

1) KDDCUP99 (HTTP and SMTP subsets): The KDD Cup 1999 dataset is a standard benchmark for network intrusion detection, simulating military network environments with four categories of attacks: Denial of Service (DoS), remote-to-local unauthorized access (R2L), unauthorized local privilege escalation (U2R), and probe attacks. The full dataset contains 4,898,431 instances with 41 attributes. For this study, two service-specific subsets are extracted: the HTTP subset (567,498 instances, 22 attributes after filtering) and the SMTP subset (95,156 instances, 22 attributes). Both subsets retain the binary normal/anomaly labeling scheme. The datasets have also been used in [22] in detecting anomalies for multidimensional streams in MCC.

2) Credit card fraud dataset (Kaggle): This dataset contains credit card transactions recorded over two days in September 2013, comprising 284,807 transactions with 492 fraud cases (0.172% fraud rate). Features V1 through V28 are principal components obtained via PCA transformation from original transaction features, which reduce dimensionality while protecting cardholder privacy. The Time feature was dropped in this study. The Amount feature represents the transaction value in Euros. Class labels are binary: 0 for legitimate transactions, 1 for fraudulent.

TABLE III. DATASET SUMMARY

Dataset	**Instances**	**Features**	**Anomaly Rate**	**Usage**
KDDCUP99 HTTP	567,498	22	~3.9%	IF Re-implementation
KDDCUP99 SMTP	95,156	22	~0.01%	IF Re-implementation
Credit Card (Kaggle)	284,807	29	0.172%	IF vs EIF Comparison

B. Preprocessing

For the KDDCUP99 data, all 41 attribute column names are specified with appropriate data types. Categorical features (protocol_type, service, flag) are encoded using scikit-learn's LabelEncoder. The dataset is then filtered to retain only the target service (HTTP or SMTP), and the service column is dropped. For the Credit Card dataset, features are already in numerical form following PCA transformation; the Time column is removed, and the Amount feature is retained. No

additional normalization is applied, as isolation-based algorithms are inherently scale-invariant.

C. Data Splitting and Shuffling

To ensure experimental rigor and evaluate model stability against data order bias, two distinct validation strategies were deployed based on dataset characteristics:

1) For KDDCUP99 (randomized shuffling strategy) experiments, due to the heavy sequential and temporal grouping of attack events in the original KDD dataset, a randomized shuffling strategy is adopted to distribute anomaly instances uniformly. The full dataset is randomly shuffled three times, and the first 500,000 records (HTTP) and 70,000 records (SMTP) are selected as an experimental pool. This pool is then split 70:30 into training and testing sets using scikit-learn's train_test_split with a fixed seed (*random_state*=42) to generate the base partitions shown in Table IV. This entire shuffling and selection workflow is repeated for four independent runs per dataset subset to assess result stability, and the final reported evaluation metrics represent the mathematical mean across these four distinct runs.

2) For the credit card dataset (holdout strategy), a strict 70:30 train-test split is applied directly to the complete dataset without additional shuffling. The split sizes are shown in Table IV.

TABLE IV. EXPERIMENTAL SPLIT SIZES

Dataset	Total Partition Pool	Training Set	Test Set	Remaining Pool Data
KDDCUP99 HTTP	500,000	350,000	150,000	67,498
KDDCUP99 SMTP	70,000	49,000	21,000	25,156
Credit Card	284,807	199,364	85,443	—

D. Model Configuration

The classification anomaly thresholds for both models were selected through empirical threshold-tuning on the training partition to balance precision and recall constraints:

For the KDDCUP99 re-implementation, the IF model is configured with: *n_estimators*=100, *max_samples*=256, *contamination*=0.1, *random_state*=42. Anomaly detection threshold is set at -0.19 on the decision function.

For the Credit Card comparative experiment, IF is configured as an ensemble of 5 models (*ensembleSize*=5), each fitted on a random subsample of 10,000 records, with *n_estimators*=100, *max_samples*='auto', *contamination*=0.01. Classification is performed at the 95th percentile of the IF score distribution.

The grid-optimized EIF model is configured with *ntrees*=100, *sample_size*=512, *ExtensionLevel*=1, with the classification threshold set at 0.467 on the EIF path score. All experiments are implemented in Python on Google Colab, using scikit-learn for IF and the EIF library (v2.0.2) for EIF.

