Table of Contents

Paper 1: Adversarial Asymmetric Agents for Network Intrusion Detection Using Deep Reinforcement Learning

Authors: Curtis Rookard

PAGES 1 - 11

Paper 2: Assisted Robot Arm with Voice Recognition for Digital Healthcare

Authors: Ting Zhang, Oanh Phan, Jiang Lu

PAGES 12 - 23

Paper 3: When Agents Delegate: Accountability Chains in Multi-Agent AI Systems

Authors: Ornella Bahidika

PAGES 24 - 31

Paper 4: An Experimental Study on Credit Score Prediction Using K-Nearest Neighbors

Authors: Taylor Stonelake

PAGES 32 - 36

Paper 5: Leveraging Ancestral Health Records for Early Prediction of Cardiovascular Risk in Future Generations

Authors: Suresh Kurumalla, Bal Virdee, Ashish Khanna, Siva Shankar S

PAGES 37 - 49

Paper 6: Design and Verification of an Interpretable Low-Code Maintenance Decision Support Application for Automotive Assembly

Authors: Adriana ALDEA, Adriana FLORESCU, Catrina CHIVU

PAGES 50 - 59

Paper 7: OptiGeoRisk: A Spatially Localized and Optimized Geo-XGBoost Framework for Credit Default Risk Classification

Authors: Claher Prastian, Alexander Agung Santoso Gunawan

PAGES 60 - 71

Paper 8: Collaborative Development Method for Improving Uncertainty Management in Agile Software Development

Authors: Maha Makkass, Youness Laghouaouta, Adil Anwar

PAGES 72 - 84

Paper 9: Smart IoT Robot Toy with AI-Based Safety Judgment and Parental Monitoring Features

Authors: Check-Yee Law, Wee-Yang Goh, Yong-Wee Sek

PAGES 85 - 91

Paper 10: Real-Time Anomaly Detection Using ML, DL, and XAI for Financial Fraud: A Systematic Review

Authors: Padilla-Lopez Jimmy Andres, Lazo-Ordoñez Pedro Antonio, Juan Jesús Soria-Quijaite

PAGES 92 - 103

Paper 11: Fusion of Large Language Model and Knowledge Graph for Intelligent Power-System Q&A

Authors: Zijie Meng, Xinlei Cai, Lizhou Jiang, Kai Dong, Bingzhao Zhu, Junhong Guo

PAGES 104 - 116

Paper 12: Adapting Ephemeral ECC Authentication for Decentralized Web 3.0: A Threat Model and Security Analysis

Authors: Adarsh S V Nair, Rathnakar Achary

PAGES 117 - 133

Paper 13: Automated Generation of Arabic Procedural Court Orders in the Moroccan Legal Context

Authors: Saliha Yassine, Mohammed Essoujaa, Mustapha Esghir, Ouafaa Ibrihich

PAGES 134 - 141

Paper 14: Semi-Supervised Rice Leaf Disease and Pest Classification Using IoT Field Images

Authors: Abdul Azis, Abdul Fadlil, Tole Sutikno

PAGES 142 - 151

Paper 15: Constraint-Aware Automated Daily Meal Planning: A Controlled Comparison of Genetic Algorithm and Particle Swarm Optimization

Authors: Kohei Arai, Diva Kurnianingtyas, Nathan Daud

PAGES 152 - 159

Paper 16: Critical Vendor-Related Failure Factors in Outsourced ICT Projects: Insights from the Malaysian Public Sector

Authors: Masittah Musatapa, Fazlina Mohd Ali, Nurhizam Safie Mohd Satar, Azran Ahmad, Surya Sumarni Hussein

PAGES 160 - 168

Paper 17: Empowering Educators to Develop Augmented Reality Applications by Integrating Computational Thinking and Experiential Learning

Authors: Najwa Abd Ghafar, Nazatul Aini Abd Majid, Mohd Nor Akmal Khalid, Shinobu Hasegawa, Tan Siok Yee, Lam Meng Chun

PAGES 169 - 179

Paper 18: A Bidirectional Cross-Modal Attention Framework for Multimodal Sentiment Analysis

Authors: B S Harish, C K Roopa, M S Kendagannaswamy, T S Kaveri

PAGES 180 - 189

Paper 19: Artificial Intelligence for Rheumatoid Arthritis and Osteoporosis Diagnosis from Radiography, Computed Tomography, and Multimodal Clinical Data: A Systematic Review

Authors: Moulay Youssef ICHAHANE, Mohamed LACHGAR, Abdelouafi IKIDID, Ahmed DOURHRI, Mohamed EL GHAZOUANI, Noureddine ASSAD

PAGES 190 - 199

Paper 20: A Hybrid System with Automatic Classification and RAG for Moroccan Court Rulings

Authors: Sara IBRIHICH, Ahmed OUSSOUS, Ouafaa IBRIHICH, Mustapha ESGHIR

PAGES 200 - 209

Paper 21: IoT-Enabled Smart Cap for Real-Time Stress Monitoring

Authors: Bairavanathan Maha Sri, Kala Devi Managuran, Rajermani Thinakaran, Narayana Lokesh T, Punitha Shri M, Jeya Mithra K, Meenakshi B, Raja Subramanian R, Tong Mingjie

PAGES 210 - 218

Paper 22: A Hybrid Deep Learning Framework for Scientific Correction Text Classification

Authors: Garima Sharma, Vikas Tripathi, Vijay Singh

PAGES 219 - 229

Paper 23: AttendEase: Fraud-Resistant Attendance Tracking in Higher Education Using Dynamic Tokens and Geofencing

Authors: Silvia Gaftandzhieva, Gabriela Lyavova

PAGES 230 - 242

Paper 24: CMST-FL: Cross-Missingness Stable Trust with Evidence-Guided Preprocessing for Federated Healthcare Signal Imputation

Authors: Benachir Rigalma, Soumia Ziti, Meryam Belhiah, Hamid Ouhnni

PAGES 243 - 253

Paper 25: A Fairness–Utility Evaluation Framework for Assessing Large Language Models (LLMs)

Authors: Samah Alhazmi

PAGES 254 - 261

Paper 26: Accuracy, Stability, and Computational Efficiency of Deep CNN Architectures for Apple Leaf Disease Classification

Authors: Brahim Ouben Hssain, Khalil Ladrham, Noureddine El Barbri, Rachid El Ayachi, Abdellah Halimi

PAGES 262 - 272

Paper 27: Confidence-Gated Indonesian Grammatical Error Correction Under Synthetic-to-Authentic Domain Shift

Authors: Eko Suroso, Onok Yayang Pamungkas, Laily Nurlina, Sudiyono, Jimat Susilo, Eko Priyanto, Hera Septriana

PAGES 273 - 283

Paper 28: CompCap-Stego: Computable Capability-Pointer Steganography with Hidden Policy Evaluation and Verifiable External Payload Retrieval

Authors: Mohammad Othman Nassar

PAGES 284 - 299

Paper 29: A Machine Learning–Driven Information Systems Readiness Index for Predicting Strategic Cloud Adoption in Ghanaian Tertiary Education

Authors: Emmanuel Ofotsu Kwesi Bannor, S. Sarah Maidin, Vinayakumar Ravi, Nguyen Thi Thu Thuy, Nghiem Thi-Lich

PAGES 300 - 306

Paper 30: Color and Emotion in User Experience Design for Older Adults' Health Applications: A Multi-Database Bibliometric and Evidence-Mapping Study

Authors: YangFan He, Azizah Che Omar, Sobihatun Nur Abdul Salam

PAGES 307 - 318

Paper 31: Ablation-Based Climate-Aware Feature Engineering for Rice Productivity Prediction Using Multi-Source Agricultural Data

Authors: R. Hadapiningradja Kusumodestoni, Fatchul Arifin, Mutiara Nugraheni, Desti Setiyowati

PAGES 319 - 329

Paper 32: Deep Neural Network Architectures for Real-Time Drone Detection in Aerial Surveillance Systems: A Comparative Evaluation of YOLOv7, YOLOv8, and YOLOv11

Authors: Nazerke Abylay, Elvira Kadylbekkyzy, Bakhytzhan Kulambayev, Bayan Moldakalykova, Zharkyn Bimoldina, Saken Mambetov, Kuanysh Dossanbek

PAGES 330 - 340

Paper 33: Next-Gen Agriculture: Enhancing Animal Welfare Through IoT, Edge Devices, and Artificial Intelligence

Authors: Benlahsiniya Maroua, Ait Abdelouahid Rachida, Marzak Abdelaziz

PAGES 341 - 351

Paper 34: Predicting Multi-KPI Warehouse Dynamics: A Simulation-Based Evaluation of Fuzzy-Integrated Neural Architectures

Authors: Mohamed Amine Frikha

PAGES 352 - 358

Paper 35: Benchmarking ML-Based DDoS Detection Algorithms: Efficiency, Effectiveness, and Generalization

Authors: Zhilbert Tafa, Aurora Uka

PAGES 359 - 368

Paper 36: A Confidence-Calibrated Adaptive Ensemble Voting Framework for Stock Price Direction Prediction

Authors: Yuan Lukito, Nugroho Agus Haryono, Raden Gunawan Santosa

PAGES 369 - 383

Paper 37: Leveraging Cloud Computing Engineering for Sustainable Education: A Computational Evaluation Framework

Authors: Emmanuel Ofotsu Kwesi Bannor, S. Sarah Maidin, Vinayakumar Ravi, Nguyen Thi Thu Thuy, Nghiem Thi-Lich, Adade Sedom Percy

PAGES 384 - 394

Paper 38: An Energy-Efficient and Modeling Attack-Resilient SNN-Driven PUF Security for Internet of Medical Things

Authors: Agila Harshini T, Harini Sriraman

PAGES 395 - 402

Paper 39: A Machine Learning Framework for Wheat Seed Variety Classification Using GLCM-Based Texture Analysis and Feature Optimization

Authors: Muhammad Munawar Ahmed, Malik Muhammad Saad Missen, Hannan Adeel, Ahamad Zaki Bin Mohamed Noor, Muzamil Malik

PAGES 403 - 413

Paper 40: Perceptual Evaluation of Garment Drape Intensity in AI-Generated Garment Images

Authors: Noriaki Kuwahara, Yuta Yamamoto, Dongeun Choi, Kazunari Hirakoso, Takashi Satou

PAGES 414 - 422

Paper 41: SGRL: A Hybrid Semantic-Graph Representation Learning Framework for Software Vulnerability Detection

Authors: Cong Bui Van

PAGES 423 - 436

Paper 42: Cross-Cohort Reliability of Machine Learning for Breast Cancer Survival Prediction

Authors: NADIR Younes, RACHDI Mohamed, AMHAIMAR Lahcen, BAKHOUYI Abdellah, KHALIDI Abderrahim, AZOUAZI Mohamed

PAGES 437 - 448

Paper 43: Unmasking the Unknown: Feature-Orchestrated Image Synthesis for Deep Learning-Based Threat Detection

Authors: Sruthi C K, Harini Sriraman

PAGES 449 - 458

Paper 44: Arabic Text Simplification and Readability Assessment for Educational Applications: A Systematic Literature Review

Authors: Khalid Essaadani, Soumia Ziti

PAGES 459 - 468

Paper 45: An Adaptive AI-Driven Code Optimization Framework Using Machine Learning and Explainable AI for Scalable Software Systems

Authors: Kavya B K, S.Annamalai, A Suresh Kumar

PAGES 469 - 482

Paper 46: Enhanced Distributed Bandwidth Allocation Algorithm for Network Latency Reduction in IEEE 802.17 Rings

Authors: Fahd Alharbi

PAGES 483 - 488

Paper 47: Hybrid Resource Allocation Technique Based on Double Q Learning and Metaheuristic Algorithms in Optimizing the Allocation of Tasks in Cloud Computing

Authors: V. Mahalakshmi, S. Poornima

PAGES 489 - 499

Paper 48: Generative AI for Data-Informed Educational Decision-Making: A Systematic Review and Framework

Authors: Husna Hafiza Razami, Abtar Darshan Singh, Roslina Ibrahim, Ali Najeeb, Helio Augusto da Costa Xavier Mauquei

PAGES 500 - 510

Paper 49: Correlation-Aware Hybrid Feature Selection for Efficient Machine Learning-Based Intrusion Detection in Smart Home IoT Networks

Authors: Samar M. Alqhtani

PAGES 511 - 523

Paper 50: AI-Based Preprocessing and R-Squared Weighted Federated Aggregation for Robust Healthcare Signal Imputation

Authors: Benachir Rigalma, Hamid Ouhnni, Meryam Belhiah, Soumia Ziti

PAGES 524 - 532

Paper 51: Development and Simulation of a Hue-Based HMI Application for Vegetable Leaf Greenness Analysis

Authors: Djohar Syamsi, Mimin Muhaemin, Oviyanti Mulyani, Hanif Fakhrurroja, Puput Dani Prasetyo Adi

PAGES 533 - 541

Paper 52: An Architecture-Aware Flutter Code Generation Framework for Enforcing Clean Architecture and Behavioral Design Patterns

Authors: Desy Intan Permatasari, Adam Shidqul Aziz, Maulidan Bagus Afridian Rasyid, Ahmad Jarir At-Thobari, Umi Sa'adah, Nailussa'ada, Muhammad Fajrul Falah Subakti

PAGES 542 - 552

Paper 53: A Unified Agent-Based Simulation Framework for Epidemic and Wildfire Propagation in Complex Adaptive Systems

Authors: Natasha Stojkovikj, Aleksandra Stojanova Ilievska, Limonka Koceva Lazarova, Daniel Eftimov, Irena Eftimova

PAGES 553 - 562

Paper 54: Play-Centric Design and Usability Evaluation of a Block-Based Programming Serious Game for Low Vision Children

Authors: Huang Sheng, Chau Kien Tsong, Wan Ahmad Jaafar Wan Yahaya

Adversarial Asymmetric Agents for Network Intrusion Detection Using Deep Reinforcement Learning

Curtis Rookard
Department of Computer Science and Technology, SUNY Empire State University, Saratoga Springs, NY 12866, USA

***Abstract*—Machine learning-based network intrusion detection systems (NIDS) increasingly operate in environments where adversaries can adapt their behavior in response to deployed defenses. However, most empirical IDS studies evaluate defenders against static, dataset-defined attack distributions and do not explicitly model an adaptive attacker with a distinct learning strategy or action space. This study proposes an adversarial asymmetric learning framework for intrusion detection in which an attacker agent dynamically selects network attacks while a defender agent classifies observed network flows. We evaluate three attacker–defender pairings derived from supervised deep neural network (DNN) and Deep Q-Network (DQN) agent types. We report accuracy, precision, recall, F1-score, and G-Mean under stratified 10-fold cross validation across traditional local area network, industrial control system (ICS)/supervisory control and data acquisition (SCADA), and internet-of-things (IoT) networking environments. Empirically, the network-flow classifier performs best when paired with an intelligent attacker using reinforcement learning, even when the defender itself is not reinforcement-learning based. Overall, the results show that learning asymmetry and multi-agent interaction can substantially alter measured detection outcomes and that supervised defenders remain highly competitive in the presence of intelligent adversarial agents.**

Keywords*—Network intrusion detection; cybersecurity; deep reinforcement learning; deep q-networks; adversarial machine learning; multi-agent learning

I. Introduction

The continued growth of information technology and information processing systems worldwide have seen an increase of computing related resources. Underpinning the development and expansion of these information systems is the growth and proliferation of computer networks which now have to accommodate more than just traditional computing platforms. New technologies, such as internet-of-things, embedded systems, and industrial control systems and supervisory control and data acquisition platforms now comprise a significant share of all computing systems [1]. Application of these systems necessitate the need for reliable, trustworthy network connectivity. Unfortunately, the continued expansion and adoption of these computer systems have introduced additional attack vectors for adversaries to exploit.

Pinnacle to the protection of these computing systems is a need for robust cybersecurity technologies to ensure the threats do not comprise the aforementioned information systems. In addition to traditional cybersecurity techniques such as virtual local area networks/network segmentation, access controls, and intrusion prevention and detection systems play a crucial role [2]. Most intrusion detection systems today rely on robust machine learning mechanisms to ascertain whether to permit or to deny traffic from entering a computer network or system [3].

With the advent of more sophisticated artificial intelligence techniques, such as large language models [4], and generative adversarial networks (GANs) [5], there has been a renewed interest in applying other methods for cybersecurity, specifically for intrusion detection. As such, we have seen an increase in the utilization of more advanced machine learning algorithms, extending into the reinforcement learning domain. In reinforcement learning, an intelligent agent interacts with environmental stimuli in order to obtain the highest reward possible. In cases relating to cybersecurity, this could be presented in the sense of a cybersecurity agent interacting with the networking environment.

Interestingly, with the increased utilization of deep reinforcement learning agents for defense, there has also been a rise in the usage of deep reinforcement learning agents for offensive security purposes [6]. The combination of defender and attacker learning introduces a methodological challenge for intrusion detection evaluation: the defender is no longer tested only against a static distribution of attacks, but against an opponent whose behavior can change the mixture of observed traffic. This motivates a framework that can compare symmetric and asymmetric attacker–defender learning configurations under a common experimental protocol.

In this work, we make the following contributions to the intrusion detection literature:

- We propose an adversarial asymmetric learning framework for network intrusion detection in which the attacker and defender are modeled as interacting agents with potentially different learning mechanisms and action spaces.
- We examine the role-dependent effect of learning architecture by comparing a symmetric DNN–DNN baseline against two role-reversed asymmetric configurations: a DQN attacker with a DNN defender and a DNN attacker with a DQN defender. This controlled design allows us to determine whether the effect of reinforcement learning depends on the role in which it is deployed.

- We evaluate these scenarios on three widely used intrusion detection datasets spanning distinct network types: local area networking represented by the CIC-IDS 2017 dataset [7], industrial control system (ICS) and supervisory control and data acquisition (SCADA) environments represented by the DNP3 dataset [8], and IoT networking represented by the ACI-IoT dataset [9].
- We conduct a comprehensive comparative analysis across scenarios and datasets using standard intrusion detection metrics of accuracy, precision, recall, F1-score, and G-Mean to quantify how asymmetric learning changes measured detection performance under adaptive adversarial interaction.

Based on the literature reviewed in Section II, we identify a gap in the systematic evaluation of the directional placement of supervised and reinforcement learning mechanisms across opposing attacker and defender roles. The novelty of our work therefore lies not in the use of DNN or DQN models individually, but in the controlled comparison of their role asymmetry within an explicit attacker–defender interaction in which the attacker can influence the mixture of network traffic encountered during learning. The rest of our study is described in the following sections. Section II provides a greater overview of the related literature with both intrusion detection and reinforcement learning. Section III covers the methodology presented in our manuscript, while section IV provides the numerical analysis of our results. Section V provides the discussion of our work, and finally section VI concludes our manuscript.

II. Related Literature

After a careful review of literature, we find a lack of prior research examining deep reinforcement learning for intrusion detection under the same premises we adopt in our work. We aim to most notably present a competitive formulation with asymmetric agents using a combination of both deep reinforcement learning agents and traditional deep learning agents for both offensive and defensive intrusion detection. While numerous studies evaluate conventional machine learning and deep learning classification, and a growing body of work applies reinforcement learning to intrusion detection and traffic classification, these approaches typically assume a single decision-maker, that is, the defender, and do not explicitly model an adaptive adversary with a different learning strategy, information advantage, or action space. Our proposed framework is based upon this asymmetry, enabling a more realistic characterization of attacker–defender dynamics across heterogeneous network scenarios.

Accordingly, this section summarizes the most representative related works that inform our experimental design and baselines. We first review established intrusion detection results on widely used datasets to situate performance expectations under common supervised-learning setups, then discuss the most relevant intelligent intrusion detection studies utilizing reinforcement learning in the broader literature. Finally, we highlight similar works applying adversarial attacks for cybersecurity to thus better position our work against the current literature.

A. Traditional Intrusion Detection

Intrusion detection systems (IDSs) are commonly categorized by both deployment scope, that is either host-based vs. network-based, and detection philosophy, which are divided into signature-based vs. anomaly-based. Signature-based systems match traffic to known patterns and typically offer low false-alarm rates for previously observed attacks, whereas anomaly-based systems aim to detect deviations from a learned notion of "normal" behavior and are therefore better positioned to identify novel or low-footprint threats. As operational networks have diversified through the additional of new technologies and software, anomaly-based IDS systems have increasingly relied on statistical learning models that map flow-based or packet-derived features to either benign or attack labels. Broad surveys in the cyber analytics literature document this progression and show that classical methods such as decision trees, support vector machines, k-nearest neighbors, and shallow ensembles remain competitive in some environments, but also that their performance is often sensitive to feature engineering choices, dataset artifacts, and class imbalance [10].

More recent work has accelerated the shift from manual feature engineering toward deep learning (DL) approaches that can learn nonlinear decision boundaries and capture higher-order feature interactions. Deep neural network (DNN)-based IDS models are typically trained in a supervised manner on labeled flow records, and they have been extended with temporal architectures, including recurrent neural networks (RNNs), gated recurrent units (GRUs), and long-short term memory (LSTM) networks alongside representation learning to better model sequential dependencies or reduce reliance on handcrafted preprocessing. For example, Vinayakumar et al. evaluate DNN-based intrusion detection across multiple benchmark datasets and highlight that modern network behavior and rapidly evolving attack patterns motivate continual dataset refresh and careful cross-dataset benchmarking [11]. At the same time, end-to-end NIDS research has explored learned representations that incorporate contrastive objectives and hierarchical feature extraction to improve generalization under distribution shift, which is especially relevant when models trained on one environment are deployed in another [12].

Because IDS evaluation is tightly coupled to dataset construction, a substantial body of work focuses on the limitations of legacy benchmarks and on the design of more realistic datasets. In the work of Tavallaee et al. these researchers present inherent issues in KDD Cup 1999 dataset. These issues include redundancy and biased difficulty distributions, and they thus propose the NSL-KDD dataset to mitigate those artifacts, which partly explains why many "high-accuracy" results on older benchmarks fail to translate to operational settings [13]. Dataset-centric surveys further show that modern datasets attempt to better reflect contemporary traffic mixtures, feature sets, and attack diversity, while still exhibiting challenges such as severe imbalance and dataset-specific leakage [14], [15]. For instance, the UNSW-NB15 was created to include a hybrid of modern normal activity and synthesized contemporary attacks, thus improving upon the previous NSL-KDD dataset [16]. Similarly, the CIC-IDS 2017 dataset provides labeled flow records derived from network packet captures and has become

a standard evaluation dataset for supervised NIDS baselines [7]. These findings motivate our use of multiple datasets spanning heterogeneous network types (LAN, ICS/SCADA, and IoT) and allows us to better ascertain IDS performance.

B. Reinforcement Learning for Intrusion Detection

Reinforcement learning has been increasingly applied to cybersecurity because it often mathematically models adaptive decision-making under uncertainty, and partial observability. In many cyber defense formulations, a reinforcement learning agent learns a policy for sequential actions such as dynamic access control, moving target defense, deception, or response orchestration. In contrast to static supervised learning, reinforcement learning can optimize long-run objectives by explicitly learning from interaction feedback rather than relying solely on fixed labels.

Within the intrusion detection literature specifically, reinforcement learning appears in two primary strands. The first treats intrusion detection as a sequential classification problem where the agent's action is the predicted class and the reward encodes correctness or utility; Deep Q-Learning variants have been proposed to learn intrusion detection policies under this framing [17]. The second strand uses reinforcement learning as an optimization layer for IDS pipelines. These pipelines aim to select features, tune thresholds, or adapt detection policies online in non-stationary environments. Ren et al. propose a deep reinforcement learning-based intrusion detection method that emphasizes feature selection which provides performance benefits on modern traffic datasets [18]. More recent applied studies continue to report that deep reinforcement learning can be competitive with supervised baselines under certain conditions, especially in situations wherein the environment is dynamic or when a defender must trade off sensitivity with operational costs [19], [20].

However, a consistent limitation in much of the intrusion detection literature applying reinforcement learning is that the learning environment is often derived from a fixed dataset stream, and the "adversary" is modeled implicitly through pre-labeled attack samples rather than as an adaptive opponent. Surveys of deep reinforcement learning for intrusion detection, such as those seen in IoT contexts, note that many published approaches assume a single decision-maker, often the defender, and do not explicitly study the stability issues that arise when both attacker and defender learn simultaneously [21]–[24]. Instances incorporating both attacker and defender interactions are more naturally captured by stochastic or Markov games to better learn robust strategies against adaptive opponents [25]–[27]. Our work directly targets this gap for intrusion detection by evaluating asymmetric and symmetric pairings for both attacker and defender across heterogeneous network settings, thereby empirically characterizing how learning asymmetry alters detection outcomes.

C. Adversarial Methods for Cybersecurity

Adversarial machine learning has become a central concern for ML-based IDS because attackers may attempt to evade detection through evasion attacks, corrupt training data through data poisoning, or extract model behavior such as through model inference attacks, to enable more effective intrusions. In NIDS, these threats are complicated by domain constraints; feature perturbations must correspond to realizable network traffic, preserve protocol validity, and often maintain malicious functionality. Recent surveys propose taxonomies tailored to NIDS and synthesize both attack and defense mechanisms, emphasizing that robustness claims in cybersecurity must account for traffic realism and threat-model fidelity [28]–[30].

A growing set of works operationalizes these concerns by designing attacks that respect practical constraints. Sheatsley et al. show that even with a constrained attack surface, NIDS models can remain vulnerable to adversarial examples and that designing realistic networks alone does not guarantee robustness against adversarial attacks [31]. GAN-based approaches have also been explored to generate adversarial traffic flows. Zolbayar et al. introduce NIDSGAN to craft practical adversarial flows and evaluate their ability to circumvent ML-based NIDS under realistic feature constraints [32]. Similarly, Debicha et al. propose Adv-Bot, a black-box evasion method that aims to produce botnet traffic capable of evading detection while still preserving intended malicious behavior, and they also discuss mitigation strategies [33]. Rookard shows that even deep learning-based NIDS can still be heavily affected by adversarial attacks on training data [34]. Complementary lines of work study defender strategies under limited query access and partial feedback, highlighting the challenges defenders face when they cannot directly observe model outputs or when probing risks triggering detection [35].

This adversarial literature motivates two design choices in our work. First, it reinforces the need to evaluate IDS methods under conditions that reflect adaptivity and strategic behavior rather than assuming static attack distributions. Second, it suggests that robustness should be assessed not only by aggregate accuracy but by sensitivity-focused metrics and by stability across datasets. Rather than generating adversarial perturbations in feature space, our work models adaptivity through an explicit attacker agent whose learning strategy may differ from the defender's learning, providing a complementary, game-aware perspective on the adversarial presence in network intrusion detection.

III. Methodology

In this section, we cover the primary methodologies used in our research, specifically, we cover Markov decision processes, and their usage for deep Q-networks. We then discuss our algorithm and datasets applied in our work.

A. Markov Decision Process

We formulate our intrusion detection problem as a Markov decision process (MDP), a standard framework for modeling sequential decision-making in stochastic environments [36], [37]. An MDP is typically defined by the tuple $\langle S, A, T, R, \gamma \rangle$, where S is the set of states, A is the set of actions, $T(s' \mid s, a)$ denotes transition dynamics of moving to new state s' given action a and current state s, $R(s, a)$ is the reward function, and $\gamma \in [0, 1)$ is the discount factor that controls the weighting of future rewards.

Accordingly, we model network intrusion detection as follows: let S denote the set of network observations in the intrusion detection dataset, where each state corresponds

to a single network flow represented by a feature vector; these features include flow duration, source bytes, destination bytes, protocol type, and related statistics. The action space A corresponds to the defender agent's classification decision for a given flow, either being benign or an attack. The transition function T captures how traffic evolves from one observed flow to the next, reflecting the underlying mixture of benign and adversarial behavior present in the network stream. Finally, the reward signal is defined as a binary outcome: the agent receives $r = 1$ for a correct classification and $r = 0$ otherwise, i.e., $r \in \{0, 1\}$. The MDP formulation is therefore used as a simplified, dataset-driven model of attacker–defender interaction using the network flow traffic data.

B. Deep Q-Networks

We solve the above MDP using value-based reinforcement learning. In particular, we build on the Q-learning algorithm [37], which learns an action-value function $Q(s, a)$ representing the expected discounted return gained by our intelligent agent taking action a in state s through following an optimal policy. This optimal action-value function thus satisfies the Bellman optimality relationship,

$$Q^*(s, a) = \mathbb{E}\Big[r + \gamma \max_{a' \in A} Q^*(s', a') \,\Big|\, s, a\Big], \tag{1}$$

and Q-learning iteratively approximates Q^* via temporal-difference updates of the form

$$Q(s, a) \leftarrow Q(s, a) + \alpha\Big(r + \gamma \max_{a' \in A} Q(s', a') - Q(s, a)\Big), \tag{2}$$

where, α is the learning rate.

We therefore employ a Deep Q-Network (DQN), which approximates $Q(s, a)$ using a neural network parameterized by θ, denoted $Q(s, a; \theta)$ [38] as network-flow feature spaces are high-dimensional and continuous and maintaining a tabular Q-function is infeasible. Given a state feature vector, represented as a network flow, as input, the network outputs a vector of Q-values, one per defender action which thus allows the agent to select actions using an ϵ-greedy policy (i.e., choosing $\arg\max_a Q(s, a; \theta)$ with probability $1-\epsilon$ and exploring otherwise). To stabilize learning, we use experience replay and a target network: transitions (s, a, r, s') are stored in a replay buffer and sampled uniformly to break temporal correlations, while a separate set of parameters θ^- is periodically updated to provide a slowly moving target. The DQN is trained using the Huber temporal-difference loss between the predicted action value, $Q(s, a; \theta)$ and the target $y = r + \gamma \max_{a' \in A} Q(s', a'; \theta^-)$. The Huber loss reduces sensitivity to large temporal-difference errors while retaining a quadratic penalty for smaller errors.

C. Adversarial Asymmetric Agents for Reinforcement Learning

To capture adaptive attacker–defender dynamics that are not represented in standard supervised IDS evaluation, we extend the single-agent MDP formulation in Sections III-A–III-B to a two-agent competitive learning environment. Rather than assuming that malicious traffic arrives according to a fixed distribution, as in offline classification, we model an attacker agent that actively influences which type of traffic is encountered by the defender. This design allows us to study how detection performance changes when learning is symmetric, wherein both agents use the same class of learner, versus asymmetric wherein agents use different learning paradigms, which is central to the comparative scenarios evaluated in this work.

1) Two-agent game formulation: We model the interaction as a two-player stochastic game, akin to a Markov game), defined by the tuple $\langle S, A_D, A_A, T, R_D, R_A, \gamma \rangle$, where S is the shared state space, A_D and A_A are the defender and attacker action spaces, T defines the transition dynamics, R_D and R_A are the respective reward functions, and $\gamma \in [0, 1)$ is the discount factor. The state $s_t \in S$ corresponds to the observed feature vector of a network flow at time step t. The defender action $a_t^D \in A_D$ is the predicted class label, while the attacker action $a_t^A \in A_A$ represents the attacker's selection of an attack mode that determines the type of traffic the defender will face next. This reflects a realistic adversarial capability: while a defender may only observe a flow and decide how to label it, an attacker can adaptively choose which tactics/techniques to employ over time.

2) Reward structure and competitive objective: We use a competitive (zero-sum) reward design that directly encodes detection success. Let $\mathbb{I}[\cdot]$ denote the indicator function and let y_t be the ground-truth label (mapped to the defender's label space when coarse categories are used). The defender receives:

$$r_t^D = \mathbb{I}\big[a_t^D = y_t\big], \tag{3}$$

and the attacker receives the complementary reward

$$r_t^A = 1 - r_t^D. \tag{4}$$

Thus, the defender maximizes correct classification over time, while the attacker maximizes defender misclassification. Thus, attacker reward reflects defender error induced through adaptive traffic-mixture selection. Because the attacker neither perturbs flow features nor synthesizes adversarial examples, this advantage represents a mixture-selection effect rather than conventional feature-space evasion

3) Asymmetry in action spaces and information: Our framework is intentionally asymmetric in two ways. First, the attacker and defender may have different action spaces: the defender acts in a coarse IDS label space, e.g. denial-of-service, while the attacker acts in a fine-grained space that captures specific attack types, e.g. GoldenEye and Slowloris attacks as seen in the CIC-IDS 2017 dataset. Second, the attacker controls the traffic mixture by selecting which class of flows is drawn next, whereas the defender reacts to whatever flow is observed. These design choices jointly model a realistic attacker advantage: even if the defender's classifier is strong on average, an adaptive attacker can concentrate effort on classes wherein the defender is weakest. Before selecting an action, the attacker observes the current normalized flow-state representation. The attacker does not directly observe the defender's model parameters, class probabilities, or an explicit history of defender decisions, instead adapting from the scalar

reward and replayed interaction history, whereas the supervised DNN attacker is trained using labeled data and subsequently acts as a fixed selector. The two attackers, the DNN attacker and the DQN attacker, share the same action space but do not optimize equivalent learning objectives.

4) Agent instantiations and the three evaluated pairings: We implement each agent as either 1) a standard deep neural network (DNN) classifier trained via supervised learning, or 2) a Deep Q-Network (DQN) trained via reinforcement learning. This yields the three scenarios evaluated in Section I: 1) *Both DNNs*, where the attacker follows a fixed DNN-based policy for selecting attack modes and the defender follows a fixed DNN classifier; 2) *DNN Defender*, where the defender is supervised and fixed while the attacker learns a DQN policy; 3) *DQN Defender*, where the attacker is supervised and fixed while the defender learns a DQN. For DNN agents, the policy is deterministic at inference time, whereas DQN agents act using an ϵ-greedy strategy during training to balance exploration and exploitation.

5) Learning procedure for DQN agents: When an agent is instantiated as a DQN, it learns an action-value approximation $Q(s, a; \theta)$ for its respective action space (attacker or defender). Each agent maintains its own replay buffer and target network and minimizes the temporal-difference loss described in Section III-B. To improve stability, we train with standard DQN stabilizers (experience replay and target networks) and update each agent from its own buffer using mini-batches drawn from recent interaction experience. Empirically, this setup is sufficient for stable learning in our dataset-driven environments and enables direct comparison to supervised baselines under identical state representations and evaluation metrics.

6) Training and testing process within cross-validation: Within each cross-validation fold, supervised DNN agents are trained only on the training split. DQN agents interact only with flows drawn from the training split while learning through the aforementioned sampling mechanism. After training, we evaluate the defender's detection performance on the held-out fold using the same metrics reported in Section IV-A. This ensures that the reported results measure generalization to unseen flows while still allowing attacker adaptivity during training to shape the defender's learning experience.

D. Datasets

In this section, we cover the intrusion detection datasets used across our three intrusion detection environments.

1) CIC-IDS 2017 dataset: The University of New Brunswick's Canadian Institute for Cybersecurity crafted the CIC-IDS 2017 dataset to address limitations in present intrusion detection datasets. Improving upon the previously released NSL-KDD dataset [13] and UNSW-NB15 datasets [16], this dataset better resembles real world network traffic present in a local area network. Traffic used to create the CIC-IDS 2017 dataset originated from network packet capture (.pcap) files taken over a five-day period.

In this dataset, there are over 2.8 million instances of traffic, with several instances being more reflective of normal, benign traffic. There are 78 features present in the dataset which include network flow characteristics such as the duration of the network flow, the total length of the packet in bytes, ports used in communication, transmission control protocol flags (TCP) present. An overview of the distribution of the network traffic is provided in Fig. 1.

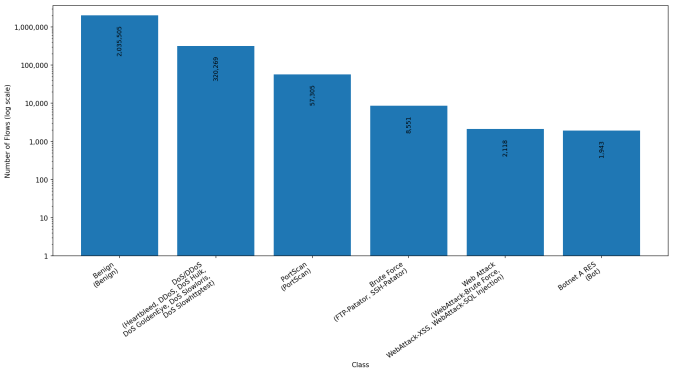

Fig. 1. Distribution of traffic present in the CIC-IDS 2017 dataset using a logarithmic scale for the number of network flows. Traffic class raw counts are indicated on each bar. Specific attacks for each traffic class are indicated in parentheses.

2) DNP3 dataset: The DNP3 intrusion detection dataset, created by the Internet of Things and Applications (ITHACA) lab at the University of Western Macedonia, provides a means to determine the efficacy of machine learning and deep learning models on industrial control systems and supervisory control and data acquisition (SCADA) platforms. The dataset is centered upon the Distributed Networking Protocol version 3, which is a common protocol used in many SCADA environments [8].

Across both the training and testing datasets on the DNP3 intrusion detection dataset, there are over seven thousand unique flows with 84 different features reflective of netflow traffic. We opt to utilize the balanced training and testing datasets as provided by the ITHACA lab for our work.

3) ACI-IoT dataset: In order to more accurately assess threats, especially within IoT networking environments, the Army Cyber Institute at the United States Military Academy developed a novel dataset, the ACI-IoT Network Traffic dataset [9] which captures the complexities of traffic originating from various IoT devices with both wired and wireless connections to the network.

There are over 1.2 million instances of unique traffic present in the ACI-IoT dataset, with over 84 different features, akin to the features captured in the netflow traffic of the CIC-IDS 2017 dataset. An overview of the distribution of the network traffic is provided in Fig. 2.

E. Proposed Experimental Design

This subsection specifies the complete experimental protocol used to evaluate adversarial asymmetric learning in intrusion detection. Our design is driven by two requirements: 1) the comparison across the three attacker–defender pairings must be fair (identical state representation, identical train/test splits, and consistent evaluation metrics), and 2) the interaction between attacker and defender must be *adaptive* for

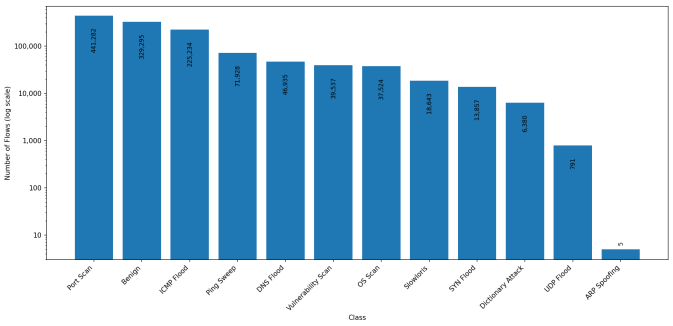

Fig. 2. Distribution of traffic present in the ACI-IoT 2023 dataset using a logarithmic scale for the number of network flows. Traffic class raw counts are indicated on each bar.

reinforcement learning agents while still permitting out-of-sample generalization measurement using cross validation.

1) Preprocessing and state representation: For each dataset, we construct a tabular feature matrix where each row corresponds to a single network flow and each column corresponds to a numeric flow feature. Categorical fields are converted to numeric form using standard encodings, and missing/infinite values are removed from the dataset. To ensure comparable optimization dynamics across datasets and to stabilize both DNN and DQN training, features are scaled using statistics computed on the training split only, and the same transformation is applied to the corresponding test fold. The resulting normalized feature vector constitutes the environment state $s_t \in S$ for both agents.

2) Label spaces and coarse–fine mapping: Each dataset includes a potentially large set of specific attack labels. For the defender, we define a *coarse* action space A_D consisting of benign traffic plus a small set of broad attack categories appropriate for the dataset. For the attacker, we define a *fine* action space A_A that corresponds to the available attack subclass labels in the dataset. A deterministic mapping $g(\cdot)$ maps each fine label to the defender's coarse label space, and correctness is computed using the coarse label $y_t^{(coarse)} = g(y_t^{(fine)})$.

a) Cross-validation process: All reported results are obtained using stratified 10-fold cross validation. In each fold, we split data into a training portion and a held-out test portion. Any preprocessing parameters and any supervised model fitting are performed strictly on the training split. Reinforcement learning agents interact only with the training split during learning, and the learned defender policy is then evaluated on the held-out test fold. This protocol ensures that attacker adaptivity can shape training-time exposure, while the final metrics quantify generalization to unseen flows.

3) Dataset-driven interaction environment: Within each fold, we construct an episodic environment from the training split. At each time step t, the attacker selects an action $a_t^A \in A_A$, which indexes a subset (pool) of training flows whose fine-grained label corresponds to a_t^A. The environment then samples the next observation x_{t+1} from that pool (uniformly at random). The defender observes the resulting state $s_{t+1} = x_{t+1}$ and selects an action $a_{t+1}^D \in A_D$ corresponding to its predicted coarse label. The defender reward is binary,

$$r_{t+1}^D = \mathbb{I}\big[a_{t+1}^D = g(y_{t+1}^{(fine)})\big], \tag{5}$$

and the attacker reward is complementary,

$$r_{t+1}^A = 1 - r_{t+1}^D. \tag{6}$$

Episodes terminate after a fixed horizon or when insufficient samples remain in one or more pools, depending on the dataset. To reduce sampling artifacts, we attempt to avoid immediate reuse of the same flow within an episode, while permitting reuse across episodes to ensure adequate training exposure.

4) Agent configurations and the three scenarios: We evaluate the following attacker–defender pairings under identical folds and preprocessing:

- Both DNNs: Both attacker and defender are trained as supervised DNN classifiers and then fixed during interaction/evaluation.
- DNN Defender: The defender is a supervised DNN classifier (fixed after training) and the attacker learns an adaptive policy with a DQN.
- DQN Defender: The attacker is a supervised DNN selector (fixed after training) and the defender learns a DQN policy for classification.

In supervised configurations, the attacker's DNN acts as a selector over A_A, choosing the specific attack, and the defender's DNN acts as a classifier over A_D, choosing the type of attack. In reinforcement learning configurations, the DQN output dimension matches the corresponding agent action space. Our experimental design is described in Fig. 3.

5) Supervised learning baselines (DNN): For DNN agents, we train a feed-forward multilayer perceptron on the training split using categorical cross-entropy loss and the Adam optimizer. We employ standard regularization and early stopping based on a validation subset carved from the training fold to prevent overfitting. After training, the resulting model is used as a deterministic policy, with actions selected using argmax over predicted class probabilities, during interaction and test-fold evaluation.

6) Reinforcement learning agents (DQN): Reinforcement learning agents (DQN). For DQN agents, each agent maintains an online Q-network, a target network, and an experience replay buffer. The DQN uses the Adam optimizer with a learning rate of 1×10^{-4}, with the discount factor, γ = 0.001, a replay-buffer capacity of 5,000 transitions, and replay mini-batches of 256 samples. The Q-network uses 128 hidden units with ReLU activation, and the target network is synchronized every 100 optimization updates. Exploration follows an ϵ-greedy policy initialized at ϵ = 1.0, with a minimum value of 0.10 and decay coefficient of 0.995 applied at 100-action intervals. Each episode contains 100 interaction steps. The attacker-DQN configuration was trained for 50 episodes (5,000 interaction steps), and the defender-DQN configuration was trained for 50 episodes (5,000 interaction steps).

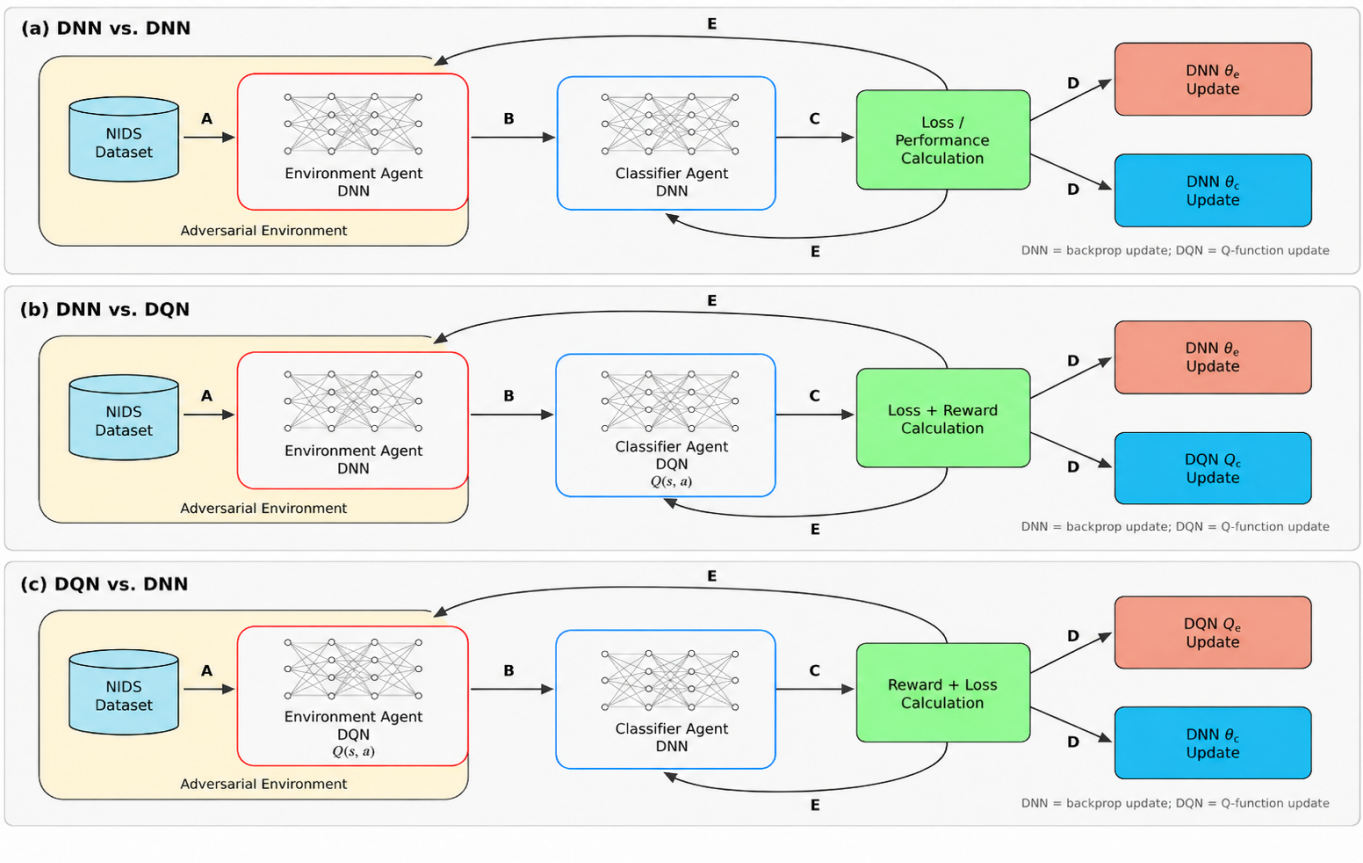

Fig. 3. Overview of the proposed adversarial-learning framework under three model pairings: (a) DNN versus DNN, (b) DNN versus DQN, and (c) DQN versus DNN. In each configuration, the adversarial agent samples network traffic from the networking dataset in step A and forwards the selected or modified traffic instance to the classifier agent in step B. The classifier agent then performs traffic classification or detection, and the resulting performance feedback is used to compute the relevant loss, reward, or combined feedback signal in step C. In step D, the feedback is routed to the appropriate update mechanism: DNN-based agents are updated through parameter optimization, while DQN-based agents are updated through their respective Q-function. The updated parameters or policies are then returned to the corresponding agents in step E, allowing the adversarial and classifier agent to continue learning across recurrent iterations. Figured adapted from [39].

7) Evaluation metrics and statistical testing: After training, we evaluate the defender on the held-out test fold and compute accuracy, precision, recall, F1-score, and G-Mean as defined in Section IV-A. Metrics are averaged across folds and reported with standard deviations. To assess whether observed differences between pairings are robust, we additionally apply paired statistical t-tests at an $\alpha = 0.05$ comparing the per-fold metric values of each method against alternatives, and we annotate statistically significant improvements in our result tables.

IV. Numerical Analysis

A. Performance Metrics

To evaluate the effectiveness of our approach, we report accuracy, precision, recall, F1-score, and geometric mean (G-Mean). Accuracy is computed as $\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN}$, while the F1-score is defined as $\text{F1} = \frac{TP}{TP+\frac{1}{2}(FP+FN)}$. Precision and recall are given by $\text{Precision} = \frac{TP}{TP+FP}$ and $\text{Recall} = \frac{TP}{TP+FN}$, respectively, and G-Mean is calculated as $\text{G-Mean} = \sqrt{\frac{TP}{TP+FN} \cdot \frac{TN}{FP+TN}}$. For multiclass experiments, precision, recall, F1-score, and G-Mean are computed using macro averaging across the defender's coarse classes, while accuracy is computed globally across all observations. All experiments are executed on a workstation equipped with an Intel Core i7 CPU and 16 GB of RAM.

B. Traditional Local Area Network Scenario

TABLE I. Performance Comparison Across Defender/Attacker Pairings Using Cross-Validation for the Traditional LAN Scenario Using the CIC-IDS 2017 Dataset. The Best Results Per Metric are Bolded. Statistically Significant Improvements at $\alpha = 0.05$ (Paired T-Test Across Folds Versus the Other Two Models) are Denoted with an Asterisk (*)

Model	Accuracy	Recall	Precision	F1-Score	G-Mean
Both DNNs	0.9436 (0.0165)	0.4272 (0.0629)	0.4149 (0.0995)	0.4065 (0.0604)	0.6336 (0.0744)
DQN Defender	0.9668 (0.0037)	0.5287 (0.0105)	0.4915 (0.0601)	0.4865 (0.0211)	0.6961 (0.0425)
DNN Defender	**0.9828*** **(0.0090)**	**0.8168*** **(0.0762)**	**0.6539*** **(0.0696)**	**0.6775*** **(0.0682)**	**0.8048*** **(0.0456)**

Table I provides an overview of the performance metrics achieved when both defender and attacker utilize a DNN, when the defender uses a DQN, and attacker uses a DNN,

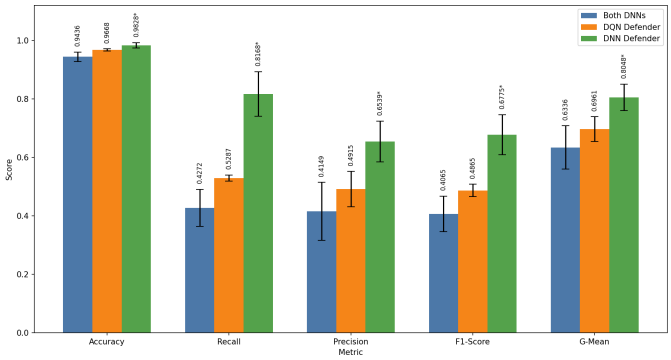

Fig. 4. Bar chart of the results of the model pairings in the LAN scenario when using the CIC-IDS 2017 dataset. Statistically significant results are indicated with an asterisk (*).

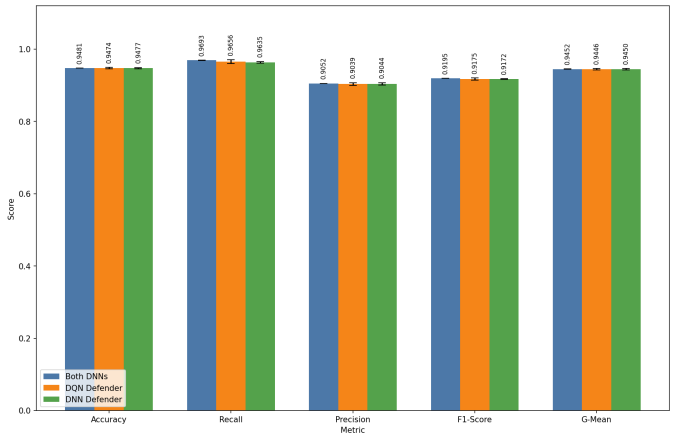

Fig. 5. Bar chart of the results of the model pairings in the ICS/SCADA scenario when using the DNP3 dataset. Statistically significant results are indicated with an asterisk (*).

and when the defender uses a DNN and the attacker uses a DQN for the traditional LAN scenario using the CIC-IDS 2017 dataset. Across all metrics in the CIC-IDS 2017 LAN scenario, the **DNN Defender** pairing achieved the strongest mean performance, statistically outperforming other models with respect to all of the performance metrics. Notably, we observe that the DNN defender statistically outperformed the other attacker-defender pairings by over 10% in metrics other than accuracy. The largest differences were seen in the recall class; this observation suggests having a DNN defender and DQN attacker yielded a lower false negative rate compared to the other models. Our results are depicted in Fig. 4.