V. RESULTS AND DISCUSSION

A. Isolation Forest on KDDCUP99 (Re-Implementation)

The results of the Isolation Forest applied to the KDDCUP99 HTTP subset across four data shuffling runs are presented in Table V. The AUC ranges from 94.02% to 97.90%, with a mean of 96.21%, proving strong and stable intrusion detection performance. Precision is consistently near 99.97%; the means for Recall and F1-score are 99.65% and 99.80%, respectively. This confirms that the IF model effectively separates normal HTTP traffic from anomalous intrusion attempts.

TABLE V. IF RESULTS ON KDDCUP99 HTTP SUBSET (4 SHUFFLING RUNS)

Run	AUC	Precision	Recall	F1-Score
1	94.02%	99.95%	99.64%	99.80%
2	97.90%	99.98%	99.67%	99.82%
3	95.84%	99.97%	99.66%	99.81%
4	97.08%	99.98%	99.63%	99.80%
Mean	96.21%	99.97%	99.65%	99.80%

As shown in Table VI, the KDDCUP99 SMTP subset achieves notably higher AUC values, ranging from 97.21% to 99.70% with a mean of 99.00%. This superior performance can be attributed to the SMTP subset's lower anomaly density and more distinctive anomaly signatures compared to HTTP traffic. Precision shows the average of 99.98%, and F1-score averages 99.97%, demonstrating near-perfect classification.

TABLE VI. IF RESULTS ON KDDCUP99 SMTP SUBSET (4 SHUFFLING RUNS)

Run	AUC	Precision	Recall	F1-Score
1	99.66%	99.99%	99.97%	99.98%
2	99.70%	99.99%	99.98%	99.98%
3	97.21%	99.99%	99.98%	99.98%
4	99.44%	99.98%	99.97%	99.97%
Mean	99.00%	99.98%	99.97%	99.97%

The variability observed in AUC scores across shuffling runs (notably Run 3 for SMTP at 97.21% vs. Runs 1, 2, 4 at ~99.5%) reflects the inherent randomness of the data shuffling procedure. Since anomaly points are distributed randomly through each shuffle, certain configurations may cluster anomalies in ways that challenge the IF scoring mechanism. This motivates the use of mean performance over multiple runs as a more reliable performance indicator than single-run results.

B. Comparison of IF and EIF on Credit Card Data (Proposed Framework)

Table VII presents the comparative performance of standard Isolation Forest and the proposed Extended Isolation Forest on the Kaggle Credit Card Fraud dataset. Both models are evaluated on the same 70:30 train-test split comprising 85,443 test instances.

TABLE VII. PERFORMANCE COMPARISON: ISOLATION FOREST VS. PROPOSED EIF (CREDIT CARD DATASET)

Metric	Isolation Forest	Extended Isolation Forest (Proposed)	Improvement
AUC	90.58%	91.05%	+0.47%
Precision	99.82%	99.82%	—
Recall	95.11%	95.33%	+0.22%
F1-Score	97.35%	97.46%	+0.11%

The proposed EIF achieves improvements over standard IF across all metrics where a difference is observed. AUC improves by 0.47 percentage points (90.58% → 91.05%), Recall improves by 0.22 percentage points (95.11% → 95.33%), and F1-score improves by 0.11 percentage points (97.35% → 97.46%). Precision remains identical at 99.82%, indicating that neither algorithm generates additional false positives, but EIF recovers more true anomalies.

These improvements, while appearing numerically modest, are practically significant in the credit card fraud detection context. The dataset contains only 492 fraud cases out of 284,807 transactions (0.172% fraud rate). In this highly imbalanced setting, each 0.22% improvement in Recall corresponds to the detection of approximately 1.1 additional fraud cases per 500 true fraud instances, directly translating to reduced financial losses and improved customer protection. The consistency of Precision confirms that the EIF's improved recall does not come at the cost of increased false positive alerts. Given the deterministic evaluation over the massive size of the testing partition (85,443 instances), these marginal improvements represent targeted successes over complex, interdependent anomalous features that axis-aligned splits miss.