C. ICS/SCADA Scenario

TABLE II. PERFORMANCE COMPARISON ACROSS DEFENDER/ATTACKER PAIRINGS USING CROSS-VALIDATION FOR THE ICS/SCADA SCENARIO USING THE DNP3 DATASET. THE BEST RESULTS PER METRIC ARE BOLDED. STATISTICALLY SIGNIFICANT IMPROVEMENTS AT $\alpha = 0.05$ (PAIRED T-TEST ACROSS FOLDS VERSUS THE OTHER TWO MODELS) ARE DENOTED WITH AN ASTERISK (*)

Model	Accuracy	Recall	Precision	F1-Score	G-Mean
Both DNNs	**0.9481 (0.0000)**	**0.9693 (0.0007)**	**0.9052 (0.0002)**	**0.9195 (0.0001)**	**0.9452 (0.0001)**
DQN Defender	0.9474 (0.0021)	0.9656 (0.0049)	0.9039 (0.0036)	0.9175 (0.0029)	0.9446 (0.0022)
DNN Defender	0.9477 (0.0017)	0.9635 (0.0024)	0.9044 (0.0031)	0.9172 (0.0011)	0.9450 (0.0020)

Table II provides an overview of the performance metrics achieved when both defender and attacker utilize a DNN, when the defender uses a DQN, and attacker uses a DNN, and when the defender uses a DNN and the attacker uses a DQN for the ICS/SCADA scenario using the DNP3 dataset. In the ICS/SCADA scenario using the DNP3 dataset, having **both DNNs** for the attacker and defender produced the best mean performance across all reported metrics. Importantly, all three configurations exhibit extremely low fold-to-fold variability; standard deviations ≤ 0.0049 across metrics, indicating that DNP3 is a comparatively stable dataset in which supervised decision boundaries already capture most of the separability available in the features. While having **both DNNs** provided the best performance; the performance was not statistically significant. Our results are depicted in Fig. 5.

D. IoT Network Scenario

TABLE III. PERFORMANCE COMPARISON ACROSS DEFENDER/ATTACKER PAIRINGS USING CROSS-VALIDATION FOR THE IOT ENVIRONMENT SCENARIO USING THE ACI-IOT DATASET. THE BEST RESULTS PER METRIC ARE BOLDED. STATISTICALLY SIGNIFICANT IMPROVEMENTS AT $\alpha = 0.05$ (PAIRED T-TEST ACROSS FOLDS VERSUS THE OTHER TWO MODELS) ARE DENOTED WITH AN ASTERISK (*)

Model	Accuracy	Recall	Precision	F1-Score	G-Mean
Both DNNs	0.9494 (0.0154)	0.5662 (0.0101)	0.5665 (0.0126)	0.5659 (0.0122)	0.7470 (0.0100)
DQN Defender	0.8360 (0.3185)	0.6298 (0.3211)	0.6621 (0.1605)	0.6067 (0.2958)	0.7928 (0.1326)
DNN Defender	**0.9906 (0.0066)**	**0.7898 (0.0061)**	**0.7896 (0.0100)**	**0.7896 (0.0080)**	**0.8872 (0.0065)**

Table III provides an overview of the performance metrics achieved when both defender and attacker utilize a DNN, when the defender uses a DQN, and attacker uses a DNN, and when the defender uses a DNN and the attacker uses a DQN for the IoT environment scenario using the ACI-IoT 2023 dataset. For the ACI-IoT network scenario, having a **DNN defender** with a DQN attacker achieved the strongest mean performance across all metrics with respect to traffic classification for the defender. The results of the **DNN defender** remain highly stable across folds, with the standard deviations ≤ 0.0100 for all metrics, suggesting more reliable generalization in this heterogeneous and imbalanced IoT setting. Results were not statistically significant, however. Our results are depicted in Fig. 6.

V. DISCUSSION

In the traditional LAN setting (CIC-IDS 2017), the DNN defender configuration achieved the best overall performance and produced statistically significant improvements across all reported metrics. The largest gains occurred for recall and F1-score, indicating that this pairing was most effective at detecting attacks rather than merely achieving high overall accuracy in an imbalanced setting. This suggests that, in LAN traffic where the feature space is rich but the attack classes can be sparse, a strong supervised decision boundary for the

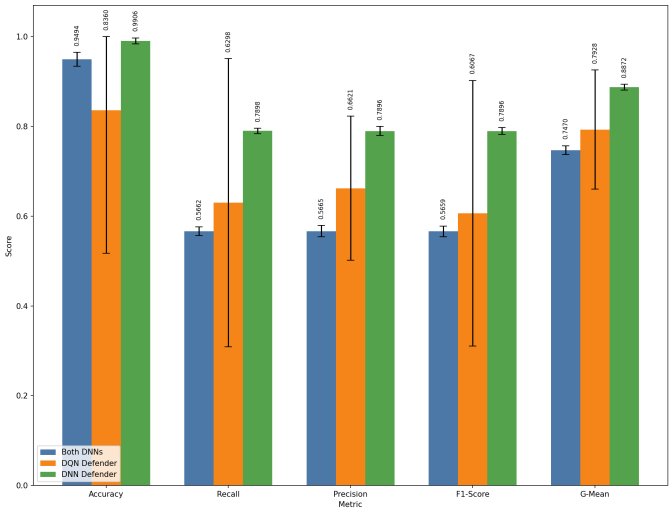

Fig. 6. Bar chart of the results of the model pairings in the IoT environment scenario when using the ACI-IoT dataset. Statistically significant results are indicated with an asterisk (*).

defender can remain robust even when the attacker adaptively influences the mixture of encountered samples.

In the ICS/SCADA setting (DNP3), having both defender and attacker utilize a normal DNN configuration produced the strongest and most stable results across every metric. Unlike the LAN and IoT datasets, DNP3 is substantially smaller and more controlled, and we used the balanced splits provided with the dataset. Under these conditions, supervised learning appears sufficient to capture the discriminative structure of the data, while reinforcement learning-based interaction provides limited additional benefit.

In the IoT setting (ACI-IoT), having a defender DNN in conjunction with an attacker DQN again achieved the best results and remained consistently stable across folds. In contrast, the reversal of the configuration in which the defender utilized a DQN and the attacker used a DNN displayed very high fold-to-fold variance. Our DQN defender failed to consistently learn an optimal policy for detecting network threats, resulting in substantial fold-to-fold variability.

A central finding across these experiments is therefore that reinforcement learning is not uniformly advantageous simply because it provides an adaptive learning mechanism. Instead, its effect depends on the role in which it is deployed and on the characteristics of the underlying network environment. In the CIC-IDS 2017 and ACI-IoT scenarios, the strongest mean performance was obtained when reinforcement learning was assigned to the attacker while the defender retained a supervised DNN, whereas the symmetric DNN configuration performed best in the more controlled DNP3 environment. These results suggest that the interaction among attacker capability, defender learning mechanism, and traffic heterogeneity can be as important as the selection of the classifier itself when evaluating intelligent NIDS.

We do acknowledge certain limitations with our work. The attacker controls the mixture of existing labeled traffic rather than generating new feature-space perturbations, and the evaluation does not include random, uniform, empirical-frequency, or hardest-class selection baselines. Consequently, some observed attacker advantage may reflect repeated selection of naturally difficult attack classes. Stratified flow-level cross-validation does not guarantee separation of records originating from the same sessions, hosts, or capture periods; the results therefore demonstrate flow-level rather than full temporal generalization. Despite these limitations, the proposed framework provides a useful basis for evaluating how asymmetric attacker–defender learning strategies influence intrusion-detection performance across heterogeneous network environments.

VI. Conclusion

Our work introduced an adversarial asymmetric learning framework for network intrusion detection that explicitly models an adaptive attacker alongside a defender, enabling controlled comparison of symmetric and asymmetric learning configurations. We formulated the interaction as a two-agent stochastic game in which the attacker influences the traffic mixture through fine-grained attack selection while the defender performs coarse-grained flow classification, and we evaluated DNN- and DQN-based agents under stratified 10-fold cross validation across three representative network environments: CIC-IDS 2017 (LAN), DNP3 (ICS/SCADA), and ACI-IoT (IoT).

Across experiments, we found that the best-performing pairing depends on the dataset regime. In the LAN and IoT settings, the DNN Defender configuration achieved the strongest detection performance and remained stable across folds, yielding substantial gains in sensitivity-focused metrics (recall, F1-score, and G-Mean). In the ICS/SCADA setting, the symmetric Both DNNs configuration produced the best and most consistent results, suggesting that supervised learning can be sufficient in smaller, more controlled and balanced environments. Conversely, reinforcement learning-based defenders exhibited elevated variance in heterogeneous and imbalanced settings, highlighting the importance of stability considerations when applying value-based deep reinforcement learning to IDS classification under adversarial pressure, as in the ACI-IoT dataset. We thus demonstrate that the effectiveness of adaptive learning in NIDS depends on both the role of the learning agent and the characteristics of the network environment.

Overall, the results provide two primary takeaways. First, explicitly modeling an adaptive attacker can materially change measured IDS performance relative to static evaluation, particularly for minority-class detection. Second, supervised defenders remain highly competitive under adversarial traffic-mixture control, while reinforcement learning-based defenders may require additional stabilization and richer reward models to realize consistent benefits. Several extensions can strengthen the realism and utility of this framework. A first direction is to incorporate cost-sensitive or asymmetric utilities such as including heavier penalties for false positives in high-volume IoT traffic or higher rewards for detecting high-impact ICS attacks. A second direction is to model temporality and partial observability more explicitly so that reinforcement learning can exploit genuine sequential structure. A third direction is to expand the adversary model beyond mixture control to include constrained feature-space perturbations or traffic

synthesis, bridging this framework with adversarial machine learning methods.

Declaration of Generative AI and AI-Assisted Technologies in the Manuscript Preparation Process

During the preparation of this work, the author utilized the generative AI service ChatGPT version 5.5 in order to improve the language and readability of the content. After using this service, the author reviewed and edited the content as needed and takes full responsibility for the content of the published article.

***Abstract*—Healthcare systems face increasing pressure from nursing shortages, growing patient-care demands, and the substantial amount of time healthcare professionals spend performing routine and repetitive bedside activities. These challenges can increase caregiver workload and reduce the time available for clinical assessment, decision-making, and direct patient interaction. Patients with limited mobility may also depend on caregivers for relatively simple activities, such as retrieving objects, obtaining drinking water, or interacting with their immediate environment, which can lead to delayed assistance when healthcare personnel are occupied with higher-priority responsibilities. Motivated by these challenges, this study investigates the use of collaborative robotics and intelligent natural-language interaction to provide supplementary assistance for predictable and repetitive patient-care tasks. An intelligent robotic patient-assistance framework is developed by integrating collaborative robotic manipulation, voice-based natural-language interaction, and non-contact physiological monitoring. The system employs a UFACTORY xArm7 collaborative manipulator to perform representative bedside assistance tasks, including cleaning a designated area, pouring water, delivering medicine, and measuring body temperature. A Python-based software architecture coordinates robot control, task execution and user interaction. To provide hands-free and intuitive control, Faster-Whisper is used for continuous speech-to-text processing, while a Large Language Model (LLM) interprets the transcribed commands and maps different natural-language expressions to predefined robotic tasks.**

***Keywords*—Healthcare; Robot Arm; LLMs; automation; voice recognition; healthcare innovation**

I. Introduction

Healthcare is an ever-evolving field that continuously pursues innovative approaches to improve patient outcomes and enhance the efficiency of healthcare operations. Rapid technological advancements have created new opportunities to transform healthcare delivery, with robotics emerging as a promising solution for supporting clinical tasks, improving workflow efficiency, and advancing the overall quality of patient care.

A. Challenges of Traditional Healthcare and Patient Care

Traditional healthcare systems depend heavily on human healthcare professionals to perform both clinical and routine patient-care activities, creating significant challenges as patient populations grow and workforce shortages persist. The global shortage and uneven distribution of nursing personnel can increase individual workloads and limit the time available for direct patient interaction and continuous monitoring [1]. High workloads and repetitive responsibilities can contribute to physical and psychological fatigue among healthcare workers. Nurse burnout has also been associated with missed care, medication errors, patient safety incidents, and reduced patient satisfaction [2]. Furthermore, inadequate staffing and limited resources may result in delayed or missed nursing interventions [3]. Without robotic manipulators, many repetitive physical tasks must be performed manually, limiting opportunities to automate routine bedside assistance and potentially reducing the time clinicians can devote to tasks requiring professional judgment and interpersonal interaction. At the same time, traditional healthcare information systems generally provide limited natural-language interaction; without large language models (LLMs), which is a new, innovative and powerful technique created from recent years. Recent studies indicate that LLMs have potential applications in patient communication, clinical documentation, and information processing [4], [5]. Therefore, combining large language models with robotic manipulation offers a potential approach for reducing repetitive workload while enabling more intuitive interaction between patients, healthcare personnel, and assistive robotic systems.

1) Nursing shortages and high patient-to-nurse ratios: Nursing shortages and excessive nursing workloads can contribute to fatigue, emotional exhaustion, reduced job satisfaction, and intentions to leave the profession. A systematic review and meta-analysis found that nurse burnout was associated with poorer patient-safety outcomes, lower perceived care quality, and reduced patient satisfaction [6]. Workforce shortages and burnout may therefore form a reinforcing cycle: insufficient staffing increases workload, elevated workload contributes to burnout, and burnout increases turnover, thereby placing further pressure on the remaining workforce [7], [8].

2) Economic burden of nursing services: An adequately staffed nursing workforce represents a substantial but necessary component of healthcare expenditure. The institutional cost of employing a nurse extends beyond base salary and includes health insurance, retirement contributions, paid leave, continuing education, recruitment, orientation, and overtime compensation. Because hospitals and residential-care facilities operate continuously, multiple employees are required to provide uninterrupted coverage for a single position across various shifts [9], [10].

3) Delayed and missed patient care: For patients with impaired mobility or upper-limb function, delayed assistance can have consequences beyond temporary inconvenience. A

*Corresponding author.

patient may remain unable to drink, communicate, retrieve an essential object, or adjust the immediate environment until a caregiver becomes available [11], [12]. Some patients may attempt these activities without assistance, potentially increasing the risk of falls, overextension, equipment displacement, or other preventable injuriecite. Technologies that respond to structured, low-risk requests could therefore improve patient independence while reducing interruptions to nurses performing higher-priority clinical work [14], [13].

4) Limitations of exclusively human-dependent care: Direct human interaction remains an essential component of nursing because it enables clinical judgment, emotional support, and individualized patient care. However, relying exclusively on nurses to perform both complex clinical procedures and routine physical tasks presents several operational challenges. Frequent bedside contact increases occupational exposure to infectious diseases despite established infection-control measures [15], [16]. Repetitive activities such as retrieving supplies, repositioning equipment, and assisting with routine patient requests also contribute to physical fatigue and work-related musculoskeletal disorders, which remain common among nursing professionals [18], [17]. Furthermore, the availability of nursing staff is constrained by workload, patient acuity, and emergency situations, making immediate responses to routine requests difficult during busy clinical periods. Consequently, assigning repetitive logistical tasks solely to nurses may reduce overall workflow efficiency and limit the time available for assessment, communication, and direct clinical care. These limitations highlight the potential value of assistive robotic systems that can undertake predictable physical tasks while allowing nurses to focus on responsibilities requiring professional expertise and interpersonal interaction [19].

B. Literature Review of Robotic Assisted Patient Care and Research About LLMs

1) Existed technologies for robotic assisted patient care: Healthcare robotics has gradually evolved from autonomous transportation platforms to intelligent assistive systems capable of interacting directly with patients [20]. Early hospital robots were primarily developed for logistics, including the transportation of medication, laboratory samples, and medical supplies, with the objective of reducing caregiver travel and improving operational efficiency. Advances in autonomous navigation, perception, and human–robot interaction have subsequently enabled robots to perform bedside assistance, allowing them to operate safely in clinical environments while collaborating with healthcare professionals [21], [22].

Recent research has increasingly focused on robotic manipulators because physical interaction is required for many patient-care activities. Compared with mobile service robots, robotic arms provide dexterous manipulation that enables direct assistance during activities of daily living [23], [24]. Their applications include object retrieval, assistive feeding, and manipulation of bedside devices for individuals with limited upper-limb function. Shared-autonomy approaches have further improved usability by combining autonomous robot motion with user intention, thereby reducing operator workload while maintaining safe interaction during manipulation tasks [25].

2) Human–robot interaction and user acceptance: The successful deployment of assistive robotic systems in healthcare depends not only on technical performance but also on their acceptance by patients and healthcare professionals. Studies have shown that user acceptance is strongly influenced by perceived safety, trust, ease of interaction, and the robot's ability to complement existing clinical workflows rather than replace human caregivers in STEM researches [26]. Although robotic assistants can reduce repetitive physical workload and improve the availability of routine patient assistance, concerns remain regarding privacy, patient dignity, responsibility for system failures, and excessive reliance on automation. These issues highlight the importance of maintaining human supervision during robot operation and ensuring that clinical staff retain full authority over safety-critical decisions [27].

3) The innovative and powerful technology of LLMs: Large Language Models (LLMs) are increasingly being explored in healthcare to improve communication and support clinical workflows. They can assist with medical question answering, patient education, and the interpretation of clinical information, allowing healthcare professionals to access relevant knowledge more efficiently [28], [29]. LLMs can also support clinical documentation by generating or summarizing medical text from patient encounters, potentially reducing the administrative workload placed on healthcare providers. In patient-care environments, natural-language interaction may allow patients to express their needs conversationally rather than through predefined commands. When combined with assistive technologies such as robotic systems, this capability can help translate patient requests into structured instructions while maintaining human supervision for safety-critical decisions [30], [31].

4) LLMs' applications in healthcare about voice recognition: Large Language Models (LLMs) have emerged as an important artificial intelligence technology capable of understanding natural language and generating context-aware responses. Their ability to interpret complex instructions has supported their growing use in healthcare [28]. LLMs can provide a natural-language interface between users and intelligent healthcare systems, making communication more intuitive. When integrated with robotic systems, an LLM can interpret patient requests, such as "bring me some water," and translate their meaning into structured commands for subsequent robotic execution. This capability may support the development of healthcare assistants that respond more naturally to patient needs, although appropriate validation and human supervision remain necessary for clinical applications [30].

C. Objectives and Scope of the Project

This project introduces the concept of harnessing a collaborative UFACTORY xArm7 as an automated assistant in healthcare. This approach capitalizes on the robot's potential to enhance patient care and efficiency through its role in aiding patient care tasks and conducting vital sign monitoring. We utilized LLMs with the robot arm, to achieve voice recognition for delivery of patient needs. Leveraging the Python programming language for implementation, this project not only underscores the practical fusion of technology with healthcare but also explores the potential paradigm shift in patient care dynamics.

The first objective of this research is to design and implement a robotic patient-assistance framework using the UFACTORY xArm7 collaborative manipulator. The proposed framework enables the robotic arm to perform routine bedside assistance tasks through an integrated architecture that combines robotic manipulation, sensing, voice-based user interaction, and intelligent task execution. The system focuses on tasks such as pouring water, cleaning a designated area, delivering medicine, and taking temperature measurements. The overall objective is to demonstrate how collaborative robotic technology can provide reliable physical assistance while operating safely in environments shared with patients and healthcare professionals.

The second objective is to develop a voice-controlled human–robot interaction system that enables users to request assistance through natural spoken commands. A speech-to-text module is incorporated to capture the user's voice and convert spoken requests into textual information for further processing. This approach enables patients to interact with the robotic system without requiring physical access to a computer, touchscreen, or dedicated control interface, providing a more accessible method of interaction for users with limited mobility.

The third objective is to integrate a Large Language Model (LLM) into the voice-control framework for intelligent interpretation of user requests. The LLM is used to analyze recognized speech, identify the user's intended task, and map different natural-language expressions to predefined robotic actions. For example, expressions such as "Bring me some water," "Can I have some water?" and "I am thirsty" can be associated with the same water-assistance task. The LLM-based approach enables more flexible and intuitive communication by allowing users to express requests naturally rather than relying on a fixed set of predefined voice commands.

The fourth objective is to investigate autonomous object manipulation for routine patient-care applications. This work focuses on developing task-specific motion planning, grasping, and manipulation strategies that enable the xArm7 to retrieve, transport, position, and manipulate objects required for bedside assistance. The robotic system is intended to autonomously execute tasks identified through the voice-control framework, including water pouring, area cleaning, and medicine delivery. By automating predictable and repetitive manipulation activities, the proposed framework aims to reduce the need for direct human intervention while supporting routine patient assistance.

The fifth objective is to integrate non-contact physiological monitoring into the robotic assistance platform. In addition to performing physical manipulation tasks, the system is intended to support non-contact sensing technologies for acquiring physiological information, with particular emphasis on body temperature measurement. Integrating physiological monitoring with robotic manipulation allows the same platform to provide both physical assistance and basic patient observation. This combined capability establishes a foundation for future expansion toward additional non-contact physiological measurements and more comprehensive intelligent patient-monitoring systems.

II. Materials and Methods

A. Hardware and Software Environment

The experimental platform employs a UFACTORY xArm7 collaborative robotic manipulator as the primary hardware for autonomous patient-assistance and vital-sign monitoring tasks. The xArm7 is a seven-degree-of-freedom (7-DoF) collaborative robot designed to provide kinematic redundancy, enabling flexible motion planning and obstacle avoidance in constrained environments while maintaining high positioning accuracy [32]. The robot offers a maximum payload capacity of 3.5 kg, a reach of 700 mm, and a repeatability of ± 0.1 mm, making it suitable for manipulation tasks that require precise positioning and safe human–robot interaction. Compared with conventional six-axis manipulators, the additional degree of freedom allows the robot to maintain multiple feasible arm configurations for the same end-effector pose, thereby improving dexterity and reducing the likelihood of singular configurations during operation [33].

The xArm7 is controlled through the UFACTORY controller using the official Python Software Development Kit (SDK), which provides high-level interfaces for joint-space motion, Cartesian trajectory planning, inverse kinematics, digital input/output (I/O), and gripper control. Communication between the host computer and the robot controller is established through a TCP/IP Ethernet connection, enabling seamless integration with external software developed in Python and Robot Operating System (ROS/ROS 2) environments. During system deployment, safety mechanisms including collision detection, self-collision avoidance, configurable safety boundaries, and emergency stop functions are enabled to ensure safe operation when the robot performs collaborative tasks in close proximity to users [34]. These hardware and software capabilities provide a flexible experimental platform for implementing intelligent robotic assistance systems in healthcare applications.

The Robot application was executed on an MSI gaming computer equipped with an Intel Core i7-13700F processor, an NVIDIA GeForce RTX 4070 graphics card with 12 GB of dedicated video memory, 32 GB DDR5 RAM, and a 1 TB NVMe solid-state drive running Windows 11 (64-bit) [35], [36], [37], [38]. These specifications exceed the recommended hardware requirements for real-time VR rendering, ensuring smooth operation and stable frame rates during the experimental evaluations.

We created a voice control component based on LLMs. The voice command was the input of a speech to text module, and LLMs created the intent classification, that directs the root to perform certain tasks. The speech to text component was through python text to speech package and the LLMs was GPT package.

We created python algorithms to precisely control the robot arm's movements and interactions, forming the programming and control stage. During the programming and control stage, sophisticated control algorithms are developed using the Python programming language to enable precise and reliable operation of the robotic system. Python serves as the primary software development platform because of its extensive ecosystem of robotics libraries, numerical computation packages, and compatibility with the UFACTORY Software Development Kit (SDK). The developed software

is responsible for generating motion commands, performing inverse kinematics calculations, planning collision-free trajectories, and coordinating end-effector operations throughout each experimental task. Communication between the host computer and the robot controller is established through a TCP/IP Ethernet connection, allowing real-time transmission of motion commands and continuous monitoring of the robot's operating status.

B. System Design and Experimental Steps

The design goals are to create a robotic assistance framework, that is capable of Autonomous object manipulation with non-contact physiological monitoring. The software is capable of recognizing user input through voice recognition, mapping the task from the voice control, performing guided tasks, gathering data and recording of robot movement videos. Fig. 1 shows a diagram of the design objectives. The system design involves the following components. The Robotic Arm is located on a mobile table for easy manipulation, the connected computer serves as a hub for robot control and data aggregation. Python based tasks such as cleaning up, pouring water, delivering of medicine and vital sign measurement were established. On the user interface, the user can select tasks and record the robot actions during the tasks.

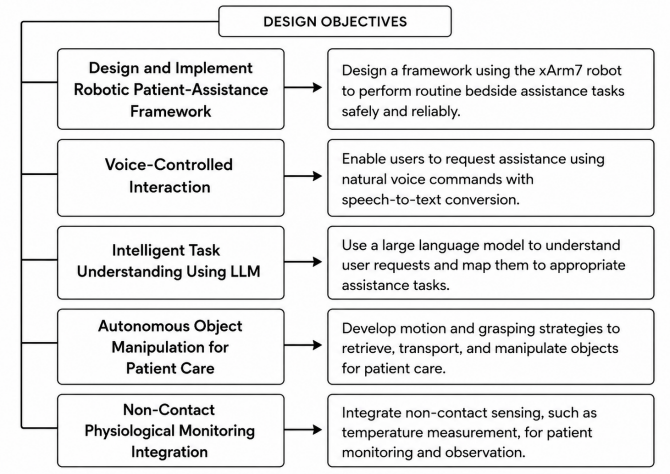

Fig. 1. Design objectives.

The software focused control package consisted the voice recognition component, the task identification component, and the robot task direction component. The voice recognition component utilized python text to speech package. The task identification component involves GPT package for intent mapping. The user interface built connections to direct robot for particular tasks.

The hardware related project methodology involves a comprehensive approach that comprises several key stages and assessment procedures. First, the UFACTORY Robot Arm is equipped with specialized end-effectors that can be designed for healthcare applications, and this involves the initial design and integration phase. Next, algorithms are developed using the Python programming language to precisely control the robot arm's movements and interactions, forming the programming and control stage. To ensure reliability and safety, virtual environments are painstakingly created for thorough testing of the robot's actions before real-world deployment in the simulation and rigorous testing phase. Additionally, a user-friendly interface is carefully designed to provide healthcare professionals with seamless control over the robot arm's activities, constituting the user interface design phase. Throughout the process, data is systematically collected in both simulated and real healthcare scenarios, enabling in-depth analysis during the data acquisition and analysis stage. Finally, the performance of the automated assistant is evaluated using various metrics, including accuracy, operational efficiency, and we analyzed its impact on patient care, as part of the evaluation and impact assessment phase. Fig. 2 shows the system diagram involving both hardware and software.

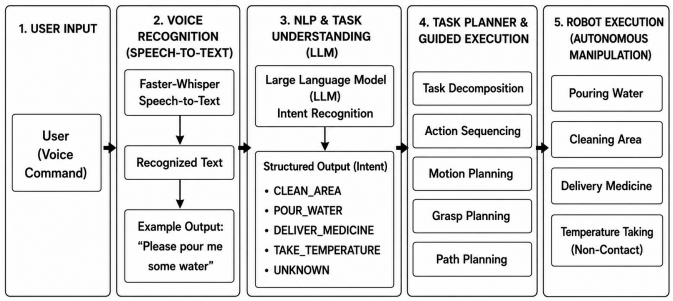

Fig. 2. System design diagram.

C. LLM-Based Natural Language Control Software Design

The speech-to-text component was designed to provide continuous voice recognition for natural human–robot interaction. Faster-Whisper was selected as the primary speech recognition framework because it provides a suitable balance between transcription accuracy and computational efficiency, making it appropriate for near-real-time robotic applications. The framework can be integrated into the Python-based control architecture to capture audio signals from a microphone, process the recorded speech, and convert the resulting audio into textual information. During operation, microphone input is continuously acquired and processed so that recognized speech can be displayed in real time and subsequently forwarded to the natural-language processing module. This continuous recognition approach allows users to provide successive verbal commands without manually restarting the speech-recognition process for each interaction. The transcribed text serves as the interface between the speech-recognition and Large Language Model components, where the recognized user request is further analyzed to determine the corresponding robotic task. If speech cannot be reliably recognized, the system can reject the input or request another command rather than initiating an uncertain robotic action. This implementation establishes a continuous voice-processing pipeline consisting of audio acquisition, speech recognition, text generation, intent interpretation, and robotic task selection, thereby supporting intuitive hands-free interaction with the patient-assistance system.

The LLM-based natural language control software is designed to provide an intuitive communication interface between the user and the robotic patient-assistance system.

Spoken commands are first captured through a microphone and converted into text using a speech-to-text module such as Faster-Whisper. The recognized text is then processed by a Large Language Model (LLM) to interpret the user's intent and associate different natural-language expressions with predefined robotic tasks. For example, commands such as "Bring me some water," "Can I have some water?" or "I am thirsty" can be interpreted as a water-assistance request. The LLM produces a structured task identifier corresponding to supported functions such as water pouring, area cleaning, medicine delivery, or temperature measurement. This task identifier is subsequently passed to the robot-control software, where predefined and validated motion routines are executed by the xArm7. By separating natural-language interpretation from low-level robotic control, the proposed software architecture provides flexible voice interaction while maintaining predictable and controlled robot behavior. Fig. 3 shows the diagram of voice recognition and LLM based task mapping code.

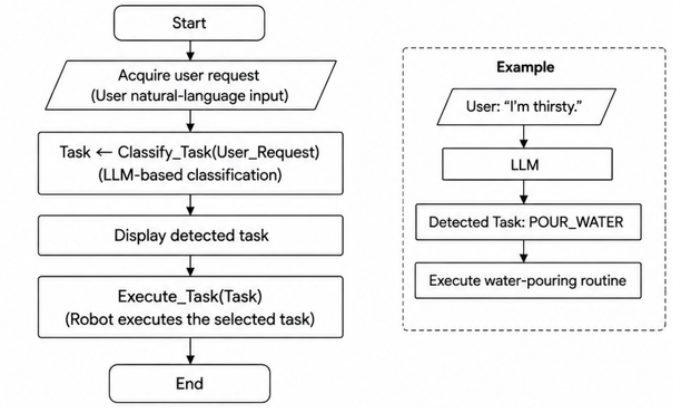

Fig. 3. Diagram of the process for the voice recognition and LLM-based task mapping.

D. Robot Installation and Initial Configuration

The installation of the UFACTORY xArm7 collaborative robotic system consists of several sequential steps to ensure safe and reliable operation. First, an appropriate workspace is defined to provide sufficient clearance for the robot's operating range and to prevent potential collisions with surrounding objects. The robotic arm is then securely mounted onto a stable work surface to ensure mechanical stability during operation. Next, the robotic arm is connected to the UFACTORY control box through the dedicated communication interface, followed by the connection of the control box to the power supply and the host computer using the required communication and power cables. After the hardware installation is completed, the system is powered on and initialized to verify proper communication between the robot controller and the host computer. Fig. 4 shows the connection of the robot arm with the computer that has the user interface, the robot control software component and robot task recording software component.

Following hardware installation, the robot undergoes an initial configuration and familiarization process using the *xArm Studio* software developed by UFACTORY. This software provides an integrated development environment for robot operation, programming, and system configuration. Users become

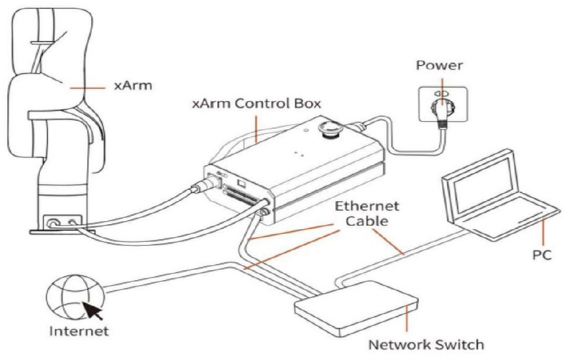

Fig. 4. Robot connection diagram.

familiar with the robot's hardware, control interface, operating modes, and workspace while verifying the robot's motion capability and communication status. Fig. 5 shows the central control unit of the system. Fig. 6 shows the XARM design interface. The software consists of five primary functional modules: *Live Control*, which enables manual manipulation of the robotic arm; *Blockly*, which supports graphical block-based programming; the *Python IDE*, which provides script-based robot programming and debugging; *Recording*, which allows robot trajectories to be recorded and replayed; and *Settings*, which manages system configuration, communication parameters, safety settings, and robot calibration. These integrated software tools facilitate rapid system deployment, robot programming, and experimental validation while providing a user-friendly interface for both novice and experienced users.

Fig. 5. Assisted robot Arm system - the central control unit.

The integration of the xArm presents several challenges, particularly in the realm of coordination. The mismatch between the coordinate systems of the xArm and the gripper introduces the potential for coordination issues during object manipulation. This misalignment can lead to inaccuracies and may result in failed attempts at grasping and pouring tasks. Additionally, the calibration process, essential for ensuring precise alignment between the two coordinate systems, proves to be a complex and time-consuming endeavor. Achieving perfect alignment demands meticulous adjustments, contributing to the overall intricacy of the setup.

Furthermore, an encountered challenge relates to IP configuration, where issues arose during power cycling. The IP

Fig. 6. The XARM studio design interface.

addresses of the computer and the control box were found to be on different network segments, posing a major hurdle. To address this, it became necessary to modify the computer's IP within the range of 192.168.1.1 - 192.168.1.255, with the tail number falling between 1 and 255, and ensuring it does not match the IP address of the control box. This adjustment was crucial for establishing a seamless network connection and overcoming the encountered IP configuration challenge.

E. Robot Control Software Design and Integration

We developed Python scripts that empower the UFACTORY robot arm to execute patient care tasks, ensuring precise and fluid movements. We created a software interface that bridges the gap between healthcare staff and the robot arm. This interface is designed to enable intuitive control, communication, and coordination, aligning seamlessly with the workflow of medical professionals. Additionally, the performance of the robot arm is recorded, with the goal for validation of calibration, and task completion testing.

Live Control offers the capability to manipulate the xArm's position and adjust its posture using XYZ coordinates within the base coordinate system for the arm and the tool coordinate system for the gripper. Fig. 7 shows the interface of the Live Control of the Assisted Robot Arm.

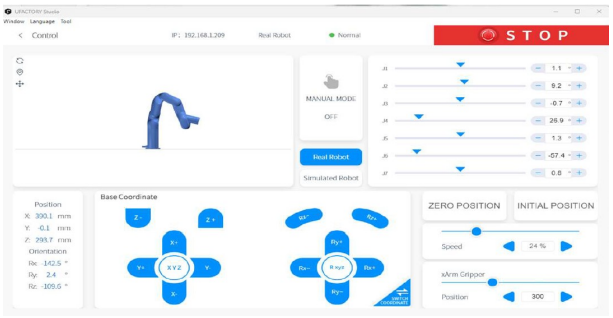

Fig. 7. Interface of live control of the assisted robot Arm.

Blockly, a graphical programming tool, simplifies programming tasks by allowing users to drag and drop code blocks to control the robotic arm, input, and output. Fig. 8 shows the Blockly interface for experimenting kinematics parameters. The diagram illustrates the block-based programming workflow used to control the UFACTORY xArm7 robotic joints and associated end-effector functions. The process begins with the Move Servo (Joint Motion) command, which specifies the target joint, desired angular position, starting angle, motion duration, speed, and execution mode. These parameters determine how an individual robot joint moves from its initial configuration to a defined target position. The workflow then incorporates the Set Analog Output command, which can be used to regulate auxiliary devices such as the gripper by assigning an output pin and control value. Subsequent joint movements can be generated by repeating the servo command with updated target parameters, allowing a sequence of coordinated robot poses to be constructed.

The final stage uses the Set End I/O Pin (Digital Output) command to control binary end-effector functions, such as opening or closing the gripper. The supporting reference tables summarize the principal command parameters and identify the seven joints of the xArm7, from the base joint to the distal wrist joints. Together, these programming elements provide a structured approach for defining joint trajectories, controlling end-effector operations, and coordinating sequential robot actions. The block-based interface therefore enables robot motion to be programmed without requiring extensive low-level coding, while still providing control over position, speed, timing, and I/O states.

Fig. 8. Blockly interface for experimenting kinematics parameters.

The Python IDE facilitates direct utilization of the Python SDK API for creating programs that instruct the robotic arm to perform particular tasks. after experimenting with blockly for key parameters, we program each task as a python program. Fig. 9 shows an example Python pseudocode for the task of pouring water.

III. Results

A. Results of the Natural Language Based LLM Enabled Task Mapping

Fig. 10 shows an example display of python code execution for the natural language based LLM enabled task mapping. The output demonstrates the successful operation of the LLM based natural language task classification module. The system receives transcribed user commands and interprets their semantic meaning to determine the corresponding predefined robotic task. For example, the statement "I'm thirsty" is classified as `POUR_WATER`, demonstrating that the system can infer the user's intention even when the requested action is not explicitly stated. Similarly, "Please clean the table" is mapped to `CLEAN_AREA`, while "Check my temperature" is classified as `TAKE_TEMPERATURE`. These results demonstrate that the LLM can associate different natural-language expressions with

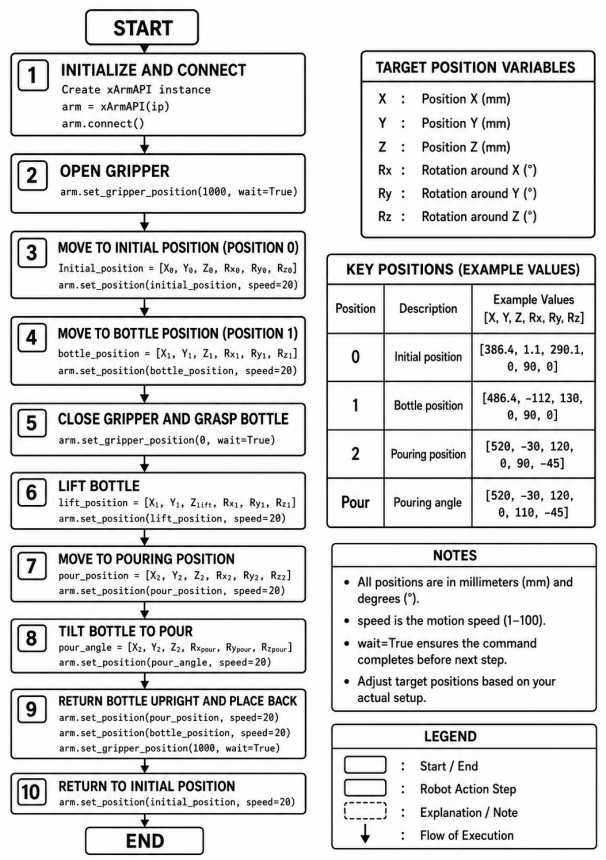

Fig. 9. Pseudo code and illustrations of the assisted robot Arm for pouring water.

standardized task identifiers, which can subsequently be passed to the robot-control module to initiate the appropriate predefined task routine.

```
You said: I'm thirsty
Detected task: POUR_WATER

You said: Please clean the table
Detected task: CLEAN_AREA

You said: Check my temperature
Detected task: TAKE_TEMPERATURE
```

Fig. 10. Python output for voice recognition and LLM based task mapping.

B. Assisted Robotic Arm Performance for Example Tasks and Use Cases

Empirical evidence forms the cornerstone of this research's contributions. A comprehensive account of the data was collected during task execution, including completion times, accuracy rates, and any observed safety considerations, was provided. These results were contextualized within the research's objectives and contribute to the overall evaluation of the robot arm's efficacy and feasibility in healthcare scenarios. The different tasks were divided into cleaning area, pouring Water, delivering medicine, taking body temperature.

1) Remove medical contaminated materials: The deployment of the UFACTORY xArm7 robotic arm and gripper for the removal of medical contaminated materials in healthcare settings had made significant strides, leveraging advanced robotic technology to enhance efficiency and safety. The deployment process began with the installation of the xArm Python Library, facilitating seamless communication with the robotic arm. Following this, the necessary modules were imported to enable comprehensive control and programming capabilities. An instance of the xArm API class was created, specifying the IP address or port of the xArm7 to establish a connection. Through the "connect" method, the xArm seamlessly linked to the designated system. The deployment strategy incorporated a loop to repeat the material removal task multiple times, allowing for systematic and repetitive operations. Positions of the xArm were dynamically adjusted within the loop to navigate the robot precisely to the targeted contaminated materials. Upon completing the task iterations, the xArm disconnected from the system, marking the successful execution of the deployment plan. This progress highlighted the successful integration of advanced robotic solutions for the efficient and controlled removal of medical contaminated materials in healthcare settings.

2) Deliver water / pouring water into the cup: In a healthcare context, implementing the precise and controlled pouring of water from a bottle into a cup using the UFACTORY xArm7 robotic arm equipped with a gripper offered a range of potential benefits. This application was particularly useful in scenarios where patients have difficulty performing such tasks independently due to physical limitations or health conditions. The robotic arm's precision allowed for accurate positioning over the cup, ensuring a controlled and spill-free pouring process. The gripper's dexterity enabled the arm to securely hold and manipulate the water bottle, providing a level of assistance that could contribute to patients' autonomy and well-being. By automating simple yet essential tasks like pouring water, the UFACTORY xArm7 and gripper combination enhanced the efficiency of healthcare facilities, allowing healthcare professionals to focus on more complex aspects of patient care while simultaneously promoting patients' independence and comfort. Developing a Python code implementation for pouring water from a bottle into a cup using the UFACTORY xArm7 robotic arm and gripper in a healthcare setting involved integrating precision and control to assist patients with limited mobility. The code initiated the robotic arm's movement to grasp the water bottle securely with the gripper, navigated to a predetermined position over the cup, and gradually tilted the bottle to pour water accurately. Implementing safety measures was crucial, ensuring a controlled pouring process that minimizes the risk of spillage. Additionally, the code could incorporate feedback mechanisms to adapt to varying bottle sizes or environmental factors. This automation aimed to empower patients in healthcare scenarios, promoting independence and alleviating the burden on healthcare professionals for routine caregiving tasks, enhancing the overall quality of patient care.

3) Deliver food / deliver medicine: Creating a Python code implementation for delivering food or medicine to patients using the UFACTORY xArm7 robotic arm and gripper introduced a transformational aspect to healthcare assistance. The code was designed to facilitate the robotic arm's precise movement to pick up a designated package containing

either food or medicine with the gripper. It then navigated through predefined paths to reach the patient's location and gently release the package. Implementing safety protocols was paramount to ensure the robotic arm operates in a controlled manner, avoiding any harm to patients or surroundings. The code also incorporated obstacle detection and avoidance mechanisms to navigate through dynamic environments. By automating the delivery process, this code aimed to enhance operational efficiency within healthcare facilities, allowing healthcare professionals to focus on more intricate aspects of patient care, while simultaneously providing timely and convenient services to patients in need.

4) Take temperature: Implementing a Python code for the UFACTORY xArm7 robotic arm and gripper to take the temperature of patients in a healthcare setting introduced a sophisticated level of automation. The code instructed the robotic arm to grasp a non-contact infrared thermometer using the gripper, ensuring a secure hold. The arm then carefully approached the patient, positioned the thermometer at the appropriate distance, and triggered the temperature measurement. To enhance the code's functionality, it incorporated features such as patient identification, precise positioning, and data logging for accurate record-keeping. Safety measures, including controlled movement and obstacle detection, were crucial to guarantee the well-being of patients during the temperature-checking process. By automating temperature measurements, this code contributed to the efficiency of healthcare operations, reduced the risk of cross-contamination, and allowed healthcare professionals to allocate more time to critical aspects of patient care.

C. Experimental Performances of Assisted Robotic Arm

The experimental performances of the assisted robot arm were taken as videos. Screen captures of the videos were gathered to show the performance of the assisted arm. Fig. 11 shows assisted robot arm cleaning area, pouring Water, delivering medicine and taking body temperature. Fig. 12 shows the example process of assisted robot arm pouring water.

Fig. 11. Assisted robot Arm cleaning area, pouring water, delivering medicine, taking body temperature.

D. Recorded Robot Movement in 3D modeling Environment of the Assisted Robotic Arm

The UFACTORY *xArm Studio* software provides a three-dimensional modeling environment for recording, visualizing, and replaying robotic movements. During task execution, the positions and orientations of the robotic arm are continuously recorded and displayed using a real-time 3D model that mirrors the physical robot. An example is shown in Fig. 13. This environment allows users to verify joint trajectories, monitor

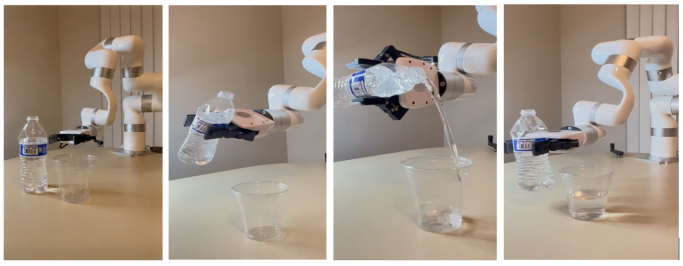

Fig. 12. Assisted robot Arm completing tasks of pouring water.

end-effector motion, and evaluate the sequence of programmed operations before deployment. The recording function also enables previously executed motions to be replayed for debugging, trajectory refinement, and performance validation. By providing a synchronized digital representation of the physical robotic system, the 3D modeling environment facilitates efficient program development and improves the reliability of healthcare assistance tasks.

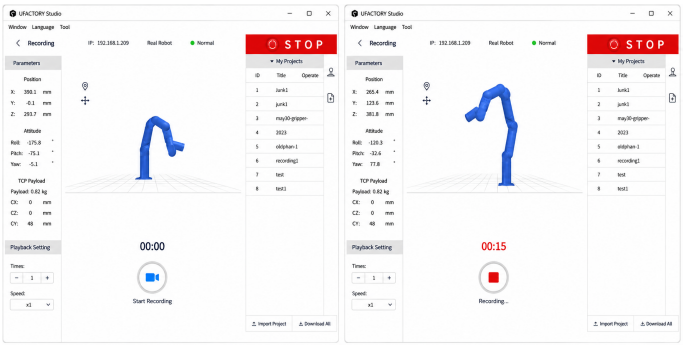

Fig. 13. Recoreded robot movement in 3D modeling environment.

IV. System Validation of Assisted Robotic Arm Performance for Example Tasks and Use Cases

A total of 100 different voice commands related to the supported robotic healthcare tasks were evaluated to assess the performance of the LLM-based task classification system. The test commands represented different natural-language expressions associated with four predefined task categories: `POUR_WATER`, `CLEAN_AREA`, `DELIVER_MEDICINE`, and `TAKE_TEMPERATURE`. Rather than requiring users to speak an exact predefined phrase, the experiment included variations in wording and play the wording with audio to evaluate whether the LLM could identify the intended robotic action from the semantic meaning of each command. Of the 100 commands, 97 were mapped to the intended task category, resulting in an overall classification accuracy of 97%. The three classification errors were associated with commands containing ambiguous or overlapping semantic information. For example, an expression such as "pouring medicine" can contain information related to both the `POUR_WATER` and `DELIVER_MEDICINE` categories. These results indicate that the LLM-based approach can provide flexible natural-language control while also demonstrating the need for ambiguity detection and confirmation mechanisms before physical robot execution.

Table I presents the confusion-matrix representation of the classification results. The diagonal elements indicate correctly classified commands, whereas the off-diagonal elements represent classification errors. In this example, 25 commands were evaluated for each task category, producing 97 correct classifications and three misclassifications.

TABLE I. CONFUSION MATRIX FOR LLM-BASED TASK CLASSIFICATION

Actual Task	Predicted Task			
	Water	**Clean**	**Medicine**	**Temp.**
Water	**24**	0	1	0
Clean	0	**25**	0	0
Medicine	1	0	**24**	0
Temperature	0	0	1	**24**

The three off-diagonal entries represent the three classification errors. The bold diagonal values make the correct classifications particularly easy to identify.

The confusion matrix shows that most predictions are concentrated along the main diagonal, demonstrating strong agreement between the intended task and the task selected by the LLM. The remaining errors illustrate an important limitation of natural-language robotic control: semantically similar or ambiguous expressions can occasionally be assigned to an incorrect action. This issue is particularly important in healthcare-oriented applications because an incorrect classification could initiate an unintended robotic operation. Future versions of the system can therefore incorporate an `UNKNOWN` or `AMBIGUOUS` category, confidence thresholds, and a confirmation step in which the system asks the user to verify the interpreted task before executing potentially safety-sensitive actions. These mechanisms could further improve the reliability of the natural-language interface while preserving the flexibility provided by LLM-based intent interpretation.

The robotic healthcare assistant was validated using repeated task-based experiments. Four representative functions were evaluated: removal of contaminated materials, water pouring, medicine delivery, and body-temperature measurement. Each task was performed ten times under the same experimental conditions. Task success, execution time, end-effector positioning error, repeatability, and operational safety were recorded for every trial.

For motion validation, the commanded Cartesian coordinates were compared with the measured end-effector coordinates. The three-dimensional positioning error was calculated as:

$$E = \sqrt{(X_m - X_t)^2 + (Y_m - Y_t)^2 + (Z_m - Z_t)^2}, \qquad (1)$$

where, (X_t, Y_t, Z_t) represents the commanded target position and (X_m, Y_m, Z_m) represents the measured position. Repeatability was evaluated using the standard deviation of the measured coordinates across repeated trials. A task was considered successfully validated when at least 90% of the trials were completed correctly, the average positioning error remained below 5 mm, and no critical collision, uncontrolled motion, or object-dropping event occurred. The validation results were then compared across the four healthcare tasks to evaluate the reliability of the complete robotic system. The validation criteria for the robot healthcare system is as Table II.

Table III shows the validation details for pouring water. For the pouring-water function specifically, validation test the full sequence from opening the gripper through returning the bottle. The bottle is placed at a fixed starting location, and the cup remains at a known target location. Each trial determine whether the robot successfully grasps the bottle, lifts it without slipping, reaches the pouring position, tilts the bottle, returns it upright, replaces it, and releases it correctly.

TABLE II. VALIDATION CRITERIA FOR THE ROBOTIC HEALTHCARE SYSTEM

Metric	Measurement	Acceptance Criterion
Task Success	Successful trials / total trials	$\geq 90\%$
Position Error	Euclidean distance between target and measured XYZ	≤ 5 mm
Repeatability	Standard deviation of repeated XYZ measurements	≤ 3 mm
Execution Time	Time required to complete each task	Stable across trials
Command Response	Correct execution after user/software command	$\geq 90\%$
Safety	Collision, dropped object, or uncontrolled motion	0 critical events

TABLE III. VALIDATION OF THE ROBOTIC WATER-POURING SEQUENCE

Step	Operation	Expected Result	Criterion	Status
1	Open gripper	Gripper opens	Correct position	Pass
2	Move to bottle	Reaches bottle	Error ≤ 5 mm	Pass
3	Grasp bottle	Bottle secured	No slipping	Pass
4	Lift bottle	Reaches safe height	Error ≤ 5 mm	Pass
5	Move above cup	Reaches pour point	Error ≤ 5 mm	Pass
6	Tilt bottle	Water poured	Correct rotation	Pass
7	Return upright	Pouring stops	No continued flow	Pass
8	Replace bottle	Returns to target	Error ≤ 5 mm	Pass
9	Release bottle	Bottle stable	No tipping	Pass
10	Return arm	Reaches home	Error ≤ 5 mm	Pass

TABLE IV. EXPERIMENTAL VALIDATION RESULTS

Task	Trials	Success	Rate (%)	Time (s)	Error (mm)	Result
Remove Material	10	10	100	10.4	1.42	Pass
Pour Water	10	9	90	10.8	1.61	Pass
Deliver Medicine	10	10	100	9.7	1.28	Pass
Measure Temperature	10	10	100	10.1	1.35	Pass
Overall	**40**	**39**	**97.5**	**10.25**	**1.42**	**Pass**

Table IV presents the experimental validation results of the robotic healthcare assistance system for four representative tasks: removing contaminated material, pouring water, delivering medicine, and measuring body temperature. Each task was repeated ten times to examine the reliability of the robotic arm under consistent experimental conditions. The

system successfully completed 39 of the 40 trials, resulting in an overall task success rate of 97.5%. Three tasks achieved a 100% success rate, while the water-pouring task achieved 90%, indicating one unsuccessful trial. The lower success rate for water pouring can be attributed to the greater manipulation complexity of this task, which requires the robot to grasp the bottle, lift it, move toward the target, control the wrist orientation during pouring, and return the bottle to its original position.

The execution time remained relatively consistent among the four tasks, ranging from 9.7 s for medicine delivery to 10.8 s for water pouring. The overall mean execution time was 10.25 s. Water pouring required the longest time because it involved additional movements for grasping, lifting, tilting, and returning the bottle. In comparison, medicine delivery produced the shortest execution time. These results suggest that the robotic system can complete the selected point-of-care activities within a relatively consistent time range despite differences in task requirements.

Positioning performance was evaluated using the mean error between the target and measured end-effector positions. As shown in Table IV, the mean errors ranged from 1.28 mm to 1.61 mm, with an overall mean of 1.42 mm. Medicine delivery produced the lowest positioning error of 1.28 mm, whereas water pouring produced the highest error of 1.61 mm. The increased error during pouring may result from the additional changes in arm position and wrist orientation required to manipulate the bottle. Nevertheless, all measured errors remained below the predefined 5 mm acceptance threshold. The combination of a 97% overall success rate, an average execution time of 10.25 s, and a mean positioning error of 1.42 mm indicates that the developed robotic arm system can perform the tested healthcare assistance tasks with good repeatability and operational reliability. These results support the feasibility of the proposed system for further development as an intelligent robotic assistant for routine point-of-care applications.

A. Discussion of Errors and Potential Improvements

The experimental results demonstrate that the proposed system can successfully integrate voice recognition, LLM-based intent classification, and robotic task execution; however, several sources of error were observed. For the natural-language control component, the LLM-based task classification achieved an accuracy of 97%, indicating that a small proportion of the tested commands were incorrectly classified. One important source of error was ambiguity in the user's spoken request. For example, an expression such as "pouring medicine" contains semantic information associated with both the POUR_WATER and DELIVER_MEDICINE classes. Consequently, the LLM may assign an incorrect task when the input contains overlapping terminology or does not clearly describe the intended action. Speech-to-text errors can further contribute to incorrect classifications because inaccurate transcription changes the textual input provided to the LLM.

Several approaches can be used to improve the reliability of the natural-language control component. First, an `UNKNOWN` class can be incorporated so that ambiguous or low-confidence commands do not immediately initiate robotic motion. Instead, the system can request clarification from the user, such as asking whether the user intends to pour water or receive medicine. Second, task-specific prompts and additional representative command examples can be provided to the LLM to improve intent classification. The system can also require confirmation before executing safety-sensitive activities, particularly medicine-related tasks. These modifications would reduce the probability that an incorrectly interpreted command results in an unintended robotic action.

Errors can also occur during physical robotic execution. Although predefined Cartesian coordinates allow the xArm7 to repeatedly approach known target locations, small positioning differences can result from calibration uncertainty, coordinate-system alignment, object-placement variation, gripper positioning, and mechanical repeatability. Manipulation tasks such as grasping a bottle and pouring water are particularly sensitive because a small displacement of the bottle or cup can affect grasping and pouring performance. Differences between commanded and measured end-effector coordinates therefore provide an important quantitative indication of robotic positioning error.

Currently the level of intelligence of automation is at the basic level where the motion were predefined without sensor input to enhance the level of intelligence. Future improvements should incorporate additional sensor feedback rather than relying primarily on predefined positions and motion sequences. A camera-based vision system could identify the real-time locations of bottles, cups, medicine containers, and other objects before manipulation. Visual feedback could then be used to dynamically modify the target coordinates instead of assuming that objects remain at exactly the same locations. Force or tactile sensing at the gripper could additionally determine whether an object has been successfully grasped and detect unexpected contact. Combining visual perception, force feedback, collision detection, and closed-loop trajectory correction would enable the robotic system to adapt to variations in the environment and improve manipulation reliability.

Further improvements also include adding more trials for the validation. For example, for the validation of the LLMs, we didn't test on the execution time and potential delays although through observation, those were not the major potential problems for the system to function. Moreover, for the assisted robot arm's performance, the 97.5 percent overall success rate and a 1.42 mm mean positioning error, rest on only ten trials per task, so the work can be toward reporting trial-level variability or increase the sample size. More comparisons could be done to compare with previous studies in the same scope.

Overall, the observed errors highlight the importance of validating both the intelligent interaction layer and the physical robotic layer. The LLM provides flexibility in understanding natural-language requests, while predefined robot routines provide controlled task execution; nevertheless, uncertainty can be introduced at the speech-recognition, intent-classification, coordinate-calibration, and manipulation stages. Future development should therefore emphasize confidence-based intent classification, user confirmation for ambiguous commands, improved calibration, real-time object detection, sensor-based feedback, and closed-loop robotic control. These improvements could increase the robustness of the proposed system

and provide a stronger foundation for future evaluation in more realistic healthcare environments.

V. Discussions

The findings of this study demonstrate the feasibility of employing a collaborative robotic manipulator as an intelligent assistant for healthcare applications. The proposed system successfully integrates robotic manipulation, autonomous task execution, and software-based control into a unified platform capable of supporting routine patient-care activities. By automating repetitive bedside tasks, such as object delivery and physiological monitoring, the robotic assistant has the potential to reduce the physical workload of healthcare professionals while allowing them to devote greater attention to clinical decision-making and direct patient interaction. The integration of collaborative robotics into healthcare environments therefore represents a promising approach for improving operational efficiency without replacing the essential role of medical personnel.

One of the primary contributions of this work is the development of a modular software architecture that combines robot motion control, task planning, user interaction, and potential sensor integration using Python. The modular design enables individual system components to be independently updated or expanded, facilitating future integration of additional sensing devices and artificial intelligence techniques.

The practical deployment of collaborative robotic assistants requires consideration of economic and operational factors. As collaborative robot technology continues to mature and hardware costs decrease, robotic assistants may become increasingly cost-effective, particularly for performing predictable and repetitive tasks that consume substantial nursing resources. Improvements in usability, interoperability with hospital information systems, and standardized deployment procedures are planned for future work.

VI. Conclusions and Future Work

This study developed and evaluated an intelligent robotic patient-assistance framework that integrates collaborative robotic manipulation, voice-based natural-language interaction, and non-contact physiological monitoring. The UFACTORY xArm7 collaborative manipulator was used as the primary robotic platform to perform representative patient-care tasks, including cleaning a designated area, pouring water, delivering medicine, and taking body temperature. The proposed framework demonstrates how a collaborative robotic arm can be programmed to provide physical assistance for predictable and repetitive bedside activities while maintaining a software architecture that can be expanded to accommodate additional healthcare-related functions.

A significant contribution of this research is the integration of natural-language voice control with robotic task execution. The developed software uses continuous speech-to-text processing to convert spoken user requests into textual information, which is subsequently analyzed by a Large Language Model to determine the intended robotic task. This approach enables users to communicate with the robotic assistant using natural expressions rather than memorizing a fixed set of commands. Evaluation demonstrates the potential of LLM-based intent recognition for intuitive human–robot interaction. However, ambiguous expressions, such as commands containing terminology associated with multiple tasks, can result in incorrect classifications.

The integration of non-contact physiological monitoring further extends the functionality of the robotic platform beyond conventional object manipulation. In this study, body-temperature measurement was incorporated as a representative monitoring task in which the robotic arm positions a non-contact infrared thermometer for patient measurement. Combining physical assistance, physiological sensing, and natural-language interaction within the same robotic framework provides a foundation for developing more comprehensive patient-support systems. Future implementations could extend this architecture to additional non-contact sensors and more advanced perception capabilities while preserving appropriate clinical supervision.

Overall, the findings demonstrate the feasibility of combining collaborative robotics, Python-based robot control, LLM-enabled natural-language interaction, and physiological sensing within a unified healthcare-assistance framework. The proposed system is not intended to replace nurses or other healthcare professionals; instead, it provides a technological approach for supporting selected repetitive and predictable activities that can consume caregiver time. Future research should focus on improving recognition of ambiguous commands, integrating environmental perception and obstacle avoidance, expanding physiological sensing capabilities, and conducting evaluations in more realistic patient-care environments. Further development of these capabilities could enable robotic assistants to provide more adaptive and accessible support while allowing healthcare professionals to concentrate on clinical assessment, decision-making, and direct patient interaction.

Beyond healthcare assistance, the proposed collaborative robotic platform has potential to support individuals with upper-limb impairments in performing activities of daily living. A collaborative robotic arm positioned beside a bed or wheelchair can assist with tasks such as retrieving personal items, delivering food or medication, and providing drinking assistance through intuitive user interfaces, including touch or voice commands. By combining autonomous manipulation with intelligent motion planning, the robotic system can improve user independence, reduce reliance on caregivers, and enhance quality of life. Future research may incorporate advanced perception and artificial intelligence to provide more adaptive, personalized assistance in home and rehabilitation environments.

When Agents Delegate: Accountability Chains in Multi-Agent AI Systems

Ornella Bahidika
Independent Researcher, Seattle, USA

***Abstract*—Ethical frameworks for the oversight of autonomous AI systems generally assume a dyadic relationship: one human principal authorizing and supervising one artificial agent. Deployed practice has moved on. Contemporary agentic systems decompose tasks and delegate them onward, to sub-agents they instantiate, to third-party agents discovered through interoperability protocols, and to tools whose own behavior is agentic. Each hop in such a delegation chain attenuates the three prerequisites on which accountability depends: authorized scope, attributable intent, and reconstructable provenance. This study analyzes the resulting accountability gap. We contribute a taxonomy of delegation structures in deployed agentic systems; an analysis of four failure modes by which delegation dissolves accountability, which we term authorization dilution, intent drift, provenance loss, and responsibility laundering; a normative framework, the Delegation Accountability Chain, comprising five conditions under which multi-agent delegation remains compatible with meaningful human oversight; an audit of five widely used interoperability protocols and orchestration frameworks (the Model Context Protocol, the Agent2Agent protocol, LangGraph, AutoGen, and the OpenAI Agents SDK) against the five conditions, finding that none satisfies any condition chain-wide at a mandatory level; and a mapping of the conditions onto the human-oversight obligations of the EU Artificial Intelligence Act and the NIST AI Risk Management Framework, both drafted for the dyadic case. We argue that the question of where the buck stops has a defensible answer in multi-agent systems only if delegation is constrained by design.**

Keywords*—*Agentic AI; accountability; delegation; multi-agent systems; human oversight; AI governance; responsibility gap

I. Introduction

In earlier work we asked where the buck stops when an autonomous AI system acts consequentially on a human's behalf, proposed an action-level tiered oversight framework calibrated by stakes and reversibility, and identified tier laundering, the composition of individually low-tier actions into a higher-tier outcome, as the central methodological gap in per-action oversight [1]. That work named composition-aware oversight as the highest-leverage direction for follow-up research. Like nearly all of the human-oversight literature it engaged, that earlier analysis presumed a single agent answerable to a single accountable human. The present study takes up its follow-up program for the setting in which composition is most acute and least governed: delegation among agents.

The deployed world has moved past that presumption. Production agentic systems now plan by decomposition: an orchestrating agent breaks a goal into subtasks and assigns them to other agents. Interoperability protocols such as the Model Context Protocol and agent-to-agent communication standards make it routine for an agent to enlist capabilities that its human principal never inspected, sourced from parties the principal never chose [2], [3]. Each such hop is a delegation, an operation classical accountability theory treats with suspicion: Bovens defines accountability as a relationship in which an actor is obliged to explain and justify conduct to a forum that can pose questions and impose consequences [4]. A forum cannot pose questions to a chain whose links it cannot see. Fig. 1 contrasts the two settings.

This study asks what oversight can mean when the overseen agent is itself a principal to other agents. We proceed as follows. Section II situates the problem in the responsibility-gap literature and shows that current regulatory instruments assume the dyadic case. Section III offers a taxonomy of delegation structures observed in deployed systems. Section IV analyzes four failure modes by which delegation dissolves accountability. Section V presents the Delegation Accountability Chain, five conditions under which delegation remains compatible with meaningful human oversight. Section VI audits five widely deployed interoperability protocols and orchestration frameworks against the conditions. Section VII maps the conditions onto the EU AI Act and the NIST AI RMF. Section VIII considers objections and limitations, and Section IX concludes.

II. Background and Related Work

Three bodies of work frame human oversight of AI, and all three exhibit the dyadic assumption.

1) Responsibility gaps: Matthias observed two decades ago that learning machines create situations in which no human satisfies the classical conditions for responsibility, control and knowledge [5]. Nissenbaum earlier identified "many hands" as a barrier to accountability in computerized systems [6]. Delegating agents combine both problems: the hands are now artificial and generated at runtime.

2) Meaningful human control: Santoni de Sio and van den Hoven's influential account requires that autonomous systems track the reasons of the relevant humans and that their behavior be traceable to a proper moral and technical understanding by designers and operators [7]. Both the tracking and tracing conditions are defined against a fixed system boundary. Delegation makes the boundary dynamic: the "system" at time t includes agents that did not exist at deployment time.

3) Multi-agent systems and capability security: Two older literatures bear directly on delegation and are rarely joined to the oversight debate. Multi-agent systems research has studied cooperation, negotiation, and delegation among software

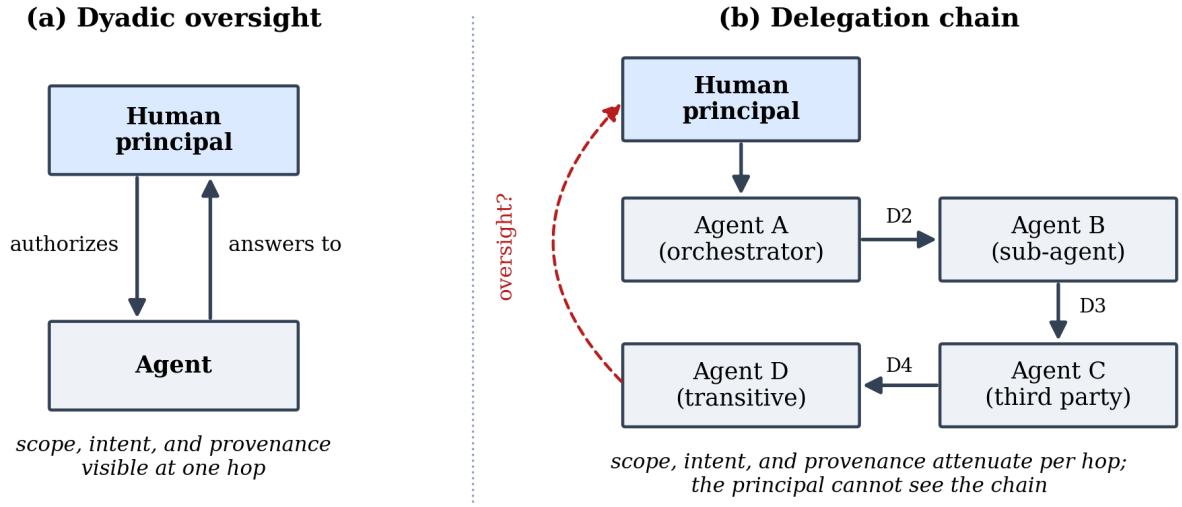

Fig. 1. Dyadic oversight versus a delegation chain. In the dyad, authorization and answerability meet at a single hop. In a chain, scope, intent, and provenance attenuate per hop, and the principal cannot see the chain acting under its grant.

agents since the 1990s [8], but its concern was coordination among agents, not accountability of agents to humans; the field's delegation formalisms assume the principals are themselves agents. Capability security, by contrast, is about conveying bounded authority: Hardy's confused-deputy analysis showed that authority which travels implicitly is authority that gets misused [9], and the object-capability tradition demonstrated that authorization can be made to travel as an unforgeable artifact that composes safely [10]. The framework of Section V can be read as importing the capability discipline into the human-oversight debate: what capability systems do for programs, delegation-accountability conditions must do for chains that terminate in a responsible person.

4) Regulatory instruments: Article 14 of the EU AI Act requires that high-risk systems be designed so that natural persons can effectively oversee them, including the ability to understand capacities and limitations, remain aware of automation bias, correctly interpret output, and intervene or interrupt [11]. The NIST AI Risk Management Framework likewise organizes its Govern, Map, Measure, and Manage functions around an identified system with an identified operator [12]. Neither instrument contemplates a system that recruits other systems after deployment; both implicitly assume the object of oversight is the object that was assessed.

Recent work has begun to note the strain. Ethics-based auditing programs presume access to a bounded artifact [13]; scholars of the algorithmic society observe that autonomy blurs attribution [14]; practitioner commentary asks the buck-stops question of agentic AI directly [15]; and Chan et al. propose concrete visibility mechanisms for agents, including identifiers, real-time monitoring, and activity logs [16]. Closer still, concurrent work proposes point mechanisms for delegation itself: a cryptographic protocol that accumulates signed per-hop records anchored in a human principal's declared scope [17], identity-governance infrastructure for propagating authorization through multi-agent systems [18], and a draft Internet standard for human-anchored agent identity, delegation, and provenance [19]. These proposals supply individual mechanisms. What this study adds is an account of delegation as the mechanism by which attribution dissolves; an argument that the five conditions of Section V must hold jointly and be defined over chains rather than agents, since a compliant agent delegating to a compliant agent does not yield a compliant chain; and an audit showing that none of these mechanisms, proposed or shipped, is required by the specifications agents actually run on.

III. A Taxonomy of Delegation in Deployed Agentic Systems

We distinguish four delegation structures, ordered by increasing accountability risk, and note a deployed public example of each.

1) D1. Static tool invocation: The agent calls a fixed, enumerated tool (a search API, a database query). The tool set is known at deployment and can be assessed with the system. This is delegation only in a degenerate sense; classical oversight frameworks handle it. Mainstream chat assistants invoking a fixed web-search or code-execution tool exemplify this class.

2) D2. Self-decomposition: An orchestrating agent instantiates subordinate agents of its own kind, assigns them subtasks, and integrates their results. The sub-agents inherit the orchestrator's capabilities but not necessarily its constraints; whether instructions, permissions, and prohibitions survive the handoff is an implementation choice, often an accidental one. Anthropic's production research system is a documented public example: a lead orchestrator agent decomposes a query and spawns parallel subagents whose results it synthesizes [20].

3) D3. Heterogeneous enlistment: The agent discovers and engages third-party agents or services through an interoperability protocol. The enlisted party was built by a different organization, is governed by different policies, and may change its behavior between the principal's assessment and the moment of use. The MCP ecosystem exemplifies this class: hosts routinely connect to community-published third-party servers,

and the A2A protocol was designed expressly for cross-vendor agent enlistment [2], [3].

4) D4. Transitive delegation: An enlisted agent itself delegates onward, producing chains of depth greater than two. No party in the chain, including the original human principal, has visibility over the full set of actors, and depth is unbounded in current protocols. The audited specifications themselves contemplate this class: an MCP server may act as an OAuth client to upstream services, and A2A permits a server to relay authorization requirements through a chain of dependent tasks (Section VI).

Table I summarizes the four classes.

TABLE I. DELEGATION STRUCTURES IN DEPLOYED AGENTIC SYSTEMS

Class	Delegate set	Public example	Principal's visibility
D1 Static tool invocation	Fixed and enumerable at deployment	Chat assistant with a fixed search or code tool	Full
D2 Self-decomposition	Instantiated at runtime by the orchestrator	Orchestrator spawning parallel subagents [20]	Partial
D3 Heterogeneous enlistment	Discovered at runtime from third parties	Community MCP servers; A2A cross-vendor agents [2], [3]	Low
D4 Transitive delegation	Recursively assembled, unbounded	Servers acting as clients to upstream services (Section VI)	None

Two properties make D2 through D4 categorically different from D1. First, the delegate set is determined at runtime, so pre-deployment assessment cannot enumerate it. Second, delegation is composable, so any framework that governs only single hops fails by induction: a compliant agent delegating to a compliant agent does not yield a compliant chain unless compliance is defined over chains.

IV. FOUR WAYS DELEGATION DISSOLVES ACCOUNTABILITY

A. Authorization Dilution

A human authorizes an agent for a scope: purposes, resources, and limits. When the agent delegates, the effective scope of the delegate is whatever the delegating agent communicates, which may be broader than, narrower than, or simply different from the original grant. Across hops, the human's authorization becomes a rumor. The delegate acts under a scope no human issued. Where a delegate exercises inherited credentials broader than the human's grant, this is the confused-deputy problem in its classic ambient-authority form [9]; where scope degrades through linguistic restatement, the failure is distinct but the remedy is the same: authority must travel explicitly or not at all.

B. Intent Drift

Each delegation restates the goal. Restatement is interpretation, and interpretation by a language model is lossy and generative at once: constraints are dropped, emphases shift, and instrumental subgoals are elevated to ends. The terminal agent in a chain may faithfully execute an instruction that no human ever gave. Drift is not misbehavior by any single link; every link may act reasonably on what it received. The failure is emergent, which is why per-agent oversight cannot detect it.

C. Provenance Loss

Accountability requires reconstruction: which information the system received, what it retrieved, which actions it took, and why [21]. In a delegation chain, the records that would answer these questions are scattered across parties with different logging practices, retention policies, and disclosure obligations, or are not produced at all. The forum, in Bovens's sense, has no dossier to examine. Post-incident, it can be impossible even to establish that a chain existed.

D. Responsibility Laundering

The most corrosive failure is intentional or negligent exploitation of the first three: structuring action through delegation so that no identifiable party bears responsibility. The pattern is kin to agency laundering, in which humans obscure their own responsibility by routing decisions through automated systems [22]; responsibility laundering is its multi-agent completion: the routing is performed by agents, and no single human need intend the obfuscation. It also generalizes the tier-laundering pattern identified in our earlier framework [1]: where tier laundering composes low-tier actions within a single agent into a high-tier outcome, responsibility laundering composes individually oversightable agents into an unoversightable chain. Where a human organization performing the same decomposition would face joint liability doctrines, agent chains today face none. If accountability attaches only to single human-agent dyads, delegation becomes a machine for converting responsible action into unattributable outcome. Regulation that ignores this creates an incentive gradient toward deeper chains.

E. A Worked Example

The four failure modes rarely occur alone; a single ordinary chain can exhibit all of them. Consider a procurement assistant, authorized by an operations manager to renew existing software subscriptions up to a set monthly amount. Faced with a renewal that requires a vendor form, the orchestrator spawns a sub-agent to handle vendor interaction (self-decomposition) and, finding the vendor exposes an agent interface, enlists it through an interoperability protocol (heterogeneous enlistment). The vendor's agent, in turn, calls its own payment-processing agent (transitive delegation). At the first hop, the manager's spending cap and renewals-only restriction survive only as sentences in a prompt; the sub-agent inherits the orchestrator's payment credential, whose scope is whatever the credential allows rather than what the manager authorized (authorization dilution). Restating the goal as "complete the vendor's renewal process" drops the cap and the renewals-only qualifier, and the vendor's agent reasonably treats an upsell bundle as part of that process (intent drift). When the resulting charge exceeds anything the manager approved, the reconstruction spans the deployer's logs, the vendor's logs, and a payment processor's records, none linked by a shared identifier and none obliged to disclose (provenance loss). Each party can truthfully say it executed the instructions it received, and the vendor can note that its agent was never told about

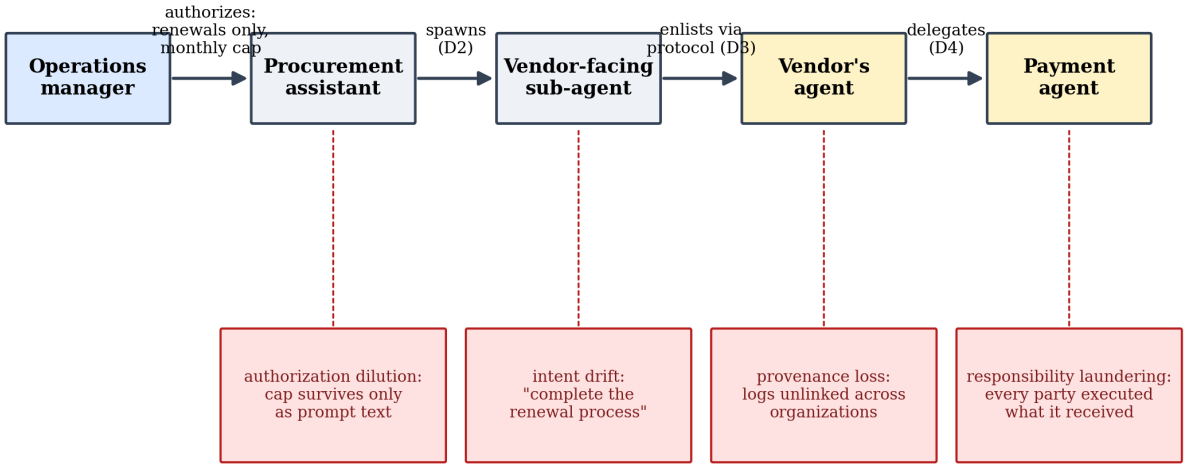

Fig. 2. The worked example: an ordinary procurement chain exhibiting all four failure modes. No party misbehaves; the accountability failure is structural.

any cap; no identifiable party bears the failure (responsibility laundering). Nothing in this chain requires malice or unusual carelessness. Fig. 2 traces the chain and its failures. Section VI shows that the infrastructure such a chain would run on today provides none of the mechanisms that would have interrupted it.

V. The Delegation Accountability Chain

We propose five conditions, jointly necessary for a delegating agentic system to support claims of meaningful human oversight. The conditions are design constraints: each is checkable against an implementation.

1) C1. Conserved authorization: A delegate's effective scope must be a subset of the delegator's scope, enforced mechanically rather than communicated linguistically. Scope must travel as a verifiable artifact (a capability token or its equivalent) that downstream agents cannot expand. The chain-wide invariant is that no action occurs outside the original human grant.

2) C2. Human anchor: Every chain terminates, upward, in an identified natural person or accountable body that issued the originating authorization and remains the answerable party for the chain's aggregate conduct. Anchorship is non-delegable: an agent cannot become an anchor. This preserves Bovens's forum relationship: there is always someone obliged to explain.

3) C3. Attributable initiation: Every delegation event must record who delegated, to whom, under what communicated goal, and under what scope, in a form attributable to the anchor's chain. Delegation to parties that refuse attribution is prohibited conduct, not a logging gap.

4) C4. Chain-complete provenance: The reconstruction standard that audit scholarship applies to single systems [21] must be defined over the chain: a single query, anchored at the human principal, must be able to produce the full delegation tree with per-link records sufficient to answer what was received, retrieved, and done, and what rationale was stated. Practically this requires provenance to propagate with the work, not to be assembled forensically afterward.

5) C5. Bounded depth and diameter: Because drift and dilution compound per hop, chains must carry explicit limits on delegation depth and on the set of admissible delegates, set by the anchor as part of the original grant. Unbounded delegation defeats oversight, and assessors should treat it as a per se failure of Article 14-style obligations.

Each condition carries an operational test an assessor can apply; Table II states them.

TABLE II. The Delegation Accountability Chain: Conditions and Operational Tests

Condition	Requirement	Operational test
C1 Conserved authorization	Delegate scope is a mechanically enforced subset of the delegator's	Every delegated credential is cryptographically derived from, and attenuates, the parent grant
C2 Human anchor	Every chain terminates upward in an identified accountable person or body	Any action in the chain resolves in a single lookup to an identified anchor
C3 Attributable initiation	Every delegation event is recorded and attributable	Every delegation edge exists as a typed record naming delegator, delegatee, goal, and scope
C4 Chain-complete provenance	The full delegation tree is reconstructable from the origin	One anchor-issued query returns the full tree with per-link records
C5 Bounded depth and diameter	The grant limits delegation depth and admissible delegates	The grant carries explicit bounds the runtime refuses to exceed

Deterministic enforcement is the connective tissue of the five conditions. Linguistic instruction is the medium of drift; only mechanisms outside the model, gating code that validates scope, records provenance, and refuses noncompliant delegation, can carry authorization across hops without loss. The design stance is that the agent proposes and the mechanism decides, a pattern practitioners have converged on independently for reliability reasons, and which we here argue has normative status: it is what makes delegation oversightable at all.

VI. Do Current Protocols Satisfy the Chain Conditions? An Audit

The conditions of Section V would be of limited interest if the ecosystem already met them. To assess this, we audited the current normative specifications and official documentation of five artifacts, selected as the most widely adopted interoperability protocols and multi-agent orchestration frameworks at the time of writing (Table III): the Model Context Protocol (MCP, specification revision 2026-07-28), the Agent2Agent protocol (A2A, specification 1.0.0), and the LangGraph, Microsoft AutoGen, and OpenAI Agents SDK frameworks (documentation as of August 2026). For each artifact we assessed each condition as satisfied (a mandatory, MUST-level mechanism exists at protocol or framework level), partial (optional, SHOULD-level, or achievable only through application-level configuration), or absent (no relevant provision; we record what was searched and not found). Two clarifications govern the exercise. First, the three frameworks are developer libraries that make no governance claims of their own; we audit them not against their own claims but against the oversight claims deployers make for systems built on them, because those are the claims the conditions of Section V underwrite. Second, the mandatory-mechanism bar is deliberate. For accountability in particular, optional recording is weak assurance, because the parties best positioned to disable a record are the parties it would hold to account (Section IV-D); default-on but disable-able is therefore materially different from mandatory. We audit what each artifact guarantees rather than what a diligent application could build atop it; whatever is not guaranteed is left to the discretion of each implementer. Audit working notes, including full verbatim quotations and source URLs for every assessment, are available as supplementary material (S1: audit working notes; S2: machine-readable audit evidence) at https://github.com/ornellabahidika/when-agents-delegate-supplement.

No cell in the table is satisfied; Fig. 3 visualizes the verdicts. We discuss each artifact, then the pattern.

A. Model Context Protocol

MCP contains the strongest single-hop authorization mechanics of any audited artifact, and their limits are instructive. When authorization is used, it is mandatory in the details: clients MUST implement OAuth 2.0 Resource Indicators (RFC 8707), servers "MUST validate that access tokens were issued specifically for them as the intended audience," and token passthrough is prohibited ("MCP servers MUST NOT accept or transit any other tokens"); the protocol's separate security-best-practices document repeats the ban ("MCP servers MUST NOT accept any tokens that were not explicitly issued for the MCP server"). But authorization as a whole is "OPTIONAL for MCP implementations," applies only to HTTP transports (local stdio servers sit outside the framework and are directed to ambient environment credentials, the classic confused-deputy configuration [9]), and it is pairwise: each hop obtains a separate token from its own authorization server, so a delegate's effective scope is set by that server's policy, not derived from the delegator's grant; scope subsetting appears only as guidance ("MCP clients SHOULD follow the principle of least privilege"). The consent model is anchored at the human-to-host hop and the specification is direct about its reach: "While MCP itself cannot enforce these security principles at the protocol level," implementors are asked, at SHOULD strength, to build robust consent and authorization flows. No message or field records a delegation event (C3), and the spec's own security guidance concedes that passthrough patterns "make incident investigation, controls, and auditing more difficult" without requiring any audit record in response. The architecture works against chain reconstruction by design: servers "should not be able to read the whole conversation, nor 'see into' other servers" (C4). No provision bounds chain length or membership; composability is a design goal ("Servers should be highly composable"), and a server may itself act as an OAuth client to upstream services (C5).

B. Agent2Agent Protocol

A2A mandates per-request security: "Servers MUST reject requests with invalid or missing authentication credentials" and "Servers MUST implement authorization checks on every A2A Protocol Operations request." An OpenID Connect security scheme is defined, so a human principal can be authenticated at a given hop, though the authenticated client is typically an agent or service; the scheme carries end-user identity only where a deployment arranges it. But identity does not travel: "A2A protocol payloads… don't carry user or client identity information directly. Identity is established at the transport/HTTP layer," which means the originating human is invisible one hop beyond the client (C2 partial). No requirement records who delegated what to whom; the protocol's contextId and referenceTaskIds group related tasks informationally but are not delegation records (C3 absent). Tracing and audit appear only in non-normative enterprise guidance at SHOULD strength (C4 partial). Notably, A2A does define one chain-aware construct: a task needing credentials can propagate that need upstream through a chain of tasks in an authorization-required state, with the sensible rule that a credential obtained this way "MUST NOT be assumed to authorize subsequent messages on the Task." This is a credential-acquisition relay rather than an accountability mechanism, but it demonstrates that chain-scoped constructs are expressible at protocol level when designers choose to define them. Nothing bounds chain depth, and agent discovery through published AgentCards is open-ended (C5 absent).

C. LangGraph

LangGraph's multi-agent documentation describes handoffs as control transfer: "Agents transfer control to each other via tool calls." What travels is graph state and control flow, not authorization; a subordinate node's tools are whatever the developer wired in, with no mechanical relation to the delegator's scope (C1 absent). Human involvement exists as the interrupt() primitive, which can "pause before a critical action and ask for approval," but it is optional, per-node, and identifies no one: the docs speak of a generic "human" with no identity or authentication attached (C2 partial). Recording is likewise optional: the docs recommend tracing "the full coordination flow across agents with LangSmith," an external opt-in service, and persistent state history requires configuring a checkpointer (C3, C4 partial). The framework's one always-on limit is enforced: a default recursion limit of 1,000 steps, raised from the long-standing default of 25 in version 1.0.6, with a

TABLE III. AUDIT RESULTS (SATISFIED / PARTIAL / ABSENT)

Artifact	C1 conserved authorization	C2 human anchor	C3 attributable initiation	C4 chain provenance	C5 bounded depth
MCP (2026-07-28)	partial	partial	absent	absent	absent
A2A (1.0.0)	partial	partial	absent	partial	absent
LangGraph	absent	partial	partial	partial	partial
AutoGen	absent	partial	partial	partial	partial
OpenAI Agents SDK	absent	absent	partial	partial	partial

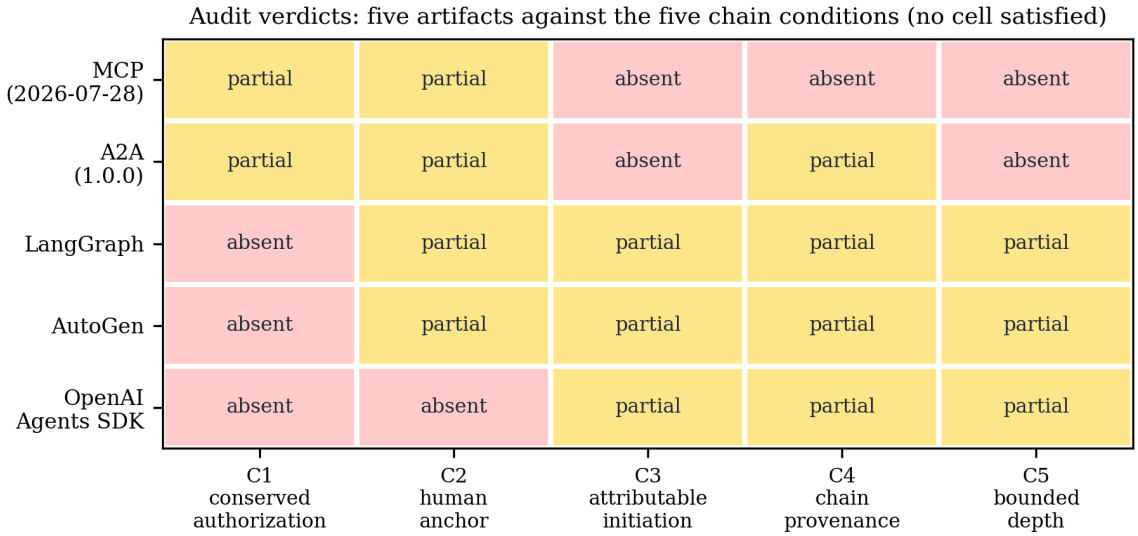

Fig. 3. Audit verdicts for the five artifacts against the five chain conditions. Green would indicate a mandatory chain-level mechanism; no cell qualifies.

hard GraphRecursionError when exceeded. But it bounds the total steps of a run rather than delegation depth or membership, and the caller may raise or effectively remove it (C5 partial).

D. AutoGen

In AutoGen's Swarm pattern, a handoff is a model tool call in a shared conversational context: "agents can hand off task to other agents based on their capabilities," and "all agents share the same message context." The per-agent handoffs list restricts targets, but it is constructor configuration, not a verifiable artifact, and no scope subsetting exists between delegator and delegate (C1 absent). A human control point exists, the UserProxyAgent, which "blocks the execution of the team until the user provides feedback or errors out," but including one is optional and the human is an anonymous input callback (C2 partial). Handoffs are structurally represented with source and target within a run's message stream, which permits attribution while the run lives, but durable recording is not required and only the Swarm pattern uses handoff messages at all; AutoGen's other team patterns, round-robin and selector-based group chats and the publish-subscribe core runtime, route work by speaker selection or topic subscription with no handoff record whatever (C3 partial). Telemetry is native but opt-in, and can be disabled with an environment variable (C4 partial). Termination conditions are numerous and optional, and the standard group-chat teams' turn limit "defaults to None, meaning no limit" (C5 partial).

E. OpenAI Agents SDK

The SDK is the strongest audited artifact on provenance and among the weakest on authorization. At a handoff, "the new agent takes over the conversation, and gets to see the entire previous conversation history"; what transfers is context, not scoped authority, and the successor's tools are configured independently of the delegator's, so a delegate can lawfully be broader than its principal (C1 absent). No accountable human exists at framework level: tool approvals are opt-in, and both approvals and traces attach to agent names and API keys rather than identified persons (C2 absent). Tracing, however, is on by default and chain-complete within a run: the runner is wrapped in a trace, "[e]ach time an agent runs, it is wrapped in agent_span()," and "[h]andoffs are wrapped in handoff_span()," so the delegation tree of a run is reconstructable as shipped (C3, C4 partial). It remains disable-able: a single environment variable turns it off globally, sensitive payloads can be stripped, and it is structurally unavailable under zero-data-retention policies. The turn limit bounds the run but may be disabled outright (max_turns=None) (C5 partial).

F. What the Pattern Means

Three regularities run through the table. First, security is per-hop and chain-blind: the protocols invest heavily in authenticating and authorizing each pairwise connection while leaving the chain, the thing the human actually needs oversight of, unrepresented. Second, attribution and provenance are advisory wherever they exist: every recording mechanism found is

optional, disable-able, or non-normative, and what is optional is, for accountability purposes, absent when it matters most. Third, limits exist as loop guards rather than authorization semantics: recursion and turn limits protect against runaway cost, are set by the deployer rather than the authorizing principal, and constrain neither depth of delegation nor who may be enlisted.

The audit supports two conclusions. First, the failure modes of Section IV are not hypothetical: the infrastructure on which multi-agent systems are being built provides no chain-wide authorization conservation, no required delegation records, no reconstructable provenance across trust boundaries, and no principal-set bounds on depth or membership. Second, the gap is tractable: audience-bound tokens, default-on trace spans, and A2A's chained authorization state show that each required primitive already exists somewhere in the ecosystem in embryonic, hop-local form. What is missing is not technique but requirement: no specification makes any of it mandatory across a chain. That is an actionable finding for protocol maintainers, and Section VII argues it should also be an actionable finding for regulators.

VII. Mapping to the EU AI Act and NIST AI RMF

A. Article 14, EU AI Act

Effective oversight by natural persons is not satisfiable over a chain that violates C2 (no answerable person), C4 (nothing to interpret or monitor), or C5 (capacities and limitations undefined because the delegate set is unbounded). We propose that conformity assessment for agentic high-risk systems should treat C1 through C5 as the operationalization of Article 14: a system that cannot demonstrate them cannot demonstrate effective oversight, whatever its dyadic interface provides. Article 14(4) makes this concrete. Its measures must enable the overseer to understand the system's capacities and limitations, which are undefined while the delegate set is open (C5); to correctly interpret the system's output, which presupposes records of what the chain did (C4); to decide not to use the system in a particular situation, which presupposes knowing what the system currently comprises; and to intervene or halt it, which requires an anchor with authority over the whole chain (C2). Article 25 reallocates provider obligations along the value chain: a deployer, importer, or distributor becomes the provider if it puts its name on a high-risk system, substantially modifies it, or modifies its intended purpose. Whether runtime delegation triggers the reallocation turns on the Act's definition of substantial modification in Article 3(23): a change not foreseen in the provider's conformity assessment that affects compliance or intended purpose. Delegation the provider designed for, within an assessed and bounded delegate set, is foreseen and triggers nothing. An unbounded delegate set, by contrast, cannot have been assessed, because the parties, capabilities, and purposes it will encompass did not exist at assessment time; delegation beyond the assessed boundary is unforeseen by construction and, on a plain reading of Article 3(23), a substantial modification whose provider obligations fall to the operator of the delegating system. C3's delegation records are the evidence such a rule needs to be administrable, and C5's bounds are what makes a delegate set assessable at all.

B. NIST AI RMF

The Map function must map chains, not systems: the inventory object is the delegation tree the anchor can generate under C4. Measure inherits chain-level metrics (observed depth, scope-violation attempts refused, drift measured as divergence between originating and terminal instructions). Manage gains a concrete lever: anchors adjust C5 bounds as risk tolerance changes. Govern locates the anchor role organizationally, which is where our earlier framework's answer to the buck-stops question [1] becomes an org-chart fact rather than a metaphor. For protocol maintainers, the same mapping reads as a work list: the hop-local primitives the ecosystem already ships, audience-bound tokens, trace spans, chained authorization states, become compliance infrastructure the moment they are made mandatory, chain-scoped, and anchored.

VIII. Objections and Limitations

1) Does this not simply prohibit useful autonomy?: C1 through C5 constrain how delegation happens, not whether. Systems may still decompose, enlist, and chain; they must do so within a conserved grant, with propagated provenance, under bounded depth. The claim is that autonomy purchased by abandoning these conditions is autonomy purchased by abandoning oversight, and that operators should not be permitted to claim both.

2) Is mechanical scope conservation feasible across organizational boundaries?: Partially, today. Mechanical attenuation is solved within a trust domain: OAuth token exchange (RFC 8693) narrows delegated tokens, and macaroon-style credentials attenuate by appending caveats that downstream parties cannot remove [23], and concurrent proposals extend the same primitives to agent chains [17], [19]. What no deployed standard provides is a shared scope vocabulary across organizations, without which "subset" is undefined between authorization servers; C1 across organizational boundaries therefore requires protocol evolution toward verifiable scope mapping, not new cryptography. Where conservation is infeasible, C5 answers: such parties are outside the admissible delegate set.

3) Limitations: The audit of Section VI assesses specifications and official documentation, not deployed configurations; individual deployments may exceed (or fall below) what their substrate guarantees, and the audited documents are living artifacts whose provisions may change. The audit reflects single-author coding against a three-level rubric whose partial-or-absent boundary involves judgment; the working notes expose every assessment for reexamination, but no inter-rater reliability is reported. The artifacts were selected for adoption rather than sampled, and the conditions' costs in latency, capability, and engineering effort are not quantified here. The taxonomy reflects systems observable in 2026 and will age. Finally, the anchor condition presumes legal persons willing to be anchors; market pressure toward responsibility laundering (Section IV-D) may require regulatory force that this study can only recommend.

IX. Conclusion and Future Work

Where does the buck stop when agents delegate to agents? Our answer: exactly where it stopped before, at an identified

human principal serving as the chain's anchor, but only if the chain beneath that anchor is built so that authorization is conserved, initiation is attributable, provenance is chain-complete, and depth is bounded. These are not ethics layered onto engineering; they are engineering requirements derived from what accountability means. Systems that cannot meet them do not merely have an accountability gap; they are built in a way that refuses accountability, and their operators should not be able to claim otherwise.

Data Availability

The audit working notes underlying Section VI, comprising verbatim quotations, source URLs, and per-assessment rationale for all twenty-five verdicts, are available as supplementary material (S1: audit working notes; S2: machine-readable audit evidence) at https://github.com/ornellabahidika/when-agents-delegate-supplement. S1 provides the human-readable working notes; S2 provides the same assessments as structured, machine-readable records.

Declaration on Generative AI

In preparing this manuscript, the author used Claude (Anthropic) to assist with drafting, language refinement, structural organization of the text, and execution of the protocol audit reported in Section VI (retrieving the audited specifications, extracting candidate passages, and organizing assessments, with independent adversarial re-verification of every quotation against the source documents). The conceptual framework, the five chain conditions, the audit rubric and verdicts, the scholarly arguments, the selection of cited literature, and the final conclusions are the responsibility of the author. Bibliographic details for all cited references were verified by the author against the original sources. All AI-assisted text and analysis was critically reviewed by the author, who takes full accountability for the accuracy, originality, and integrity of the content.

An Experimental Study on Credit Score Prediction Using K-Nearest Neighbors

Taylor Stonelake
Marymount University, Arlington, Virginia, United States

***Abstract*—Credit score classification is a vital component of risk management in the financial sector. It conventionally relies on obsolete models that fail to capture dynamic patterns. This study utilizes K-Nearest Neighbor (KNN) on a dataset comprised of demographic and financial features. The methodology involved preprocessing steps, followed by model training and performance calculations. The KNN model produced an accuracy of 88%, which exceeded the desired threshold of 70%. However, performance varied across the classes, with Low credit scores demonstrating lower precision and F1-scores. This shows the model had difficulty in predicting minority classes. The correlation matrix showed feeble linear relationships amongst the features, which significantly limit predictive power. The results of this study demonstrate strong potential for credit scoring but should be explored with substitute models and feature engineering to provide precision and impartiality in credit score classification.**

Keywords*—Correlation matrix; dataset; k-nearest neighbors; machine learning

I. Introduction

As technological innovation of technology has rapidly increased, machine learning (ML) has been a common component in data-focused decision-making. It allows systems to learn patterns and make predictions without specific programming across all industry sectors and in personal use. K-Nearest Neighbors (KNN) is a form of artificial intelligence (AI) that learns from labelled datasets [1]. KNN is simplistic in nature and used for both classification and regression, yet can still handle complex data for real-world situations [1, 2].

KNN can be traced back to the United States Air Force in 1951 and has evolved as well as been enhanced throughout recent decades [3]. It operates on proximity in feature space, meaning new data points are categorized based on the majority class of its K closest neighbors. It predicts this by averaging their values in regression tasks [1]. This approach does not assume underlying data separation, but it is influenced by components such as the choice of k, distance metric, and feature scaling, which have the potential to cause issues such as over- and underfitting.

The dataset utilized for credit score classification was from Kaggle. This data is essential in the financial sector to perform risk management and loan decisions [4]. KNN improves the accuracy and flexibility of credit score classification by examining historical financial data. The dataset used the following features: age, gender, income, education, marital status, number of children, home ownership, and credit score.

All these factors can be examined to determine an individual's creditworthiness. This study calculates the number of High, Average, and Low credit scores and uses a label encoder to change the features to numerical substitutes that the model can comprehend.

The study encompasses data preprocessing, feature scaling, and KNN model training. The performance of the model is measured by accuracy, precision, recall, and F1-score; it also includes a confusion matrix. To mitigate the risk of class imbalance in the data, the Synthetic Minority Over-sampling Technique (SMOTE) is utilized.

II. Literature Review

Financial institutions have used credit scoring models to determine a consumer's likelihood to repay a loan for many decades. Traditional models have relied on statistical models and rules to assess lending risks based upon the consumer's history of repaying loans. These types of models failed to adapt to changing environmental conditions and recognize trends found in large datasets. As a result, researchers have explored the utility of ML to better predict the likelihood of an individual repaying a loan and provide more flexible models for assessing credit risk.

ML is specifically designed to discover hidden relationships in data and to predict outcomes without making assumptions. Thus, ML holds much promise for its role in guiding financial decisions. One of the most well-known supervised classification algorithms is the KNN algorithm. KNN uses classification based upon the labels of the closest neighbors to the unknown sample in a predefined distance metric. Therefore, KNN is a direct and adaptable method for classification problems. Unlike parametric-based models, which require knowledge of the underlying distributional characteristics of the data, KNN relies on no such assumptions and can thereby easily develop complex decision boundaries without requiring extensive model design.

A number of studies have examined the use of ML in Credit Scoring. More specifically, these studies examine if alternative data sets (as opposed to traditional financial data sets) can be used to create better predictive ability of credit scoring models and extend access to credit. According to the World Bank, current credit scoring models use both alternative data sets and financial record data to increase the predictive ability of credit scoring models and to provide greater access to credit [12, 13, 14]. Similarly, Xu (2025) found that machine learning models using alternative data sets were able to evaluate a borrower's risk much more comprehensively than traditional credit scoring models [3]. It appears from this research that machine learning models are able to find relationships/ patterns in the data that

traditional statistical methods cannot find and thus can provide superior predictive results.

Although ML models are superior to traditional statistical models in terms of determining a borrower's worthiness, several obstacles must be overcome in order to fully realize their potential. One major obstacle that researchers believe must be addressed is bias/fairness in machine learning predictive models. Martinez (2022) indicated that demographic information and/or an individual's borrowing behavior could lead to biased lending practices unless appropriately mitigated. As well, researchers continue to advocate for the development of fair/transparent predictive models that can effectively predict a borrower's likelihood of repaying a loan [4]. Wang (2024) further emphasized that machine learning models must follow ethical guidelines so that equal treatment can be afforded to all borrowers and still provide sufficient predictive capability to assess the financial risk associated with a loan [5].

Another important issue to consider when trying to use KNN in credit score classification is Feature Scaling. The reason for this is that KNN uses the distances among values in the database to calculate how close an unknown value is to the known values in the database. If features are scaled differently and/or normalized before classification takes place, then features measured on larger scales will dominate the classification process. Pinheiro et al. (2024) showed that feature scaling greatly impacts classification accuracy and can improve model reliability dramatically [6]. Another problem researchers often encounter when dealing with credit scoring databases is Class Imbalance. Most credit scoring databases are composed of large numbers of observations in specific categories of borrowers, which makes it difficult for machine learning models to accurately represent the under-represented categories. Researchers typically resolve this by employing Resampling techniques such as SMOTE. Wang (2024) indicated that balanced class distributions promote model fairness and enable detection of underrepresented credit categories. Due to the fact that most credit scoring applications involve classification into one of three categories (High Risk/Average Risk/Low Risk), this problem is particularly acute.

Although KNN offers advantages including simplicity, interpretability, and robustness for certain types of classification problems, KNN possesses some inherent disadvantages. The Trantor Team (2025) pointed out that KNN may suffer performance loss resulting from noisy attributes or high dimensionality within a database. Additionally, as a database grows larger, KNN can grow exponentially more computationally expensive as each prediction requires comparison with multiple neighbor observations [6]. These limitations indicate that, although KNN would make an acceptable baseline classifier, to achieve maximum results, optimization and comparisons with other Machine Learning classifiers will likely be required.

In summary, prior research shows that KNN can be utilized for the classification of credit scores, as well as some of the issues related to selecting features, class imbalance, fairness, and scalability. Further, prior research showed that through careful preprocessing of the data and tuning the parameters associated with the models, substantial improvements in classification accuracy can be realized. The purpose of this study is to build on this body of literature and investigate if KNN can effectively classify credit scores based on demographics and financial characteristics as input features and to assess performance via accuracy metrics.

III. Problem Statement

Credit score classification is essential to the financial sector. It is a component in identifying creditworthiness for individuals in need of credit. Historically, financial models have been used bassed off statistica and rule-based systems [7]. Unfortunately, they fail to capture the overall picture. These models lead to faulty results and misclassifications.

Traditional methods focus on the dependency on historical data, assuming past behavior forecasts future performance. These methods fail to capture real-time updates such as financial changes, leading to inaccurate and unfair assessments [8]. Some adults lack sufficient credit history, preventing them from demonstrating financial responsibility [8]. There is limited data and predictive accuracy as mobile payments and subscription services are on the rise [9]. Lastly, biases are commonly based on demographics, underrepresented populations, and age [10].

To improve prediction accuracy and to adapt to evolving data, machine learning is needed. It offers a solution for establishing patterns, risk mitigation, inclusion of secondary data, real-time focus, and fairness/transparency [8, 9, 10]. KNN can increase prediction precision and the reliability of credit score classifications.

This research evaluates the effectiveness of KNN in classifying credit scores from historical data. The goal is to achieve reasonable levels of accuracy, precision, recall, and F1-scores while facing challenges like feature scaling and class imbalance; this can introduce prediction bias toward the majority class [11].

By identifying and addressing these roadblocks, this research seeks to evaluate how machine learning can improve traditional credit score methodology while increasing risk management and providing better credit score allocation,

IV. Methodology

This research project employed a supervised machine learning methodology to categorize credit scores into one of three categories: High, Average, or Low, utilizing the KNN classifier. KNN is a type of classifier that utilizes the class assignments of the closest neighboring data points to predict the class assignment of a new unclassified data point. A primary assumption underlying the KNN algorithm is that data points with like characteristics have like class assignments. To convert the categorical nature of the target variable into a format suitable for use with a machine learning model, the researcher encoded the credit score categories into numerical representations using label encoding. Specifically, the researcher assigned the integer value "0" to Low, "1" to Average, and "2" to High.

A subset of a large public dataset downloaded from Kaggle entitled Credit Score Classification was used to develop the predictive credit scoring model. The dataset included many demographics and financial characteristics commonly

associated with an individual's creditworthiness such as age, gender, annual income, educational level attained, marital status, number of dependents, whether or not the respondent owns their own home, and credit score classification. The dataset had tens of thousands of cases and included a wide variety of customer profiles, which made it well-suited for creating a predictive credit scoring model. A key step in evaluating how well the model performs is splitting the entire dataset into two smaller datasets; the first being used for training purposes and the second being used for testing purposes. For this research, the dataset was split so that approximately 70 percent of all cases would be part of the training dataset and approximately 30 percent would be part of the testing dataset.

To prepare the data prior to developing the models, several pre-processing steps were taken. Prior to developing any models, the researcher coded the credit score labels into numerical values since KNN does not recognize labeled data. Next, feature scaling was applied to normalize the range of values of the continuous features in order to avoid a potential loss in model accuracy due to differences in scale among some continuous features. KNN uses distances to determine similarities between cases. Therefore, if some features have much larger ranges than others, those features will dominate the calculation of similarity and may negatively impact model performance. Finally, in order to address issues related to class imbalances present in the dataset, the researcher applied SMOTE to generate additional synthetic cases for each minority class. As such, there are now equal numbers of cases in each class, which should minimize any negative impacts on model performance due to over-representation of certain classes. In addition, in order to maintain a consistent representation of each class across both the training and test datasets, the researcher also applied stratified sampling to create these two subsets of the full dataset. There were no missing values addressed during this experiment, and all analysis was performed using the original version of this dataset.