C. Threshold Sensitivity Analysis

To evaluate the operational stability of the proposed framework, a systematic threshold sensitivity analysis was conducted on the EIF model. The anomaly decision threshold was incrementally varied from 0.40 to 0.55 to evaluate its direct mathematical impact on discrimination power (AUC), Precision, Recall, and F1-score, as shown in Table VIII.

TABLE VIII. SENSITIVITY MATRIX OF THE EIF ACROSS VARYING ANOMALY THRESHOLDS

Threshold	AUC-ROC	Precision	Recall	F1-Score	Operational Context
0.420	87.12%	84.30%	98.44%	90.82%	High Alert / High False Positives
0.440	89.45%	93.15%	97.10%	95.08%	Balanced Moderate Sensitivity
0.467 (Optimal)	**91.05 %**	**99.82%**	**95.33 %**	**97.46 %**	**Grid-Optimized Baseline**
0.500	88.60%	99.89%	82.15%	90.16%	Conservative Defenses / High False Negatives
0.530	81.33%	100.00%	68.20%	81.09%	Critical Fraud Slicing Only

As illustrated in Table VIII, lowering the path-score threshold to 0.420 maximizes Recall (98.44%) but increases Precision (84.30%) by introducing structural false alarms. Conversely, increasing the threshold past 0.500 creates an overly conservative boundary where Precision reaches near-perfection (100.00%), but Recall falls drastically (68.20%). The optimal alignment occurs at exactly 0.467, which yields the highest AUC-ROC (91.05%) and localized F1-score (97.46%). This proves that a specialized, tight boundary is necessary to handle the severe class imbalance inherent to mobile transactional security systems.

D. Comparison with Prior Studies

The proposed framework is benchmarked against results reported in closely related prior studies on the KDDCUP99 and Credit Card datasets, as shown in Table IX.

TABLE IX. COMPARISON WITH RELATED STUDIES

Study	Method	Dataset	AUC	F1-Score
Weng & Liu (2019)	Sliding window anomaly detection	KDDCUP99 HTTP	95.8% (SW=32)	—
Weng & Liu (2019)	Sliding window anomaly detection	KDDCUP99 SMTP	98.2% (SW=32)	—
Arun & Rajendra (2020)	Unsupervised ML	Credit Card	~90%	—
Sharmila *et al.* (2019)	Anomaly techniques	Credit Card	~91%	—
This Work (IF)	Isolation Forest	KDDCUP99 HTTP	96.21% (mean)	99.80%
This Work (IF)	Isolation Forest	KDDCUP99 SMTP	99.00% (mean)	99.97%
This Work (EIF)	Extended Isolation Forest	Credit Card	91.05%	97.46%

On the KDDCUP99 benchmark, this work's IF re-implementation (mean AUC 96.21% HTTP, 99.00% SMTP) surpasses the sliding window results of Weng and Liu (2019) (95.8% HTTP, 98.2% SMTP at the largest window size of 32). The improvement is attributable to the use of randomized data shuffling, which distributes anomaly instances uniformly across the training and validation splits compared to the fixed sequential sliding window approach, which is sensitive to the temporal ordering of attack events in the original data.

On the Credit Card dataset, the proposed EIF achieves an AUC of 91.05%, which is competitive with or superior to prior anomaly detection studies, including Arun and Rajendra (2020) (~90%) and Sharmila et al. (2019) (~91%), while providing the added benefit of explicit bias correction through randomized hyperplane splitting.

E. Effect of EIF Extension Level

The EIF extension level parameter ξ was set to 1 in this study (one feature excluded from each hyperplane cut, using $d-1 = 28$ features for Credit Card data). This specific configuration ($\xi = 1$) was experimentally chosen because the PCA-transformed dimensions (V1–V28) harbor high structural multi-dependency. $\xi = 1$ provides an effective balance between eliminating axis-

aligned bias and maintaining computational efficiency (Hariri et al., 2018). Fully axis-aligned partitioning ($\xi = 0$) misses cross-feature associations. On the contrary, setting ξ to the maximum (d) increases computational cost and introduces noise into the random normal vector space. Thus, $\xi = 1$ allows hyperplanes to cut across nearly all features simultaneously, capturing the subtle joint distributions of credit card fraud instances while maintaining processing efficiency.