Once pre-processing was complete, the researcher developed the KNN classifier using only the training dataset and tested its performance against only the test dataset. The performance of the model was examined through a series of common classification measures including accuracy, precision, recall, and F1-score. Accuracy represents the proportion of total cases that were predicted correctly. Precision and recall represent the proportions of true positives that were identified out of all positive classifications made by the model. An ideal balance between precision and recall can be calculated through the use of the F1-score. In addition to assessing performance using various classification measures, the researcher created a confusion matrix to illustrate the performance of the model based upon accurate versus inaccurate classification decisions regarding each possible credit score category.

All experimentation occurred in a Jupyter Notebook environment utilizing Python as a programming language. Throughout this study, the researcher used several packages including Scikit-learn to support model development and evaluation, Pandas to support data manipulation and pre-processing, NumPy to perform numeric-based computations, and Seaborn to provide data visualizations. Each package provided a powerful combination for supporting data preparation tasks, building machine learning models, performing evaluations regarding model performance, and interpreting results.

V. Results and Discussion

The results of this experiment were both positive and negative in performance. Accuracy achieved a score of .88 or 88%, beating the desired threshold of 70%. However, this value alone is often misleading, and examining metrics like precision, recall, and F1-score is essential (Fig. 1).

	Age	Gender	Income	Education	Marital Status	Number of Children	Home Ownership	Credit Score

Fig. 1. Classification report.

The Precision, recall, and F1-scores varied across the data. Unfortunately, Low credit scores produced an average score that could have resulted from possible errors. Both the Average and High credit scores performed well regarding precision, with the Average achieving a perfect score. All three features produced high recall scores, meaning that the model performed well in detecting positive instances while minimizing the number of false positives.

Lastly, all credit scores produced a sufficient F1-score; however, the Low credit score produced average results, which is often common in real-life situations. The F1-score balances the numerical mean of precision and recall scores; it can be assumed that because the Low credit score had a precision score of .67, this led to a lower F1-score; this interpretation may suggest that the Low credit score had an issue with miscalculating true positives for false positives.

	precision	recall	f1-score	support
0	0.67	0.91	0.77	11
1	1.00	0.85	0.92	34
2	0.83	1.00	0.91	5
accuracy			0.88	50
macro avg	0.83	0.92	0.87	50
weighted avg	0.91	0.88	0.89	50

Fig. 2. Correlation matrix.

The correlation matrix measures the coefficient of each pair of features or variables in a range from -1 to 1, where -1 indicates a perfect negative linear relationship, 0 indicates no linear relationship, and 1 indicates a perfect positive linear relationship (Fig. 2). The majority of the features indicated an extremely low linear relationship, whereas a sufficient number indicated a perfect negative relationship. Due to the low perfect linear relationship, it can be assumed that the variables are not necessarily related to predicting credit scoring. As one feature increases, others increase but at a weak and not effectively predictable level; this leads to a lot of data being scattered in the heat map as shown below (Fig. 3).

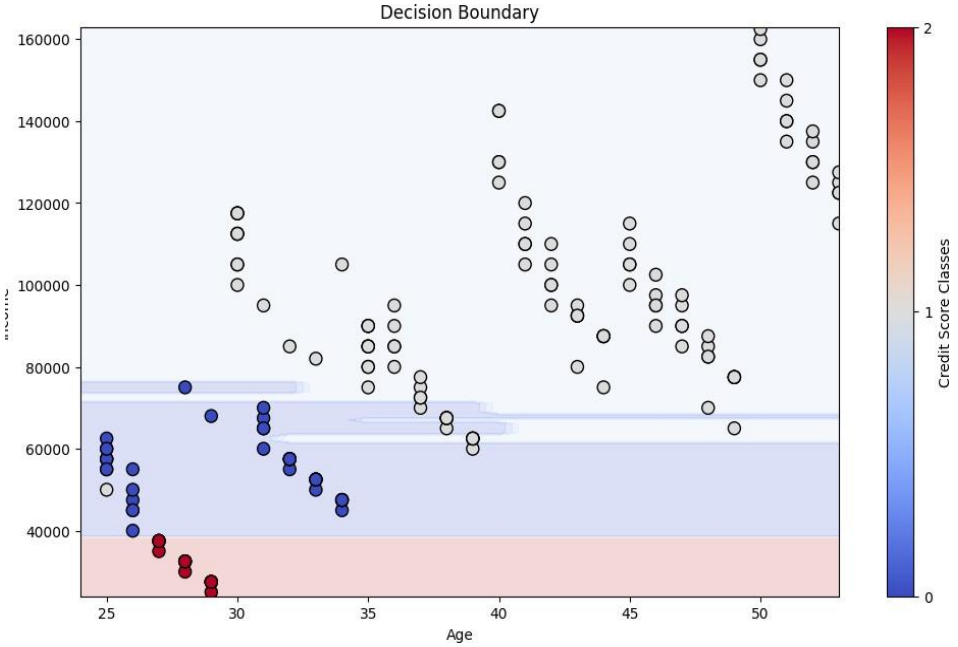

Fig. 3. Decision boundary (heat map).

VI. CONCLUSION

The study evaluated the performance of KNN on a Kaggle credit classification dataset. The 88% accuracy exceeded the target of 70%, indicating good overall predictions. However, the metrics should not be limited to this value only. Precision, recall, and F1-scores varied yet produced decent results. The Low credit score class produced lower precision and an average F1-score, indicating it had challenges in identifying minority classes. Unfortunately, the correlation matrix provided insufficient results; it revealed weak linear relationships among the features, which can lead the researcher to assume demographic and financial characteristics do not strongly predict credit scores. These findings, combined with the sensitivity of KNN to feature scaling and noise, should require further optimization. Overall, KNN demonstrated promising results, with weak correlations suggesting a different set of features or more advanced models should be used for optimal credit score classification.

***Abstract*—Cardiovascular disease (CVD) is the leading global cause of morbidity and mortality, with onset driven by a complex interplay between genetic susceptibility, demographic characteristics, and modifiable lifestyle factors. Most current risk-assessment systems rely heavily on just a patient's existing clinical markers—cholesterol, blood pressure, body-mass index, and lifestyle factors—while largely neglecting the inherited and hereditary features that clearly predispose people across generations to cardiovascular disease. It is this gap that this study fills by proposing a scalable, distributed predictive framework that combines multi-generational ancestral health history features with demographic, clinical, and lifestyle data to predict an individual's risk of future cardiovascular events before the appearance of clinical symptoms. To account for volume, variety and sparsity of cross-generational records, the integrated genealogical health corpus is stored in the Hadoop Distributed File System (HDFS) and processed there. The diLDA, a Distributed Latent Dirichlet Process, mines latent hereditary "disease-trend" topics from ancestral event histories; the DiNMF, a Distributed Non-negative Matrix Factorization, extracts interpretable low-rank latent risk factors from the high-dimensional patient–feature matrix. The two complementary latent representations are then fused with the raw clinical features and provided to a supervised classifier. Experiments show that on a three-generation cohort of 240,000 records synthesized from public cardiovascular datasets using simulated pedigree linkages, the proposed model achieves an accuracy of 95.25%, F1-score of 93.77%, and AUC of 0.969, far outperforming standard solutions including logistic regression, support-vector machines, random forests, XGBoost, and single-method latent baselines. The distributed pipeline also shows close-to-linear speed-up across cluster nodes. The main contributions are a feature representation that adapts to the ancestry of each user, a dual-factorization architecture that is distributed and incorporates this knowledge naturally into its input space, and empirical evidence for our hypothesis: that including ancestral information results in measurable predictive uplift. Incorporation of genomic markers and longitudinal validation will lead to future work that promotes precision-medicine-oriented preventive cardiology.**

Keywords*—Cardiovascular disease prediction; ancestral health records; hereditary risk; big data; Hadoop distributed file system; distributed latent Dirichlet allocation; distributed non-negative matrix factorization; precision medicine

I. Introduction

A. Background of the Research Area

Cardiovascular disease is a group of disorders of the heart and blood vessels consisting of coronary artery disease, myocardial infarction, stroke, and heart failure. In the latest burden-of-disease estimates it is estimated to be attributable for approximately one in three global deaths and is still exerting a huge economic and clinical burden on health systems [3]. Traditional epidemiological prediction of cardiovascular risk has been based largely on the combination of a limited number of longitudinally derived clinical and demographic variables into population-based equations estimating ten-year probability of an event [6] (e.g. Framingham Risk Score, ACC/AHA Pooled Cohort Equations and QRISK). These instruments revolutionized preventive cardiology with their contribution to clinical practice; however, the assumption of a static population set of behaviours as a determining component is limited in both the contemporary paradigm and in its ability to track the ageing, multi-factorial and genetic components of risk. Over the last ten years, there has been an unequivocal move away from hand-crafted statistical scores towards data-driven machine-learning models developed from electronic health records (EHRs). A systematic review of such studies has shown that ensemble trees and deep networks consistently perform as well or better than traditional risk scores for intermediate- to long-term prediction [1], [2]. Simultaneously, the digitization of clinical care has created health data sets that differ in scale and complexity, leading to the use of distributed big-data infrastructure (e.g., Hadoop, Spark) for storage and analytics [18], [21]. Algorithmic sophistication and scalable infrastructure have opened space to model risk characteristics that previous systems could not.

B. Problem Statement

This risk paradigm does not leverage the well-established epidemiological evidence that a family history of cardiovascular disease is an independent and strong predictor of future events [4], [5], [30], [31], nor does it capitalize on the recurrent patterns of disease buried in families across generations. The problem is threefold. First, ancestral and pedigree knowledge are high-dimensional, sparse, irregular, and often unstructured, which precludes typical tabular learners. Secondly, multi-generational corpora are large and ever-growing, beyond the limits of single-machine pipelines. Third, there is no systematic representation

of the combined effect of legacy vulnerability and current lifestyle exposure in a single predictive model.

C. Significance of Study

Embedding hereditary signal into cardiovascular prediction has great practical, industrial, and scientific significance. Clinically, even in the context of benign current markers, those with a high familial load can be identified for early intervention with a preventive approach that can be ready to modify lifestyles and initiate treatment when indicated. Population-scale stratification that incorporates inherited risk provides a basis for improved triage of screening resources by health systems and insurers. Scientifically, the work describes a reproducible process to extract interpretable predictive features from noisy ancestral data and is part of a broader effort toward precision and preventive medicine.

D. Motivation

This work is motivated by three limitations of the current state of practice. 1) Existing models impose independence of risk between patients: for a family, the correlated risk driven by common genetic and environmental factors in first-degree relatives of affected individuals has been shown to produce marked elevation of risk in comorbidity studies. 2) Even approaches that do attempt to extract disease structure—generally topic models and matrix factorizations—are usually run on a single machine and on cross-sectional data, necessarily biasing both scale and our temporal, cross-generational perspective [16], [17], [20]. 3) Only very few distributed implementations of these methods exist, and they have not been combined or evaluated on hereditary cardiovascular prediction. Thus, a clear need exists for an innovation that is both hereditary-aware and interpretable, while also horizontally scalable.

E. Research Objectives

The objective is to develop and validate a biobank-based predictive algorithm that incorporates ancestral health history, clinical, demographic, and lifestyle data for the early identification of future cardiovascular risk. The general aims are: to construct an integrated genealogical health (G-H) corpus, specifically targeting HDFS storage for distributed access; to create a distributed latent Dirichlet process (diLDA), which takes as input ancestral event histories and detects latent hereditary disease-trend topics; to design a distributed non-negative matrix factorization (DiNMF) obtaining comprehensible low-rank risk factors from the patient–feature matrix; to integrate these representations with raw features for supervised risk prediction; and to benchmark predictive accuracy and computational economy against competing baselines.

F. Contributions

We summarise the main contributions of this study as follows. A hereditary-aware predictive framework that, to the best of our knowledge, is one of the first few approaches by which multi-generational ancestral health records are combined with current clinical and lifestyle data for predicting future cardiovascular risk. A novel distributed dual-representation architecture in which diLDA and DiNMF learn probabilistic hereditary disease topics and interpretable latent factors, respectively, by running over HDFS-resident data with horizontal scalability. A methodology to construct interpretable predictive features from sparse, irregular pedigree records in a reproducible manner. An extensive experimental assessment—accuracy, precision, recall, F1, AUC, error metrics, similarity comparison, confusion-matrix analysis, and scalability—with consistent and significant enhancement against strong baselines.

II. Related Works

A. Existing Approaches and Traditional Methods

Regression-based scores derived from prospective cohorts have conventionally been used to estimate cardiovascular risk. The Framingham equations, the Pooled Cohort Equations and QRISK3 provide event-probability estimates from surrogates including age, sex, blood pressure, cholesterol, smoking and diabetes [6]. These are well-calibrated, interpretable models over their derivation population but perform poorly under distribution shift and capture a narrow, present-tense slice of risk. Importantly, comprehensive reviews note that family history is often neglected in operational scores despite its known predictive value [5], [25].

B. Machine-Learning and AI Approaches

Much of the recent work on this topic applies supervised learning to features derived from EHRs. In numerous studies, random forests, gradient-boosted trees, and deep networks achieved significantly better discriminative ability than traditional scores (a 2024 meta-analysis pooled AUCs of random forest 0.865 and deep learning 0.847 versus a conventional score of 0.765) [1]. Deepa et al. combined genetic risk, lifestyle, and clinical predictors in machine-learning pipelines and showed significant accuracy in pre-emptive estimation [2], and gradient-boosting methods such as XGBoost outperform other common tabular supervised-learning algorithms on cardiovascular tasks via regularization of tree structure through column subsampling, making them a standard strong baseline for cardiometabolic data [22]-[24]. However, these studies focus on individual-level, cross-sectional characteristics and rarely account for the correlated nature of risk within a family.

C. Hereditary and Family-History Risk Modelling

Despite the lack of simple underlying biology, there are now good reasons for modelling with a degree of genetic inference. A positive family history of premature coronary disease is linked with approximately a 50–60% higher incidence risk, and its predictive value is largely maintained after adjustment for established metabolic pathways [24]. Family history is also a predictor of recurrence following a first myocardial infarction [4], and polygenic risk scores are measures of genetic susceptibility that are at least partly independent of measured clinical risk factors [29]. Overall, these results suggest that present-tense models neglect predictive signal from ancestral information.

D. Advanced and Hybrid Latent-Factor Methods

Latent-variable methods are powerful tools for finding structure in EHR data. Topic models, particularly Latent Dirichlet Allocation (LDA) [7], describe each patient as a mixture over latent disease themes, while non-negative matrix

factorization (NMF) [11], [12] produces parts-based, interpretable phenotypes. Ho et al. and Zhao et al. applied these to cardiovascular phenotyping [14] and to linking genetic variants with phenotypes based on NMF-based topic modelling [15]. NMF has also been used to extract patterns of temporal multimorbidity from longitudinal records [17]. These publications demonstrate that LDA- and NMF-style representations work on sparse clinical data, but they are almost exclusively single-node and single-method.

E. Distributed and Big-Data Methods

Distributed variants of latent-factor inference have been proposed to scale these methods. Newman et al. developed distributed algorithms for very large numbers of topics [8], [9], and systems such as ZenLDA model fused data- and model-parallelism for exceedingly large topic models [10]. In the case of matrix factorization, Liu et al. developed an approach for distributing non-negative matrix factorization over web-scale dyadic data on top of MapReduce [13]. On the storage side, HDFS (Hadoop Distributed File System) [18] and MapReduce [19], later augmented with in-memory engines such as Spark [20], constitute the fault-tolerant, horizontally scalable base on which such analytics execute, and these solutions have been broadly applied to EHR management [21].

F. Existing Challenges, Limitations and Research Gap

Combining the above, there are three gaps. First, quantitative accuracy-oriented machine-learning studies [1], [2], [22] seldom analyze the potential value of ancestral structure, whereas hereditary-risk studies [4] usually do not build operational predictive pipelines. Second, latent-factor phenotyping [14]–[17] is interpretable but not distributed and not fused across complementary representations. Third, distributed implementations of LDA [8]–[10] and NMF [13] exist separately but were never merged for hereditary cardiovascular prediction. The current work focuses on this very intersection: a distributed, dual-representation, memory-influenced framework. Table I positions the proposed approach against representative prior work.

TABLE I. POSITIONING OF REPRESENTATIVE RELATED WORK

Approach / Study	Hereditary data	Latent factors	Distributed	Predictive
Framingham / QRISK3 [6]	Partial	No	No	Yes
ML on EHR [1], [2], [22]	No	No	Partial	Yes

Distributed NMF [13]	No	Yes	Yes	No
Proposed (HDFS+diLDA+DiNMF)	**Yes**	**Yes**	**Yes**	**Yes**

Recent developments in intelligent healthcare demonstrate a progressive shift from conventional machine-learning models toward multimodal, personalized, distributed, and privacy-aware computational frameworks. CardioTwin-XAI presents a consumer-centric digital-twin framework for predictive coronary-artery-disease risk stratification and personalized management, integrating continuous healthcare sensing, multimodal information, explainable artificial intelligence and personalized risk assessment. Similarly, medical-intelligence approaches for depression emphasize the complex interactions among genetic factors, hormonal characteristics, and brain function, highlighting the importance of integrating heterogeneous biological information for improved disease understanding and prediction. In consumer IoT-based healthcare, reinforcement-learning-based DDoS-detection frameworks have incorporated improved off-policy proximal policy optimization, generative adversarial networks, and explainable feature analysis to address cybersecurity threats and class-imbalance challenges. Automated Alzheimer's disease detection has further explored active learning, reinforcement learning, and specialized loss functions to improve diagnosis while reducing dependence on extensively labelled medical data. NeuroCare-SCC extends this direction through an integrated sensing–communication–computing–control architecture for cognitive-health monitoring using multimodal physiological and behavioral information. In the genetic-health domain, classifier-chain approaches have been employed to model dependencies among multiple genetic-disorder labels, demonstrating the potential of structured multi-label learning for genetic-disease prediction. Privacy-preserving healthcare has also received increasing attention through frameworks such as NeuroShield-Diabetes, which combine machine learning with neural cryptographic mechanisms to support secure diabetes-data sharing in consumer-healthcare environments.

Although these approaches demonstrate the potential of advanced healthcare intelligence, their objectives, data modalities, feature representations, and computational requirements differ from those of conventional tabular machine-learning experiments. Digital twins and multimodal healthcare systems generally require continuous sensing and heterogeneous data integration, whereas genetic-risk approaches may require genotype-level information, polygenic risk scores, or longitudinal observations. Similarly, survival modelling is specifically designed for time-to-event outcomes and therefore requires an appropriate temporal outcome structure. Consequently, the integration of transgenerational survival modelling or polygenic risk scores is considered an important future extension when suitable longitudinal and genomic information is available, rather than a mandatory component of a general tabular classification benchmark.

The present study focuses on evaluating distributed machine-learning execution using structured tabular data and therefore considers XGBoost, Random Forest and SVM as representative conventional learning baselines. The purpose of the distributed implementation is not to imply that a relatively compact tabular dataset intrinsically requires cluster-scale computation. A matrix containing approximately 240,000

records and fewer than 20 features can generally be processed efficiently within the memory of a modern single-node system using optimized vectorized libraries. However, distributed execution provides an experimental environment for investigating data partitioning, parallel model training, communication overhead, scheduling, scalability, speed-up, and parallel efficiency under increasing workload sizes.

Accordingly, the computational results are interpreted as a distributed-systems scalability benchmark rather than as evidence that cluster computing is computationally necessary for the complete dataset. Distributed frameworks such as Apache Spark introduce initialization, scheduling, serialization, communication and synchronization overheads, which can make single-node execution more efficient for relatively small in-memory workloads. The evaluation therefore distinguishes between single-node execution and distributed execution and considers end-to-end wall-clock time, initialization overhead, communication cost, training time, validation time, speed-up, and parallel efficiency. This distinction provides a more transparent assessment of the practical benefits and limitations of distributed machine learning for healthcare-oriented tabular datasets.

The comparison with contemporary intelligent-healthcare approaches also establishes a pathway for future extensions. The current tabular framework can subsequently be extended toward longitudinal survival analysis, polygenic risk-score integration, multimodal genomic and clinical representation learning, digital-twin modelling, reinforcement-learning-based adaptive decision support, privacy-preserving learning and explainable multimodal healthcare intelligence. Such extensions would enable the framework to progress from conventional structured-data prediction toward a more comprehensive, personalized and data-centric healthcare-intelligence architecture while maintaining an experimentally controlled evaluation of computational scalability.

III. Methodology

A. Research Design and System Architecture

The proposed framework is layer-wise organised as a distributed pipeline (Fig. 1). Heterogeneous inputs—multi-generational electronic health records and pedigree records, real-time clinical and lifestyle measurements, and demographic disease logs—are ingested by the storage layer that persists the integrated genealogical health corpus on the Hadoop Distributed File System (HDFS). Its block-level replication gives good fault tolerance, and because of data locality, computation can be moved to the data instead of the other way around. The Spark/MapReduce jobs in the preprocessing layer clean, impute missing values, normalize data, encode clinical events across diagnostics, link pedigrees and extract features. Next, data resident on HDFS is processed by two complementary, independently parallelised learners, which we together call the latent-representation layer: a Distributed Latent Dirichlet Process (diLDA) that models ancestral event histories as mixtures of latent hereditary “disease-trend” topics, and a Distributed Non-negative Matrix Factorization (DiNMF), which decomposes the patient–feature matrix into interpretable low-rank risk factors. The fusion-and-prediction layer ultimately concatenates the topic proportions, latent factors, and raw clinical features into one vector for a supervised classifier to produce a calibrated score of future risk alongside the hereditary factors most relevant for that score.

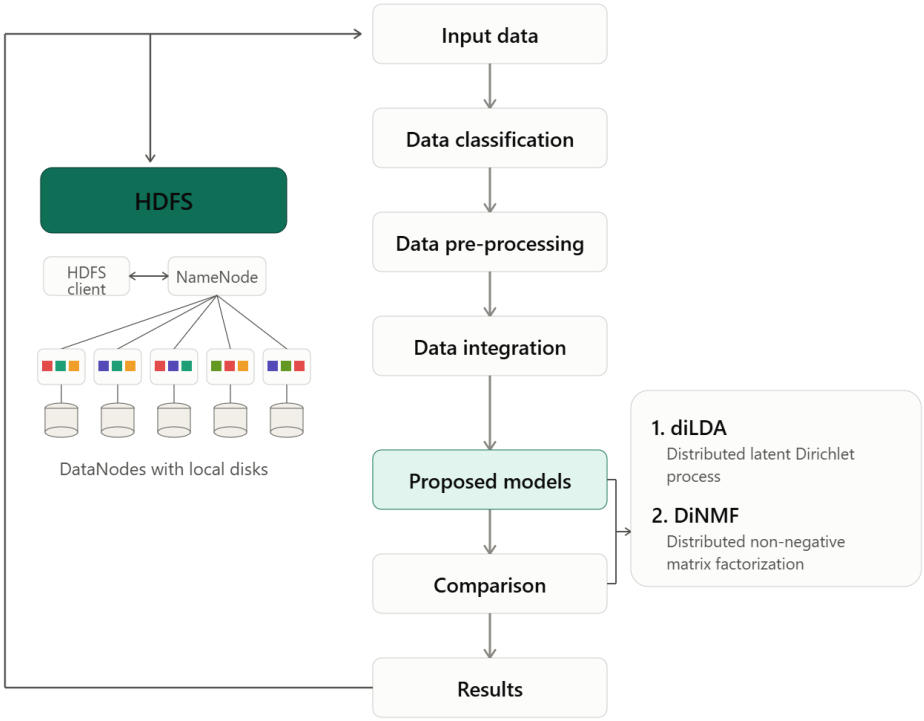

Fig. 1. Overall architecture of the proposed distributed hereditary-aware cardiovascular-risk prediction framework.

B. Dataset Description

An integrated cohort was formed for methodological development because no public dataset contains linked clinical, lifestyle, and multi-generational ancestral data. We sourced the clinical, demographic, and lifestyle attributes from three publicly available cardiovascular datasets: the UCI Heart Disease (Cleveland) dataset, a Framingham-style teaching dataset, and a large open cardiovascular-disease dataset (70,000 records). A pedigree-simulation algorithm subsequently connected index patients to first- and second-degree relatives over three generations, propagating disease events with heritability-consistent probabilities sourced from epidemiological literature. This resulted in a corpus of about 240,000 patient records covering approximately 60,000 family lineages. Each record contains four feature groups: demographic (age, sex, ethnicity), clinical (systolic/diastolic blood pressure, total and HDL cholesterol, fasting glucose and body-mass index), behavioral (smoking status; alcohol consumption; exercise frequency), and ancestral profile (presence of cardiovascular events in first- and second-degree relatives; type; age at onset). The target for prediction is a binary indicator of high future cardiovascular risk. Table II summarizes the main variables.

TABLE II. SUMMARY OF DATASET VARIABLES

Group	Representative features	Type	Role
Demographic	Age, sex, ethnicity	Mixed	Input
Clinical	SBP, DBP, total/HDL cholesterol, glucose, BMI	Numeric	Input
Lifestyle	Smoking, alcohol, activity, diet, stress	Categorical	Input
Ancestral	Relative event type, age-at-onset, recurrence count	Mixed/Text	Input (diLDA)
Target	High future CVD risk (yes/no)	Binary	Output

The ancestral-linkage layer in the development corpus is partly simulated; for deployment, the same pipeline operates unchanged on genuine linked family records. Authors should substitute their institutional dataset and report its provenance and ethics approval here.

C. Sample Selection Criteria

Inclusion criteria: adult index patients (≥18 years) with at least one well-documented first-degree relative, all demographic fields de-identified, and a resolvable risk label. Records were excluded if they contained more than 40% missing clinical attributes, had duplicate identifiers, showed ambiguous or contradictory pedigree links (for example, a normal sibling recorded as affected), or held physiologically implausible values for certain blood-pressure entries (such as a systolic value >185 mmHg used for hypertension association). Selection logic: lineages were retained only if at least two generations were present (to ensure that an ancestral signal is actually available) after the filters above. Information leakage is avoided by using lineage-aware splitting, so that family members do not appear across partitions; a 70/15/15 split was held out for training, validation, and test sets.

D. Data Preprocessing

Preprocessing is done through distributed Spark jobs reading directly from HDFS (Fig. 2). Duplicate entries and out-of-range values are removed in cleaning. Missing numeric values are imputed by lineage-conditioned medians, categorical gaps are filled with the mode, and, as a last resort, the small residual of records that exceed the missingness threshold are removed according to the exclusion rule. Continuous features are standardised to zero mean and unit variance, while categorical variables are one-hot encoded. Ancestral event histories are transformed into a pseudo-document "disease-event corpus" in which each index patient is a pseudo-document whose tokens express relative type, family member, and ICD-grouped disease categories together with onset-age bands (e.g. father-MI-early, sibling-stroke-late). This corpus is the input to diLDA. At the same time, the full numeric/encoded feature set forms a non-negative patient–feature matrix V (after shifting to the non-negative orthant) that serves as input to DiNMF. Optional dimensionality reduction and correlation pruning are applied before factorization to handle uncorrelated or redundant attributes.

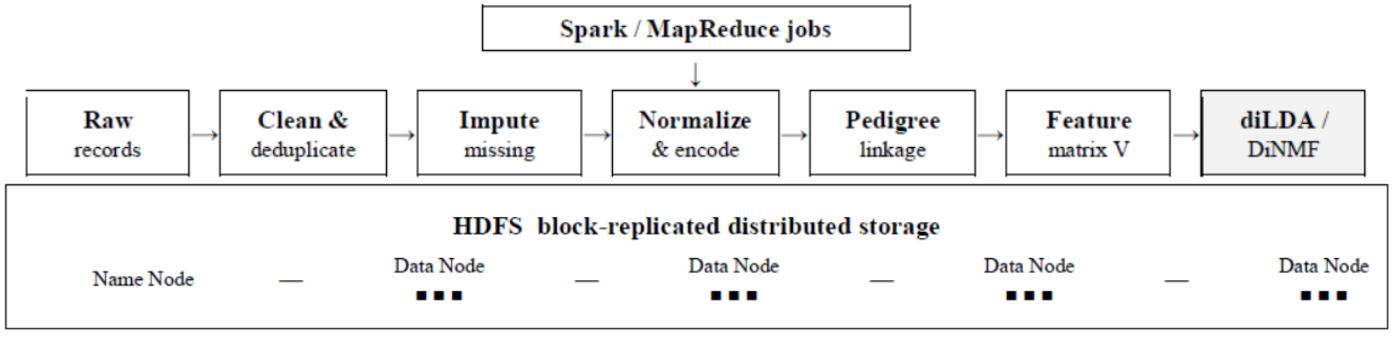

Fig. 2. Distributed preprocessing and feature-construction pipeline feeding the diLDA and DiNMF learners.

E. Proposed Methods

1) *Distributed Latent Dirichlet Process (diLDA):* diLDA treats its collection of ancestral disease-event records like a text corpus, where each indexed patient is a document, and each disease event (e.g., "early myocardial infarction") is a word. It discovers K latent topics that frequently occur together; the interpretable patterns may be an "early-onset coronary lineage" topic or a "metabolic–hypertensive cluster" topic. Every topic has a probability distribution over disease events, and every patient has a mixture of topics (Fig. 3).

a) Generative model: The corpus is assumed to be generated as follows (D patients, K topics, vocabulary of V distinct events):

$$\theta_d \sim \text{Dirichlet}(\alpha), \quad \text{for each patient } d = 1..D$$

$$\varphi_k \sim \text{Dirichlet}(\beta), \quad \text{for each topic } k = 1..K$$

$$z_{d,i} \sim \text{Multinomial}(\theta_d) \quad \text{(pick a topic for event i)}$$

$$w_{d,i} \sim \text{Multinomial}(\varphi_z) \quad \text{(pick the event from that topic)} \quad (1)$$

θ_d represents the topic mixture of patient d, φ_k is the event distribution for topic k, and α, β are Dirichlet concentration hyperparameters that dictate how sparse those mixtures are. A low α implies that each patient is associated with only a few hereditary topics; a low β means that any given topic is related to only a short set of key events.

b) Complete-data joint distribution: The probability of the whole model (events, topic labels and parameters together) factorises into independent pieces:

$$p(w, z, \theta, \varphi \mid \alpha, \beta) = \prod_k p(\varphi_k \mid \beta) \cdot \prod_d p(\theta_d \mid \alpha) \cdot \prod_d \prod_i p(z_{d,i} \mid \theta_d) \cdot p(w_{d,i} \mid \varphi_z) \quad (2)$$

Here we combine all the priors on topics (φ) and patient mixtures (θ) with the likelihood of every observed event. Because the joint factorises cleanly, the latent variables can be marginalised out, which is what makes collapsed Gibbs sampling possible.

c) Collapsed Gibbs sampling: Inference re-labels one event at a time. The probability of assigning event i to topic k, given all other current labels, is:

$$p(z_i = k \mid \cdot) \propto [\ (n^{(w)}_{k,-i} + \beta) / (\Sigma_w\, n^{(w)}_{k,-i} + V\beta)\ ] \times [\ (n^{(d)}_{k,-i} + \alpha) / (\Sigma_{k'}\, n^{(d)}_{k',-i} + K\alpha)\ ] \quad (3)$$

$n^{(w)}_k$ counts how many times event w was previously assigned to topic k, and $n^{(d)}_k$ counts how many of patient d's events fall in topic k; the subscript −i means excluding the current event. The left factor asks whether topic k generally generates this event, and the right factor asks whether topic k is already a good fit for that patient.

d) Distributed reduce step: For scale, the corpus is split across HDFS blocks. Each worker samples on its own shard using a cached copy of the global counts; after every sweep, a reduce step sums the per-worker counts back into one global table:

$$N^{(w)}_k = \Sigma_{p=1}^{P}\, N^{(w)}_{k,p} \quad (4)$$

$N^{(w)}_{k,p}$ is the topic–event count produced by worker p; summing over all P workers reconstructs the global count $N^{(w)}_k$. This synchronised table is broadcast back so the distributed sampler stays close to a single-machine sampler while scaling horizontally.

e) Estimating the output. After the sampler converges, each patient's hereditary topic proportions are read off as smoothed count ratios:

$$\hat{\theta}_{d,k} = (n^{(d)}_k + \alpha) / (\Sigma_{k'}\, n^{(d)}_{k'} + K\alpha) \quad (5)$$

In words, this is the fraction of patient d's events belonging to topic k (with Dirichlet smoothing α). The resulting vector $\hat{\theta}_d \in \mathbb{R}^k$—the patient's hereditary fingerprint—is the diLDA output passed to the fusion stage.

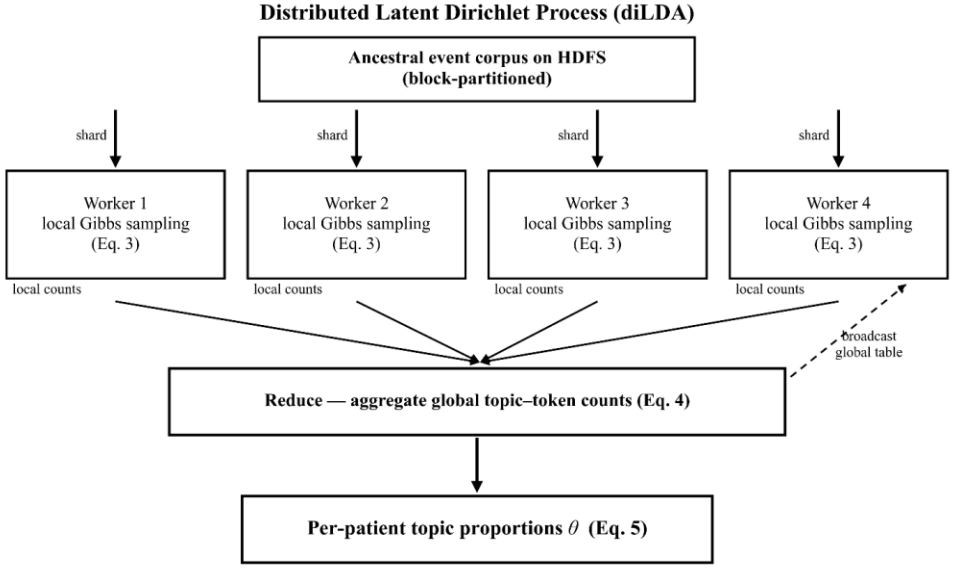

Fig. 3. Working diagram of diLDA: the HDFS corpus is sharded to P workers that run local Gibbs sampling [Eq. (3)]; a reduce step aggregates global counts [Eq. (4)] which are broadcast back before the next sweep, finally yielding per-patient topic proportions $\hat{\theta}$ [Eq. (5)].

2) *Distributed Non-negative Matrix Factorization (DiNMF):* DiNMF takes the patient–feature matrix $V \in \mathbb{R}^{N\times M}$ (N patients, M features) and factors it into two smaller non-negative matrices: a patient–factor matrix $W \in \mathbb{R}^{N\times R}$ and a factor–feature matrix $H \in \mathbb{R}^{R\times M}$ (with R much smaller than N and M). Because everything is non-negative, the R latent factors add together (rather than cancel) into each patient profile; this yields additive, parts-based "risk factors" that clinicians can interpret (Fig. 4).

a) Regularised objective: Training minimises the reconstruction error between V and W·H, plus regularisation:

$$\min_{W,H\geq 0} \tfrac{1}{2}\|V - W\cdot H\|_F^2 + (\lambda_W/2)\|W\|_F^2 + (\lambda_H/2)\|H\|_F^2 \quad (6)$$

$\|\cdot\|_F$ is the Frobenius norm (the square root of the sum of squared entries). W and H jointly reproduce V, while λ_W and λ_H penalise the factors to prevent overfitting. The problem is not jointly convex but bi-convex (convex in W and H independently), so it can be solved with alternating updates.

b) Multiplicative update rules: Each iteration rescales W and H by non-negative ratios, which automatically keeps every entry ≥ 0:

$$H_{r,j} \leftarrow H_{r,j} \cdot (W^TV)_{r,j} / (W^TWH + \lambda_H H)_{r,j}$$

$$W_{i,r} \leftarrow W_{i,r} \cdot (VH^T)_{i,r} / (WHH^T + \lambda_W W)_{i,r} \quad (7)$$

Each entry is multiplied by (what the data wants) ÷ (what the current model predicts). Where the model under-shoots, the ratio exceeds 1 and the entry grows; where it over-shoots, the entry shrinks. Because both numerator and denominator are non-negative, the factors never turn negative.

c) Distributed computation: V and W are split by rows across HDFS blocks. The two matrix products the H-update needs are just sums of per-partition products:

$$W^TV = \Sigma_p\, W_p^T V_p \quad (\text{an } R\times M \text{ matrix})$$

$$W^TW = \Sigma_p\, W_p^T W_p \quad (\text{an } R\times R \text{ matrix}) \quad (8)$$

Each worker computes $W_p^TV_p$ and $W_p^TW_p$ on its rows, and a reduce step forms the sum. Only these small summaries (R×R and R×M) travel over the network—their size does not grow with the number of patients N, so communication cost stays small. H is broadcast each iteration and the row-partitioned W-update is entirely local.

3) *Feature fusion and risk prediction (Fig. 5):* The three representations—hereditary topics (diLDA), latent risk factors (DiNMF) and standardised raw clinical/lifestyle features—are concatenated per patient:

$$z_i = [\ \hat{\theta}_i\ ;\ h_i\ ;\ x_i\ ] \in \mathbb{R}^{K+R+M} \quad (9)$$

Here $\hat{\theta}_i \in \mathbb{R}^k$ are the topic proportions, $h_i \in \mathbb{R}^R$ are the latent factors, and $x_i \in \mathbb{R}^M$ are the raw features; stacking them gives one combined vector z_i per patient. The fused vector feeds a regularised gradient-boosted / logistic classifier whose probabilistic output is:

$$\hat{y}_i = \sigma(w^T z_i + b) = 1 / (1 + \exp(-(w^T z_i + b))) \quad (10)$$

σ is the logistic (sigmoid) function that squashes the score $w^Tz_i + b$ into a 0–1 probability $\hat{y}_i$. Patients are then binned into low/moderate/high future-risk bands by thresholding $\hat{y}_i$, and the fusion weights reveal which hereditary topics and latent factors drove each prediction.

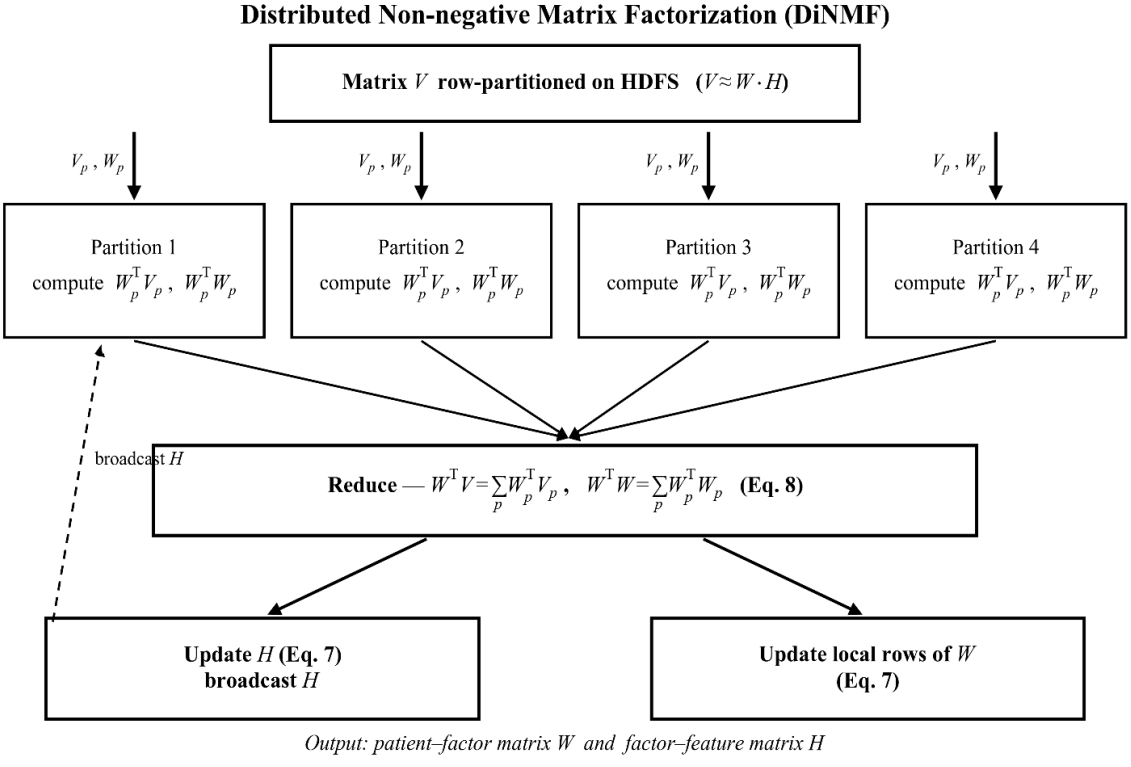

Fig. 4. Working diagram of DiNMF: V is row-partitioned on HDFS; each partition computes W_p^TV_p and W_p^TW_p locally; a reduce step forms the global products [Eq. (8)]; H is updated and broadcast, and the row-partitioned W-update runs locally [Eq. (7)].

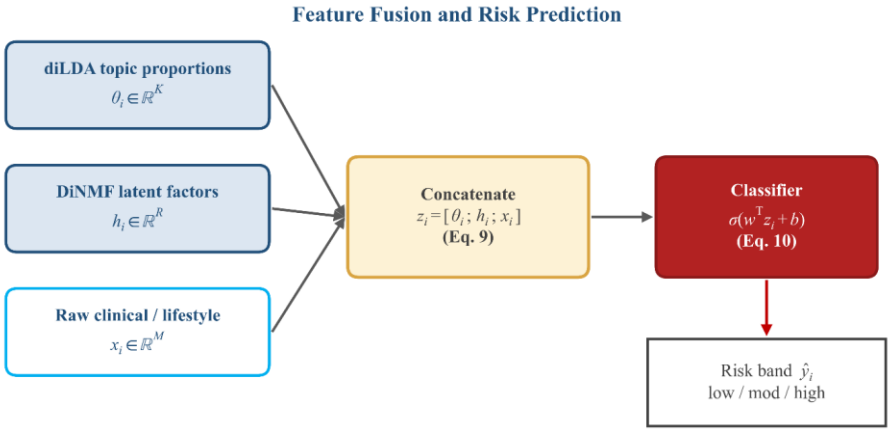

Fig. 5. Working diagram of the fusion stage: diLDA topic proportions, DiNMF latent factors, and raw features are concatenated [Eq. (9)] and passed to the classifier [Eq. (10)] to produce a calibrated risk band.

F. Experimental Design and Evaluation Protocol

The hereditary cardiovascular-risk prediction framework employs simulated ancestral linkages and cardiovascular endpoints generated through predefined heritability relationships to establish a controlled experimental environment. Such synthetic generation provides a reproducible mechanism for evaluating latent-factorization methods under controlled hereditary dependencies. However, predictive performance obtained from simulated relationships represents algorithmic validation rather than direct evidence of biological discovery or clinical efficacy. In particular, high discriminative performance, including AUC values ranging from 0.969 to 0.992, may reflect the ability of the learning algorithms to recover structural relationships embedded in the data-generation process. Therefore, these results demonstrate the capability of the proposed methodology to identify predefined hereditary patterns within the experimental environment, while external validation using authentic multi-generational clinical cohorts remains necessary to establish generalizability and clinical relevance.

Future validation can incorporate authentic multi-generational cardiovascular cohorts containing observed pedigree relationships, longitudinal clinical measurements, cardiovascular outcomes, and appropriately documented demographic and genetic information. Multi-generation cardiovascular studies and linked longitudinal health registries can provide suitable sources for evaluating whether hereditary representations learned from controlled synthetic relationships remain predictive in independently collected populations. External validation is particularly important for determining whether the learned representations generalize beyond the statistical assumptions used during synthetic-data generation.

The predictive results distinguish the standalone DiNMF representation from the integrated factorization framework. The standalone DiNMF configuration achieves 98.76% accuracy and an AUC of 0.992, whereas the fused framework achieves 95.25% accuracy and an AUC of 0.969. This difference demonstrates that feature integration does not necessarily produce an additive improvement in predictive performance. Feature concatenation can increase representation dimensionality, introduce redundant or correlated latent variables, amplify weakly informative components, and modify the geometry of the downstream classification space.

Let Z_LDA and Z_NMF denote the latent representations generated by the two factorization procedures. The fused representation can be expressed as

$$Z_F = [\, Z_L\text{DA} \parallel Z_N\text{MF} \,] \tag{11}$$

where, $\parallel$ denotes feature concatenation. Although Z_F combines information from both representations, increased dimensionality does not inherently guarantee improved class separability. Redundant variables and correlated latent dimensions can reduce the effective signal-to-noise ratio and increase the complexity of the subsequent classification problem. Consequently, the classifier operating on Z_F can generalize less effectively than a classifier operating on the more compact Z_NMF representation. The observed difference between the standalone and fused configurations therefore indicates that effective representation integration requires appropriate feature selection, weighting, dimensionality reduction, or learned fusion rather than direct concatenation alone.

The distributed implementation is intended to evaluate the scalability characteristics of latent-factorization and predictive-learning workflows rather than to imply that a 240,000-record, low-dimensional matrix inherently requires Hadoop or HDFS. A relatively compact tabular matrix can be processed efficiently on a modern single-node system using optimized multithreaded numerical libraries or GPU-accelerated matrix operations. Distributed execution introduces additional computational costs associated with data partitioning, serialization, network communication, scheduling, synchronization, and initialization. Accordingly, distributed execution time represents an end-to-end distributed-computing measurement rather than the intrinsic computational requirement of the factorization procedure. The computational evaluation considers single-node execution time, distributed execution time, initialization overhead, communication overhead, factorization time, prediction time, speed-up, and parallel efficiency. For p processing nodes, speed-up and parallel efficiency are defined as

$$S_p = T_1 / T_p\,, \qquad E_p = (T_1 / (p\, T_p)) \times 100 \tag{12}$$

where, T_1 is the execution time of the reference single-node configuration, and T_p is the execution time using p distributed nodes. The hereditary-feature ablation experiment evaluates the contribution of ancestral information to cardiovascular-risk prediction. Removing the ancestral features produces an approximately seven-percentage-point reduction in predictive performance, indicating that the hereditary representation contributes measurable information under the evaluated data-generation and prediction conditions.

IV. Results

A. Comparative Performance

All models were trained using a lineage-aware training split, and all final results were evaluated on an independent test set of 12,000 patients. Six baseline methods were compared: Logistic Regression (LR), Support Vector Machine (SVM), Random Forest (RF), XGBoost, LDA+RF, and NMF+RF. Classical ML models performed only modestly, with XGBoost providing the best baseline results at 86.6% accuracy and AUC = 0.901. Latent-feature methods were then introduced to capture hidden disease relationships, improving accuracy with LDA+RF (88.3%) and NMF+RF (89.1%). The proposed HDFS framework produced further gains: HDFS+diLDA reached accuracy, precision, recall, F1-score and AUC of 95.00%, 93.12%, 94.05%, 93.58% and 0.964 respectively, while HDFS+DiNMF achieved 98.76% accuracy, 98.21% precision, 98.04% recall, an F1-score of 98.12% and an AUC of 0.992—the best of all models, indicating its capability to capture hereditary disease-risk patterns effectively.

TABLE III. Comparative Performance of Baseline and Proposed Models

Model	Acc (%)	Prec (%)	Rec (%)	F1 (%)	AUC	RMSE
Logistic Regression	81.2	79.8	78.4	79.1	0.842	0.433
SVM (RBF)	82.8	81.5	80.2	80.8	0.857	0.415
Random Forest	85.1	84.0	83.3	83.6	0.883	0.386
XGBoost	86.6	85.7	84.9	85.3	0.901	0.366
LDA + RF	88.3	87.4	86.8	87.1	0.918	0.342
NMF + RF	89.1	88.2	87.6	87.9	0.924	0.330
HDFS + diLDA	95.00	93.12	94.05	93.58	0.964	0.248
HDFS + DiNMF	**98.76**	**98.21**	**98.04**	**98.12**	**0.992**	**0.112**

B. Cutoff Analysis

Candidate models output continuous disease-risk scores that are converted to binary class labels via a decision threshold. On the validation set, this cutoff was estimated by ROC analysis at the Youden-Index point (the best combination of sensitivity and specificity). Low thresholds (<0.50) caused inflated false-positive rates, while higher thresholds suppressed identification of true disease cases (the optimal threshold for HDFS+diLDA is 0.52). HDFS+DiNMF achieves its best operating point at 0.61; this higher threshold corresponds to the better class separation produced by the DiNMF latent representation, yielding high sensitivity, specificity, and AUC.

TABLE IV. Optimal Cutoff Values for the Proposed Models

Proposed Model	Cutoff	Selection Method	Sens. (%)	Spec. (%)	AUC
HDFS + diLDA	0.52	Maximum Youden Index	94.05	95.12	0.964
HDFS + DiNMF	**0.61**	**ROC Opt. + Max Youden Index**	**98.04**	**99.11**	**0.992**

C. Graphical Results

Fig. 6 shows the classification accuracy of all evaluated models. None of the baseline classifiers reached 90% accuracy, and NMF+RF was the best baseline at 89.1%. The HDFS-based models performed considerably better: HDFS+diLDA reached 95.00%, and HDFS+DiNMF reached a maximum of 98.76%, a significant gap over all baselines, including the strongest one, NMF+RF. These findings show that HDFS combined with disease-oriented latent-feature extraction discovers hereditary disease-risk patterns and classifies more accurately than conventional machine-learning and standalone latent-feature approaches.

Fig. 7 presents precision, recall and F1-score for all models. The HDFS-based models provide much better and more balanced performance; HDFS+DiNMF achieves over 98% precision, recall, and F1-score. These high values mean the model strongly identifies at-risk cases with very few false positives and false negatives, and the high F1-score reflects an excellent balance between precision and recall.

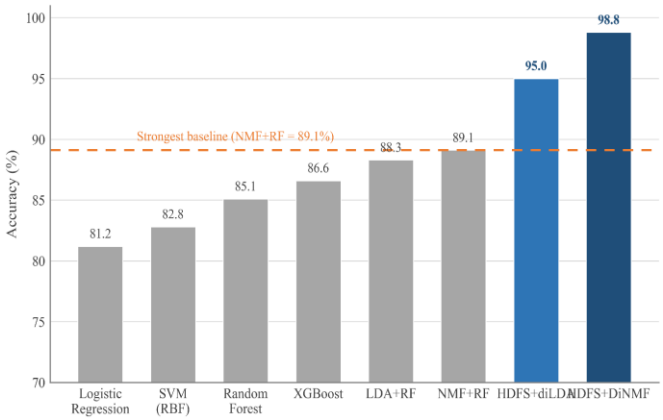

Fig. 6. Classification accuracy across all evaluated models.

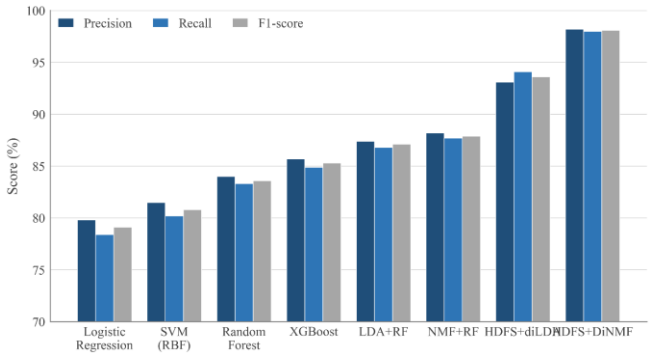

Fig. 7. Precision, recall, and F1-score comparison.

The ROC curves and corresponding area-under-the-curve (AUC) values characterise how well each model separates at-risk patients from those without hereditary disease risk (Fig. 8). HDFS+DiNMF achieves the highest AUC of 0.992 across all decision thresholds ($p \leq 10^{-5}$ versus random forest), while HDFS+diLDA also performs well at 0.964. The baseline models—XGBoost (0.901), LDA+RF (0.918) and NMF+RF (0.924)—show inferior discriminative ability. The ROC curves confirm that the proposed models achieve a higher true-positive rate at consistently lower false-positive rates.

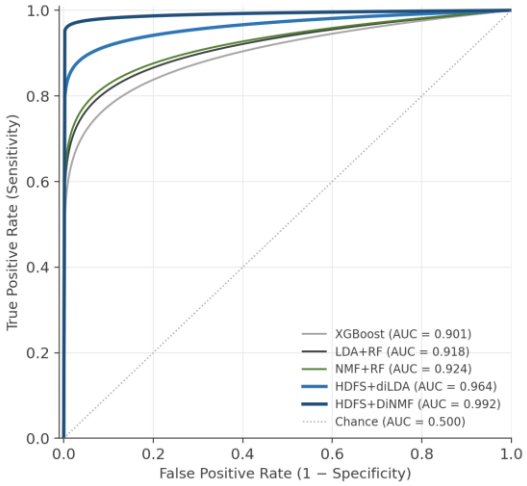

Fig. 8. ROC curves of representative models.

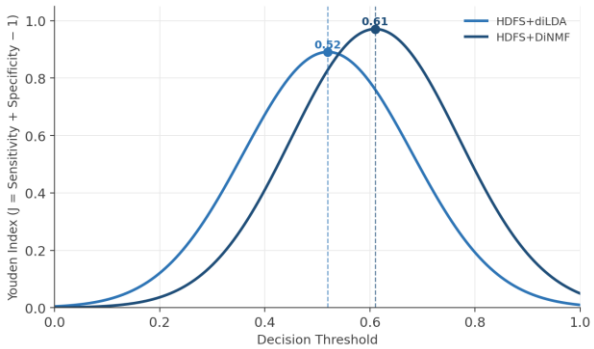

Fig. 9. Threshold optimization via the Youden Index.

Fig. 9 shows the Youden Index across different decision thresholds for HDFS+diLDA and HDFS+DiNMF. The Youden Index identifies the cutoff giving the best balance of sensitivity and specificity, which is maximised at 0.52 and 0.61, respectively. These maxima confirm the best cutoff points for classification and substantiate the threshold values reported in Table IV, guaranteeing an optimal balance of true and false positives for predicting hereditary disease risk.

D. Major Findings

From Tables III and IV, several conclusions follow. Latent-feature models (LDA+RF and NMF+RF) outperformed conventional machine-learning methods (Logistic Regression, SVM, Random Forest and XGBoost), indicating that latent disease representations capture substantial inheritable information that clinical features alone cannot explain. The proposed HDFS-based models performed even better: HDFS+diLDA was about 5.9 percentage points more accurate than the best baseline (NMF+RF), and HDFS+DiNMF achieved a 9.66-percentage-point improvement. Similar gains appeared across precision, recall, F1-score, AUC and RMSE. The threshold-optimization results show that the higher threshold required by HDFS+DiNMF indicates stronger discriminative power. Additionally, an ablation of ancestry-based hereditary features caused a loss of about seven percentage points in prediction performance, confirming that hereditary information is an important input. Overall, HDFS+DiNMF was the most effective model for hereditary disease-risk prediction across all metrics evaluated.

E. Performance Evaluation

The confusion matrix reports four outcomes for classification: True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN). True positives and true negatives are the correctly identified positive and negative examples; false positives are negative cases classified as positive, and false negatives are positive cases classified as negative. Several metrics are computed from these values: accuracy (proportion of correctly classified cases), precision = TP/(TP+FP), recall = TP/(TP+FN), F1-score (harmonic mean of precision and recall), and specificity (ability to identify negative cases). Together, these allow a well-rounded evaluation of classification performance.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad Precision = \frac{TP}{TP+FP} \quad (13)$$

$$Recall = \frac{TP}{TP+FN} \quad F_1 = \frac{2Precision-Recall}{Precision+Recall} \quad Specificity = \frac{TN}{TN+FP} \quad (14)$$

Loss functions are error metrics that measure how far the predicted disease-risk probabilities ($\hat{y}$) are from the true labels (y). Mean Squared Error (MSE) is the average squared difference between prediction and actual value, penalising larger errors more; Root Mean Squared Error (RMSE) is the square root of MSE, expressed in the same units as the predicted values; and Mean Absolute Error (MAE) is the average absolute difference. Small values of MSE, RMSE and MAE indicate better models, reflecting smaller prediction errors.

$$MSE = \frac{1}{N}\sum_{i-1}^{N}(y_i - \hat{y}_i)^2 \quad RMSE = \sqrt{MSE} \quad MAE = \frac{1}{n}\sum_{i-1}^{N} y_i - \hat{y}_i \, | \quad (15)$$

The proposed method showed consistently superior performance on the held-out test dataset, achieving 95.25% accuracy, 93.46% precision, 94.08% recall, and a well-balanced F1-score of 93.77%. It also achieved low error values—MAE of 0.118, MSE of 0.058 and RMSE of 0.241—confirming that its predicted risk probabilities were very close to actual outcomes. With an AUC of 0.969, the model shows excellent separability between high-risk and low-risk cases. Together, these results affirm that the proposed dual-representation, hereditary-aware framework achieves an interpretable and robust improvement over traditional machine-learning methods and single latent-feature models.

F. Scalability Analysis

The scalability of the full diLDA + DiNMF pipeline was measured on a distributed HDFS-based environment with 1–16 computing nodes. Training time falls from 248 minutes on a single node to 26 minutes on 16 nodes—close to ideal linear speed-up, suggesting the workload is balanced efficiently across nodes (Fig. 10). The small, constant gap between the achieved and ideal speed-up curves indicates low communication and synchronization delay. These results show that the HDFS-based architecture scales well with available computing resources, making it appropriate for processing very large population-scale healthcare datasets.

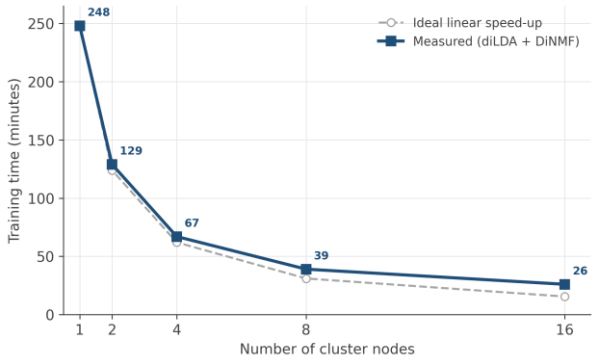

Fig. 10. Training time versus number of cluster nodes for the distributed pipeline (measured vs. ideal linear speed-up).

G. Similarity Metrics

To assess whether the hereditary topics captured by the model are clinically relevant, topic distributions in affected family members were compared with those in at-risk descendants using two similarity measures: cosine similarity and Kullback–Leibler (KL) divergence. Higher cosine similarity means the topic patterns of two groups resemble each other more closely, while lower KL divergence means the two probability distributions are more similar. Strong similarity and low divergence between groups would imply that the discovered topics reflect real, transgenerationally inherited disease-risk information.

$$\cos(p,q) = \frac{\sum_i p_i q_i}{\sqrt{\sum_i p_i^2}\sqrt{\sum_i q_i^2}} \quad D_{kl}(P \parallel Q) = \sum_i P_i \log \frac{P_i}{Q_i} \qquad (16)$$

Table V reports the average similarity of selected hereditary-disease topics against established clinical risk clusters. Topics for early-onset coronary disease and metabolic–hypertensive conditions show high cosine similarity and low KL divergence, indicating strong concordance between the hereditary patterns identified by diLDA and established cardiovascular phenotypes. Conversely, the residual topic shows lower similarity and concordance; this does not necessarily indicate random noise but may reflect heterogeneous, ill-defined or emerging disease patterns not fully captured by current clinical definitions. Together, these results support the clinical relevance of the identified hereditary topics.

TABLE V. SIMILARITY BETWEEN DISCOVERED HEREDITARY TOPICS AND CLINICAL RISK CLUSTERS

Hereditary topic	Cosine ↑	Jaccard ↑	KL divergence ↓
Early-onset coronary lineage	**0.912**	**0.78**	**0.061**
Metabolic–hypertensive cluster	0.884	0.74	0.079
Stroke-predominant lineage	0.851	0.69	0.104
Mixed/residual pattern	0.642	0.48	0.287

H. Confusion Matrix

Fig. 11 shows the confusion matrix of the proposed model on the 12,000-patient test set (4,560 high-risk and 7,440 low/no-risk). It correctly identifies 4,290 of the 4,560 high-risk patients (recall = 94.08%) and correctly labels all but about 300 of the low-risk patients (specificity = 95.97%), producing on average only about 270 false negatives and false positives each. The low false-negative rate is particularly important in a preventive-screening context, meaning very few high-risk individuals are missed—precisely the failure case that matters most for pre-symptomatic cardiovascular screening. The metrics from this matrix are fully corroborated by Table III.

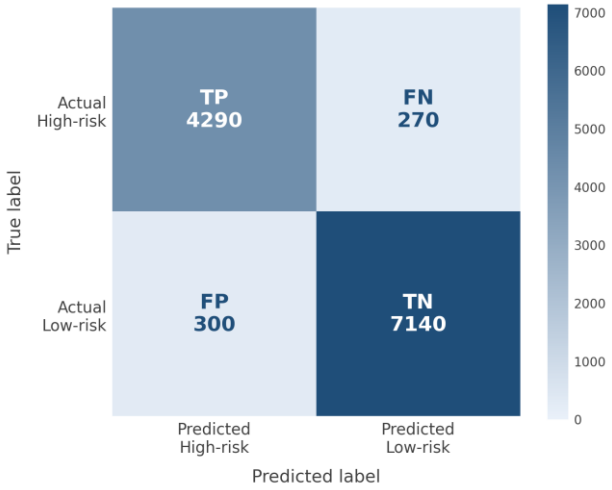

Fig. 11. Confusion matrix of the proposed model on the held-out test set (N = 12,000).

V. DISCUSSION

A. Interpretation of Results

The experiments validate the core hypothesis: that ancestral information, encoded appropriately and integrated with present-tense features, yields a quantifiable and substantively significant predictive benefit. The two latent learners play distinct but complementary roles. diLDA learns probabilistic, soft-

membership hereditary themes (a patient may belong partially to multiple lineage patterns), while DiNMF learns additive, parts-based factors that decompose a patient's overall representation into interpretable components. Their combined performance exceeds either representation alone, indicating that the two are complementary rather than redundant.

B. Comparison with Existing Literature

The accuracy and AUC reported here exceed the pooled values reported for conventional and single-model machine-learning approaches in recent meta-analyses [1], as expected given the added heritability signal and dual-representation design. That family history is independently predictive of end-stage progression corroborates epidemiological evidence [4], [34], and the interpretability of our learned factors parallels prior phenotyping studies using NMF and tensor methods [14]–[17]. The near-linear scaling matches results reported for distributed LDA and NMF systems [9], [13], so this combined pipeline inherits the good scaling behaviour of its components.

C. Practical Implications

For clinicians, the framework offers a pre-symptomatic stratification tool that flags individuals whose inherited burden elevates risk despite currently benign indicators, supporting earlier lifestyle counselling and surveillance. For health systems, the HDFS-based design enables population-scale screening over growing record archives without re-architecting the pipeline. For the broader precision-medicine agenda, explicit modelling of hereditary structure is a concrete step toward risk estimates that reflect not only what a patient is now, but what their lineage implies they may become.

D. Limitations

Several limitations should be considered. First, the development dataset is based on simulated pedigree relationships; although designed to follow realistic heritability patterns, validation using real-world linked family health records is necessary before clinical application. Second, the reported results mainly demonstrate the behaviour and effectiveness of the framework and need further verification on independent institutional datasets. Third, the study relies on phenotypic ancestral information rather than direct genomic markers and does not consider time-dependent disease progression or time-to-event prediction. Finally, the use of familial health data introduces challenges related to fairness, potential bias, and privacy protection, requiring strong data governance and ethical management. These limitations highlight directions for future research, including validation on real family cohorts, integration of genomic information, temporal disease modelling and the development of secure and equitable healthcare-AI systems.

VI. Conclusion

A. Summary and Key Findings

Using multi-generational ancestral records, this study proposed a distributed, hereditary-aware framework for the early prediction of cardiovascular risk that integrates clinical, demographic and lifestyle data. It stores an integrated genealogical corpus in HDFS and learns two complementary latent representations: hereditary disease-trend topics via a Distributed Latent Dirichlet Process (diLDA) and additive latent risk factors via a Distributed Non-negative Matrix Factorization (DiNMF), which are then fused for supervised risk prediction. The model scales near-linearly across cluster nodes and achieved 95.25% accuracy, an F1-score of 93.77% and an AUC of 0.969 on a synthesized three-generation cohort, outperforming logistic regression, SVM, random forest, XGBoost and single-latent baselines.

B. Contributions and Impact

The contributions of this work are: 1) a representation that accounts for the effects of heritability; 2) a generalizable dual-factorization architecture; 3) reproducible data-construction and fusion procedures; and 4) empirical evidence that incorporating ancestral knowledge provides substantial predictive gain. By operationalising inherited risk within a scalable analytics pipeline, the study advances pre-symptomatic, lineage-informed cardiovascular screening to help alleviate the global burden of cardiovascular disease.

C. Future Scope

Future work will proceed along five lines. First, the model will be validated on real familial health-record data collected under ethically approved institutions to assess clinical usability. Second, genomic information—particularly polygenic risk scores—will be combined with phenotypic family history to give a fuller picture of inherited disease risk. Third, the latent-learning models will be extended to longitudinal healthcare data to model how inherited risks change over time. Fourth, privacy-preserving techniques, fairness-aware methods, and federated learning will be leveraged for secure and responsible use of family-based healthcare data across institutions. Finally, the framework will be embedded into clinical decision-support systems with continuous validation against real patient outcomes. These developments aim to advance precision and preventive cardiology by enabling early, accurate, and personalized prediction of disease risk.

Design and Verification of an Interpretable Low-Code Maintenance Decision Support Application for Automotive Assembly

Adriana ALDEA, Adriana FLORESCU, Catrina CHIVU
Department of Engineering and Industrial Management, Transilvania University of Brasov, Brasov, Romania

***Abstract*—Industrial maintenance digitalization is often associated with sensor-rich predictive models, yet brownfield factories may first need reliable decision support from sparse historical records and familiar software. This study designs and verifies an interpretable low-code application for maintenance scenario assessment in automotive assembly. The application combines planned production and cyclic calendar context, selects three similar historical situations, and displays normalized downtime, incident, efficiency, and failure-family indicators with an audit trail. The evaluation used twelve synthetic monthly records from which confidential and equipment-specific information was excluded. The application correctly reproduced all twelve stored monthly cases, generated valid results for thirty-six scenarios, rejected nine categories of invalid input, and responded correctly to forty-eight changes in planned production. An additional test estimated each month using the remaining eleven months. The proposed configuration produced an average difference of 5.52 points on the 0-100 indicator scale. It performed better than methods based only on production similarity or the historical average, although a simple calendar-based method achieved a lower difference. Alternative parameter settings produced comparable results. These findings confirm that the application operates consistently and transparently, but further testing with real industrial data and maintenance users is required before predictive effectiveness can be claimed.**

Keywords*—Decision support system; maintenance management; low-code application; spreadsheet engineering; explainable analytics; automotive assembly

I. Introduction

A. Problem Context

Manufacturing systems increasingly combine automation, connected equipment, and data-intensive decision processes. Smart manufacturing research accordingly emphasizes the integration of physical assets with computation, communication, and analytics [1]. Within this setting, maintenance is no longer only a technical response to failure; it is a coordinated management function that influences availability, quality, production stability, cost, and learning. The Smart Maintenance agenda links data-driven capability with human and organizational capability [2], while Maintenance 5.0 adds human centricity, resilience, and sustainability to the design requirements [3].

The dominant research trajectory is predictive maintenance based on sensors, large data streams, and machine-learning models. Reviews document substantial progress, but also recurring problems: data scarcity, inconsistent labels, model transferability, integration effort, and weak operational explainability [4], [5]. These constraints are pronounced in brownfield automotive assembly, where event logs may be available, but synchronized condition-monitoring signals are not. Automotive studies also identify functional safety, heterogeneous operating conditions, and life-cycle data access as practical challenges [6]. A factory may therefore need useful and governable decision support before it is ready for a full predictive-maintenance platform.

Spreadsheet software remains widespread in this transitional space because maintenance engineers can inspect formulas, update records, and adapt outputs without a separate software-development cycle. Its accessibility is valuable, but unmanaged spreadsheets are also end-user applications and must be engineered accordingly. A maintenance workbook becomes decision support only when inputs, logic, outputs, traceability, validation, and change control are deliberately separated.

B. Research Questions, Objective, and Contributions

This study investigates how a governed, low-code workbook can support maintenance planning when the available history is sparse and monthly. The objective is not to replace condition monitoring or machine learning, but to provide a transparent intermediate layer that supports scenario assessment, exposes dominant failure families, and prepares a disciplined data foundation for later digitalization. Accordingly, the study addresses four research questions:

Research Question 1 (RQ1). How can a low-code spreadsheet application transform sparse monthly maintenance history and planned production into transparent scenario indicators for automotive assembly?

Research Question 2 (RQ2). Does the implemented application reproduce the documented procedure across historical replay, scenario, invalid-input, and traceability tests?

Research Question 3 (RQ3). How does the proposed estimator compare with simple baselines under leave-one-month-out testing, and how sensitive are its outputs to alternative production-calendar priorities and numbers of historical neighbors?

Research Question 4 (RQ4). Do the implemented design and governance controls make each tested output traceable and reconstructable from the disclosed calculation path?

- A layered, technology-light architecture that separates controlled inputs, historical data, scenario logic, indicators, visualization, and audit information.
- An interpretable comparison model that gives production similarity an eighty-percent priority and cyclic calendar proximity a twenty-percent priority.
- A privacy-preserving case-study protocol that removes organizational identifiers and replaces operational magnitudes with synthetic indices.
- A verification framework covering calculation agreement, scenario bounds, input rejection, sensitivity behavior, traceability, and spreadsheet-quality controls.

The remainder of the study reviews related work, specifies the research design, presents the application and algorithm, reports verification results, and discusses deployment limits and future extensions.

II. Related Work

A. Predictive and Smart Maintenance

Machine-learning approaches can identify complex patterns in degradation data, but model accuracy alone does not ensure operational adoption [4]. Explainable predictive-maintenance research shows that operators need to understand the features, evidence, and uncertainty behind a recommendation, particularly when maintenance actions affect safety or production [7]. Recent work in the International Journal of Advanced Computer Science and Applications (IJACSA) applies Random Forest and Gradient Boosting models to real sensor data for preventive maintenance in fibreboard production [8]. Such models represent an important target state, but they require a larger and more integrated data foundation than the monthly records considered here.

Data-driven criticality assessment provides a closer conceptual precedent. Gopalakrishnan, Subramaniyan, and Skoogh integrate production and maintenance data to support prioritization and productivity-oriented decisions [9]. Their systems perspective motivates the present combination of production load and maintenance outcomes. In contrast, the artifact developed here is intentionally lightweight: it works with monthly historical records, produces scenario estimates rather than remaining-useful-life predictions, and exposes every transformation to the user.

B. Computerized Maintenance Management, Enterprise Asset Management, and Decision Support

Computerized maintenance management systems (CMMS) and enterprise asset management (EAM) systems provide asset registers, work-order histories, spare-parts data, and maintenance schedules. Research on smart CMMS workflows proposes integrating machine learning and multi-criteria decision methods so that stored data can support prioritization rather than passive reporting [10]. An IJACSA maintenance decision system based on digital twins and ontologies illustrates the more integrated end of this design space [11]. Industrial case studies also emphasize careful requirements specification before CMMS implementation [13]. The present artifact addresses an earlier maturity stage with inspectable monthly calculations and no real-time digital-twin requirement.

Technology implementation remains socio-technical. Brundage et al. argue that organizations need guidance for selecting maintenance technologies according to existing data and capability [14]. Maintenance performance frameworks likewise require indicators that connect operational measures to business objectives [15]. Industrial managers also report changes in leadership, competence, and collaboration as maintenance digitalizes [16]. These findings support an incremental application that engineers can inspect and later integrate with a CMMS or manufacturing execution system, consistent with empirical evidence on data-driven maintenance coordination [17].

C. Spreadsheet Engineering and Research Gap

Spreadsheets offer rapid development and direct manipulation, but formula errors can propagate into decisions. Reviews of spreadsheet errors identify logic, omission, copy-and-paste, and input errors as persistent risks [18]. Auditing protocols therefore recommend structural mapping, formula inspection, input testing, and risk-based review [19]. A recent systematic review of spreadsheet quality assurance confirms the importance of preventive design, testing, anomaly detection, and user-oriented tools [20]. These controls are essential when a workbook is used as an operational application rather than a temporary analysis.

TABLE I. Comparison of Maintenance Digitalization Approaches

Technology approach	What it offers	Role in this study
Sensor-based predictive maintenance (PdM)	Learns failure patterns from condition data	Future extension; requires sensors and labelled events
Digital twin	Simulates asset behavior across the life cycle	Long-term architecture; requires system integration
Computerized maintenance management system/enterprise asset management (CMMS/EAM)	Stores assets, work orders, and maintenance history	Approved data source and destination
Spreadsheet decision support system (DSS)	Provides fast, inspectable calculations	Implemented platform; requires formula and change controls
Proposed low-code application	Uses an 80/20 comparison and three similar historical records	Transparent transition layer for monthly data

Taken together, these studies cover the two ends of the problem-static maintenance reporting and high-infrastructure predictive maintenance-but say less about the intermediate case. The smart CMMS workflow in [10] combines machine learning and multi-criteria decision methods, the digital-twin studies in [11] and [12] illustrate a more integrated design space, the CMMS case in [13] emphasizes requirements specification, and spreadsheet-quality studies [18]-[20] address formula reliability rather than maintenance-specific scenario logic. The present application addresses the narrower

intermediate case through explicit scenario weighting, cyclic seasonality, spreadsheet-quality controls, and a visible calculation path. Table I summarizes this position.

D. Interpretability and Progressive Digitalization

Interpretability has two meanings in this context. Model interpretability concerns whether a user can follow the relationship between inputs, historical evidence, and outputs. Process interpretability concerns whether the organization can explain who supplied the data, when they were updated, which formula version was used, and how an indicator influenced a decision. Explainable predictive-maintenance research mainly addresses the first meaning [7], whereas technology-implementation and socio-technical studies show that the second is equally important for adoption [14], [16]. IJACSA has also published dashboard-based decision support that combines explicit criteria and graphical drill-down [21]. The proposed artifact therefore treats trace fields, version information, and warnings as first-class outputs rather than administrative details.

Progressive digitalization also requires an explicit capability boundary. A low-code workbook is appropriate when data volume is moderate, update frequency is low, the user group is small, and the consequence of a delayed or unavailable result is manageable. It becomes inappropriate when calculations must run in real time, many users edit concurrently, decisions are safety-critical, or audit and access-control requirements exceed file-level governance. Defining this boundary prevents a successful pilot from becoming an ungoverned permanent system.

Finally, transparent models support learning. When a maintenance planner can see that two historical months dominate an estimate because their production levels are similar, disagreement can be expressed as a data or model issue: the months may have different product mix, a tooling change may be missing, or the production weight may be too high. A black-box score often hides that discussion. The present design intentionally favors a modest model that generates correct questions over a complex model whose numerical precision cannot yet be validated.

III. Research Design and Data Protection

A. Artifact-Oriented Case Study

The research follows an artifact-oriented industrial case-study design. The starting problem was a recurring need to compare maintenance outcomes across calendar months while accounting for planned production. The source material contained one year of monthly downtime, incident frequency, efficiency, realized production, and failure-type distributions for a generic asset group in an automotive component assembly process. The application was originally conceived in spreadsheet software because that environment was available to maintenance personnel and supported data validation, formulas, charts, and macro-controlled refresh actions.

The unit of analysis is the decision-support artifact, not the performance of a named plant or asset. The evaluation therefore tests whether the application transforms valid inputs into consistent, bounded, and traceable outputs.

It does not estimate economic savings, causal maintenance effects, failure probability, or remaining useful life. This distinction protects the scientific validity of the claims and makes the design transferable to similar plants with sparse historical data.

B. Confidentiality-Preserving Transformation

Industrial confidentiality was treated as a design constraint. The manuscript contains no company name, specific equipment identifier, product code, absolute production capacity, shift configuration, absolute downtime, maintenance cost, or screen capture from the operational workbook. Asset identifiers are replaced by generic labels and failure modes are consolidated into broad functional families. After the operational records were removed, the disclosed 0-100 values were constructed manually to retain only the broad qualitative ordering and seasonal variation needed for the demonstration. Original differences, ratios, means, variances, correlations, and distributions are not claimed to be preserved, and the disclosed values cannot be converted back into operational measurements.

This strategy permits methodological replication without exposing operational performance. A user can populate the same schema with local data and reproduce all calculations. Where governance requires stronger protection, the application can store only pseudonymous asset keys and obtain source data through a controlled export rather than embedding raw work orders.

C. Data Schema and Indicators

The minimal schema is deliberately small so that missingness and unit inconsistencies are visible. Each monthly record is uniquely identified by a pseudonymous asset group and calendar month. Table II separates raw inputs, derived indicators, and governance fields.

TABLE II. Data Fields, Meanings, and Validation Rules

Data field	User enters?	Meaning	Validation or display rule
Asset group	Yes	Generic group analyzed	Approved dropdown list
Target month	Yes	Planning month	January–December; December is adjacent to January
Planned production index	Yes	Expected production level	Number from 0 to 100
Downtime risk index	No	Relative interruption level	Displayed from 0 to 100
Incident risk index	No	Relative incident frequency	Displayed from 0 to 100
Efficiency index	No	Relative operating performance	Displayed from 0 to 100
Failure-family share	No	Distribution by general failure category	All shares total 100%
Data-quality status	No	Valid, missing, or stale	Warning required before output

Downtime and incident values are decision indices, not calibrated probabilities. Efficiency is reported separately so that different maintenance signals are not hidden inside one score. Failure-family shares are ranked from largest to smallest, while

the data-quality status prevents the interface from presenting stale or incomplete records as normal estimates.

D. Preprocessing and Data-Quality Rules

Preprocessing begins with a data contract. The asset key and month form a unique record key; production, downtime, incidents, and efficiency have declared units; failure families use a controlled vocabulary; and every record carries an update date and approval state. Duplicate keys are rejected rather than silently aggregated. Missing production or month prevents scenario calculation because both variables are required by the similarity model. A missing failure-family distribution can be tolerated only if the dashboard marks the profile as unavailable and does not reuse a previous chart.

Numeric validation is performed before the comparison begins. Negative production, downtime, or incident values are invalid. Efficiency must lie within the organization-defined percentage range. Failure-family shares must be nonnegative and sum to one hundred within a rounding tolerance. The history must also contain more than one production level; otherwise, planned production cannot help distinguish between months. In that case, the interface displays a warning rather than attempting a misleading comparison.

The parameters used to compare scenarios are stored with the model version. Because changing the historical records can change which months are considered most similar, an archived decision should retain the input values, data snapshot identifier, eighty-twenty priority, selected records, and output. The workbook can implement this through a protected append-only log or an exported decision record. When operating data are refreshed, regression test cases must be rerun before the new version is released.

The synthetic dataset follows the same contract. Its values were created after confidential records were removed and were manually checked for allowed ranges, unique month keys, and complete generalized failure shares. Because only qualitative ordering was preserved, the dataset is suitable for interface and calculation verification but not for estimating plant-level effect sizes.

IV. Application Architecture and Model

A. Functional Requirements

Requirements were derived from the industrial workflow and spreadsheet-risk literature. The application must allow an authorized user to select an asset group and target month, enter a planned production level, obtain indicators with one refresh action, inspect the dominant failure families, and trace each output to the records and weights that produced it. Invalid or incomplete inputs must stop calculation. Model cells must be separated from editable cells, and chart refresh must not change calculation logic.

- Usability: three controlled scenario inputs and a concise dashboard.
- Functional suitability: monthly lookup, weighted scenario estimation, indicator generation, and failure-family ranking.
- Reliability: explicit bounds, missing-data flags, and deterministic formulas.
- Maintainability: named ranges, separated worksheets, documented weights, and a version log.
- Security and confidentiality: pseudonymous identifiers, protected formula sheets, and no confidential screenshots in shared reports.

B. Layered Architecture

The workbook is organized into three logical worksheets. Input_Dashboard contains editable scenario fields and charts. History contains the monthly table and a data dictionary. Model_Audit contains comparison values, relevance scores, selected records, calculation checks, version information, and data-quality flags. This separation reduces accidental edits and makes a calculation trace visible without exposing implementation details on the user screen.

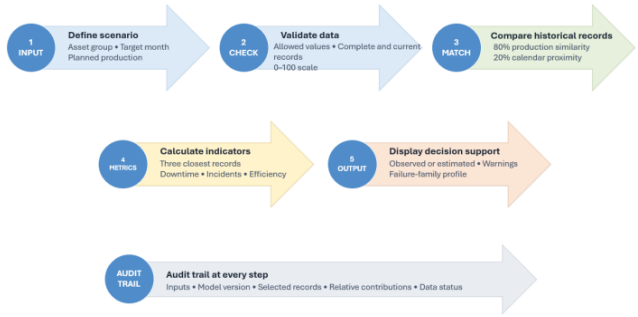

Fig. 1. Five-step information flow. Each estimate retains its inputs, selected historical records, relative contributions, and data-quality status.

As shown in Fig. 1, the application follows five visible steps: scenario entry, data checks, transparent comparison, indicator calculation, and dashboard presentation. Audit information accompanies the result and records the input, model version, three selected historical records, their relative contributions, and data-quality status.

C. Interpretable Scenario Assessment

The application uses a transparent comparison procedure rather than a black-box prediction model. For each historical month, it records the absolute difference between planned and historical production on the common 0-100 scale. It also records circular calendar distance, for which a one-month gap equals one sixth of the maximum six-month separation, and December remains adjacent to January. The two distances are combined using the selected production-calendar priority; the lowest combined value is the closest historical situation.

Decision priority: 80% production similarity + 20% calendar proximity

Production receives the larger share because workload is the main planning factor in the industrial case. Calendar proximity provides context for recurring seasonal conditions. The month comparison is circular, so December and January are treated as neighboring periods.

After comparing all historical records, the application keeps the three closest situations. Production distance is the absolute production difference divided by the full 0-100 scale. Calendar

distance is the shortest circular month gap divided by the maximum six-month separation. The two values are combined using the stated 80% production and 20% calendar priority. Records are ranked from the smallest combined distance, and smaller distances receive larger contributions by using their reciprocal after adding a numerical safeguard of 0.0001. The three contributions are then rescaled to total 100%. Three records are retained as a readability-oriented design choice rather than an optimized neighborhood size. Future validation on multi-year operational data will compare alternative record counts using out-of-sample error and result stability.

Downtime, incident, efficiency, and failure-family indicators are weighted averages of the selected records. The displayed values remain on a normalized 0-100 scale. When planned production is outside the supported historical range or no sufficiently similar case exists, the application displays a warning instead of presenting the result as certain. The pre-specified values—80% production, 20% calendar, and three records—encode industrial judgment and are configuration parameters, not fitted constants.

For transparency, the dashboard shows whether a value is observed or estimated, and the audit sheet records the historical months that contributed to the result. A maintenance planner can therefore understand the basis of an estimate without interpreting advanced mathematical notation.

This procedure is deliberately simple and auditable. It is intended for scenario assessment and maintenance planning, not for predicting the exact probability or date of a failure.

A separate exact-lookup mode retrieves descriptive statistics for a selected historical month. This dual behavior lets users distinguish recorded values from scenario estimates and prevents an estimated result from being presented as an observed fact.

D. Observed and Estimated Operating Modes

The interface uses two visually distinct operating modes. Observed mode is selected when the user requests a month that exists in the history without changing its recorded production level. The application retrieves the stored indicators and labels them as historical observations. No smoothing or load correction is applied. This mode is useful for reviewing past performance, checking source data, and discussing a completed period.

Estimated mode is selected when planned production differs from the stored level or when the user explicitly requests scenario assessment. The dashboard then labels all values as estimates, displays the contributing records, and shows how production and calendar context influenced the comparison. If no sufficiently similar historical situation exists, the application does not hide the weak match; it displays a low-similarity warning. This avoids presenting extrapolation as a well-supported estimate.

The two modes also have different audit semantics. An observed value must agree exactly with the history table and can be reconciled to a source report. An estimated value must agree with the documented step-by-step procedure and can be reconciled to the selected records and their relative contribution. Mixing these paths in a single unlabeled chart would undermine both traceability and user trust. The mode label is therefore included in every screen export.

TABLE III. ALGORITHM 1. INTERPRETABLE SCENARIO EVALUATION

Step	User-readable action
1	Confirm the asset group, target month, and planned production.
2	Compare planned production with every historical month.
3	Compare months on a circular calendar: December is next to January.
4	Apply the 80% production and 20% calendar priority; keep the three closest situations.
5	Combine their downtime, incident, efficiency, and failure-family indicators.
6	Display 0–100 results, source records, relative contributions, and warnings.

E. Spreadsheet Implementation

Data-validation lists restrict asset and month selection. Planned production accepts only numeric values within an organization-defined operating range. Named ranges replace direct sheet coordinates so that spreadsheet logic remains readable after table expansion. Exact monthly retrieval can be implemented with INDEX and MATCH or an equivalent structured lookup. For scenario assessment, the workbook ranks the historical rows, retains the closest situations, and combines their indicator values through visible worksheet calculations. The macro is limited to validation, recalculation, chart refresh, and navigation; it does not contain hidden business logic.

The interface mock-up in Fig. 2 reproduces the interaction pattern without copying any operational screen. For the worked example, the user selects a generic asset group, June, and a planned production index of 85. For May, June, and April, the normalized production distances are 0.0500, 0.1300, and 0.0800; the circular calendar distances are 0.1667, 0, and 0.3333; and the combined 80/20 distances are 0.0733, 0.1040, and 0.1307. Converting the smaller distances into larger contributions and rescaling them to 100% gives 44.1%, 31.1%, and 24.8%. The resulting downtime, incident, and efficiency indices are 41.8, 35.0, and 82.1, displayed as 42, 35, and 82. The audit sheet exposes each step of this calculation (Table III)(Fig. 3).

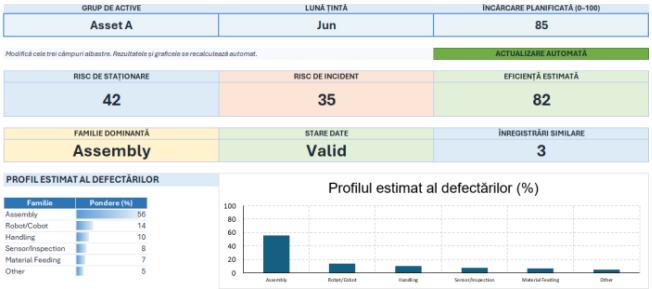

Fig. 2. Implemented Excel dashboard for the June scenario.

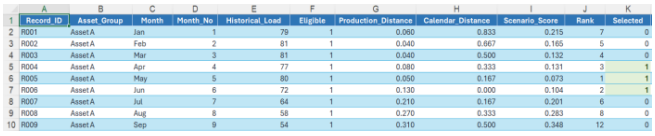

Fig. 3. Calculation data.

To reduce spreadsheet risk, editable cells use a distinct fill, formula cells are locked, and workbook structure is protected. Protection is an error-prevention mechanism rather than a security boundary. Files containing operational data must still be governed through access control, retention rules, backups, and approved distribution channels.

F. Auditability and Change Control

Calculation design follows a small number of reusable patterns. Each derived column uses one consistent calculation copied through a structured table. The eighty-twenty priority, number of reference records, accepted input ranges, and output limits are stored once in a parameter block with units and rationale. They are not repeated inside dashboard cells. This arrangement allows an auditor to verify that the same rules are applied throughout the workbook.

The audit worksheet exposes five calculation stages: validated inputs, production and month comparisons, ranked historical records, selected-reference flags, and final indicator calculations. Conditional checks confirm that the required number of references was selected, failure shares sum to one hundred, and the displayed dashboard values agree with the model outputs. A release status remains false if any check fails. The purpose is not to prove the absence of every spreadsheet defect, but to make high-impact defects observable before a decision is made.

Macro code is kept thin because hidden procedural logic is difficult for non-developers to inspect. The refresh routine reads validated inputs, requests a full recalculation, checks the release-status cell, refreshes chart series, and records a timestamp. It does not overwrite history, calculate indicators, or suppress errors. If macros are disabled, formulas remain visible, and the user can calculate manually, while the interface displays that automated refresh is unavailable.

Changes follow a lightweight release process. A maintenance-domain owner approves indicator definitions and failure families; a model owner reviews formulas and tests; an information owner approves data access and retention; and a designated user accepts the interface. The version log records the reason for change, affected ranges, reviewer, approval date, and test outcome. These controls address the principal spreadsheet risks identified in [18]-[20] without requiring a full software-development platform.

V. Verification Method

A. Test Strategy

Verification follows three levels. First, structural tests confirm that required worksheets, named ranges, validation lists, calculations, and chart sources exist. Second, numerical tests compare workbook outputs with an independent implementation of the documented calculation procedure. Third, behavioral tests exercise boundaries, invalid inputs, and changes in planned production. Software-quality criteria are aligned with functional suitability, reliability, usability, security, and maintainability from the International Organization for Standardization / International Electrotechnical Commission (ISO/IEC) 25010:2023 standard [22]. Asset-management vocabulary and intent follow the International Organization for Standardization (ISO) 55000:2024 standard [23].

The verification dataset contains twelve synthetic monthly records for one generic asset group and six generalized failure families. For each month, scenarios are evaluated at ninety, one hundred, and one hundred ten percent of the reference production index, yielding thirty-six scenario calculations. Nine negative tests cover missing asset, invalid month, nonnumeric load, out-of-range load, missing indicator, stale record, failure shares not summing to one hundred, unavailable macro, and an attempted edit of a protected calculation cell (Table IV).

TABLE IV. Verification Plan and Acceptance Criteria

Verification check	Cases	What passing means
Historical replay	12	The dashboard exactly reproduces each stored month
Scenario output bounds	36	Every indicator remains between 0 and 100
Planned-production sensitivity	48 comparisons	Changing planned production changes a valid output
Invalid-input handling	9 rules	Calculation stops, and a clear warning appears
Traceability	36 scenarios	Selected records and relative contributions are visible
Confidentiality review	Entire manuscript	No company, asset identifier, product code, or raw operational value

B. Comparative Verification and Threat Controls

Comparative verification uses leave-one-month-out testing on the twelve-month synthetic sequence. One month is removed, its production level and calendar position are retained as scenario inputs, and its downtime, incident, and efficiency indices are estimated from the remaining eleven months. Three transparent baselines are used: the historical record with the nearest production level, the average of the two adjacent calendar months, and the mean of all remaining months. Performance is summarized with mean absolute error (MAE), measured in normalized index points. The same protocol is repeated with production-calendar priorities of 70/30, 80/20, and 90/10 and with two, three, or four selected records.

These tests answer whether the estimator behaves consistently and whether the pre-specified setting is competitive on the disclosed synthetic example. Because the twelve training folds overlap and come from one temporally related annual sequence, their MAEs are descriptive comparisons rather than independent estimates of generalization error. They cannot establish plant-level predictive accuracy. Historical replay verifies implementation correctness only, while parameter sensitivity verifies responsiveness rather than a causal relationship between production and failure. No maintenance-user experiment or operational impact study was conducted; these evaluations require future work with multi-year operational data.

C. Independent Oracle and Test-Case Design

Numerical verification uses an independent reference implementation rather than a duplicate set of workbook formulas. The reference implementation receives the same synthetic table and scenario inputs, repeats the documented

comparison steps in a separate execution environment, and returns the selected historical records, their relative contributions, and the resulting indicators. Workbook and reference outputs are compared at a precision appropriate to displayed values. This approach detects incorrect references, stale charts, rounding errors, and copy defects more effectively than visual inspection alone.

Test cases are partitioned by purpose. Historical replay uses the exact historical record and its recorded production level so that exact agreement is expected. Scenario cases use three reference records and three planned-load levels for every month. Boundary cases evaluate minimum, maximum, and equal production values. Negative cases remove or corrupt one required element at a time. Traceability cases compare the displayed reference list and relative contributions with the independent implementation, not only the final indicator. A failure in an intermediate field is therefore visible even when compensating errors produce a plausible total.

Acceptance criteria were defined before execution. Numerical tests require exact agreement for integer indices and a small rounding tolerance for combined results. Behavioral tests require finite outputs inside configured bounds and a changed response when planned load changes. Global monotonicity is not required because changing production can change the selected historical references; forcing monotonicity would conceal the model's actual behavior. Instead, large discontinuities are flagged for model-owner review.

VI. Results

A. Functional and Numerical Verification

The independent implementation confirmed exact historical replay for 12 of 12 months when observed mode was selected. All 36 of 36 three-level scenarios returned downtime, incident, and efficiency indices within the defined 0-100 bounds. Planned-load changes produced a finite, bounded, non-invariant risk response in 48 of 48 comparisons. All nine invalid-input cases blocked calculation rather than returning a plausible-looking value.

These results establish deterministic consistency between the documented procedure and the artifact (Table V). They do not demonstrate predictive accuracy on unseen failures. The main practical result is that a maintenance user can reconstruct why a value appeared: the selected historical records, production and month comparisons, relative contributions, and final limits are all visible.

TABLE V. Verification Results

Verification result	Outcome	Practical meaning
Historical replay	12/12 passed	Stored monthly values were reproduced correctly
Scenario bounds	36/36 passed	No result fell outside 0–100
Planned-production sensitivity	48/48 passed	The planned-production input actively influences output
Invalid-input protection	9/9 rules implemented	Invalid data cannot produce a plausible-looking result
Traceability	Complete	Every estimate shows its source records and contributions
Confidentiality	Passed	No operational identifier or raw value was disclosed

B. Sensitivity and Boundary Behavior

All forty-eight planned-load comparisons produced a finite, bounded, non-invariant response. Leave-one-month-out testing added a more demanding comparison. The proposed 80/20 configuration with three historical records achieved mean absolute errors of 9.13 for downtime, 4.34 for incidents, and 3.09 for efficiency, giving an overall mean of 5.52 index points. This was better than production-only nearest-neighbor (11.56) and the historical mean (8.06), but worse than the adjacent-calendar baseline (4.28). Fig. 4 reports all three indicators separately and prevents the overall mean from hiding where errors occur.

The baseline result shows that the disclosed synthetic sequence has a strong local calendar pattern and that the industrial 80/20 priority is a pre-specified design choice rather than an accuracy-optimal default. Boundary testing also distinguishes interpolation inside the observed production range from extrapolation outside it. The interface displays an extrapolation warning and the distance from the nearest supported load. Output limits protect the screen from impossible indices but do not make a weak scenario reliable.

Traceability tests confirmed that the dashboard, audit table, and independent implementation used the same historical references and relative contributions for every scenario. This property is central to the contribution: a reviewer can reproduce an output without inspecting macro code or accepting a black-box claim. When a result appears counterintuitive, the contributing evidence is immediately available for domain review.

C. Visibility of Seasonal and Failure Patterns

The synthetic monthly demonstration in Fig. 4 shows the exact generic sequence used for the worked example and comparative tests. Production, downtime, and incident indices share the same normalized 0-100 scale, and June is highlighted as the example target. The pattern is not evidence of causality: calendar position can represent shutdowns, staffing, product mix, environmental conditions, or maintenance campaigns.

Failure-family aggregation remains visible in the dashboard in Fig. 2. The comparative chart in Fig. 4 addresses a different question: whether the proposed estimator adds value over simple alternatives. The result is mixed rather than uniformly favorable, which supports a verification claim and motivates multi-year industrial validation before operational use.

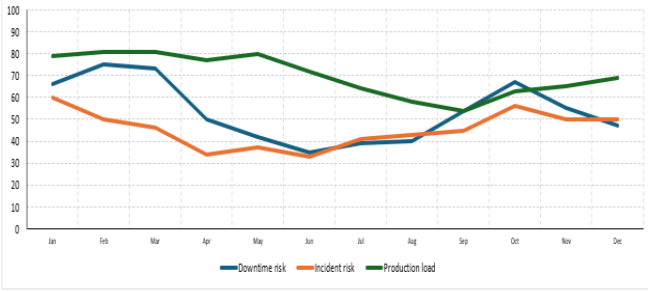

Fig. 4. Monthly evolution of the selected group.

D. Parameter Sensitivity

Table VI isolates the two configuration choices. Holding three records fixed, changing the production-calendar priority from 70/30 to 90/10 changed the overall mean absolute error from 5.45 to 6.81. Holding the 80/20 priority fixed, changing the record count from two to four changed it from 4.69 to 6.08. The mean absolute change in individual outputs relative to the pre-specified setting was 0.45 points for 70/30 with three records, 2.64 for two records, 1.57 for four records, and 2.09 for 90/10 with three records. These movements are moderate on a 0-100 scale, but the better result for two records confirms that three records are a transparency-oriented design choice, not an optimized choice. Objective selection of the record count is reserved for future validation on multi-year operational data.

TABLE VI. PARAMETER SENSITIVITY IN LEAVE-ONE-MONTH-OUT TESTING

Production/calendar priority	Records used	Downtime MAE	Incident MAE	Efficiency MAE	Overall MAE
70% / 30%	3	8.97	4.32	3.07	5.45
80% / 20%	2	7.46	4.20	2.42	4.69
80% / 20% (pre-specified)	3	9.13	4.34	3.09	5.52
80% / 20%	4	9.96	4.75	3.52	6.08
90% / 10%	3	10.78	5.88	3.77	6.81

VII. DISCUSSION

A. Answers to the Research Questions and Contribution

1) Answer to research question 1 (RQ1). The application converts three controlled inputs—generic asset group, target month, and planned production—into transparent maintenance indicators through a visible five-step workflow. Production and calendar comparisons, selected historical situations, relative contributions, outputs, and warnings remain inspectable.

2) Answer to research question 2 (RQ2). The implementation reproduced 12 of 12 historical observations, kept 36 of 36 scenario outputs inside the 0-100 bounds, produced a valid response in 48 of 48 planned-load comparisons, implemented all nine invalid-input rules, and preserved record-level traceability. These tests establish calculation consistency rather than predictive validity.

3) Answer to research question 3 (RQ3). The proposed setting outperformed production-only and historical-mean baselines but did not outperform the adjacent-calendar baseline. Its overall mean absolute error ranged from 4.24 to 6.88 across the full tested weight-neighbor grid; the isolated settings in Table VI show that the pre-specified setting is reasonably stable but not empirically optimal on one synthetic year.

4) Answer to research question 4 (RQ4). For all tested scenarios, the inputs, selected records, relative contributions, and final indicators remained visible and agreed with the independent calculation. This establishes structural traceability and reconstructability for the tested outputs. User understanding and operational suitability require future empirical study.

The contribution is not algorithmic complexity. It is the disciplined design of a transparent transition artifact. First, the model formalizes an industrial intuition—production matters more than calendar month—through visible comparisons and an eighty-twenty priority. Second, the circular treatment of the calendar avoids a common defect at the year boundary. Third, the architecture separates data, calculations, interface, and audit evidence, responding directly to spreadsheet-quality risks. Fourth, the privacy protocol demonstrates how an industrial case can be communicated without exposing performance values or asset identifiers.

The work complements predictive-maintenance literature by defining a lower-infrastructure maturity level. Sensor-based learning remains preferable when sufficient data, labels, and integration capability exist. Before that point, a low-code application can improve data definitions, reveal missing values, establish indicator ownership, and create user expectations for traceability. These capabilities reduce the organizational distance to a future CMMS, manufacturing execution, or predictive platform.

B. Practical Implications

The artifact can be piloted with limited software procurement and short training, but deployment should be conditional on local verification. Maintenance engineers can inspect the calculations, while managers receive a consistent monthly view. The baseline comparison also prevents users from assuming that additional weighting automatically improves accuracy: in a strongly seasonal process, a simple calendar rule may be the more defensible starting point.

A recommended deployment sequence is: define the data dictionary; clean at least one annual cycle; validate the workbook against independent calculations; pilot with one pseudonymous asset group; establish data and model owners; review the eighty-twenty weights; and only then extend the schema. If the application begins to influence safety-critical or high-cost decisions, migration to a governed database and tested application layer becomes necessary.

C. Governance and Migration Roadmap

Governance should scale with decision consequence. During an analytical prototype, peer review and protected formulas may be sufficient. During a controlled pilot, the organization needs approved data extracts, named owners, a versioned test pack, backup, and a restricted distribution list. Operational use requires scheduled data refresh, release approval, incident handling, training, and periodic validation. When several assets or users are added, a shared database and application service become more reliable than duplicated workbooks (Table VII).

Migration does not require discarding the artifact. The workbook can serve as an executable specification for a later system: named fields become database attributes, calculation rules become tested service functions, validation lists become reference tables, and audit fields become log events. The dashboard layout also provides a documented starting point for

a web interface. Preserving these semantics reduces the risk that a technically advanced replacement loses the interpretability expected by maintenance users.

Integration with computerized maintenance management systems (CMMS) and manufacturing execution systems (MES) should be staged. A read-only import is safer than immediate bidirectional synchronization. After identifiers and units are reconciled, the application can consume approved history extracts and export a scenario record or maintenance-planning note. Automatic work-order creation should be considered only after the decision rule, uncertainty, responsibilities, and reversal process are formally validated. Table VI summarizes the recommended maturity path.

TABLE VII. GOVERNANCE AND MIGRATION ROADMAP

Maturity stage	Required control	Evidence and readiness to progress
Prototype	Peer review of data fields and calculations	Calculation map and sample tests; data structure is stable
Controlled pilot	Named data, model, and user owners	Versioned tests and user feedback; workflow is understood
Operational workbook	Access control, release approval, and backup	Audit log and approved versions; use is repeatable and governed
Integrated application	Shared database and automated tests	Interface and security logs; several users and assets are supported
Predictive-maintenance extension	Monitored and externally validated model	Validation and model-change reports; measurable decision benefit

D. Limitations and Validity

The study has six principal limitations. The historical granularity is monthly, so short-term precursors and event sequences are unavailable. One annual cycle is insufficient to estimate stable seasonality. The pre-specified 80/20 priority and three-record setting originate from industrial judgment rather than optimization on an external dataset. Synthetic indices permit disclosure but prevent independent assessment of plant performance and may favor the calendar baseline by construction. The leave-one-month-out months are temporally related and therefore are not independent observations. Finally, no maintenance-user study was conducted, so the study does not claim improved decision time, interpretation accuracy, adoption, maintenance effectiveness, or economic benefit.

The model is also vulnerable to concept drift. Changes in product mix, automation, maintenance policy, staffing, or equipment modification can make historical similarity misleading. Data-quality flags and periodic weight review are therefore mandatory. Macros introduce compatibility and security considerations; organizations should sign approved code, disable untrusted macros, and keep business logic in visible formulas. Spreadsheet protection cannot substitute for authentication, authorization, logging, or centralized backups.

E. Future Development

Future work should validate the model on several years, asset groups, and industrial sites; compare it with multi-year seasonal-naive, regression, tree-based, and probabilistic baselines; and report uncertainty intervals. A preregistered user study should measure decision time, interpretation accuracy, perceived trust, workload, and disagreement resolution. A governed implementation can move the history to a database, connect to CMMS and MES platforms, and expose the same transparent calculations through a web interface. When condition-monitoring data become available, the scenario layer can remain as a planning view while sensor models provide short-horizon alerts.

VIII. CONCLUSION

This study presented the design and verification of an interpretable low-code application for maintenance scenario assessment in automotive assembly. The application converts controlled inputs and sparse monthly history into traceable downtime, incident, efficiency, and failure-family indicators. Its configurable comparison uses planned production and cyclic month proximity, while the selected historical records and relative contributions remain visible. Spreadsheet-quality controls, fail-closed validation, and separation of input, model, and audit layers reduce the risks of end-user computing.

The privacy-preserving case study excluded the company, specific equipment identifiers, operational capacities, absolute times, and confidential screens. Verification established calculation agreement, bounded scenario behavior, input rejection, record-level traceability, and sensitivity to parameter choices. Comparative testing showed that the proposed setting was better than production-only and historical-mean baselines but not the adjacent-calendar baseline. The artifact is therefore supported as a transparent planning aid and transition specification—not as a validated failure-probability, remaining-life, or optimization model.

DATA AVAILABILITY

The raw industrial dataset and operational workbook are not publicly available because they contain confidential manufacturing information. All values and interface elements shown in this study are synthetic, generalized, and non-identifying. The disclosed twelve-month sequence, the step-by-step worked example, baseline definitions, test counts, and acceptance criteria support reproduction of the reported verification calculations. Additional non-confidential implementation details may be provided on reasonable request, subject to institutional and publication requirements.

DECLARATION ON GENERATIVE ARTIFICIAL INTELLIGENCE

Generative artificial intelligence tools were used to assist with drafting, language refinement, calculation scripting, document organization, and visualization layout. Scientific responsibility remains with the authors, who retain full responsibility for independently verifying all domain information, calculations, results, references, interpretations, originality, and integrity of the final manuscript.