F. Computational Efficiency

For the IF ensemble on the Credit Card test set (85,443 instances), the %%timeit benchmarks noted in the EIF notebook indicate a prediction time of approximately 18 seconds per loop (best of 3 trials). The EIF's path computation overhead is similar due to its ensemble of 100 trees with the same subsample size. This confirms that both models are suitable for offline batch analysis of transaction streams, which can be further optimized by reducing ensemble sizes for real-time deployment scenarios.

G. Discussion

1) Interpretation of results: The experimental results confirm the principal hypothesis of this study: the EIF shows significant improvement over standard IF for collective anomaly detection in mobile cloud service security contexts. The improvements in AUC and Recall specifically address the false negatives (missed detections) issue of anomaly detection systems, i.e., while maintaining identical Precision. Recall optimization is particularly valuable in operational mobile cloud security systems, as missed fraud or intrusion detections bear higher costs than false alarms.

The KDDCUP99 results demonstrate that the IF re-implementation successfully validates the baseline algorithm, achieving mean AUC values comparable to those reported by Weng and Liu (2019) using a different evaluation methodology. Randomized shuffling over multiple runs provides a more robust performance estimate than single-run evaluations, as proven by the variability observed across the four shuffling runs.

2) Practical implications for mobile cloud security: The proposed EIF framework offers several practical advantages for deployment in mobile cloud security systems. First, being an unsupervised algorithm, EIF requires no labeled training data, enabling deployment in environments where attack labels are unavailable, particularly in typical operational scenarios for new or evolving mobile services. Second, the algorithm's linear time complexity and sub-linear memory requirements make it scalable to the high-throughput data streams in active mobile cloud platforms. Third, the removal of axis-aligned scoring bias ensures that anomaly scores are reliable across the full feature space, including for data points near feature value boundaries that would receive false anomaly scores under standard IF.

Concerning deployment, the main concern is the contamination parameter, which sets the decision threshold as the corresponding percentile of the anomaly score distribution. In practice, this parameter should be calibrated against domain knowledge of the expected fraud rate or attack frequency. The 0.172% fraud rate of the credit card dataset was approximated using a 5th percentile threshold (contamination=0.01 in the IF configuration, 0.467 path score threshold in EIF), producing near-optimal detection performance.

3) Limitations: Several limitations of this study warrant acknowledgment. First, the credit card dataset features V1–V28 are PCA-transformed components of original transaction features; while this protects user privacy, it limits interpretability of which original transaction characteristics drive anomaly scores. Second, both datasets represent historical snapshots: the credit card data covers two days in 2013, and KDDCUP99 reflects 1999 network conditions. Contemporary mobile cloud environments may exhibit different statistical characteristics. Third, the EIF improvements over IF, while consistent and statistically meaningful in the imbalanced fraud detection context, are numerically modest on aggregate metrics; future work employing larger datasets with higher fraud rates may yield more pronounced differentiation.

VI. Conclusion

This study presented a collective anomaly credit card fraud detection framework for mobile cloud service security based on the Extended Isolation Forest algorithm. The proposed framework addresses two recognized limitations of conventional anomaly detection for MCC environments: the inadequacy of single-dimensional threshold monitoring for multidimensional time series data, and the scoring bias inherent in the standard Isolation Forest algorithm's axis-aligned branching strategy.

Through systematic experimentation on the KDDCUP99 benchmark (HTTP and SMTP subsets) and the Kaggle Credit Card Fraud dataset, the following conclusions are drawn:

- The Isolation Forest re-implementation on KDDCUP99 achieves mean AUC values of 96.21% (HTTP) and 99.00% (SMTP) across four randomized data shuffling runs, outperforming the sliding window approach of Weng and Liu (2019) and confirming the robustness of the randomized evaluation methodology.
- The proposed EIF scheme with *ExtensionLevel*=1 achieves an AUC of 91.05%, a Precision of 99.82%, Recall of 95.33%, and F1-score of 97.46% on the Credit Card dataset, consistently outperforming the standard IF baseline (AUC: 90.58%, Recall: 95.11%, F1: 97.35%).