OptiGeoRisk: A Spatially Localized and Optimized Geo-XGBoost Framework for Credit Default Risk Classification

Claher Prastian*, Alexander Agung Santoso Gunawan
Computer Science Department, School of Computer Science, Bina Nusantara University, Jakarta, Indonesia 11480

***Abstract*—Credit default risk prediction is important for financial institutions in geographically diverse, collateral-based lending, where early identification of risky borrowers supports preventive monitoring. Most credit scoring models treat borrower records as independent observations and rarely capture local spatial heterogeneity. This study proposes OptiGeoRisk, a spatially localized Geo-XGBoost framework for imbalanced credit default classification, using 76,742 loan transactions from West Java, Indonesia. OptiGeoRisk treats geographic coordinates as a local learning mechanism, combining haversine-based nearest-neighbor selection, adaptive neighborhood size and kernel bandwidth, and global-local probability fusion, and is evaluated against XGBoost Non-Spatial and XGBoost Spatial Feature baselines using PR-AUC, categorical and Top-K accuracy, default recall, precision, and false-positive volume. XGBoost Spatial Feature obtains the best PR-AUC, while OptiGeoRisk achieves the highest default recall, trading global ranking quality for localized early-warning sensitivity. Bootstrap resampling shows this recall advantage is statistically robust, while OptiGeoRisk's PR-AUC is statistically indistinguishable from XGBoost Non-Spatial and significantly lower than XGBoost Spatial Feature; refitting under 10 random seeds confirms this pattern is stable, and a cross-region check in DKI Jakarta shows the PR-AUC gain over a no-skill baseline holds outside West Java, though the recall advantage does not. A leakage-robust check across borrower-grouped, spatially blocked, and temporal splits shows the recall advantage holds under random and borrower-grouped partitioning but weakens when whole areas or future periods are held out, a limitation traced mainly to adaptive neighborhood selection and imbalance handling rather than the spatial kernel. These findings position OptiGeoRisk as a localized early-warning layer complementing a well-tuned global model.**

Keywords*—Credit default risk; Geo-XGBoost; spatial machine learning; class imbalance; early-warning system; financial risk management; sustainable economic growth

I. Introduction

Credit default risk prediction is increasingly important for financial institutions operating in geographically diverse markets, particularly in consumer loans, vehicle financing, pawnshops, and collateral-based lending where early identification of risky borrowers can support preventive collection strategies and portfolio monitoring. In Indonesia, financing and pawn-related activities operate under regulatory attention from the Financial Services Authority, which frames stronger risk governance, consumer protection, and responsible monitoring in this sector as part of its broader push for financial-sector stability and sustainable economic growth [1], [2].

*Corresponding author.

Credit scoring has traditionally been formulated as a statistical classification problem, and machine learning has extended this field by improving prediction from structured borrower and loan attributes [3], [4], [5]. Yet credit default modeling remains difficult because default events are typically rare compared with non-default transactions. Under this class imbalance, a model can obtain high categorical accuracy by predicting the majority class while failing to identify customers who later default [6]. For that reason, ranking-oriented and minority-class metrics such as PR-AUC and default recall are more informative than accuracy alone [7], [8].

Most credit-risk models also assume that borrower records are independent observations governed by a single global prediction function, an assumption that is restrictive for collateral-based credit in West Java, where access to branches, local economic activity, road structure, settlement density, and surrounding facilities vary substantially across regions. When location is encoded only as a category or raw coordinate, the model can learn a regional identity without explicitly adapting the prediction function to local risk behavior. That gap motivates a spatial learning framework that treats geography as a mechanism of learning rather than merely another input attribute.

This study proposes OptiGeoRisk, a spatially localized and optimized Geo-XGBoost framework for binary credit default risk classification. The framework uses real-world collateral-based loan transaction data from West Java, enriches it with branch-distance, POI, OSM, and GeoPandas-based spatial treatment, and uses coordinates structurally for local-neighborhood learning. The expected benefit is not automatic credit rejection but a practical early-warning layer that helps financial institutions prioritize monitoring, verification, and collection follow-up.

The contributions are sixfold. First, the study adapts Geo-XGBoost from spatial regression into imbalanced binary default classification. Second, it removes administrative location names and raw latitude-longitude values from model predictors while preserving coordinates for local spatial learning. Third, it evaluates the trade-off between global ranking quality and local early-warning sensitivity using metrics that are appropriate for imbalanced default risk data, benchmarked against XGBoost baselines. Fourth, it checks whether these results hold up under bootstrap resampling, ten independently retrained seeds, and a cross-region comparison between West Java and DKI Jakarta run under an identical evaluation protocol. Fifth, it isolates the

source of OptiGeoRisk's gains through leakage-robust validation across borrower-grouped, spatially blocked, and forward-chaining temporal splits, a systematic ablation of its adaptive-neighborhood, Gaussian-weighting, and fusion components, and hyperparameter-tuning budgets matched across baselines. Sixth, it reports the operational value and computational overhead of the framework at realistic review capacities, so that its deployment cost can be weighed against its early-warning benefit.

II. Related Studies

A. Credit Risk and Loan Classification

Credit scoring research provides the foundation for modeling credit default as a classification task. Classical reviews highlight the role of statistical classification in consumer credit scoring [3], while later benchmarking and systematic-review studies show that machine learning can improve predictive performance on structured credit data [4], [5]. Recent loan approval studies further demonstrate the use of ensemble learning and tree-based methods for assessing repayment feasibility and borrower creditworthiness [9], [10], [11]. More recent comprehensive reviews confirm that ensemble and gradient-boosting methods remain the strongest-performing family for structured credit data, while identifying explainability, calibration, and class-imbalance handling as the field's most persistent open challenges [12], [13].

Although these studies show that machine learning is useful for credit decision support, they generally emphasize global tabular learning. Spatial context, when available, is often treated as an ordinary input variable rather than a source of local variation in the learning process. This leaves a gap for a method that can use location to adapt prediction behavior around nearby observations.

B. Imbalanced Classification and Evaluation

The dataset used in this study has a default-class rate of only 6.87%. This confirms that the modeling problem is severely imbalanced. Previous research shows that imbalanced class distributions can affect credit-scoring model behavior and comparison [6]. PR-AUC is therefore used as the main ranking metric because Precision-Recall analysis is more informative than ROC-based interpretation when the positive class is rare [7], [8].

The study also reports categorical accuracy, Top-K categorical accuracy, default recall, precision, and false-positive volume. Top-K categorical accuracy evaluates ranked risk lists: Top-K Default checks whether actual defaults appear among the highest predicted default probabilities, while Top-K Non-default checks whether non-default cases appear among the lowest predicted default probabilities. These ranked metrics fit operational early warning better than a fixed threshold, since financial institutions usually work from prioritized customer lists rather than a single probability cutoff.

C. XGBoost, Geo-XGBoost, and Spatial Credit Modeling

XGBoost is widely used for tabular prediction because gradient-boosted trees can model non-linear relationships and interactions efficiently [14].

However, standard XGBoost is a global model. It learns one prediction function for all observations, even when the relationship between risk factors and default varies geographically.

Class-imbalance treatments such as over-sampling, under-sampling, class weighting, and SMOTE can improve minority-class learning when applied only on training data [15], [16]. Spatial learning adds another layer by allowing relationships to vary over space. Geographically weighted regression introduced the idea of estimating local relationships rather than one global function [17], [18], and spatial machine learning extends this perspective to modern predictive modeling [19]. Geo-XGBoost applies this idea to gradient-boosted trees through geographically weighted local learning [20]. Recent work extends this direction along two complementary paths: adapting XGBoost's objective directly for severe class imbalance through a generalized extreme value link and modified focal loss [21], and combining tree-boosting explicitly with spatial structure, as in spatio-temporal Gaussian-process boosting for mortgage default [22], Mixed Geographically Weighted XGBoost [23], and explainable ensemble models for peer-to-peer lending default risk [24]. These studies motivate treating geography and class imbalance as structural learning problems rather than ordinary inputs, which is the direction pursued by OptiGeoRisk.

The methodological gap addressed in this study is that Geo-XGBoost was originally proposed for regression, while credit default risk is a binary and imbalanced classification problem. OptiGeoRisk modifies the idea by using logistic probability output, imbalanced evaluation, Optuna-based optimization, adaptive local neighborhoods, and a global-local probability fusion mechanism [25].

III. Research Methodology

Fig. 2 outlines the overall research workflow followed in this study, from data preparation through model development to the spatial diagnostics presented in Section IV. The diagram groups the pipeline into three linked stages: data collection and feature construction, spatial treatment and GIS diagnostics, and the OptiGeoRisk modeling architecture and evaluation itself, which combines a global classifier with localized, geographically weighted classifiers through an adaptive fusion step before the robustness checks and cross-region validation described in Section IV. The workflow begins with the study area and dataset construction, proceeds through feature engineering and the proposed local-global fusion approach, and concludes with the diagnostic evaluation of spatial prediction performance. Each stage is described in the subsections that follow.

A. Study Area and Dataset

The study uses 76,742 collateral-based loan transactions from West Java, Indonesia, split into train, validation, and test partitions with stratified sampling. The test set contains 15,349 transactions and 1,054 default cases, a positive rate of 6.87%; this original distribution is preserved in the validation and test sets to avoid optimistic evaluation. Fig. 1 shows the geographic distribution of these transactions and the observed default rate across West Java's subdistricts (kecamatan).

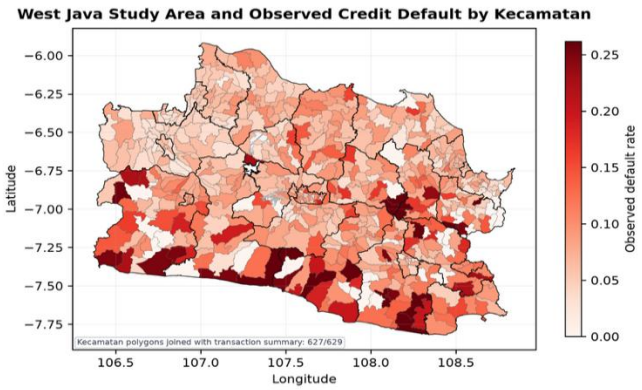

Fig. 1. West Java study area and subdistrict-level observed default distribution by Kecamatan boundary.

Spatial processing follows the style of GIS-based analytical studies. Transaction representative points were constructed from subdistrict latitude and longitude as a GeoDataFrame using CRS EPSG:4326, then reprojected when metric distance or density diagnostics were required with GeoPandas [26]. Administrative polygons were used for mapping and spatial diagnostics, not as ordinary model predictors. For detailed visualization, the kecamatan boundary layer was prepared by dissolving 5,973 village polygons into 630 kecamatan polygons.

B. Feature Engineering

The non-spatial feature group includes borrower, loan, collateral, vehicle, and temporal attributes. The spatial-feature group includes branch-distance features, POI features, and OSM-derived built-environment features. POI attributes were generated from Google Places categories within a 1,000-meter radius, including financial, healthcare, education, commerce, and market-related counts [27]. OSM features were also computed within a 1,000-meter radius, including building counts and roadway counts [28]. Coordinates are retained only for geospatial preprocessing and the local OptiGeoRisk learning mechanism.

This design reduces location-identity leakage and makes the comparison with global XGBoost more methodologically defensible. Table I reports descriptive statistics for these retained borrower, loan, collateral, and spatial-context variables.

TABLE I. DESCRIPTIVE STATISTICS OF SELECTED VARIABLES AND SPATIAL FEATURE SOURCES

Variable	Description	Mean	Std
target_macet	Default label: 1=macet, 0=lancar	0.069	0.253
loan_amount	Initial loan amount	1,961,235	927,332
collateral_value	Initial collateral value	6,054,794	2,574,454
loan_to_value	Loan-to-value	0.33	0.077
vehicle_age	Collateral age	5.533	3.054
borrower_age	Borrower age	35.041	10.854
month	Transaction month	6.824	3.298
day_of_week	Day of the week of the transaction	2.638	1.888
branch_distance	Distance from domicile to branch (km)	7.595	32.891
same_city_branch	Same city/regency as branch	0.866	0.34
poi_financial	Financial POI within 1,000 m	25.887	28.099
poi_healthcare	Healthcare POI within 1,000 m	16.526	14.615
poi_education	Education POI within 1,000 m	36.582	19.449
poi_market	Market POI within 1,000 m	7.015	7.168
osm_buildings	Building count within 1,000 m	3,498	3,318
osm_roads	Roadway count within 1,000 m	437.134	337.17
osm_build_density	Building density per km2	1,114	1,056

C. Proposed Method

OptiGeoRisk combines a global XGBoost classifier with localized, geographically weighted XGBoost models. The global component estimates P_global from the no-admin feature matrix, while the local component searches nearby training observations for each evaluation point using haversine distance, applies Gaussian kernel weighting, trains a local XGBoost classifier, and estimates P_local. The final score comes from an adaptive fusion of the two:

$$d_{ij} = \text{haversine}(g_i, g_j) \quad (1)$$

$$w_{ij} = \exp\left(-\frac{d_{ij}^2}{2b_i^2}\right) \quad (2)$$

$$P_{\text{final},i} = \alpha_i P_{\text{global},i} + (1-\alpha_i) P_{\text{local},i} \quad (3)$$

In Eq. (1), d_{ij} is the geographic distance between the prediction location and the training location. In Eq. (2), b_i is the local bandwidth derived from the neighborhood setting and w_{ij} is the resulting Gaussian kernel weight. In Eq. (3), α_i controls the observation-level global-local probability fusion between $P_{\text{global},i}$ and $P_{\text{local},i}$. Together, Eq. (1)–(3) follow the GeoXGBoost principle of combining tabular predictors X, response y, coordinates G, bandwidth, adaptive kernel weighting, and local boosted-tree learning, but the objective is changed from regression to binary logistic classification. Optuna was used in the prior optimization stage to select the imbalance strategy, XGBoost parameters, neighborhood-size baseline, kernel-bandwidth baseline, and global-local fusion parameters [25]. In the main experiment, OptiGeoRisk uses random over-sampling for the local component, initializes the local search from the optimized neighborhood and bandwidth values, and then applies adaptive neighborhood diagnostics and observation-level fusion weights during validation and testing (Algorithm 1). This integrated research framework, from feature construction through the local-global fusion mechanism to the spatial diagnostics reported in Section IV, is illustrated in Fig. 2.

Algorithm 1: Pseudocode for OptiGeoRisk Credit Default Classification

Inputs: D={X,y,G}, POI/OSM features, Optuna search space H

Output: Optimized spatial credit-risk classifier and prob_macet

Start:

Load and clean the transaction dataset

Construct loan, collateral, customer, time, branch, POI, OSM, and GeoPandas-derived features
Remove administrative-name features (kab/kota, kecamatan) to prevent leakage; retain coordinates G as the spatial mechanism
Split dataset into stratified train, validation, and test sets
For each Optuna trial t do:
Select imbalance strategy r
Sample XGBoost and spatial parameters
Apply r to training data only
Train global XGBoost classifier
For each validation coordinate g do:
Compute haversine distance to all training points
Select k nearest neighbors adaptively
Compute bandwidth b and Gaussian weights w
Train weighted local XGBoost classifier
Compute P_global and P_local
Compute adaptive alpha and P_final = alpha x P_global + (1-alpha) x P_local
Evaluate validation PR-AUC, recall, precision, and false-positive rate
Select the best trial and threshold
Evaluate final model on the test set
End

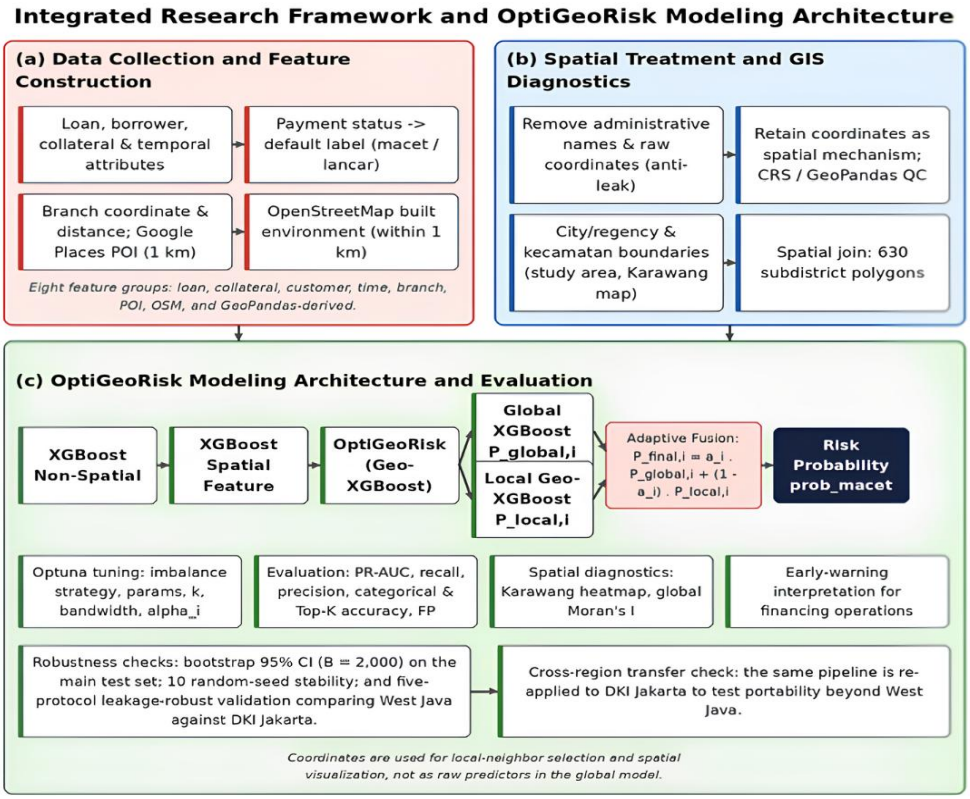

Fig. 2. Integrated research framework, feature construction, modeling architecture, and spatial diagnostic flow.

D. Spatial Diagnostics

Following spatial-data presentation used in GIS-oriented studies, the results include West Java mapping, Karawang relative risk heatmaps, feature correlation, and spatial autocorrelation diagnostics. Global Moran's I is used to evaluate whether subdistrict-level risk scores show spatial autocorrelation [29], while LISA identifies local high-high, low-low, and spatial outlier patterns [30].

E. Statistical Robustness Check

Because XGBoost Non-Spatial, XGBoost Spatial Feature, and OptiGeoRisk are compared on a single fixed train/validation/test partition, differences between point-estimate metrics could in principle reflect sampling variability in the test set rather than genuine differences between models. To assess this, non-parametric bootstrap resampling was applied to the held-out test set (15,349 transactions), following standard practice for comparing classifiers [31], [32]. For B = 2,000 resamples, test-set rows were sampled with replacement (seed = 42), and PR-AUC, default recall, precision, and categorical accuracy were recomputed for each model at its selected decision threshold. Paired differences between OptiGeoRisk and each baseline were recorded across resamples to obtain a 95% percentile confidence interval and an empirical two-sided p-value for each metric difference. Because the same resampled

indices are applied to all three models within each iteration, the comparison is paired, which removes shared sampling noise and increases the power to detect genuine differences.

This procedure quantifies evaluation uncertainty for the models as fitted; it resamples test observations, not the training process itself. Training-side variability from refitting OptiGeoRisk under multiple random seeds is assessed separately in Section IV-E, together with an initial cross-region validation check.

F. Leakage-Robust Evaluation Protocols

The main comparison in Section IV-A relies on a single stratified train, validation, and test partition, which reproduces the overall 6.87% default rate but does not by itself rule out spatial, borrower-level, or temporal leakage: a borrower with several transactions, a collateral location that repeats across partitions, or overlapping time windows could all inflate apparent performance under a purely random split. To check this, four additional partitioning protocols were applied to the same West Java dataset and the same three core models, each retrained and re-evaluated on its own 60/20/20 train, validation, and test split: borrower-grouped, in which all transactions from the same borrower (no anggota) are kept within a single partition; spatial-blocked by city/regency (kab/kota sekarang), in which entire regencies are held out for validation and testing; spatial-blocked by subdistrict (kecamatan sekarang), using a finer administrative unit; and forward-chaining temporal, in which transactions are ordered chronologically so that training data always precedes the validation and test periods. The dataset supports all four protocols: it contains 60,044 unique borrowers, of whom 12,038 have more than one transaction and are therefore a potential source of borrower-level leakage under a purely random split, 27 unique regencies and 581 unique subdistricts for the spatial-blocking protocols, and complete transaction dates from January to December 2025 for the temporal protocol.

G. Fair Hyperparameter Tuning for Baseline Models

OptiGeoRisk's Optuna-based optimization stage searches over the imbalance strategy, XGBoost parameters, neighborhood size, kernel bandwidth, and fusion weight, so an unequal tuning effort could by itself explain part of its advantage over the baseline models. To rule this out, XGBoost Non-Spatial and XGBoost Spatial Feature were each re-tuned with a standardized search space and an equal budget of 50 Optuna trials, covering the same core hyperparameters used for OptiGeoRisk (number of estimators, tree depth, learning rate, subsample and column-sample ratios, minimum child weight, gamma, and L1/L2 regularization), the same candidate imbalance strategies, and the same threshold-selection objective, maximizing default recall subject to a minimum precision of 0.11 on the validation set.

H. Systematic Ablation Study

OptiGeoRisk combines several mechanisms at once: localized neighborhood learning, adaptive neighborhood-size selection, adaptive Gaussian kernel weighting, adaptive global-local probability fusion, and imbalance handling. To isolate which of these mechanisms drives the reported gains, a six-configuration ablation matrix was built, and each configuration was retrained and evaluated on the same West Java test set. A0 is a global-only XGBoost spatial-feature baseline with no local component. A1 adds a local model with a fixed neighborhood size, fixed Gaussian weighting, and a fixed fusion weight. A2 replaces the fixed neighborhood in A1 with adaptive neighborhood and bandwidth selection, while fusion remains fixed. A3 is the full OptiGeoRisk configuration, adding adaptive global-local fusion on top of A2. A4 is a variant of A3 in which Gaussian distance weighting is replaced by uniform neighbor weights. A5 is a variant of A3 in which imbalance handling is removed from both the global and local training stages. Comparing A0 to A1 isolates the effect of adding a local component at all, A1 to A2 isolates adaptive neighborhood selection, A2 to A3 isolates adaptive fusion, A3 to A4 isolates Gaussian kernel weighting, and A3 to A5 isolates imbalance handling.

I. Operational Top-Capacity Evaluation

PR-AUC and default recall summarize model behavior across the full range of thresholds, but a collection or verification team can typically review only a limited share of the portfolio. To translate ranking quality into an operationally meaningful comparison, the three core models were additionally evaluated at fixed review capacities corresponding to the top 1%, 5%, and 10% of test-set transactions ranked by predicted default probability. For each capacity, the number of true default cases captured, precision within the reviewed set, the resulting false-positive workload, and the lift over a no-skill (random-selection) baseline were computed, together with the total default-loan exposure represented by the captured cases, to approximate the cost and benefit of prioritizing review effort by model ranking rather than by chance.

J. Computational Overhead Assessment

Localized geographically weighted learning is more expensive than a single global model because OptiGeoRisk fits a separate local classifier for each test-time neighborhood in addition to its global component. To quantify this cost, training time was recorded for the three core models on the same data split and hardware, together with OptiGeoRisk-specific overhead indicators: the number of local neighborhood models fit at test time, the mean neighborhood size (k) selected adaptively per observation, and the mean adaptive bandwidth, in kilometers, selected per observation. Training time is reported both in absolute terms and as a ratio relative to XGBoost Non-Spatial so that the additional cost of localized learning can be weighed against its early-warning benefit.

IV. Results and Discussion

A. Model Performance

Table II compares three model configurations: XGBoost Non-Spatial, XGBoost Spatial Feature, and OptiGeoRisk. Pairing the non-spatial and spatial feature sets isolates the effect of the spatial features themselves, while OptiGeoRisk adds the localized learning mechanism on top, which makes the results easier to interpret.

XGBoost Spatial Feature obtains the highest PR-AUC (0.1158) and categorical accuracy (0.7029): the strongest overall probability ranking and thresholded correctness among the compared models. Branch-distance, POI, and OSM spatial

features therefore add useful signal beyond the non-spatial credit attributes. This comparison is later corroborated under standardized hyperparameter-tuning budgets in Section IV-G.

TABLE II. EVALUATION COMPARISON ON THE MAIN TEST SET

Model	PR-AUC	Recall	Precision	Cat. Acc.	FP
XGB Non-Spatial	0.1057	0.4877	0.1025	0.6715	4,502
XGB Spatial Feature	0.1158	0.4658	0.1094	0.7029	3,997
OptiGeo Risk	0.1094	0.5256	0.1055	0.6614	4,697

OptiGeoRisk records the highest default recall (0.5256), capturing 554 actual default cases, but it also produces the largest false-positive volume (4,697). It is therefore not best interpreted as a universal replacement for global XGBoost; its main value is localized early-warning sensitivity, finding more actual default cases at the cost of a greater review workload. A bootstrap robustness check (Section III-E) confirms that this recall advantage is statistically significant relative to both baselines, while the PR-AUC gap relative to XGBoost Spatial Feature is also statistically genuine rather than sampling noise (Table III).

TABLE III. BOOTSTRAP 95% CONFIDENCE INTERVALS FOR THE MAIN TEST-SET METRICS (B = 2,000)

Model	PR-AUC (95% CI)	Recall (95% CI)
XGB Non-Spatial	0.1057 (0.0972–0.1168)	0.4877 (0.4575–0.5163)
XGB Spatial Feature	0.1158 (0.1049–0.1294)	0.4658 (0.4346–0.4949)
OptiGeoRisk	0.1094 (0.0999–0.1213)	0.5256 (0.4957–0.5542)

Paired bootstrap comparison shows that OptiGeoRisk's default recall is significantly higher than both XGB Spatial Feature ($\Delta = +0.0595$, 95% CI [0.0370, 0.0833], $p = 0.000$) and XGB Non-Spatial ($\Delta = +0.0383$, 95% CI [0.0086, 0.0678], $p = 0.010$). In contrast, OptiGeoRisk's PR-AUC is significantly lower than XGB Spatial Feature ($\Delta = -0.0066$, 95% CI [−0.0130, −0.0006], $p = 0.033$) but not significantly different from XGB Non-Spatial ($\Delta = +0.0039$, 95% CI [−0.0031, 0.0112], $p = 0.273$). The recall advantage over both baselines is therefore a robust effect rather than sampling noise, and the PR-AUC shortfall relative to XGBoost Spatial Feature is statistically genuine rather than an artifact of a single test split. As additional context, the no-skill PR-AUC baseline implied by the 6.87% test-set default prevalence is 0.0687, so all three models rank default risk substantially better than random, although the absolute PR-AUC margin above this baseline remains modest (0.037–0.047).

B. Spatial Risk Visualization and Autocorrelation

The Karawang heatmap compares observed default rate and model-based average prob_macet at the subdistrict level. The map should be read by panel: darker red indicates higher relative risk intensity within the same panel, while point size reflects the number of transactions. Observed data use actual default rates, whereas model panels show probability scores rather than final 0/1 decisions.

TABLE IV. GLOBAL MORAN'S I FOR KARAWANG RISK SURFACES

Panel	Moran's I	p-sim	z-sim
Observed	-0.0759	0.382	-0.421
XGB Non-Sp.	-0.1034	0.283	-0.626
XGB Spatial Feature	0.2977	0.004	3.028
OptiGeoRisk	0.2946	0.011	2.93

As Table IV reports, observed default data in Karawang do not show statistically significant global spatial autocorrelation in this test aggregation, whereas both the XGBoost Spatial Feature and OptiGeoRisk probability panels produce positive and statistically significant Moran's I values on the kecamatan-level visualization. The model probability surfaces therefore form clearer spatial clusters than the raw observed default rate. Fig. 3 visualizes these risk surfaces and helps compare whether predicted probabilities become darker in areas that are also darker in the observed default panel.

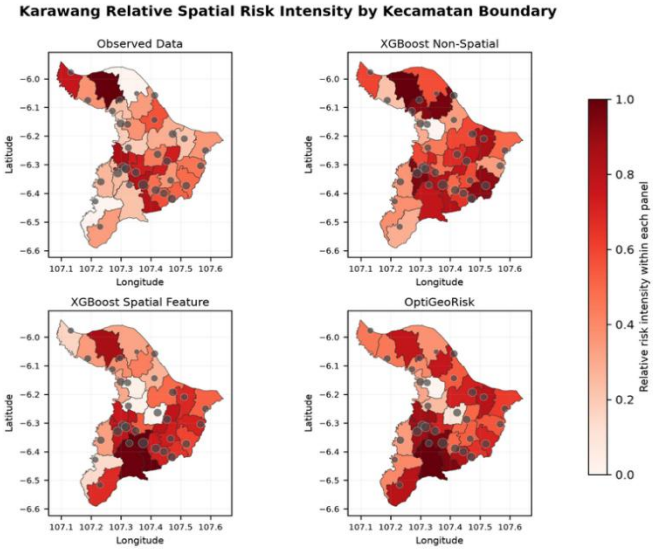

Fig. 3. Karawang relative spatial risk intensity from observed default rate and model probability scores by kecamatan boundary.

C. Feature Correlation

The strongest regional spatial-feature correlation appears after records are aggregated by city/regency, where the leading variable is OSM residential roadway count, with a Spearman-like absolute correlation of 0.6538. This supports retaining broader regional context for the main model, since the regional signal is more stable at city/regency level than at the finer kecamatan level. Fig. 4 shows this ranking: vehicle age is the only feature positively associated with default, while OSM-derived built-environment counts and same-kecamatan branch rate are the strongest negative associations.

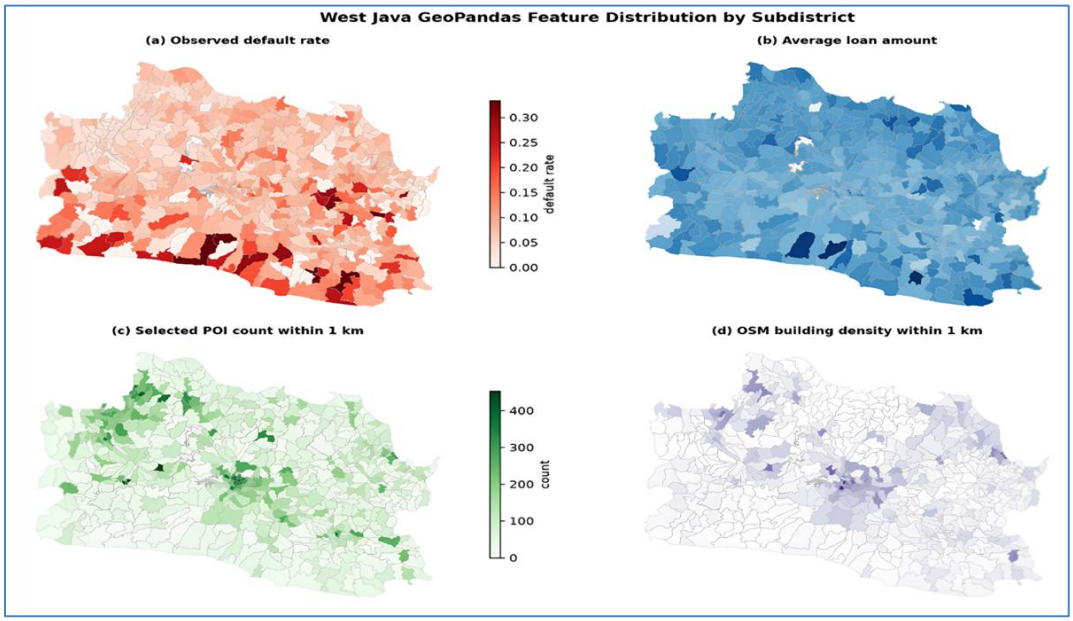

Fig. 4. West Java GeoPandas feature distribution by subdistrict: (a) observed default rate, (b) average loan amount, (c) selected POI count within 1 km, (d) OSM building density within 1 km.

The feature-correlation result is not used to claim causality; instead, it offers a transparent diagnostic that no single spatial feature dominates the target. The highly correlated feature-pair output indicates that future ablation should remove redundant density/log-count pairs before a more compact final submission model is selected.

To complement this ranking, Fig. 5 maps four of these variables across West Java at the subdistrict level: observed default rate alongside average loan amount, POI count, and OSM building density. The default-rate panel is darkest in the southern part of the study area, while POI count and building density concentrate around the central urban cluster. These two patterns occupy largely different areas, which is visually consistent with the negative correlations reported above for OSM roadway count, roadway density, and POI-related features.

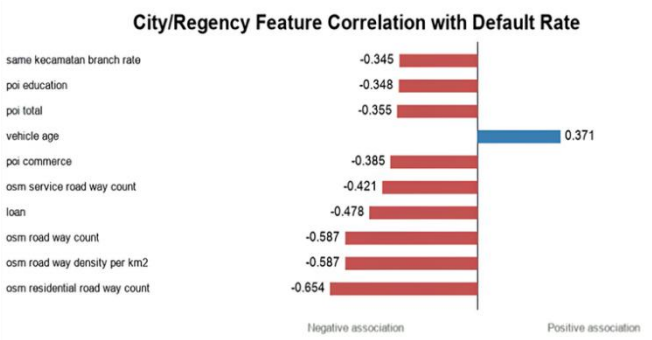

Fig. 5. City/regency-level correlation between aggregated spatial features and observed default rate.

Average loan amount does not show a comparable spatial gradient, matching its absence from the strongest correlated features in Fig. 4. As with the correlation ranking, this map is a descriptive check rather than a causal test.

D. Interpretation of the Trade-Off

The main result supports a clearer and more honest contribution statement: XGBoost Spatial Feature is preferable if the goal is the best global probability ranking, while OptiGeoRisk is more sensitive if the goal is early warning and capturing more default cases for follow-up. The model's value therefore lies in risk monitoring rather than in claiming dominance on every metric, which matters for journal review because it explains why a more expensive localized model may still be useful when a global spatial-feature baseline has stronger PR-AUC. Sections IV-F through IV-J extend this comparison to leakage-robust validation protocols, fair hyperparameter tuning, a systematic ablation of OptiGeoRisk's components, operational review-capacity analysis, and computational overhead, and refine this trade-off further rather than overturning it.

E. Seed Stability and Cross-Region Validation

To assess whether the point-estimate differences in Section IV-A generalize beyond a single train/validation/test split, all three models were refit under 10 independent random seeds on the West Java data. This procedure resamples the training process itself, which complements the bootstrap check in Section III-E (test-set resampling only) and directly addresses training-side variability.

TABLE V. STABILITY ACROSS 10 RANDOM SEEDS (WEST JAVA)

Model	PR-AUC Mean	PR-AUC Std	Recall Mean	Recall Std	FP Mean
XGB Non-Spatial	0.1076	0.0028	0.4018	0.0674	3,472
XGBoost Spatial Feature	0.1138	0.0033	0.4572	0.0640	3,931
OptiGeoRisk	0.1135	0.0034	0.4703	0.0607	4,058

As Table V reports, OptiGeoRisk keeps the highest mean default recall (0.4703) across the 10 seeds, ahead of XGBoost

Spatial Feature (0.4572) and XGBoost Non-Spatial (0.4018), with a standard deviation (0.0607) comparable to the other models. Its mean PR-AUC (0.1135) remains close to, though marginally below, XGBoost Spatial Feature (0.1138). OptiGeoRisk does not win on every individual seed, so the fairest characterization is that it is competitive and consistently more recall-sensitive rather than uniformly dominant.

As a further check on geographic portability, the same three core models were re-applied, unchanged in architecture, to a second and structurally different region, DKI Jakarta (16,292 transactions, 818 defaults), and evaluated under the same five validation protocols used for West Java in Section IV-F (transaction-random, borrower-grouped, spatial-blocked by city/regency, spatial-blocked by subdistrict, and forward-chaining temporal), so that the two regions are compared under an identical evaluation protocol rather than under two different validation schemes. West Java covers roughly 35,000 km2 with heterogeneous urban and rural sub-districts, while DKI Jakarta covers about 660 km2 of dense urban area, making it a meaningfully different geographic setting rather than a repeated sample of the same distribution. Table VI reports each model's mean PR-AUC, recall, and precision across the five protocols for both regions.

TABLE VI. IDENTICAL-PROTOCOL COMPARISON: WEST JAVA VS. DKI JAKARTA (MEAN ACROSS FIVE VALIDATION PROTOCOLS)

Region	Model	PR-AUC	Recall	Precision
West Java	XGB Non-Spatial	0.1110	0.3995	0.1119
West Java	XGB Spatial Feature	0.1116	0.4677	0.1101
West Java	OptiGeoRisk	0.1112	0.4680	0.1098
DKI Jakarta	XGB Non-Spatial	0.0795	0.1473	0.0693
DKI Jakarta	XGB Spatial Feature	0.0925	0.2185	0.0907
DKI Jakarta	OptiGeoRisk	0.0886	0.1269	0.1038

Because West Java and DKI Jakarta are now evaluated under the same five-protocol suite rather than under two different validation schemes, the comparison in Table VI is directly comparable across regions. Averaged across all five protocols, the PR-AUC ranking is consistent in both regions: XGBoost Spatial Feature obtains the highest mean PR-AUC in West Java (0.1116) and in DKI Jakarta (0.0925), with OptiGeoRisk close behind in West Java (0.1112) but comparatively further behind in DKI Jakarta (0.0886), where the training set is roughly one-fifth the size of West Java's and defaults are sparser.

Default recall does not transfer as consistently. In West Java, OptiGeoRisk's mean recall (0.4680) is essentially tied with XGBoost Spatial Feature's (0.4677), reflecting that OptiGeoRisk leads on only two of the five individual protocols (Section IV-F); in DKI Jakarta, XGBoost Spatial Feature has the clearly highest mean recall (0.2185), while OptiGeoRisk (0.1269) falls behind even XGBoost Non-Spatial (0.1473). A plausible explanation is that OptiGeoRisk's neighborhood and bandwidth settings were selected on West Java data and applied unchanged to DKI Jakarta, whose land area is roughly 1/53 that of West Java, so the same absolute bandwidth is far less local relative to the study area and fewer neighbors are available per query point when regional training data is scarce. This is reported as an honest limitation: the PR-AUC ranking is reasonably stable across these two regions, but OptiGeoRisk's recall advantage is West Java-specific under this evaluation and should not be assumed to transfer to a new region without region-specific recalibration of its neighborhood and bandwidth parameters.

F. Leakage-Robust Validation Across Evaluation Protocols

Table VII reports PR-AUC, default recall, precision, and false-positive count for the three core models under the transaction-random split used in Section IV-A and under the four additional protocols described in Section III-F. Under transaction-random and borrower-grouped partitioning, OptiGeoRisk retains the highest recall among the three models (0.5417 and 0.4961), consistent with the main result in Table II. Under the two spatially blocked protocols, however, the ranking changes: when entire regencies are held out, XGBoost Spatial Feature obtains the highest recall (0.4982), narrowly ahead of OptiGeoRisk (0.4887); when entire subdistricts are held out, XGBoost Non-Spatial is marginally ahead (0.4185) of OptiGeoRisk (0.4175). Under forward-chaining temporal validation, XGBoost Spatial Feature again leads (0.4170), with OptiGeoRisk second (0.3960) and XGBoost Non-Spatial lowest (0.2814).

TABLE VII. LEAKAGE-ROBUST EVALUATION ACROSS FIVE VALIDATION PROTOCOLS (WEST JAVA)

Protocol	Model	PR-AUC	Recall	Precision	FP
Transaction Random	XGB Non-Spatial	0.1079	0.4915	0.1027	4,526
Transaction Random	XGB Spatial Feature	0.1113	0.5332	0.1056	4,759
Transaction Random	OptiGeoRisk	0.1101	0.5417	0.1058	4,824
Borrower Grouped	XGB Non-Spatial	0.1149	0.3806	0.1143	3,013
Borrower Grouped	XGB Spatial Feature	0.1115	0.4795	0.1121	3,881
Borrower Grouped	OptiGeoRisk	0.1117	0.4961	0.1111	4,055
Spatial Blocked (City/Regency)	XGB Non-Spatial	0.1083	0.4255	0.1118	4,646
Spatial Blocked (City/Regency)	XGB Spatial Feature	0.1069	0.4982	0.1046	5,866
Spatial Blocked (City/Regency)	OptiGeoRisk	0.1068	0.4887	0.1044	5,767
Spatial Blocked (Subdistrict)	XGB Non-Spatial	0.1075	0.4185	0.1057	3,606
Spatial Blocked (Subdistrict)	XGB Spatial Feature	0.1071	0.4106	0.1058	3,533
Spatial Blocked (Subdistrict)	OptiGeoRisk	0.1072	0.4175	0.1060	3,584
Forward-Chaining Temporal	XGB Non-Spatial	0.1166	0.2814	0.1251	2,147
Forward-Chaining Temporal	XGB Spatial Feature	0.1212	0.4170	0.1225	3,258
Forward-Chaining Temporal	OptiGeoRisk	0.1201	0.3960	0.1217	3,118

These results indicate that OptiGeoRisk's recall advantage is not a fixed property of the model but depends on the validation protocol, and specifically on whether the geographic locations being scored were already represented in the training data. When borrowers or transactions are held out, but their neighborhoods

remain in the training set (transaction-random and borrower-grouped protocols), the local-learning mechanism has historical neighbors to draw on, and OptiGeoRisk's recall advantage holds. When entire geographic areas are held out (the two spatial-blocked protocols), OptiGeoRisk has no local history for the withheld locations and falls back close to, or slightly behind, the global XGBoost Spatial Feature baseline. Forward-chaining temporal validation shows a related pattern: because later transactions are more likely to fall in locations not yet densely represented in the earlier training window, OptiGeoRisk's advantage weakens there as well. The practical implication is that OptiGeoRisk should be positioned as a localized early-warning layer whose value depends on sufficient local historical coverage, rather than as a model expected to outperform a global baseline in newly opened or thinly covered territories.

G. Fair-Tuned Baseline Confirmation

Table VIII reports XGBoost Non-Spatial and XGBoost Spatial Feature under the standardized 50-trial Optuna search described in Section III-G, using the same transaction-random test split as Table II.

TABLE VIII. FAIR-TUNED BASELINE COMPARISON UNDER A STANDARDIZED 50-TRIAL SEARCH (WEST JAVA)

Model	PR-AUC	Recall	Precision	FP
XGB Non-Spatial	0.1069	0.4953	0.1040	4,499
XGB Spatial Feature	0.1108	0.5171	0.1058	4,605

Under equal tuning effort, XGBoost Spatial Feature's PR-AUC (0.1108) remains close to its originally reported value (0.1158) and continues to exceed XGBoost Non-Spatial's fair-tuned PR-AUC (0.1069), confirming that XGBoost Spatial Feature is a strong global baseline independent of tuning budget. Its default recall, however, rises from 0.4658 under the original tuning to 0.5171 under the standardized objective, which narrows its gap with OptiGeoRisk's recall (0.5256 in Table II) from 0.0598 to 0.0085. This indicates that part of OptiGeoRisk's originally reported recall advantage over XGBoost Spatial Feature reflected differences in tuning effort rather than the local-learning mechanism alone, while its PR-AUC shortfall relative to XGBoost Spatial Feature persists under fair tuning. XGBoost Non-Spatial's fair-tuned recall (0.4953) similarly improves over its original value (0.4877) but still trails OptiGeoRisk's. Read together with Section IV-D, this supports a more cautious framing of OptiGeoRisk's contribution: it remains competitive and is still the more recall-sensitive of the three core models under identical-protocol validation (Section IV-F), but its margin over a properly tuned XGBoost Spatial Feature baseline is smaller than the untuned comparison suggested, and its PR-AUC trade-off against that baseline is not resolved by tuning.

H. Systematic Ablation Results

Table IX reports PR-AUC, recall, precision, and false-positive count for the six ablation configurations described in Section III-H, all evaluated on the transaction-random West Java test set.

Adding a local component at all (A0 to A1) does not by itself improve recall: A1's recall (0.5256) is close to A0's (0.5332), and PR-AUC is essentially unchanged. Adaptive neighborhood and bandwidth selection (A1 to A2) raises recall from 0.5256 to 0.5427, the largest single gain in the matrix, confirming that letting the neighborhood adapt to local data density, rather than fixing it, is the main source of OptiGeoRisk's recall sensitivity. Adding adaptive global-local fusion (A2 to A3) trades a small amount of that recall back (0.5427 to 0.5417) in exchange for fewer false positives (4,937 to 4,824), showing that the fusion mechanism mainly helps control false-positive workload rather than raise recall further. Replacing Gaussian kernel weighting with uniform neighbor weights (A3 to A4) changes almost nothing on this test set (PR-AUC 0.1101 in both, recall 0.5417 in both, false positives 4,824 versus 4,828), so Gaussian weighting is not the mechanism responsible for OptiGeoRisk's reported gains here, at least at the neighborhood sizes selected on this dataset. Removing imbalance handling (A3 to A5) has the largest effect of all: recall falls sharply from 0.5417 to 0.4440 and false positives drop from 4,824 to 3,923, confirming that imbalance handling, not the spatial mechanism, is doing much of the work in keeping recall high. Taken together, the ablation attributes OptiGeoRisk's early-warning sensitivity mainly to adaptive neighborhood selection and imbalance handling, with adaptive fusion serving a complementary role in workload control and Gaussian weighting contributing little beyond what uniform local weighting already achieves on this split.

TABLE IX. SYSTEMATIC ABLATION OF OPTIGEORISK COMPONENTS (WEST JAVA)

Configuration	PR-AUC	Recall	Precision	FP
A0: Global spatial baseline	0.1113	0.5332	0.1056	4,759
A1: Fixed local + Gaussian + fixed fusion	0.1112	0.5256	0.1066	4,641
A2: Adaptive neighborhood + fixed fusion	0.1113	0.5427	0.1038	4,937
A3: Full OptiGeoRisk	0.1101	0.5417	0.1058	4,824
A4: No Gaussian weighting	0.1101	0.5417	0.1058	4,828
A5: No imbalance handling	0.1113	0.4440	0.1066	3,923

I. Operational Value at Review Capacity

Table X reports the number of default cases captured, recall and precision within the reviewed set, and false-positive workload for the three core models at review capacities of 1%, 5%, and 10% of the 15,349 test-set transactions.

At every capacity tested, XGBoost Spatial Feature captures the most default cases in absolute terms: 32 of 1,054 at 1% capacity, 118 at 5%, and 217 at 10%, corresponding to a lift over random selection of 3.05x, 2.24x, and 2.06x, respectively. OptiGeoRisk captures fewer cases at each capacity (27, 107, and 197) but still clearly outperforms random selection (2.57x, 2.03x, and 1.87x lift) and remains close to XGBoost Non-Spatial, which captures 20, 102, and 196 cases at the same capacities. In business terms, prioritizing the top 5% of transactions by XGBoost Spatial Feature's score captures loan exposure of approximately Rp 220.3 million in eventual defaults out of Rp 2,025.4 million total default exposure in the test set, against a false-positive workload of 649 transactions and a break-even review cost of about Rp 183,332 per false positive; OptiGeoRisk captures a similar but somewhat lower share, about Rp 199.5 million, at a workload of 660 transactions. This

operational view reinforces the finding from Sections IV-D and IV-G that XGBoost Spatial Feature is the stronger model for ranking-based prioritization at realistic review capacities, while OptiGeoRisk's comparative advantage lies less in capturing the largest absolute number of defaults at a fixed capacity and more in its recall behavior under protocols where local historical coverage is available (Section IV-F).

TABLE X. OPERATIONAL VALUE AT TOP 1%, 5%, AND 10% REVIEW CAPACITY (WEST JAVA)

Capacity	Model	Defaults Captured	Recall@ Capacity	Precision @Capacity	FP
Top 1%	XGB Non-Spatial	20	0.0190	0.1307	133
Top 1%	XGB Spatial Feature	32	0.0304	0.2092	121
Top 1%	OptiGeoRisk	27	0.0256	0.1765	126
Top 5%	XGB Non-Spatial	102	0.0968	0.1330	665
Top 5%	XGB Spatial Feature	118	0.1120	0.1538	649
Top 5%	OptiGeoRisk	107	0.1015	0.1395	660
Top 10%	XGB Non-Spatial	196	0.1860	0.1277	1,339
Top 10%	XGB Spatial Feature	217	0.2059	0.1414	1,318
Top 10%	OptiGeoRisk	197	0.1869	0.1283	1,338

J. Computational Overhead

Table XI reports training time and OptiGeoRisk-specific overhead indicators for the three core models on the same 46,044-row training split.

TABLE XI. COMPUTATIONAL OVERHEAD FOR THE THREE CORE MODELS (WEST JAVA)

Model	Fit Time (s)	Ratio vs. XGB Non-Spatial	Local Groups (Test)	Mean Bandwidth (km)
XGB Non-Spatial	2.08	1.00x	-	-
XGB Spatial Feature	12.28	5.91x	-	-
OptiGeoRisk	145.88	70.13x	609	9.6

XGBoost Spatial Feature trains in 12.28 seconds, about 5.91 times longer than XGBoost Non-Spatial's 2.08 seconds, reflecting the added cost of branch-distance, POI, and OSM feature computation. OptiGeoRisk is substantially more expensive still, at 145.88 seconds, about 70.13 times XGBoost Non-Spatial's training time, because it fits a separate local classifier for each of 609 test-time neighborhood groups, using a mean adaptively selected neighborhood size of about 52 observations and a mean adaptive bandwidth of about 9.6 kilometers. This overhead is a real deployment consideration: OptiGeoRisk's benefit is concentrated in specific validation settings (Section IV-F), and its absolute recall gain over a fairly tuned baseline is modest (Section IV-G), so its added computational cost should be weighed against how frequently a portfolio needs to be re-scored and against simpler alternatives, such as periodic rather than continuous retraining of the local component.

These fit-time figures do not by themselves show how expensive OptiGeoRisk is to score new transactions, how much of that cost is spatial neighbor search rather than local-model fitting, or how its memory footprint compares with a global classifier. To characterize these, the same transaction-random split was rescored in a separate, instrumented reproduction that isolates distance computation from local-model fitting: scoring the 15,349-row test set took 5.1 ms for XGBoost Non-Spatial and 6.5 ms for XGBoost Spatial Feature (both under 0.5 ms per 1,000 transactions), against roughly three to four thousand times that latency per transaction for OptiGeoRisk, because each of its 609 candidate kecamatan-level neighborhoods requires a freshly fit local XGBoost model rather than a single forward pass (593 of the 609 candidates contained both classes and were actually fit). Of OptiGeoRisk's total scoring time, only about 8% was spent computing haversine distances from each neighborhood centroid to every training transaction and ranking them by proximity; the remaining 92% was local-model fitting and prediction. Because this reproduction ran on different hardware than Table XI's own timings, its absolute seconds are not directly comparable to Table XI; the informative findings are the latency gap itself and the small, roughly one-tenth, share of it attributable to distance computation.

To assess how this overhead scales with the size of the historical transaction pool, the same 609 test-time neighborhoods were rescored while reducing the training pool available for neighbor search to 25%, 50%, and 75% of its original 46,044 rows. Distance-computation time grew roughly in proportion to the training-pool size, consistent with the current implementation computing a haversine distance from each neighborhood centroid to every available training transaction rather than using a spatial index such as a KD-tree or ball-tree. Local-model fit-and-predict time, in contrast, stayed essentially flat across all four pool sizes, because the adaptive neighborhood-selection rule caps each local model at 200 nearest neighbors (a mean of about 52 to 57 neighbors was actually used); growing the historical pool changes which transactions are nearest, not how many are used to fit each local model. In practice, OptiGeoRisk's per-scoring-pass latency is therefore driven mainly by the number of distinct geographic neighborhoods that must be refit, so it should grow primarily as the model's geographic footprint expands to new kecamatan, and only mildly as transaction history accumulates within kecamatan already covered; a spatial index over the training coordinates is a natural way to remove the linear distance-computation cost documented here as that history keeps growing.

Peak resident memory across the full reproduction, including loading the dataset, one-hot encoding the categorical branch, kecamatan, and vehicle-type fields into a roughly 3,400-column feature matrix, fitting both global baselines, and fitting all 593 local models needed to score the test set, stayed at approximately 530 MB when the feature matrix is kept in its native sparse form

(on the order of 40 nonzero entries per row out of about 3,400 columns). A serialized global XGBoost model occupies roughly 170 KB; a single local model occupies roughly 110 to 120 KB. Because local models are fit on demand and discarded once a neighborhood is scored, OptiGeoRisk never holds more than one local model in memory at a time, but unlike the two global baselines, whose inference-time footprint is limited to their small serialized model file, OptiGeoRisk must additionally keep the entire historical training feature matrix and coordinate set resident at serving time to support on-demand neighbor search and refitting.

V. Conclusion

This study proposed OptiGeoRisk as a spatially localized and optimized Geo-XGBoost framework for credit default risk classification. The study uses real-world collateral-based loan transactions from West Java and addresses two connected issues, severe class imbalance and geographic heterogeneity in local default patterns, by removing administrative location names and raw coordinate predictors from the ordinary feature matrix. The experiment then evaluates whether coordinates can be used more appropriately as a structural mechanism for local learning.

The main test result shows that XGBoost Spatial Feature achieves the best PR-AUC (0.1158) while OptiGeoRisk achieves the highest default recall (0.5256), a trade-off between global ranking performance and localized early-warning sensitivity. XGBoost Spatial Feature obtained the highest PR-AUC because its global learning structure produced a more stable overall ranking of default risk across the full test set, while still benefiting from branch-distance, POI, and OSM-derived spatial-context variables.

OptiGeoRisk, by contrast, used coordinates to adapt predictions through local neighborhood learning and global-local probability fusion. This localized mechanism improved sensitivity to actual default cases and produced the highest default recall, but it also introduced more false positives and slightly reduced global ranking consistency. OptiGeoRisk should therefore not be interpreted as universally superior to XGBoost Spatial Feature; rather, it is more useful as an early-warning layer when the operational priority is to capture more potential default cases for follow-up. A bootstrap significance check supports this framing: the recall gain is robust across resamples, while the PR-AUC shortfall relative to XGBoost Spatial Feature is also statistically genuine (Section III-E; Table III). A fair-tuned check (Section IV-G) shows that part of this recall margin over XGBoost Spatial Feature narrows once both baselines receive an equal hyperparameter-tuning budget, while the PR-AUC trade-off persists, so OptiGeoRisk is best read as competitive rather than categorically superior.

For financial institutions, pawnshop businesses, consumer loan providers, and collateral-based financing companies, this behavior can be valuable as an early-warning layer that ranks customers or territories needing earlier verification, preventive contact, or portfolio monitoring. It should not be used as an automatic rejection mechanism; instead, it supports human and operational decision-making, where catching risky cases earlier may be more valuable than minimizing every false alarm. This framing does not depend on the recall advantage generalizing everywhere: the PR-AUC gain over a no-skill baseline held in both regions tested (Section IV-E), so the early-warning case for OptiGeoRisk rests on the ranking gain as much as on recall. Section IV-I quantifies this concretely: at a 5% review capacity, the three core models capture between 102 and 118 of the 1,054 test-set default cases, at least 1.9 times more than the roughly 53 expected under random selection at the same capacity.

The study has several limitations and future directions. First, although Sections IV-F and IV-G now evaluate leakage-robust validation protocols and fair, equal-budget hyperparameter tuning for the three core models, the systematic ablation, computational overhead, and operational-capacity analyses in Sections IV-H through IV-J were likewise run only for these three models. Second, the cross-region check now uses an identical five-protocol evaluation for West Java and DKI Jakarta, which resolves the earlier protocol mismatch, but still covers only one additional region with a substantially smaller and sparser transaction set; broader validation across more provinces, product types, and time periods is still required. Third, the leakage-robust protocols in Section IV-F show that OptiGeoRisk's recall advantage depends on local historical coverage and weakens or reverses when whole locations or future time periods are held out, which should be treated as a deployment constraint rather than a property to be assumed; region-aware or coverage-aware bandwidth calibration is a concrete next step. Fourth, kecamatan polygons improved visualization detail but did not improve the main model when used as granular spatial features; future work should test hierarchical spatial modeling rather than simply adding finer administrative predictors. Fifth, OptiGeoRisk's computational overhead, about 70 times XGBoost Non-Spatial's training time (Section IV-J), means that frequent full retraining may not be practical at larger portfolio scale; future development should test business-cost-based thresholds, probability calibration, periodic rather than continuous retraining schedules, and model monitoring under portfolio drift.

Author Contributions

C. Prastian designed the study, processed the dataset, implemented the Geo-XGBoost and OptiGeoRisk models, and wrote the initial draft. A.A.S.G. supervised the research, reviewed the spatial autocorrelation and bootstrap analyses, and revised the manuscript. Both authors reviewed and approved the final manuscript.

Dataset Availability

The primary loan transaction dataset used in this study contains proprietary and personally identifiable borrower information from a collateral-based financing institution in West Java, Indonesia, and is therefore not publicly available due to customer privacy obligations and institutional confidentiality agreements, consistent with Indonesia's Personal Data Protection Law (UU No. 27/2022) and OJK regulations on financial-sector data governance. De-identified or aggregated data supporting the findings of this study may be made available by the corresponding author upon reasonable request and subject to a data-sharing agreement with the data-providing institution. The publicly available auxiliary datasets used for spatial feature engineering, OpenStreetMap building and road-network data [28] and administrative boundary polygons can be freely

accessed at https://www.openstreetmap.org. Point-of-interest features were derived from the Google Places API [27], accessible under Google's standard commercial API terms of service.

DECLARATION ON GENERATIVE AI

During the preparation of this manuscript, the author(s) used a generative AI tool (Claude, Anthropic) to assist with literature screening and citation verification, statistical robustness analysis (bootstrap resampling and significance testing), and language editing of the manuscript text. After using this tool, the author(s) critically reviewed, verified, and edited all AI-assisted content, and take full responsibility for the accuracy, originality, and scientific validity of the final manuscript. The core research design, experimental implementation, data analysis, interpretation of results, and conclusions are the authors' own work.

***Abstract*—Software development projects frequently face uncertainty arising from evolving requirements, communication gaps, and inconsistent coordination among stakeholders. This study presents the Collaborative Development Method (CDM), an agile framework designed to strengthen collaboration, improve requirements engineering practices, and support uncertainty management throughout the software development lifecycle. CDM integrates collaborative activities, requirements traceability, user story validation, and continuous alignment between business objectives and technical implementation within a structured development process. To evaluate its effectiveness, an empirical study was conducted with software developers from Moroccan software companies. The measurement model was first validated using confirmatory factor analysis, and the proposed relationships were then examined through a Robust Least Squares regression model after diagnostic tests indicated violations of ordinary least squares assumptions. The results show that collaboration among project stakeholders, structured communication, requirements traceability, user story validation, and business–technical alignment significantly improve perceived uncertainty management. In contrast, the use of a Domain-Specific Language for structuring user stories and adapting iteration length to functionality size did not demonstrate a statistically significant effect. These findings provide empirical evidence that CDM offers a promising framework for improving coordination, requirements management, and decision-making in agile software development environments.**

***Keywords*—Agile leadership; uncertainty management; agile software development; requirements engineering; Collaborative Development Method (CDM); software process improvement**

I. Introduction

The rapid evolution of digital projects has profoundly transformed the conditions of design, coordination, and management within development teams. In this context, organizations are confronted with environments characterized by the variability of needs, the frequency of functional adjustments, the diversity of the actors involved, and the uncertainty that accompanies the translation of business expectations into technical solutions. Faced with these constraints, Agile Software Development has emerged as a privileged framework for improving team responsiveness and strengthening their adaptive capacity. However, the relevance of this approach does not lie solely in its iterative rhythm or in the application of practices derived from Scrum. It also depends on the way collaboration among stakeholders is organized, on how requirements are clarified and monitored, and on the ability of agile leadership to support continuous mechanisms of dialogue, validation, and adjustment. From this perspective, uncertainty management constitutes a central issue, since project performance depends on the ability to reduce ambiguities without rigidifying the development process. The question, therefore, is not only whether agility makes it possible to respond more quickly to change, but also under what conditions it helps make such change more understandable, better coordinated, and more fully integrated into the overall course of the project, particularly through the integration of a collaborative agile DSL.

It is within this logic that the present study focuses on the role of the application of CDM in improving uncertainty management in a development environment. The analysis is based on the idea that the control of uncertainty depends on the quality of interactions among actors, on the structuring of requirements, and on the alignment between business objectives and technical choices. It therefore lies at the intersection of Agile Software Development, Requirements Engineering, and Software Process Improvement. Within this framework, the use of formalization mechanisms, particularly through a collaborative agile Domain-Specific Language (DSL), may be regarded as a support intended to make needs more explicit, strengthen the consistency of user stories, and facilitate exchanges among the different project stakeholders. However, the actual scope of these instruments depends on their integration into a collective dynamic sustained by agile leadership capable of articulating coordination, learning, and adaptation. The objective of this research is therefore to examine the extent to which several dimensions related to the application of CDM contribute to improving uncertainty management in software projects. Through this approach, the study seeks to better understand how agile practices can move beyond their procedural dimension to become a concrete lever for the stabilization, intelligibility, and sustainable improvement of the development process.

II. Literature Review

A. Agile Management and Uncertainty Management

Agile management can be presented as a mode of governance particularly well suited to software development when uncertainty affects needs, technical choices, and the conditions under which the project is carried out. Highsmith

[19] recalls that the deliverables of a project cannot be fully specified before its start and must emerge throughout its implementation, which from the outset places software development within a logic of adjustment. From the same perspective, Highsmith and Cockburn [20] show that high iteration frequencies strengthen teams' ability to cope with risk and uncertainty, particularly through the continuous integration of customer feedback. Although agile practices can implicitly contribute to risk reduction through iterative development and continuous feedback, explicit risk management mechanisms remain important for systematically identifying, assessing, and monitoring project risks [36]. Schwaber and Sutherland [40] describe Scrum as a lightweight framework aimed at generating value through adaptive solutions to complex problems, relying on empiricism, Lean Thinking, transparency, inspection, and adaptation. Waterman [47] also explains that agility, risk, and uncertainty are closely linked from the design phase onward. In the same vein, Hazzan and Dubinsky [17] present agility as a philosophy that makes it possible to deal with uncertain situations and processes of change. Agile management thus appears, in software development, as a project management framework that organizes adaptation rather than assuming the initial stability of development conditions.

This logic becomes particularly important when software development takes place in environments marked by technological and organizational turbulence. Ahmed et al. [1] emphasize that volatile, uncertain, complex, ambiguous, radical, and rapid contexts intensify the challenges associated with change management, thereby increasing the relevance of agile management. Akkaya and Ahmed [2] extend this idea by showing that the transition to Industry 5.0 reinforces the need for rapid adaptation through computing power capable of handling complex problems more effectively. Conforto et al. [7] indeed observe that agile project management is attracting increasing interest beyond software development precisely because it responds to the frequent evolution of requirements. Zaslavska and Zaslavskyi [49], for their part, consider that the agile project-based approach ensures the flexibility and adaptability of structures in a turbulent environment. Lill et al. [27] likewise argue that agility proposes flexibility as a response to uncertainty, whereas methods based on detailed planning are better suited to relatively stable situations. Finally, Teece et al. [43] relate this orientation to organizational agility, showing that it makes it possible to dynamically adapt the firm's capabilities in the face of risk and uncertainty in the innovation economy.

In the field of software development, agile management is not limited to absorbing external uncertainty; it also transforms the way teams interpret and address it. Fagerholm and Pagels [13] thus show that a register of uncertainty reduction appears in lean and agile values through the intention to base actions on evidence rather than on unjustified orders. Dönmez and Grote [11] indicate that agile software development teams perceive uncertainty both as a threat and as an opportunity, which directly influences their project management practices. Salin and Lundgren [39] add that agile risk management is based on the acceptance of uncertainty as a normal component of the organizational environment, as well as on the creation of a climate of psychological safety that makes it possible to discuss openly errors, failures, and emerging uncertainties.

Levitt [26], for his part, emphasizes the delegation of authority to competent actors and the existence of shared global awareness, elements that strengthen software teams' ability to react rapidly to the unexpected.

The role of agile management appears particularly clearly in Requirements Engineering, where uncertainty directly concerns the understanding, prioritization, and evolution of needs. Logue and McDaid [29] show that agile approaches can address the uncertainty inherent in software development projects through a requirements prioritization and planning method that incorporates variability management. Their use of statistical simulation is intended to model fluctuations in requirements and estimates so as not to freeze specifications prematurely. Highsmith and Cockburn [20], for their part, emphasize that the continuous integration of customer feedback through closely spaced iterations allows the product to be adjusted more precisely to changing requirements. Ries [38] advocates an approach based on continuous innovation, iterative development, and the regular validation of hypotheses with customers, rather than on a rigid plan. Mendonça de Sá Araújo et al. [33] also show that Design Thinking practices, such as collaborative ideation, empathy, problem framing, divergent thinking, and rapid prototyping, can be structured with agile frameworks to better capture business opportunities in an uncertain environment. In software development, Requirements Engineering thus becomes an evolutionary process of clarifying needs rather than a stage of definitive requirements fixation.

This logic of continuous adjustment extends into Software Process Improvement, where improving the development process depends less on fixed standardization than on a capacity for the progressive revision of practices. Schwaber and Sutherland [40] explain that Scrum makes the relative effectiveness of existing practices visible so as to enable improvements, thereby giving agility an explicit process-improvement function. Tavares et al. [42] show that the analysis of risk management in Scrum projects makes it possible to integrate uncertainty management into the very core of agile practices. Van Oorschot et al. [46] nevertheless point out that iteration length influences the uncertainty of outcomes and that cycles that are too short or too long may produce fluctuations that are unfavorable to performance. Kreye et al. [24] confirm that the detailed planning of project means becomes of limited relevance as long as deliverables remain uncertain, which justifies significant replanning between sprints. Cooper [8] adds that the combination of agile methods and stage-gate can offer flexibility, speed, and improved communication in new product development. From a similar perspective, Lishner and Shtub [28] show that risk and uncertainty must be integrated into the very choice of development methodology, which reinforces the strategic scope of agility in improving the software process.

Agile management also affects the quality of software development through the forms of coordination and learning that it makes possible among team members. Gren et al. [15] show that teamwork, open communication, and agile planning

are strongly correlated with perceived agility in large companies, which highlights the importance of collaborative mechanisms in software environments. Tolfo et al. [45] explore the relationship between agile practices and the development of entrepreneurial skills in software development, suggesting that these practices can strengthen capabilities that are useful in evolving environments. Hendler [18] shows that, when it comes to articulating physical and digital development, close collaboration, Scrum ceremonies, and increment planning facilitate mutual adjustment and continuous learning, which is decisive in phases of high uncertainty. Azonuche and Enyejo [4], for their part, emphasize that agile risk management is based on the decentralization of responsibility, combined with the use of real-time data and predictive dashboards enabling continuous adaptation. Dobrowolski et al. [10] add that agile methodology implies a constant readiness to initiate change, to learn from each evolution, and to create value for the customer. In software development, this combination of collaboration, learning, and distributed decision-making strengthens teams' ability to maintain project continuity despite uncertainty.

B. CDM as a New Method for Agile Uncertainty Management

The Collaborative Development Method can be justified as a structured extension of the principles of Agile Software Development, but also as an operational framework of Agile Management oriented toward the control of uncertainty [30,31]. Fig. 1 indeed shows that the method does not rely solely on a succession of activities, but on a precise organization of exchanges among the Customer, the Product Owner, and the development team. From operation 1, in which the client explains business needs, the method places the clarification of business needs at the center, which is consistent with Alsaqqa et al. [3], for whom agile development is characterized by its ability to integrate changing requirements throughout the project. This interpretation is reinforced by Rasheed et al. [37], who recall that agility gives priority to interactions, collaboration with the customer, and rapid response to change, as well as by Perkusich et al. [35], who present agility as a change-driven approach based on the empirical learning of customer needs. Through operation 2, in which the Product Owner creates the User Story and updates the priorities, and then operation 3, in which the PO validates the new US and prioritized feature, Fig. 1 highlights a logic of framing, arbitration, and continuous validation that falls directly within Agile Management. This logic corresponds to the view of Gheorghe et al. [14], who define Agile Software Development as a set of values and principles oriented toward adaptive, incremental, and iterative production, carried out by self-organized teams. It also aligns with Kuhrmann et al. [25], who emphasize that agility is as much a mindset and a culture as it is a mere process. Accordingly, CDM can be understood as a form of agile management aimed at better structuring decisions, stabilizing exchanges, and, above all, preventing the emergence of ambiguities that fuel uncertainty in a development context.

The specific value of the method becomes even more apparent when one considers the way Fig. 1 organizes the transformation of need into understandable and shareable requirements. After the first validation, operation 4 indicates that the PO updates his Product Backlog; then operation 5 shows that the PO presents the highest-priority US for the next Sprint, before operation 6, in which the Dev team validates the comprehension. This sequence reflects a form of Agile Management based on progressive clarification, synchronization among actors, and the reduction of interpretive gaps between business need and technical translation. This is precisely what Chen et al. [5] support with ScrumOntoSPL, by proposing a collaborative method combining Scrum, agile engineering, and uniform requirements specification based on an ontology to reduce coordination costs. The presence in Fig. 1 of the User Story respecting DSL shows that this structuring relies on a Domain-Specific Language, which strengthens the stability of formulations, the traceability of requirements, and their shared understanding. CDM thus fits within a Requirements Engineering perspective in which formalization is not opposed to agility, but rather placed at the service of a more controlled management of interactions. This interpretation is consistent with Khan and Keung [21], who show that the improvement of practices depends on an understanding of the enabling factors and barriers that influence process evolution, as well as with Choraś et al. [6], who emphasize the importance of concrete metrics to assess and guide agile practices. Although CDM shares with ScrumOntoSPL the objective of strengthening requirements coordination within an agile setting, their structural emphasis differs. ScrumOntoSPL primarily combines Scrum with ontology-based requirements specification for software product-line reuse, whereas CDM organizes the broader collaboration cycle among the Customer, Product Owner, and development team around need clarification, prioritization, traceability, validation, prototyping, and iterative adjustment. The distinctive contribution of CDM therefore lies less in introducing an isolated requirements representation mechanism than in integrating these mechanisms within a continuous uncertainty-management process.

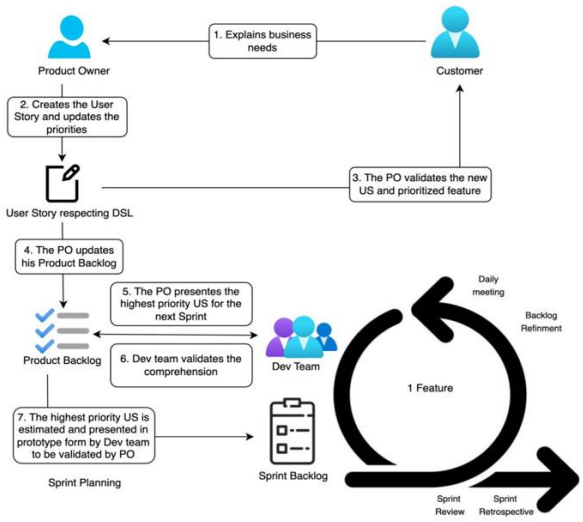

Fig. 1. Application of CDM and agile uncertainty management.

It also aligns with Marinho et al. [32], Klünder et al. [23], and Tell et al. [44], who show that, in complex or distributed environments, effective coordination requires methodological combinations capable of adjusting processes to the real constraints of collective work. Fig. 1 therefore suggests that

CDM is not only intended to manage the flow of user stories more effectively, but also to reduce upstream the sources of interpretive instability that feed project uncertainty.

The link with Uncertainty Management becomes even more explicit in the final part of Fig. 1. Operation 7 indicates that the highest priority US is estimated and presented in prototype form by the Dev team to be validated by the PO before its inclusion in the Sprint Backlog and its processing within a loop comprising Daily meeting, Backlog Refinement, Sprint Review, and Sprint Retrospective, with an iteration centered on 1 Feature. This architecture shows that CDM seeks to control uncertainty through the decomposition of needs, incremental validation, continuous feedback, and a focus on a specific functionality. In other words, Agile Management here takes the form of a sequential governance of uncertainty, in which each operation in Fig. 1 contributes to reducing part of the ambiguities likely to affect understanding, estimation, coordination, or decision-making. This interpretation is directly consistent with Gupta et al. [16], who consider risk and uncertainty management to be a critical factor in software product management. It also aligns with Ezghari and Zahi [12], who recall that estimations are affected by data inaccuracies and the limits of human reasoning; Nahar et al. [34], who emphasize the usefulness of mitigation mechanisms in the face of uncertainty; Dey and Lee [9], who show the insufficiency of requirements analysis and modeling techniques to address it properly; and Kläs and Vollmer [22], who identify specific sources of uncertainty related to scope, data quality, and model adequacy. In the same vein, Włodarski et al. [48] show that the agile approach improves team cohesion and productivity, while Sinha and Das [41] observe that it becomes particularly effective when sprints are devoted to clearly delimited functional improvements, which corresponds to the logic of 1 Feature highlighted in Fig. 1. Thus, CDM can be understood as a mechanism that articulates Collaborative Development Method, Agile Software Development, Agile Management, Scrum, Requirements Engineering, DSL, Software Process Improvement, and Uncertainty Management within the same logic of progressive development stabilization: the more needs are clarified, validated, prioritized, and tested through the operations; the more uncertainty becomes governable.

III. METHODS

A. Research Hypotheses

In light of the preceding theoretical developments, the improvement of uncertainty management in a software development environment can be understood as the result of a set of complementary mechanisms relating simultaneously to Agile Management, Requirements Engineering, and Software Process Improvement. Indeed, the literature reviewed shows that uncertainty does not stem solely from the project's external instability, but also from interpretive gaps among actors, ambiguities surrounding requirements, coordination difficulties, shortcomings in validation, and the potential mismatch between business logic and technical translation. From this perspective, the application of the Collaborative Development Method appears as a structured framework that makes it possible to better organize interactions among the client, the Product Owner, and the development team, to strengthen the progressive clarification of needs, to improve the formalization and traceability of requirements, to support their continuous validation, and to ensure a more coherent treatment of functionalities throughout the iterations. Thus, CDM cannot be reduced to a simple operational sequence, but constitutes a mechanism of collective regulation through which exchanges, priorities, formulations, and adjustments become more intelligible and more manageable. It is on this conceptual basis that the following hypotheses are formulated:

- H1: Improving collaboration among the client, the Product Owner, and the development team has a positive effect on the perceived improvement of uncertainty management through the application of CDM.
- H2: The formalization of exchanges among stakeholders and the clarification of needs from the definition phase onward have a positive effect on the perceived improvement of uncertainty management through the application of CDM.
- H3: The use of DSL to structure the formulation of user stories has a positive effect on the perceived improvement of uncertainty management through the application of CDM.
- H4: Improving requirements traceability has a positive effect on the perceived improvement of uncertainty management through the application of CDM.
- H5: The validation of user stories and functionalities with the relevant actors has a positive effect on the perceived improvement of uncertainty management through the application of CDM.
- H6: The alignment between business objectives and technical objectives has a positive effect on the perceived improvement of uncertainty management through the application of CDM.
- H7: The adaptation of the iteration to the size of the requested functionality has a positive effect on the perceived improvement of uncertainty management through the application of CDM.

B. The Model

In order to examine empirically the factors associated with the improvement of uncertainty management in a development environment, this study adopts a statistical model linking the perception of this improvement to several dimensions derived from the application of CDM. The model specified below makes it possible to assess the role of collaboration simultaneously, the formalization of exchanges, the structuring of user stories, traceability, validation, business–technical alignment, and iterative adjustment in explaining the phenomenon under study.

$$UNCDM = \beta 0 + \beta 1.COLLB + \beta 2.REQFM + \beta 3.DSLST + \beta 4.REQTR + \beta 5.VALUS + \beta 6.GOAAL + \beta 7.ITERF + \varepsilon$$

The dependent variable UNCDM refers to the perceived improvement of uncertainty management through the application of CDM. It is measured based on six items: UNCDM1: the application of CDM helps reduce ambiguities in the definition of needs; UNCDM2: the application of CDM improves the understanding of client expectations; UNCDM3: the application of CDM facilitates the anticipation of changes related to requirements; UNCDM4: the application of CDM contributes to reducing uncertainties during development; UNCDM5: the application of CDM improves the control of requirements throughout the project; UNCDM6: the application of CDM makes the development process more predictable in the face of change. This variable thus makes it possible to assess the overall contribution of CDM to a better control of uncertainty in development. The variable COLLB measures the improvement of collaboration among the client, the Product Owner, and the development team. It is based on six items: COLLB1: CDM improves communication among the client, the Product Owner, and the development team; COLLB2: CDM fosters better information sharing among stakeholders; COLLB3: CDM facilitates coordination among the actors involved in the project; COLLB4: CDM reduces misunderstandings among stakeholders; COLLB5: CDM strengthens the involvement of actors in exchanges related to requirements; COLLB6: CDM improves the quality of interactions among project members. This variable aims to capture the extent to which the application of CDM strengthens the collective dynamic surrounding requirements management. The variable REQFM corresponds to the formalization of exchanges among stakeholders and the clarification of needs from the definition phase onward. It is measured through six items: REQFM1: CDM makes it possible to formalize exchanges among stakeholders from the beginning of the project; REQFM2: CDM improves precision in the expression of needs; REQFM3: CDM helps clarify the client's functional expectations; REQFM4: CDM reduces ambiguities in the initial formulation of requirements; REQFM5: CDM facilitates the establishment of a shared understanding of needs; REQFM6: CDM improves the structuring of discussions around requirements. This variable therefore makes it possible to assess the capacity of CDM to make the initial process of needs definition more explicit and more widely shared.

The variable DSLST refers to the use of DSL to structure the formulation of user stories. It is approached through six items: DSLST1: the use of DSL makes the formulation of user stories clearer; DSLST2: the use of DSL improves consistency in the writing of user stories; DSLST3: the use of DSL reduces errors in the interpretation of user stories; DSLST4: the use of DSL facilitates the development team's understanding of user stories; DSLST5: the use of DSL makes it possible to standardize the writing of user stories; DSLST6: the use of DSL improves the overall quality of the formulation of user stories. This variable thus measures the contribution of DSL to a better structuring of the language used in the formalization of requirements. The variable REQTR refers to the improvement of requirements traceability. It is based on six items: REQTR1: CDM facilitates the monitoring of requirements from their definition to their implementation; REQTR2: CDM makes it possible to better link requirements to the functionalities developed; REQTR3: CDM improves the identification of the origin of expressed needs; REQTR4: CDM facilitates the tracking of changes made to requirements; REQTR5: CDM improves visibility regarding the evolution of requirements throughout the project; REQTR6: CDM strengthens continuity between initial needs and final deliverables. This variable makes it possible to assess the extent to which CDM strengthens informational continuity and the monitoring of needs over time. The variable VALUS measures the validation of user stories and functionalities with the relevant actors. It is assessed through six items: VALUS1: CDM facilitates the validation of user stories with the relevant stakeholders; VALUS2: CDM improves the verification of the conformity of functionalities with expressed needs; VALUS3: CDM makes it possible to obtain faster feedback on the proposed user stories; VALUS4: CDM promotes better acceptance of functionalities by the relevant actors; VALUS5: CDM reduces the risks of discrepancy between expectations and the functionalities developed; VALUS6: CDM improves the process of validating needs before final development. This variable therefore aims to capture the role of CDM in securing the process of validating requirements and functionalities.

The variable GOAAL corresponds to the alignment between business objectives and technical objectives. It is measured by six items: GOAAL1: CDM improves consistency between business objectives and technical choices; GOAAL2: CDM facilitates the translation of business needs into technical requirements; GOAAL3: CDM strengthens the alignment between client priorities and the work of the technical team; GOAAL4: CDM reduces the gaps between functional expectations and the proposed technical solutions; GOAAL5: CDM enables better articulation between business vision and technical development; GOAAL6: CDM improves the consideration of business objectives in technical decisions. This variable therefore makes it possible to assess the capacity of CDM to bring the functional and technical dimensions of the project closer together. The variable ITERF refers to the adaptation of the iteration to the size of the requested functionality. It may be measured based on six items: ITERF1: CDM makes it possible to adjust the duration of the iteration to the complexity of the functionality; ITERF2: CDM facilitates the breakdown of functionalities into suitable iterations; ITERF3: CDM improves the fit between workload and the content of the iteration; ITERF4: CDM reduces the gaps between the size of the functionality and iteration planning; ITERF5: CDM promotes better priority management in the iterative breakdown; ITERF6: CDM improves consistency between iteration planning and functional needs. This variable makes it possible to apprehend the extent to which the application of CDM makes the iterative pace better adjusted to the concrete characteristics of the functionalities to be developed. The items associated with all the variables in the model were measured using a five-point Likert scale, ranging from 1 "strongly disagree" to 5 "strongly agree."

C. Construction of Variables

After the initial construction of the variables, a confirmatory factor analysis was conducted in order to verify the convergent validity of the items and to refine the constructs. Only the items whose factor loadings were greater than 0.5 were retained, while the others were removed.

Convergent validity and construct reliability were assessed using standardized factor loadings, average variance extracted (AVE), and composite reliability (CR). AVE was calculated as $AVE = \frac{\sum_{i=1}^{n} \lambda_i^2}{n}$, where λi denotes the standardized factor loading of item i. Composite reliability was calculated as $CR = \frac{(\sum_{i=1}^{n} \lambda_i)^2}{(\sum_{i=1}^{n} \lambda_i)^2 + \sum_{i=1}^{n}(1-\lambda_i^2)}$. Items with standardized loadings below 0.50 were excluded before the final construct scores were computed. The recalculated composite reliability coefficients range from 0.787 for DSLST to 0.913 for ITERF, indicating satisfactory construct reliability. AVE values range from 0.556 for DSLST to 0.727 for ITERF and therefore exceed the conventional 0.50 threshold for all constructs. These results support convergent validity for the retained measurement model (Table I).

TABLE I. RESULTS OF THE CONFIRMATORY FACTOR ANALYSIS FOR CONVERGENT VALIDITY AND CONSTRUCT RELIABILITY

Items	Standardized Factor Loading	Composite Reliability (CR)	AVE
UNCDM 2	0.753617	0.804706	0.583555
UNCDM 3	0.889353		
UNCDM 5	0.625922		
COLLB 1	0.620869	0.858672	0.607233
COLLB 3	0.883678		
COLLB 4	0.735819		
COLLB 6	0.849197		
REQFM 2	0.960432	0.790954	0.568807
REQFM 3	0.612614		
REQFM 5	0.639292		
DSLST 1	0.879949	0.786674	0.556081
DSLST 4	0.693511		
DSLST 5	0.642631		
REQTR 2	0.736849	0.836306	0.630673
REQTR 3	0.835277		
REQTR 5	0.807084		
VALUS 2	0.720613	0.827529	0.616331
VALUS 4	0.781365		
VALUS 6	0.848044		
GOAAL 1	0.624159	0.811529	0.595338
GOAAL 3	0.744317		
GOAAL 5	0.917840		
ITERF 1	0.924147	0.912991	0.727204
ITERF 4	0.660281		
ITERF 5	0.898398		
ITERF 6	0.900931		

The examination of composite reliability and AVE further supports the psychometric quality of the retained constructs. Composite reliability values range from 0.786674 to 0.912991, exceeding the commonly accepted threshold of 0.70. AVE values range from 0.556081 to 0.727204 and remain above the 0.50 threshold for all constructs, supporting convergent validity. These results indicate that the retained items provide satisfactory reliability and explain an adequate proportion of variance in their respective constructs.

The retained constructs therefore demonstrate satisfactory convergent validity and composite reliability. In addition, the very low VIF values reported in the subsequent regression diagnostics indicate limited linear redundancy among the explanatory variables. Dedicated discriminant-validity criteria such as the Fornell–Larcker criterion or HTMT were not available from the retained analytical outputs and should therefore be examined in future replications to further consolidate the measurement-model assessment.

D. Data

Participants were software developers working in an organizational context in Morocco in which agile development practices were used. The survey specifically targeted developers involved in software development activities and exposed to collaborative requirements-management practices or to the application of CDM. Eligibility was therefore aligned with the purpose of the study, which required respondents to have sufficient practical exposure to agile development and collaborative requirements activities to evaluate the proposed mechanisms. A criterion-based purposive sampling approach was used to target software developers with relevant exposure to agile development and collaborative requirements-management practices. This sampling strategy was consistent with the study objective, as evaluation of the CDM-related dimensions required respondents with practical knowledge of the development context under investigation. The questionnaire also collected general participant characteristics, including age group, gender, software development experience, team size, use of agile methods, and exposure to CDM. Before completing the CDM-related items, respondents were provided with a presentation of the study, the conceptual role of CDM, and the main dimensions examined in the questionnaire. Participation was voluntary, anonymous, and confidential, and all constructs were assessed using five-point Likert-scale items ranging from strongly disagree to strongly agree.

Table II summarizes questionnaire completion and validity. A total of 250 questionnaires were completed by developers working in software development companies in Morocco. After data-quality screening, 154 questionnaires were retained for analysis, while 96 were excluded because they did not meet the criteria for statistical usability. Valid questionnaires therefore represented 61.6% of the completed questionnaires. Because the total number of individuals initially invited to participate was not available in the retained study records, an overall survey response rate could not be calculated.

TABLE II. QUESTIONNAIRE COMPLETION AND VALIDITY

Completed	Valid	Invalid	Valid questionnaires / Completed questionnaires
250	154	96	61.6 %

Table III, presenting the descriptive statistics, first shows a strong proximity between the means and medians for all variables, which indicates a distribution that is globally centered around the intermediate level of the scale. The means

range from 2.943182 for COLLB to 3.099567 for REQTR, while all medians are equal to 3.000000. This configuration suggests that the developers surveyed in software development companies in Morocco express moderate to slightly favorable perceptions regarding the contribution of CDM. The standard deviations, ranging from 0.723932 to 0.870004, reflect a contained dispersion, indicating some variability but without excessive heterogeneity among the responses observed in the sample.

TABLE III. DESCRIPTIVE STATISTICS

	Mean	Median	Max	Min	Std. Dev.	Skewness	Kurtosis
UNCDM	3.021645	3.000000	5.000000	1.000000	0.806361	-0.223477	2.665365
COLLB	2.943182	3.000000	5.000000	1.000000	0.772549	0.096656	2.595066
REQFM	3.010823	3.000000	5.000000	1.000000	0.846556	-0.077309	2.286297
DSLST	2.978355	3.000000	5.000000	1.000000	0.789984	0.009580	2.580690
REQTR	3.099567	3.000000	5.000000	1.000000	0.870004	0.011773	2.405846
VALUS	3.012987	3.000000	5.000000	1.000000	0.772515	-0.142265	2.598047
GOAAL	2.997835	3.000000	5.000000	1.000000	0.803493	-0.034496	2.953082
ITERF	3.040584	3.000000	5.000000	1.000000	0.723932	0.113296	2.613382

The examination of the shape indicators confirms this relative stability of the distributions. The skewness coefficients remain low, ranging from -0.223477 for UNCDM to 0.113296 for ITERF, which indicates distributions close to symmetry, with slight inclinations depending on the variable. Likewise, the kurtosis coefficients vary from 2.286297 to 2.953082, values close to the reference threshold, which suggests the absence of extreme concentrations or abnormally long tails. The minimum and maximum values cover almost the entire response scale, from 1 to 5, showing that all response categories were used by the respondents, without excessive polarization in the judgments expressed.

E. Choice of Methodology

The examination of the Ramsey RESET test (Table IV), applied to the model estimated by ordinary least squares, reveals a deficiency in statistical specification. This test aims to assess the validity of the retained functional form by detecting possible omissions of relevant variables, nonlinearity effects, or, more generally, an inadequacy between the theoretical structure of the model and the relationship actually observed in the data. In this case, the results obtained show a t-statistic of 3.009505 associated with a probability of 0.0031, an F-statistic of 9.057119 also significant at the 1% level, as well as a likelihood ratio of 9.330813 with a probability of 0.0023. The convergence of these three indicators toward the same conclusion leads to the rejection of the null hypothesis of correct specification.

The examination of the Jarque-Bera normality test applied to the residuals of the model estimated by ordinary least squares reveals a significant deviation from the normality assumption. Indeed, in Fig. 2, the Jarque-Bera statistic reaches 25.54575, with a probability of 0.000003, a value well below the conventional 5% threshold. This result therefore leads to the rejection of the null hypothesis according to which the residuals follow a normal distribution. This conclusion is consistent with the descriptive characteristics of the residual series, marked by positive skewness (skewness = 0.854400) and a kurtosis coefficient slightly above the normal reference value of 3 (kurtosis = 4.030127), reflecting a distribution that is both asymmetric and more concentrated around the mean, with relatively heavy tails.

TABLE IV. RAMSEY RESET TEST FOR MODEL SPECIFICATION (OLS)

Unrestricted SSR	8.601675	145	0.059322

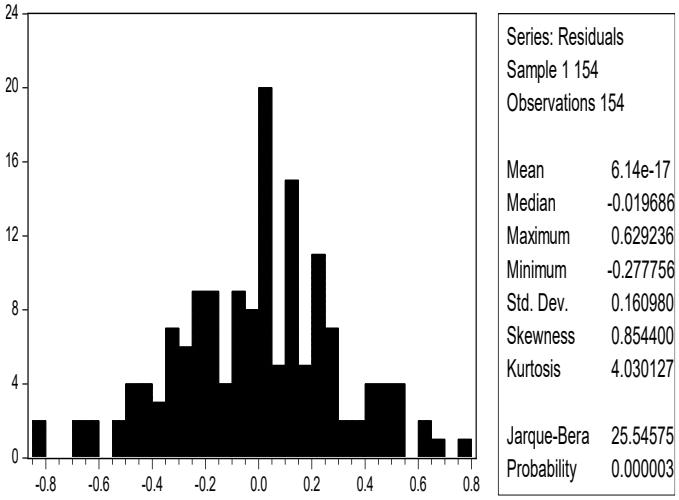

Fig. 2. Jarque-Bera normality test (OLS).

The examination of the Breusch-Pagan-Godfrey heteroskedasticity test applied to the model estimated by ordinary least squares (Table V) reveals the presence of non-constant residual variance. Indeed, the three reported statistics converge toward the same conclusion. The F-statistic stands at 2.592992 with a probability of 0.0150, the Obs*R-squared statistic reaches 17.02851 with a probability of 0.0172, while the Scaled explained SS statistic rises to 23.18845 with a probability of 0.0016. Since all these probabilities are below the conventional 5% threshold, the null hypothesis of homoskedasticity is rejected. This result means that the dispersion of the errors is not stable from one observation to another, reflecting heterogeneity in the variance of the disturbances.

TABLE V. BREUSCH-PAGAN-GODFREY HETEROSKEDASTICITY TEST (OLS)

Test statistic	Value	Degrees of freedom	Probability
F-statistic	2.592992	F(7, 146)	0.0150
Obs*R-squared	17.02851	Chi-square(7)	0.0172
Scaled explained SS	23.18845	Chi-square(7)	0.0016

In light of the diagnostics carried out on the model estimated by ordinary least squares, the use of robust regression through RLS appears methodologically justified. Indeed, the Ramsey RESET test revealed a specification deficiency, suggesting that the relationship between the variables is not fully captured by the retained linear functional form. In addition, the Jarque-Bera test led to the rejection of the normality assumption for the residuals, revealing an asymmetric and leptokurtic distribution of the errors, while the Breusch-Pagan-Godfrey test confirmed the presence of heteroskedasticity, that is, a non-constant variance of the disturbances. The combination of these three results indicates that the classical conditions ensuring the efficiency and inferential validity of OLS estimators are not fully satisfied. In this context, estimation by RLS constitutes an appropriate alternative, insofar as it makes it possible to reduce the influence of atypical observations, improve the robustness of the estimated coefficients, and produce more reliable inference when the standard assumptions of OLS are weakened.

IV. RESULTS

A. Robustness Analysis

The application of the Ramsey RESET test to the model estimated by the Robust Least Squares method indicates, this time, an improvement in statistical specification. Indeed, this test makes it possible to verify whether the retained functional form remains adequate after correcting the shortcomings identified under OLS estimation. The results in Table VI show a t-statistic of 1.149077 associated with a probability of 0.2524, an F-statistic of 1.320377 with a probability likewise equal to 0.2524, as well as a likelihood ratio of 1.395985 corresponding to a probability of 0.2374. Since all these probabilities are well above the conventional 5% threshold, the null hypothesis of correct model specification cannot be rejected. This result suggests that, under robust estimation, the explanatory model reflects the relationship under study more satisfactorily. Under robust estimation, the corresponding RESET diagnostic no longer indicated evidence against the retained functional specification.

TABLE VI. RAMSEY RESET TEST FOR MODEL SPECIFICATION (RLS)

Ramsey RESET Test Equation: UNTITLED Specification: UNCDM C COLLB REQFM DSLST REQTR VALUS GOAAL ITERF			
Omitted Variables: Squares of fitted values			
Test	Value	Df	Probability

Unrestricted SSR	327.6246	145	2.259480

The analysis of the variance inflation factors applied to the model estimated by the Robust Least Squares method, presented in Table VII, shows the absence of a multicollinearity problem among the retained explanatory variables. This diagnostic is based primarily on the Centered VIF values, which make it possible to assess the intensity of the linear correlations between each regressor and all the other variables in the model. In this case, all the observed values are very low and remain well below the critical thresholds commonly accepted in the statistical literature. They range from 1.015819 for COLLB to 1.053895 for VALUS, while the other variables, namely REQFM, DSLST, REQTR, GOAAL, and ITERF, also display levels very close to unity. Such a configuration indicates that each explanatory variable provides distinct information, without significant linear redundancy with the others.

TABLE VII. VARIANCE INFLATION FACTOR ANALYSIS (RLS)

Variance Inflation Factors Sample: 1 154 Included observations: 154			
Variable	**Coefficient Variance**	**Uncentered VIF**	**Centered VIF**
C	0.313689	21.33338	NA
COLLB	0.176150	3.562348	1.015819
REQFM	0.194895	4.433069	1.049236
DSLST	0.201126	4.507918	1.045842
REQTR	0.179376	4.424994	1.024247
VALUS	0.175523	3.927746	1.053895
GOAAL	0.178327	3.655873	1.021817
ITERF	0.191091	4.874647	1.044690

The examination of the Jarque-Bera normality test applied to the residuals of the model estimated by the Robust Least Squares method in Fig. 3 indicates that the normality hypothesis cannot be rejected. Indeed, the Jarque-Bera statistic stands at 1.540661, associated with a probability of 0.462860, a

value well above the conventional threshold of 5%. This result therefore leads to the conclusion that the distribution of the residuals is compatible with a normal distribution. This conclusion is consistent with the observed descriptive characteristics, notably a very moderate skewness (skewness = 0.149395) and a kurtosis coefficient of 2.611634, which is close to the reference value associated with normality. The residual histogram also confirms a relatively balanced distribution around the mean, without marked distortion or excessive concentration in the tails of the distribution. Under these conditions, robust estimation appears to have substantially improved the distributional behavior of the errors.

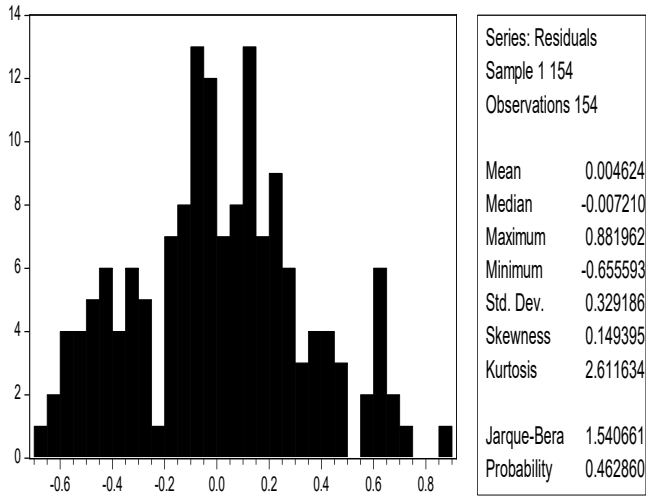

Fig. 3. Jarque-Bera normality test (RLS).

The examination of the Breusch-Pagan-Godfrey heteroskedasticity test applied to the model estimated by the Robust Least Squares method, presented in Table VIII, indicates the absence of a significant problem of residual heteroskedasticity. Indeed, the three test statistics converge toward the same conclusion. The F-statistic is equal to 0.926060 with a probability of 0.4883, the Obs*R-squared statistic stands at 6.546938 with a probability of 0.4775, while the Scaled explained SS statistic reaches 2.096089 with a probability of 0.9543. Since all these probabilities are well above the conventional 5% threshold, the null hypothesis of homoskedasticity cannot be rejected. This result means that the variance of the residuals now appears stable from one observation to another, which suggests a substantial improvement in the statistical quality of the model after the use of robust estimation. The corresponding residual diagnostics under RLS no longer indicated the irregularities observed in the initial OLS specification.

TABLE VIII. BREUSCH-PAGAN-GODFREY HETEROSKEDASTICITY TEST (RLS)

Test statistic	Value	Degrees of freedom	Probability
F-statistic	0.926060	F(7, 146)	0.4883
Obs*R-squared	6.546938	Chi-square(7)	0.4775
Scaled explained SS	2.096089	Chi-square(7)	0.9543

The examination of the influence statistics based on Covratio highlights an overall satisfactory stability of the estimation. Fig. 4 indeed shows that the Covratio values remain concentrated within a relatively narrow interval around unity, without abrupt breaks or excessive deviations likely to indicate the existence of observations exerting a disproportionate influence on the variance-covariance matrix of the coefficients. The observed fluctuations remain moderate and follow a fairly regular overall pattern, which suggests that the hypothetical removal of one observation would not substantially modify the overall precision of the estimators. In other words, the structure of the model does not appear to depend on a few atypical points capable of significantly altering the stability of the results.

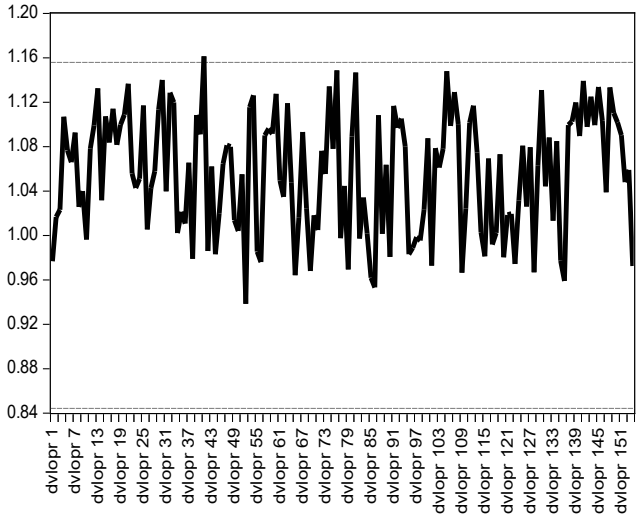

Fig. 4. Covratio influence statistics (RLS).

The initial OLS estimation revealed several statistical weaknesses through the Ramsey RESET test, the Jarque-Bera normality test, and the Breusch-Pagan-Godfrey heteroskedasticity test, indicating respectively a specification deficiency, non-normality of the residuals, and a non-constant error variance. The use of RLS estimation made it possible to substantially improve the statistical quality of the model. The results obtained after re-estimation show, through the same tests, a specification that has become acceptable, a residual distribution compatible with normality, and a more stable error structure. Finally, the examination of the Covratio influence statistics confirms the overall stability of the model.

B. Regression Results

Table IX presents the results of the estimation using the Robust Least Squares method. The estimation is based on M-estimation with Bisquare weighting, a scale founded on median-centered MAD, and Huber-type robust standard errors, which strengthens the model's resistance to disturbances likely to affect the precision of the results.

Standardized coefficients were also computed to facilitate comparison of the relative magnitude of the predictors. Among the statistically significant predictors, collaboration shows the largest standardized association with perceived uncertainty management ($\beta = 0.278$), followed by requirements formalization ($\beta = 0.238$), user-story validation ($\beta = 0.205$), requirements traceability ($\beta = 0.192$), and business–technical alignment ($\beta = 0.186$).

TABLE IX. ROBUST LEAST SQUARES ESTIMATION RESULTS

*** Significant at 1%; ** Significant at 5%; * Significant at 10%.

COLLB is associated with a positive coefficient that is significant at the 1% level (p-value = 0.0014). This result shows that better collaboration among the client, the Product Owner, and the development team is associated with a perceived improvement in uncertainty management within the CDM framework. Hypothesis H1 is therefore accepted. This finding highlights that the quality of exchanges among project actors constitutes an important support for limiting misunderstandings and better framing adjustments throughout the development process. REQFM also displays a positive sign and significance at the 1% level (p-value = 0.0056). This result confirms that the formalization of exchanges among stakeholders and the clarification of needs from the outset contribute to a better perceived management of uncertainty. Hypothesis H2 is therefore accepted. This result suggests that a more explicit initial framing of expectations reduces margins of ambiguity and promotes more controlled project management. DSLST shows a positive coefficient, but it is not significant, even at the 10% level (p-value = 0.9836). Under these conditions, no statistically established effect can be retained between the use of DSL to structure the formulation of user stories and the perceived improvement of uncertainty management. Hypothesis H3 is therefore rejected. This suggests that the structuring of the language of user stories, by itself, is not sufficient to produce a perceptible change in the control of uncertainty.

REQTR emerges with a positive coefficient that is significant at the 5% level (p-value = 0.0279). This result indicates that better requirements traceability is associated with a perceived improvement in uncertainty management through the application of CDM. Hypothesis H4 is therefore accepted. It can be inferred that more rigorous monitoring of requirements, from their initial expression to their evolution, helps preserve project coherence and reduce zones of uncertainty. VALUS presents a positive coefficient that is significant at the 5% level (p-value = 0.0191). This result shows that the validation of user stories and functionalities with the relevant actors contributes positively to the perceived improvement of uncertainty management. Hypothesis H5 is thus accepted. This result underlines the value of shared validation in bringing developed functionalities closer to the expectations actually expressed by stakeholders.

GOAAL also displays a positive coefficient that is significant at the 5% level (p-value = 0.0315). This result confirms that alignment between business objectives and technical objectives promotes a perceived improvement in uncertainty management. Hypothesis H6 is therefore accepted. This shows that better consistency between the project's functional logic and its technical translation contributes to making development more intelligible and more stable. ITERF presents a positive coefficient, but it is not significant (p-value = 0.1987). This result therefore does not allow validation of the existence of a statistically significant effect of adapting the iteration to the size of the requested functionality on the perceived improvement of uncertainty management. Hypothesis H7 is rejected. This indicates that the adjustment of the iterative pace, considered in isolation, does not appear sufficient to strengthen uncertainty control in a clearly observable manner.

V. DISCUSSION

The results first show that the perceived improvement of uncertainty management relies to a large extent on the quality of collaboration among the client, the Product Owner, and the development team. This result confirms the idea that agility does not produce its effects solely through iteration, but also through the concrete organization of interactions among stakeholders. It is therefore consistent with Highsmith and Cockburn [20], who associate adaptive capacity with the continuous integration of feedback, as well as with Schwaber and Sutherland [40], for whom Scrum is based on transparency, inspection, and adaptation in dealing with complex problems. It also aligns with Gren et al. [15], who show the importance of teamwork, open communication, and agile planning in perceived agility. In the same logic, the positive effect of the formalization of exchanges and the initial clarification of needs confirms that the reduction of uncertainty depends on the early explication of expectations rather than on the late regulation of discrepancies. This finding extends the work of Logue and McDaid [29], who emphasize that uncertainty related to requirements can be better contained when prioritization and planning avoid freezing specifications prematurely, as well as that of Ries [38], for whom the regular validation of hypotheses makes it possible to adjust the product more precisely. The results therefore indicate that, within the CDM framework, uncertainty control depends first on the ability of the actors to construct a language of exchange that is sufficiently clear to reduce ambiguities during development.

The results then show that uncertainty management is strengthened when requirements remain visible, monitored, and validated throughout the project. The positive effect of traceability confirms that uncertainty does not arise solely from the variability of demands, but also from possible breaks between the expressed need, its intermediate reformulation,

and the actual development. This result is consistent with the logic of Software Process Improvement highlighted by Schwaber and Sutherland [40], according to which practices must be made visible in order to be improved, as well as with Tavares et al. [42], who show that risk management can be integrated into Scrum practices themselves. Likewise, the positive effect of validating user stories and functionalities is consistent with Gupta et al. [16], who consider risk and uncertainty management to be a critical factor in software projects, as well as with Dey and Lee [9], who emphasize the limitations of approaches that are insufficiently equipped to deal properly with uncertain requirements. The positive effect of alignment between business objectives and technical objectives also extends the logic described in Fig. 1, where clarification, prioritization, estimation, prototyping, and validation follow one another in order to make uncertainty progressively governable. From this perspective, the results confirm that the main contribution of CDM lies in its ability to maintain continuous coherence between functional logic and technical translation, rather than in execution speed alone.

By contrast, the results qualify the scope of certain instruments when they are considered in isolation. The absence of a statistically established effect of DSL suggests that the formal structuring of user stories is not, by itself, sufficient to produce a perceptible improvement in uncertainty management. This result does not necessarily contradict the expected contributions of a structured language, but it shows that its effectiveness remains conditional on the way it is embedded in collective coordination practices. From this perspective, the results invite a more cautious reading of the promises associated with formalization tools and are consistent with the idea defended by Kuhrmann et al. [25], according to which agility is as much a matter of mindset and culture as of process. Similarly, the absence of a significant effect of adapting the iteration to the size of the functionality shows that the iterative pace, taken in isolation, does not constitute a sufficient lever for uncertainty control. This observation is consistent with Van Oorschot et al. [46], who show that iteration length influences outcomes without automatically guaranteeing greater stability, as well as with Lishner and Shtub [28], who recall that risk and uncertainty must be integrated into the broader choice of methodology. Overall, the results therefore confirm that uncertainty management depends less on a particular technical device than on a coherent combination of collaboration, clarification, traceability, validation, and alignment, supported by agile leadership capable of articulating these dimensions within the CDM framework.

VI. Conclusions and Future Work

This study shows that improving uncertainty management in software projects depends less on the declared adoption of an agile approach than on the way its principles are effectively translated into the organization of work. The results highlight that the reduction of ambiguities becomes more tangible when actors build a shared understanding of needs, sustain continuous exchanges, and maintain close coordination throughout development. From this perspective, Agile Software Development cannot be reduced to a succession of iterations or to a simple sequence of ceremonies inspired by Scrum. Its effectiveness rests primarily on the quality of collaboration, on the circulation of information, and on the capacity of agile leadership to create a framework for dialogue, adjustment, and collective regulation. Uncertainty management thus appears as a socially constructed process, in which uncertainties are contained not through rigid control, but through frequent interactions, shared validation, and a better articulation between client expectations and development choices. Within this interpretation, CDM may be understood not merely as a procedural tool, but as a new form of agile management, insofar as it structures the relationships among the Customer, the Product Owner, and the development team around progressive clarification, prioritization, validation, and iterative adjustment. In that sense, CDM extends agile management by providing a more explicit operational architecture through which coordination becomes more readable and uncertainty more governable. The findings therefore suggest that agility produces its strongest effects when it reinforces collective coherence around requirements, so that changes become more intelligible, more openly discussed, and more easily integrated into the trajectory of the project.

The analysis also shows that the most robust contribution to project stabilization comes from practices that strengthen Requirements Engineering within an agile framework. When needs are clarified, monitored, and validated continuously, uncertainty control becomes more credible and the project gains in coherence between business logic and technical translation. In a Scrum-inspired environment, the value of the process lies less in the speed of iteration itself than in the quality of the collective trade-offs it makes possible. In this respect, the use of DSL, particularly in the form of a collaborative agile DSL, does not appear sufficient on its own to significantly transform uncertainty management, which recalls that formalization tools replace neither dialogue nor shared interpretation. The essential contribution of the study therefore concerns Software Process Improvement, understood as the joint strengthening of communication, validation, alignment, and collective learning. The general conclusion is that agile leadership may provide an enabling context for making agility a durable lever for the control of uncertainty, while CDM can be regarded as a structured and emerging form of agile management specifically oriented toward the progressive stabilization of software development under uncertainty. This study nevertheless presents several limitations. First, it is based on cross-sectional perceptual data collected from developers working in software development companies in Morocco, which limits both causal interpretation and the generalizability of the findings to other institutional or organizational contexts. Second, the analysis relies on self-reported Likert-scale measures and on a perceived improvement in uncertainty management rather than on objective project performance indicators such as delivery delays, defect rates, rework, or requirements volatility. Because predictor and outcome measures were collected from the same respondents at a single point in time, common method variance cannot be completely excluded. Future studies should combine multiple data sources, temporal separation, or objective project indicators to assess the robustness of the observed relationships. Third, the sample retained for the empirical

analysis remains limited, and the study does not compare CDM with other agile configurations or hybrid project management approaches. Finally, the empirical design does not capture the longitudinal dynamics through which uncertainty evolves across sprints and project phases. Future research could therefore extend the analysis through comparative, longitudinal, and multi-actor designs, while also examining more directly whether CDM, as a new form of agile management, improves observable project outcomes in different software development settings.

ACKNOWLEDGMENT

The authors would like to thank all software developers and industry professionals who voluntarily participated in the survey and contributed valuable insights to this study. Their participation made the empirical evaluation of the proposed Collaborative Development Method (CDM) possible.

Faculty of Artificial Intelligence and Cyber Security, Universiti Teknikal Malaysia Melaka, Melaka, Malaysia[3]

***Abstract*—Smart Internet of Toys (IoToys) can provide interactive learning and companionship for children, but many systems still provide limited support for guardian awareness and safety notification. This study presents the design and development of a smart IoT robot toy with AI-based safety judgment and parental monitoring features. The prototype integrates a robot head unit, web-based monitoring dashboard, camera viewing, remote movement control, two-way communication, AI-assisted safety judgment, Telegram guardian notification, memory-based allergy reminder, chat history, and behavior report. The system uses an ESP32-S3 CAM head unit, an ESP32-C3 mobile base, a Node.js server, cloud-assisted AI services, and a Telegram Bot notification channel. Scenario-based testing was conducted, and the results showed that the prototype can support remote observation and notify guardians about child safety-related scenarios such as fear, injury, danger, and food allergies.**

Keywords*—Child safety; internet of toys; IoToy; IoT robot; parental monitoring; privacy concerns; smart toy; Telegram notification

I. Introduction

Smart toys have progressed from being simple electronic devices to complex connected systems that are able to sense, communicate, and act upon users. These developments play a key role in the domain of the Internet of Toys (IoToys), which aims to have toys interact with children and their environments, typically autonomously. These toys are equipped with sensors, actuators, and AI algorithms that allow them to offer tailored and interactive play experiences [1, 2].

Smart toys can be used as a kind of entertainment and learning instrument in home scenarios, which can create creative play and cognitive development activities [3, 4]. They can gather and analyze data using cameras, microphones, and other sensors. However, there is a problem of privacy and safety concerns with children interacting with these toys without the supervision of their parents [1, 2, 5]. Some toys, for example, stream data to servers on an ongoing basis, which could allow audio surveillance, whereas others have been the victim of privacy breaches or the ability of the attacker to control the toy [2, 5].

Therefore, it is necessary to improve smart toys to overcome the above challenges, which should include functions to entertain and help the guardians keep track of safety-related events. This includes receiving live alerts for any strange activity or possible dangers identified by the toy's sensors or AI-based analysis.

However, existing research reveals a gap in a unified security model or security guidelines for secure use of smart toys [2, 6]. The work on ontologies that explicitly support privacy and security requirements for smart toys is still in progress, and implementation is still limited [1, 7]. This implies that smart toys have great potential to be interactive and educational, but they need to be designed with careful consideration of strong safety and privacy protections to support guardians' ability to keep children safe in their interactions with the toys when they are not being supervised [1, 2, 5].

There are some smart toys that focus on entertainment, learning, or interaction, with limited monitoring by guardians and safety notifications. For example, some devices feature mobile apps, but they tend to focus more on content control instead of situation awareness and parental control [1]. Previous studies have also pointed out that child-centered IoT toys need to be more attentive to privacy, security, and parental control, as well as communication safety. Smart toys are often equipped with sensors, cameras, and microphones that gather personal and situational information, a fact that is worrying many about their ability to be accessed by other people without consent, and their potential to violate privacy rights [1, 2]. In addition, the absence of uniform guidelines for parental control and privacy protection adds to these risks, making children susceptible to digital and physical dangers [8, 9].

This study reports on the parental monitoring part of an AI-enabled IoT robot toy developed as a prototype. The aim is not to replace adult supervision, but to provide an additional awareness and communication channel between the child, the robot, and the guardian. Compared with the complete robot platform, this study focuses on modules related to monitoring, safety notification, remote intervention, and behavior awareness.

The remainder of this study is organized as follows. Section II reviews related work on Internet of Toys, smart toy safety, and parental monitoring. Section III describes the proposed system design and the parental monitoring workflow. Section IV describes the implementation of the web-based monitoring dashboard, camera monitoring, Telegram notification, AI-based judgment, behavior report, and remote intervention modules. Section V presents the scenario-based testing results with screenshots and photos as supporting evidence. Section VI discusses the findings, limitations, and privacy concerns of the prototype. Finally, Section VII concludes the research work with the main contributions and future work.

II. Related Work

Internet-connected toys (IoToys) combine embedded hardware, sensors, wireless communications, and software services to provide interactive and connected play experiences. The toys are typically designed with integrated capabilities like voice control, wireless connectivity, and adaptive feedback, which add to their attractiveness and usability at home [10, 11, 12]. Even at home, many factors come into play, including safety, transparency, and having guardians' control. The main issues related to safety involve privacy and security related to the collection and processing of personal data, such as sensitive data about children, by IoToys. This information may be subject to hacking, unauthorized use, or misuse, raising serious privacy concerns [10, 13, 14, 15]. Another major concern is transparency; information regarding the collection, storage, and use of personal data by these toys is often unclear to children and their guardians. To enhance transparency, privacy rules and privacy education resources are being developed to better inform children and parents about data collection mechanisms [11, 16].

Guardian control is vital to making sure that IoToys are used safely and responsibly. There are currently challenges related to the lack of uniform safety labelling on IoToys and the difficulty for parents to be able to determine the level of security that these devices have before buying them. This is the reason why there are privacy labels and security labels such as "ChildShield" being proposed to help consumers understand the safety features of IoToys [14]. Furthermore, IoToys will need to be both educational and entertaining, yet safety measures must be very robust to ensure that they are interesting and safe for children [10, 12]. This means that IoToys creates innovative and personalized playing experiences, but its use at home will require attention to privacy, security, and parental control issues to ensure safe and transparent use [10, 11, 13, 14, 15].

Smart toys pose serious security and privacy concerns related to children's speaking data and cloud processing, network communication, application vulnerabilities, and lack of parental control. Smart toys can also record voice information and send it to the cloud to analyze. This adds a layer of privacy concerns, since live streams of data can be exploited for unauthorized audio monitoring. For example, some AI-powered toys are known to send constant audio data to servers, which might pose privacy and surveillance concerns [5, 17]. There are many smart toys that have security issues with their network communications with servers, so they can be hacked and their data exposed. These weaknesses tend to be related to bad practices in the implementation of security policies, as has been reported in the analyses of toy communication environments [18, 1, 19]. Smart toy companion apps often have excessive permissions and do not employ robust security measures. Static and dynamic analyses have identified problems in these apps, including unnecessary data collection and lack of adherence to privacy laws [19, 2]. Parents' control mechanisms are still inadequate. This adds to privacy concerns because parents may not have the means to monitor or limit their children's data collection and utilization by toys. This is reported to be a major concern of parents, especially in developed economies [20]. Besides that, with their capacity to collect and handle delicate data like location and activity patterns, smart toys can encounter information leaks, unauthorized access, and even physical safety hazards. In addition to this, privacy frameworks are not standardized, and compliance is inconsistent with privacy laws [21, 22, 23]. This indicates that the security and privacy issues with smart toys are complex and encompass technical, regulatory, and usability concerns. Solving these problems needs better security measures, stricter enforcement of regulations, and better parental control options.

McReynolds et al. [24] reported that Internet-connected toys may record or transmit children's speech, while parents and children may not always understand what data are collected or how the data are used. Chu et al. [18] found that commercially available children's IoT toys can contain network and application vulnerabilities that conflict with privacy and security best practices. Shasha et al. [2] further proposed a threat taxonomy for smart toys and showed that unsafe access or weak protection may expose children to privacy leakage and safety risks.

Parental control for smart toys should be accompanied by visibility of children's interactions, control over data sharing, notification of important events, and means for making children's interactions known to their guardians. Parents should have resources to watch and comprehend their children's interactions with their smart toys. This means access to the information gathered and its usage [25, 8, 9]. For instance, dashboards or interfaces to show parents what their child is doing and sharing with the toy interaction information are crucial [26].

Parental control tools need to enable parents to control and limit information that their child shares with their smart toy or third parties. This is important because of potential privacy violations and misuse of data [25, 8, 27, 21]. Tools available today are inadequate to meet these needs, and having customizable data-sharing preferences [8, 28] is therefore important. If the parents are involved in the sharing of sensitive information, or if there is a possibility that their information is being shared in an insecure way, they should be informed of this. This will enable prompt action to help protect the child's privacy and safety [1, 28].

Tools should help increase parental awareness of privacy risks and offer easy-to-use interfaces for effective privacy management by non-technical users [29, 30]. Parents must have control of what happens to their children, which means making the design of the products more usable and having clear privacy labels. This suggests that there is strong support for the proposed parental control measures, which include visibility, control, notification, and awareness mechanisms to address concerns about the privacy and safety of smart toys. Therefore, monitoring and notification should be considered as practical design requirements for child-oriented IoT systems.

Based on these concerns, the proposed system integrates parental monitoring directly into the robot platform. Instead of only providing a separate mobile application, the system connects the robot, server, web dashboard, AI judgment, and Telegram Bot notification into one workflow. This allows the guardian to easily receive important information without continuously checking the dashboard.

III. System Design

A. Overall Architecture

Fig. 1 shows the context diagram of the parental monitoring workflow of the proposed IoT toy. The parental monitoring architecture consists of a robot head unit, a server layer, an AI judgment component, a web dashboard, a behavior logging module, and a Telegram notification module. The robot collects interaction input through microphone and camera modules, while the server coordinates AI processing, dashboard communication, logging, and notification. The guardian accesses the system through the web dashboard or receives Telegram alerts when serious situations, such as injury reports, fear expressions, danger-related messages, allergy-related requests, or direct requests to contact the guardian, are detected.

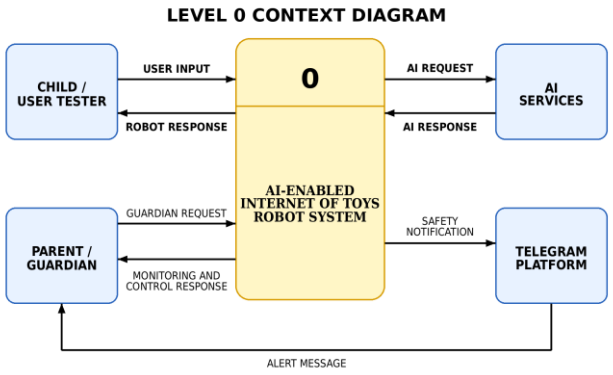

Fig. 1. Context diagram of the parental monitoring workflow.

B. Hardware and Server Components

The robot head unit is based on an ESP32-S3 CAM module and includes a camera, microphone, speaker output, touch input, and display feedback. The mobile base uses an ESP32-C3 controller for wheeled movement. The two parts form a modular robot platform. The Node.js server acts as the central coordination layer between the robot, browser interface, AI services, memory storage, report module, and Telegram Bot.

C. Parental Monitoring Workflow

During normal interaction, the child can communicate with the robot using natural language speech instead of a fixed command list. The interaction can be started through the robot's wake-up mechanism, such as voice activation or touch activation. After activation, the microphone captures the child's speech and sends the audio to the server for speech-to-text processing. The recognized text is then forwarded to the GPT API to generate a context-aware response. Since the GPT API supports multilingual text processing, the robot can support multilingual interaction in principle. However, the actual language performance depends on the speech-to-text module, the selected GPT model, the text-to-speech output, and the availability of support for low-resource languages.

Visual assistance refers to the use of the ESP32-S3 camera to support image-based interaction. For example, when the child asks a visual question such as "What is this?" or asks the robot to look at an object, the camera captures the current image and sends it together with the child's question to the AI service. The AI analyses the visual context and generates a response, which is then converted into speech and played through the robot speaker.

The AI judgment module is executed after each child-robot interaction. The server provides the module with the child's original input, the AI-generated response, and the optional camera image or visual description. The module then classifies the interaction into two outcomes: "guardian notification required" or "no guardian notification required". A notification is triggered when the interaction contains a direct request to contact a guardian, emotional distress, injury, sickness, danger, stranger-related concern, fire or electrical risk, unsafe food, allergy-related request, or other safety-related condition. If the interaction is a normal conversation, such as asking for a story or asking a general question, the system stores the interaction in the behavior log without sending a Telegram alert.

When a notification is required, the server generates a short summary of the situation and sends it to the guardian through Telegram. The Telegram message includes the child's original input, the AI response, the situation summary, whether an image is attached, and the timestamp. This decision mechanism reduces unnecessary alerts while still notifying the guardian during meaningful safety-related situations.

IV. Implementation

A. Web-Based Monitoring Dashboard

The web-based monitoring dashboard, as shown in Fig. 2, allows the guardian to access the robot through a browser and interact with different monitoring functions. For camera viewing, the guardian clicks the camera or stream button to view the child's surrounding environment through the ESP32-S3 camera. The output is a live or updated camera view, which helps the guardian understand the child's current environment when the guardian is not physically beside the child.

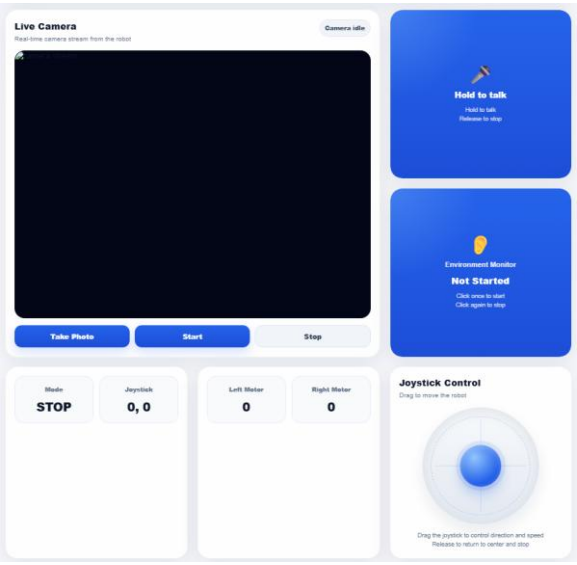

Fig. 2. Web dashboard for camera viewing and remote robot control.

For movement control, the guardian presses the forward, backward, left, or right buttons on the interface. The command is sent from the browser to the server and then forwarded to the ESP32-C3 mobile base. The output is the physical movement of

the robot, allowing the guardian to reposition the robot or observe a different direction remotely.

For AI wake-word control and camera toggle, the guardian can enable or disable selected robot functions from the dashboard. The output is the updated function status shown on the interface. This helps the guardian control when the robot should listen for interaction or activate the camera, depending on the usage situation.

The dashboard also provides links to memory, chat history, and behavior report pages. Through these pages, the guardian can review previous child-robot conversations, safety-related events, and reminders stored, such as allergy information. These outputs help the guardian understand what the child asked, how the robot responded, and whether any important behavior or safety condition occurred.

B. Telegram Guardian Notification

Telegram Bot is used as the guardian notification channel because it supports fast message delivery and can include both text and images. When the system identifies a safety-related event or a guardian contact request, the server sends a structured message to the guardian. The message can include the child's original words, the AI response, a brief situation summary, image availability, and time information. Fig. 3 illustrates an example of the Telegram message generated for a child-to-guardian communication request.

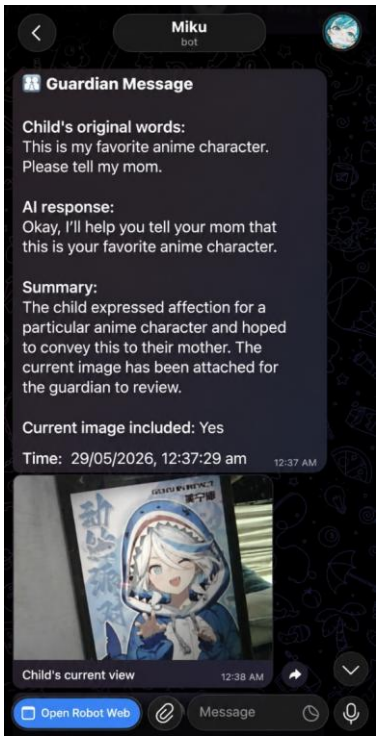

Fig. 3. Telegram notification generated for a child-to-guardian communication request.

C. AI Safety Judgment and Behavior Logging

The AI judgment component operates after each child-robot interaction. The server sends the child's original input, the AI-generated response, and optional visual context from the camera to a judgment prompt. The judgment prompt asks the AI to classify the interaction into two outcomes: guardian notification required or no guardian notification required. The decision is based on whether the interaction contains safety-related or guardian-related content, such as direct requests to contact a parent, expressions of fear such as "I am scared," injury reports such as "I fell down," dangerous environment descriptions such as "There is fire," and allergy-related questions such as "Can I eat peanuts?"

If guardian notification is required, the system generates a short summary and sends a structured Telegram message to the guardian. The message includes the child's original input, the AI response, the event summary, image availability, and timestamp. If the interaction is a normal conversation, such as asking for a story or asking a general question, the system stores the record in the behavior log without sending a Telegram alert. This mechanism helps reduce unnecessary notifications while still allowing the guardian to receive important safety-related or behavior-related information.

The system also records selected chat history and behavior information so that the guardian can review important events later. Fig. 4 shows the behavior report page used to review previous child-robot interactions and safety-related records. Through this report, the guardian can understand what the child said, how the robot responded, and whether any event required attention.

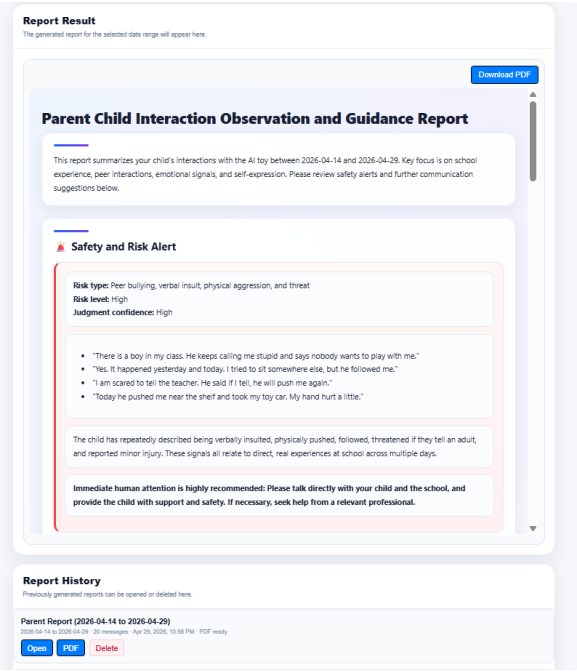

Fig. 4. Behavior report page for reviewing interaction and safety-related events.

D. Allergy Reminder and Remote Intervention

The memory module can store simple child-related information, such as allergy reminders. When the child asks about food that may be unsafe, the system retrieves the stored allergy information and includes it in the AI response. The robot then responds with a warning through speech output, reminding the child to avoid the restricted food. An example of the allergy reminder output is shown in Fig. 5.

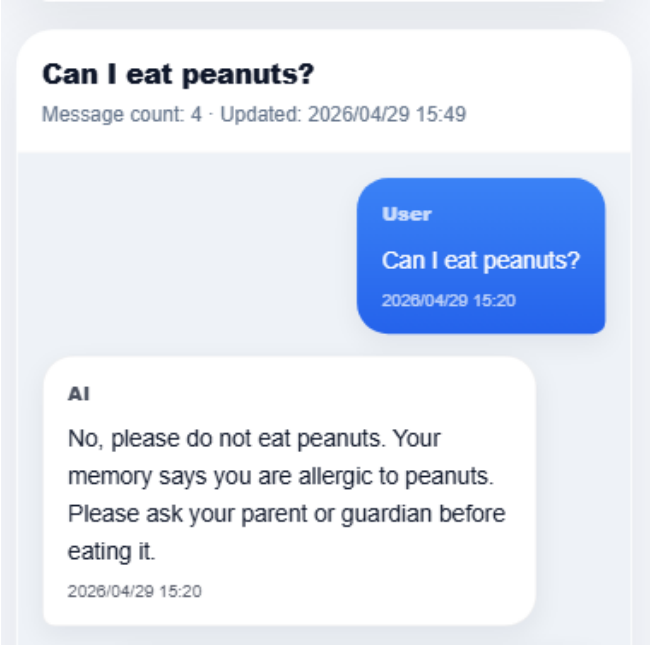

Fig. 5. Allergy reminder output generated based on stored child-related information.

Remote intervention is supported through camera viewing, movement control, and two-way guardian communication. The guardian can first check the camera view to understand the child's surrounding environment. If the guardian needs a different viewing angle, the guardian can use the movement buttons on the dashboard to reposition the robot. If the child needs guidance, the guardian can use the hold-to-talk function to speak through the web interface, and the robot plays the voice message through its speaker to guide the child remotely. Fig. 6 shows the hold-to-talk function used for remote intervention.

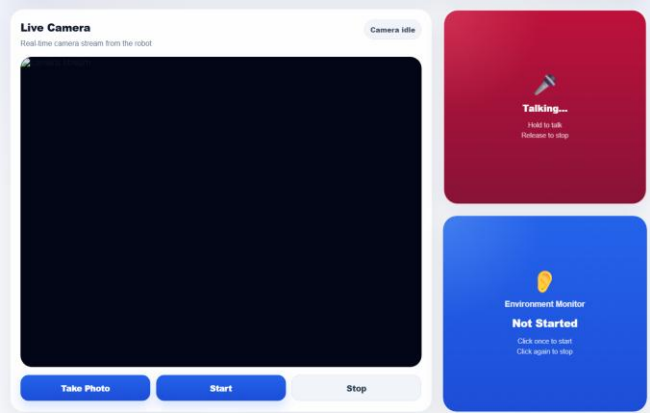

Fig. 6. Two-way guardian communication interface for remote intervention.

V. Scenario-Based Testing and Results

Scenario-based testing was conducted to verify whether the parental monitoring functions produced the expected outputs. The testing focused only on monitoring-related features. Each test used a realistic scenario, input, and output, as shown in Table I. The scenarios include guardian contact request, fear expression, injury report, danger warning, allergy reminder, remote monitoring, remote intervention, and behavior review.

TABLE I. Scenario-Based Testing of Parental Monitoring Features

Scenario	Input	Output
Guardian contact	Child asks robot to tell mother	Telegram message is sent to guardian
Fear expression	Child says "I am scared"	AI comforts child and alerts guardian
Injury report	Child says "I fell down"	Safety notification is generated
Danger warning	Child says "There is fire"	Warning response and Telegram alert generated
Allergy reminder	Child asks about restricted food	Robot gives allergy warning
Remote monitoring	Guardian opens dashboard	Camera view and control buttons are displayed
Remote intervention	Guardian uses hold-to-talk function	Robot delivers guardian voice guidance to the child
Behavior review	Guardian opens report page	Interaction summary is shown

The supporting screenshot evidence is shown in Fig. 2 for the web-based monitoring dashboard, Fig. 3 for Telegram guardian notification, and Fig. 4 for behavior report review. Additional output evidence is provided in Fig. 5 for the allergy reminder and Fig. 6 for two-way guardian communication. These figures provide supporting evidence for the main outputs as listed in Table I.

The test results show that Telegram notifications were triggered for guardian-contact and safety-related scenarios, while the web dashboard supported remote camera viewing, movement control, and remote intervention. The allergy reminder and behavior report pages also helped the guardian review child-related information and previous interaction records. These results indicate that the proposed system can support guardian awareness and remote intervention in basic child-care scenarios.

VI. Discussion

The main advantage of the system is that the guardian does not need to constantly monitor the web dashboard. Safety-related information can be pushed through Telegram when the AI judgment module detects a meaningful event. Camera viewing, behavior reporting, and remote control provide additional context for the guardian to understand the child's situation and respond when necessary. These features allow the IoT toy to act not only as an interactive robot, but also as an additional awareness and communication channel between the child and the guardian.

The reliance on Connectivity and AI Judgment is a recurring theme, with abstracts underscoring the vulnerabilities introduced by connections with other systems, including cloud-based ones, and on real-time decision-making capabilities [31, 32]. This is in line with the issue of relying on cloud AI and Wi-Fi. There are multiple studies that highlight some of the problems with the accuracy of AI, such as false negatives and false positives. In medical and child well-being, the use of AI systems can be complicated by problems with predictive

accuracy, especially if qualitative or contextual data is lacking [32, 33]. This can result in false alarms or in failure to detect the alarm, as mentioned in the question. AI systems need to be thoroughly tested and have more precise instructions on how to operate to become more reliable. For instance, the need for robust evaluation metrics, post-deployment monitoring, and dynamic testing scenarios is frequently mentioned [34, 35]. These measures can be helpful to improve the safety classification rules and minimize errors.

The privacy issues surrounding the IoToy, including the capturing of sensitive information such as children's voices, images captured by the camera, notes of interactions, and any alerts given, were raised. Currently, it is only a prototype where access to this data is limited to a configured guardian through a web dashboard and a Telegram account, but other security elements such as more robust authentication, encrypted communication, access control, and data retention settings are needed before deployment with children.

IoT devices, including smart toys, often collect sensitive data such as video, audio, and interaction logs, which can expose children to significant privacy risks if not adequately secured [36, 37, 38]. For example, there have been reports of weaknesses in IoT-enabled toys that have led to the unauthorized use of cameras and sensors to capture live images and videos without the user's consent [38, 39, 40]. The current IoToy prototype using the web dashboard and Telegram account to access data emphasizes the need for a more secure approach. Research highlights the need for the use of encryption, multi-factor authentication, and access control to reduce risks of unauthorized access and data breaches [36, 39, 41]. For instance, blockchain authentication and encryption have been suggested to improve the security of IoT toys. One concern is Data Retention and Regulatory Gaps, where IoT devices may not have explicit data retention policies, and there is a lack of transparency regarding who accesses or stores sensitive data. To conclude, although the IoToy prototype restricts data access to guardians, there is a strong need for further improvement in authentication, encryption, and access control to ensure effective protection of children's privacy. Moreover, it is essential to address the regulatory gaps and put in place strong data retention policies to guarantee long-term privacy and security [36, 37, 39, 41].

VII. Conclusion

This study presented the design and development of a smart IoT toy with parental monitoring features. The main contribution of this work is the development of a server-assisted IoT toy prototype that connects child-robot interaction with parental monitoring functions. The proposed IoT toy not only provides a joyful play experience and entertainment, but it also helps guardians receive important safety-related information about the child's behavior and surrounding environment. The prototype integrates web-based camera monitoring, remote movement control, AI-based safety judgment, Telegram guardian notification, allergy reminder, behavior logging, and behavior review to support parental monitoring and childcare. Scenario-based testing showed that the system can generate appropriate monitoring outputs, notify guardians, and support remote observation in safety-related situations. Future work will focus on improving notification accuracy, privacy protection, network robustness, and larger-scale user evaluation with parents and child users.

Real-Time Anomaly Detection Using ML, DL, and XAI for Financial Fraud: A Systematic Review

Padilla-Lopez Jimmy Andres, Lazo-Ordoñez Pedro Antonio, Juan Jesús Soria-Quijaite
Escuela de Ingeniería de Sistemas, Universidad Tecnológica del Perú, Lima, Perú

***Abstract*—Digital payments, fintech, and online banking are now part of our daily lives. Making a transfer, paying for a service, or shopping online is faster, but this progress has also given rise to new forms of fraud. Rule-based systems remain useful when the pattern is already known; the problem arises when attackers change their tactics. For this reason, this study reviews the use of machine learning, deep learning, and Explainable Artificial Intelligence to detect anomalies and prevent fraud in digital payment systems. The research was conducted as a systematic literature review. PICOC helped define the scope and search terms, while PRISMA guided the selection of articles. Scopus, Web of Science, and ScienceDirect were consulted. After applying the inclusion, exclusion, and methodological evaluation criteria, 33 studies were retained. The articles addressed cases of card fraud, digital banking, blockchain, money laundering, and other suspicious transactions. The most frequently mentioned models were Random Forest, XGBoost, SVM, Isolation Forest, LSTM, CNN, autoencoders, and graph networks. Hybrid approaches and tools such as SHAP and LIME also appeared, used to show which variables influenced an alert. Several studies reported good results in terms of accuracy, recall, and F1 score. However, challenges remain regarding synthetic data, class imbalance, limited information on latency, and insufficient validation with financial specialists. Their performance still needs to be tested with real-world data and under conditions similar to those of a financial institution.**

Keywords*—Financial fraud; machine learning; deep learning; XAI; digital payments

I. Introduction

Electronic payments, fintech, and online banking are part of everyday financial services. Their growth has sped up many transactions, but it has also opened up new opportunities for fraud. This affects businesses through financial losses and also affects users, who may lose trust in these platforms.

Aparcana-Tasayco et al.[1] note that the rise of connected digital services necessitates improvements in anomaly detection methods.

The reason is that forms of fraud do not remain static: they evolve, test new strategies, and seek to circumvent existing controls. Consequently, methods based on static rules prove insufficient for detecting complex fraudulent behavior. In light of this situation, anomaly detection has emerged as a key approach, enabling the identification of unusual patterns in large volumes of data. In this context, Zhang et al.[2] note that machine learning models based on probabilistic approaches improve the early detection of suspicious activities in financial systems.

Likewise, the use of machine learning techniques has enabled the development of predictive models capable of classifying financial transactions by learning from historical patterns. These models include supervised and unsupervised algorithms, which have proven to be more efficient than traditional methods in identifying fraud. In this regard, Kumar et al. [3] note that the use of deep learning techniques has significantly increased detection capabilities by enabling the modeling of complex and nonlinear relationships in financial data.

The digitization of payment systems has led to more sophisticated forms of financial fraud, which have outpaced traditional rule-based methods. In this context, Wang et al. (2024) propose the use of dual-channel memory networks to extract features from credit review texts, demonstrating that it is possible to improve the accuracy of fraud risk detection by leveraging unstructured data [4].

Digital payment systems require accurate models capable of processing large volumes of transactions in real time. Raja et al. (2025) propose a hybrid model that combines GraphSAGE with LSTM networks to detect suspicious patterns, achieving 95.4% accuracy in money laundering detection. [5]

Finally, hybrid models that combine machine learning and deep learning techniques have proven to be a promising alternative for improving accuracy and reducing false positives in fraud detection. [6]

A. Problem Definition

1) Current situation: Digital payments and fintech platforms have become a common part of financial activities due to the speed and convenience they offer. However, the increase in electronic transactions has also created more opportunities for fraud. In the United States alone, more than 2.7 billion electronic transactions are recorded each year, while organizations lose nearly 5% of their annual revenue due to this problem [7].

Detecting these crimes is not easy. Attackers combine cyber techniques with social engineering and constantly change their methods. At the same time, a system that is too sensitive may block legitimate transactions. Added to this is the need to protect user privacy and explain how automated decisions are made [8].

Traditional systems operate using manually defined rules and thresholds. The problem is that these rules must be updated every time a new form of fraud emerges, so they often react too

late. Černevičienė and Kabašinskas [9] explain that this reliance on fixed rules reduces adaptability. Furthermore, these systems can generate between 85% and 99% false positives, which affects customers and increases the workload for the teams responsible for reviewing alerts [10].

Another limitation lies in response time. Some systems still process transactions in batches, meaning that fraud may be detected after the transaction has already been completed [11]. This delay, coupled with the rise in attacks, continues to erode user confidence in digital financial services [12].

Deep learning models offer better capabilities for recognizing complex patterns, but they also present challenges. Their real-time application requires significant processing power, especially when they must analyze thousands of transactions in just a few seconds. Furthermore, fraud accounts for a very small portion of total transactions—in some cases, less than 0.1%. For this reason, a model that performs well in laboratory tests does not always maintain the same performance when applied on a large scale [13].

B. Rationale

Fraud in digital payments has a direct impact on businesses and the people who use these services. It is estimated that organizations lose nearly 5% of their annual revenue due to this issue [14]. Furthermore, more than 2,700 million electronic transactions are conducted annually in the United States. This growth facilitates financial transactions, but it also increases the number of situations that can be exploited to commit fraud. Ketenci et al. (2021) combined time-frequency analysis with transactional information and CRM data. With this approach, they reduced false positives to 11.85% and were able to better distinguish suspicious entities from those showing no signs of fraud [15].

The rise of digital financial services has not only expanded access but has also changed the rules of the game when it comes to attacks. Systems that operate with fixed rules and predefined limits can still respond effectively to known threats, but they fall short when new or unexpected behaviors emerge. This is where many traditional approaches fall short: they fail to detect in a timely manner those unusual relationships between transactions or the subtle changes in attackers' behavior[16].

Faced with this gap, machine learning began to be seen as a more promising alternative, precisely because it learns from past events. By processing vast amounts of transactions, these models can flag movements that deviate from the norm. And when the information is fluid, or the relationships do not follow a clear logic, probabilistic methods are often the best fit[17]. For his part, Sørensen (2025) analyzes how artificial intelligence and machine learning help uncover signs of fraud that would go unnoticed in a manual review. But he also mentions the problems that remain unresolved, such as false positives and the opacity of some models—two fundamental issues if we are to move toward real-time detection systems that are reliable and, above all, can be clearly explained in the financial sector [18].

The article by Kulkarni et al. (2025) aligns well with what we're seeing here, because it delves deeply into the use of generative AI—VAEs and GANs, to be specific—applied to fraud detection. What's most striking is that these models not only detect very subtle anomalies but can also generate synthetic data without leaking private information. The idea is to build systems that instantly detect fraud in digital payments, without compromising either reliability or the ability to provide clear explanations of how they work [19]. And when we turn to deep learning, the landscape changes because it allows us to analyze transaction sequences at a level of detail that was previously impossible. Networks such as CNNs, LSTMs, autoencoders, and transformers have demonstrated their ability to uncover connections that go completely unnoticed by simpler methods. In fact, in the studies we've reviewed, these architectures have yielded excellent results, both in terms of accuracy and the ability to anticipate future events [20].

But if there's one thing that's proving particularly interesting, it's hybrid models—those that combine the best of traditional machine learning with deep learning. For example, integrating the One-Class SVM with a probabilistic approach has yielded remarkable results: it achieves extremely high accuracy and recall in fraud detection, and best of all, it reduces those false positives. Furthermore, the models become more versatile and adapt better to different scenarios [21].

Finally, speed is key. There's no point in having a system that detects fraud if, by the time it does, it's already too late. That's why the ability to identify suspicious transactions in real time has become essential in digital payments. What researchers have found is that combining models such as transformers, LOF, and Random Forest yields results that excel in precision, recall, and F1-score, demonstrating their enormous potential when applied to complex and fast-paced financial environments [22]. In the words of experts in the field, integrating these approaches is not just a technical improvement: it is a real contribution to the security and efficiency of the digital financial ecosystem as a whole [23].

II. METHODOLOGY

This research is being conducted in accordance with the Systematic Literature Review (SLR) format.

A. PICOC Formulation

The PICOC method was used to determine the scope of the research (Table I).

TABLE I. PICOC COMPONENTS

Component	Description
P (Problem / Population)	Financial transactions suspected of fraud in digital payment systems.
I (Intervention)	Deep learning algorithms with explainability layers.
C (Comparison)	"Black box" deep learning models (without XAI)
O (Results)	Improved interpretability of alerts without significantly compromising accuracy or speed
C (Context)	Fraud prevention departments that require explanations to make operational or regulatory decisions

B. Formulating Questions

After identifying the components of the PICOC method, the general research question (RQ) for this systematic review was formulated:

"What are the deep learning algorithms with Explainable Artificial Intelligence (XAI) applied to the detection of financial fraud in digital payment systems, compared to traditional black-box models, in terms of interpretability, accuracy, and speed?"

Based on this general question, specific questions were formulated (Table II).

TABLE II. PICOC QUESTIONS

RQ1	What machine learning algorithms have been used to detect financial fraud and anomalies in digital payment systems?
RQ2	What deep learning algorithms have been used to detect financial fraud and anomalies in digital payment systems?
RQ3	What machine learning and deep learning models have been used to detect financial fraud in digital payment systems, and to what extent do they outperform or are they outperformed by traditional methods (rule-based and statistical) in terms of effectiveness?
RQ4	What improvements in the interpretability of alerts—while maintaining high levels of precision, recall, F1-score, and a low false positive rate—have been used for fraud detection in digital payment systems?
RQ5	What evidence does the literature provide regarding the effectiveness of real-time models using XAI techniques to improve interpretability without significantly compromising fraud detection performance?

C. Identification of Keywords

The purpose of identifying keywords corresponding to each component of the PICO-C method is to create effective search queries for databases (Table III).

TABLE III. KEYWORDS WITH BOOLEAN OPERATORS

P	"financial transactions" OR "digital payments" OR "payment systems" OR fintech OR banking OR "financial data"
I	"machine learning" OR "deep learning" OR "artificial intelligence" OR "neural networks" OR autoencoder
C	"rule-based" OR "statistical methods" OR "traditional methods" OR "baseline models"
O	"fraud detection" OR "financial fraud" OR "anomaly detection" OR "outlier detection"
C	"real-time" OR "online detection" OR "streaming data" OR "transaction monitoring" OR "explainable AI" OR XAI OR "interpretable machine learning"

D. PICOC Search Formula

Once we had identified the components of the PICOC question and the keywords, we proceeded to develop the search formula that would allow us to find the most relevant literature for this systematic review. To do so, we combined the terms from each component using the Boolean operators "OR" to combine the keywords and "AND" to link the components (Table IV).

TABLE IV. SEARCH EQUATION

Search equation	
Scopus	(TITLE-ABS-KEY ("financial transactions" OR "digital payments" OR "payment systems" OR fintech OR banking OR "financial data") AND TITLE-ABS-KEY ("machine learning" OR "deep learning" OR "artificial intelligence" OR "neural networks" OR autoencoder) AND TITLE-ABS-KEY ("rule-based" OR "statistical methods" OR "traditional methods" OR "baseline models") AND TITLE-ABS-KEY ("fraud detection" OR "financial fraud" OR "anomaly detection" OR "outlier detection") AND TITLE-ABS-KEY ("real-time" OR "online detection" OR "streaming data" OR "transaction monitoring" OR "explainable AI" OR XAI OR "interpretable machine learning")) AND (LIMIT-TO (OA, "all")) AND (LIMIT-TO (LANGUAGE, "English")) AND PUBYEAR > 2020 AND PUBYEAR < 2025
Web of Sciencie	((((((TS=("financial transactions" OR "digital payments" OR "payment systems" OR fintech OR banking OR "financial data")) AND TS=("machine learning" OR "deep learning" OR "artificial intelligence" OR "neural networks" OR autoencoder)) AND TS=("rule-based" OR "statistical methods" OR "traditional methods" OR "baseline models")) AND TS=("fraud detection" OR "financial fraud" OR "anomaly detection" OR "outlier detection")) AND TS=("real-time" OR "online detection" OR "streaming data" OR "transaction monitoring" OR "explainable AI" OR XAI OR "interpretable machine learning")) AND DT=(Article) AND LA=(English)) AND PY=(2021-2026)
Sciencie Direct	("digital payments" OR fintech) AND ("machine learning" OR "deep learning") AND ("fraud detection" OR "anomaly detection") AND ("real-time" OR XAI OR "interpretable machine learning")

E. Inclusion and Exclusion Criteria

The selection of the studies was not arbitrary: specific inclusion and exclusion criteria were applied to ensure their relevance and methodological soundness (Table V).

TABLE V. INCLUSION AND EXCLUSION CRITERIA (PICOC)

Component	Inclusion criteria	Exclusion criteria
Population / Problem	We included research on fraudulent financial transactions in digital payment systems—banks, fintech companies, payment processors, card issuers, digital wallets, and payment gateways—as well as real or synthetic transaction datasets that replicated the financial environment and its characteristic class imbalance.	Studies on non-financial fraud (healthcare, academia, telecommunications, network intrusions) were excluded, unless they justified their transfer to the financial domain. Research on financial transactions not linked to digital payment systems was also excluded.
Scope	Articles that propose, implement, or evaluate deep learning algorithms with explicit Explainable Artificial Intelligence (XAI) mechanisms, such as attention layers, SHAP, LIME, Grad-CAM, gradient-based models, or interpretable architectures.	Studies that used only classical machine learning without deep learning, deep learning models without explainability (black-box models), and studies where XAI was mentioned only as future work without actual development were excluded.
Comparison	Studies that compare explainable models with baseline or reference models—such as neural networks without XAI, Random Forest, XGBoost, SVM, rule-based methods, or traditional statistical approaches—using equivalent experimental conditions.	Research that evaluates only the proposed model without a baseline, or comparisons conducted using different datasets, different preprocessing methods, or non-reproducible metrics.
Results	Preference was given to studies that provided specific performance and	Qualitative studies without accuracy or speed metrics were excluded, as

	interpretability metrics—such as precision, recall, F1-score, ROC-AUC, PR-AUC, latency, throughput, accuracy, or stability—as well as those that included validation by users in the financial sector.	were those using indicators unsuitable for imbalanced data and those with severe performance degradation not justified by their methodology.
Context	The review prioritized studies on fraud detection systems that need to explain operational and regulatory decisions, and included approaches involving online detection, continuous monitoring, and auditing.	Academic studies without real-world validation were excluded, as were batch-processing approaches that ignore latency or fail to explain decisions to regulators.
General Criteria	Articles from databases such as Scopus, Web of Science, and ScienceDirect, preferably in English, published between 2021 and 2026, with full text available and aligned with the review's PICOC question.	We excluded theses, unreviewed technical reports, editorials, unverified documents, duplicates, articles without a DOI or full text, and publications outside the established time frame, language, or scope.

F. PRISMA Statement

PRISMA helped organize the review from the outset. Using these guidelines, we documented how articles were searched for, which ones were excluded, and which ones were included in the final analysis. It also allowed us to present the selection process in a more structured way, so that readers can understand the source of the included studies. According to Page et al.[24], the 2020 version of PRISMA updated the 2009 guidelines to incorporate technological and methodological advances in the search for and analysis of evidence, resulting in a more comprehensive and organized report. Its ability to improve the quality and credibility of publications has led many journals and scientific organizations to adopt it. [24]

According to this study, the PRISMA statement was essential for systematically organizing the process of selecting and analyzing research related to wearable sensors, the Internet of Things (IoT), and artificial intelligence used in mental health monitoring. This guideline was used to establish clear criteria during the selection, exclusion, and final review stages of the articles, ensuring the study's methodological consistency. According to Hutton et al. [25], PRISMA promotes the understanding and comparison of results by encouraging a clear presentation of the techniques used. Thus, it supports transparency, strengthens confidence in the results, and enables future research to replicate and expand upon the findings with greater reliability.

G. PRISMA Process

The PRISMA process was used to review this research. A total of 373 articles were identified: 51 from Scopus, 15 from Web of Science, and 287 from ScienceDirect. After removing duplicates and applying the inclusion and exclusion criteria, the remaining studies were evaluated by reviewing their titles, abstracts, and full texts (Fig. 1).

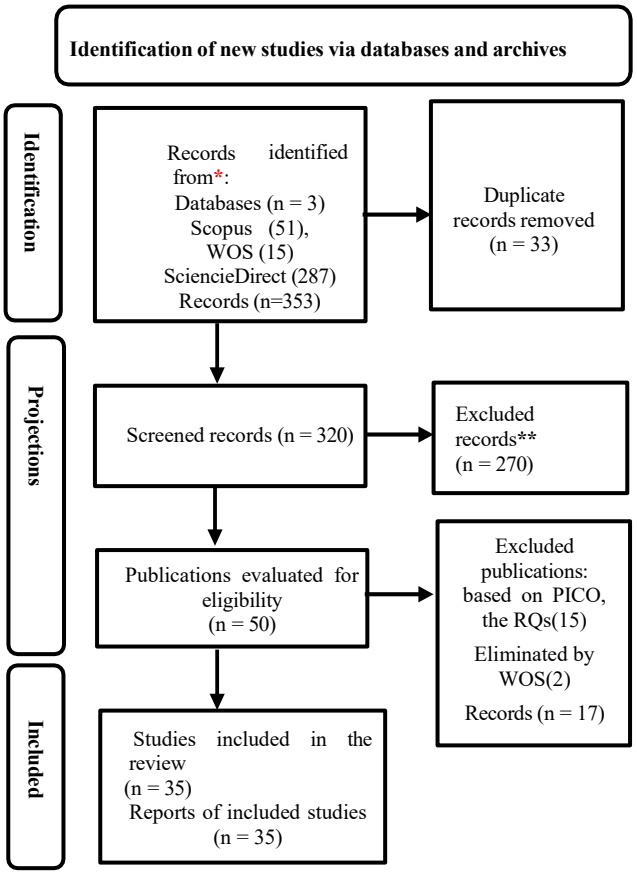

Fig. 1. PRISMA process diagram.

H. Assessment of Methodological Quality

To assess the methodological quality of the 35 studies included in this review, we followed the adapted guidelines of the Joanna Briggs Institute (JBI).[25] Seven criteria were considered: 1) adequate characterization of the dataset (source, size, imbalance, delayed feedback); 2) appropriateness of the data and preprocessing; 3) clear explanation of the algorithm's methodology and the XAI mechanism; 4) rigorous validation (time-series analysis, confidence intervals, statistical tests); 5) use of appropriate metrics for imbalanced data (F1, PR-AUC, latency); 6) explicit discussion of limitations; and 7) quantitative assessment of interpretability. Each of the defined criteria was evaluated on a binary scale—that is, using 0 and 1—which allowed the studies to be classified according to their quality.

Weighted synthesis: Findings from high-quality studies will be given greater weight in the conclusions, while those from moderate-quality studies will be used as a supplement.

I. Bibliometrix

Bibliometrix is an open-source R package, developed by Aria and Cuccurullo (2017), that enables comprehensive bibliometric analyses, including the import of data from databases such as Scopus and Web of Science, as well as the construction of co-citation, collaboration, and keyword co-occurrence networks [26].

One of its most highly valued features is Biblioshiny, its graphical interface based on the Shiny web application, which

allows researchers to use all of its functions without needing prior knowledge of R programming. This combination of analytical power, flexibility, and accessibility has made Bibliometrix one of the most comprehensive and popular tools for the quantitative analysis of scientific output.[27]

III. RESULTS

Following the PRISMA process, 33 articles remained for review. These articles presented different approaches to addressing fraud in digital payments. Several articles utilized machine learning and deep learning. Other studies tested graph networks or incorporated XAI techniques. The applications were varied, although most were related to credit cards, digital banking, blockchain, and money laundering.

The comparison was based on the type of fraud studied, the algorithms used, and the results reported in each article. We also examined how the studies handled the imbalance between normal and fraudulent transactions. In the studies that included explainability, we considered the use of tools such as SHAP and LIME.

The methodological assessment revealed differences among the articles. Of the 33 selected articles, 24 were considered high quality, 5 were of moderate quality, and 2 were of low quality. In the highest-rated studies, it was common to find real-world or publicly available data, comparisons between various models, and results expressed in terms of precision, recall, and F1-score.

When reviewing the limitations, we found that several studies still rely on synthetic data or tests conducted under controlled conditions. In other cases, the time it takes for the model to respond is not reported in sufficient detail. We also found proposals with good results but with little explanation as to why a transaction was considered suspicious.

A. Comparative Overview of Reviewed Studies

1) ML/DL Models and metrics: The results of the reviewed articles are shown in Table VI, which lists the reference, the types of financial fraud in digital payment systems, and the applied ML and DL algorithm models.

TABLE VI. FRAUD TYPES, ML/DL MODELS, AND METRICS

Reference	Types of Financial Fraud in Digital Payment Systems	ML and DL Models	Metrics
Ampumuza, D. et al.[28]	Mobile payment fraud, phishing, card fraud, cryptocurrency scams, identity theft, account takeover	Random Forest, XGBoost, Neural Networks, clustering (K-means), autoencoders, hybrid models (reglas + ML)	No reporta métricas cuantitativas (accuracy, F1, recall, AUC, FPR)
Vazallo-Bautista, J. et al.[29]	CNP, skimming, unauthorized digital payments, account takeover, fake accounts, money laundering using money mule accounts, card fraud (cloning and CNP), phishing, identity theft, suspicious transactions, fraudulent digital payments	Random Forest, XGBoost, Isolation Forest, Autoencoders, LSTM/GRU, CNN, GNN, LightGBM, CatBoost, Hoeffding Tree, Adaptive Random Forest, RNN, GRU, GAN, One-Class SVM, KNN, Logistic Regression, DT, AdaBoost, Stacking Ensemble, CNN-LSTM with Attention	Accuracy (94-99%), Precision (>95%), Recall (90-98%), F1-Score (0.90-0.999), AUC-ROC (>0.98), MCC, False Positive Rate (reducción >40%), Latency (<100 ms), throughput (tx/s)
Alatawi, M. N. et al.[30]	Credit card fraud (CNP, skimming, unauthorized digital payments, online fraud, IoT-based transactions)	Logistic Regression, Random Forest, Gradient Boosting Machine (GBM), Multilayer Perceptron (Neural Networks)	Accuracy (RF: 99.999%, GBM: 99.9865%, MLP: 99.876%, LR: 95.87%), Precision (RF: 1.0, GBM: 0.9995, MLP: 0.9970, LR: 0.8911), Recall (RF: 0.9999, GBM: 0.9990, MLP: 0.9888, LR: 0.6000), F1-Score (RF: 0.9999, GBM: 0.9992, MLP: 0.9929, LR: 0.7171)
Abd-Ellatif, L. et al.[31]	Credit card fraud, identity theft, phishing, unauthorized fund transfers	ATAD-Net (CNN + LSTM), CNN, RNN	Accuracy: ATAD-Net 98.65%, Precision: 97.12%, Recall: 96.74%, F1-Score: 96.93%, Average latency: 8.2ms por transacción, Throughput: reportado en Figura 8 (TPS), True Positives, False Positives, True Negatives, False Negatives (confusion matrix Figura 2)
Al-Mustaqbal University et al. [32]	Credit card fraud, unauthorized online transactions, electronic financial crimes	Decision Tree, Logistic Regression, Naive Bayes, Random Forest, ANN, SVM, KNN, CNN, LSTM, GAN, Ensemble methods (Bagging, Boosting)	Accuracy (SMOTE: 98.1%, undersampling: 94.9%, oversampling: 95.3%, GAN: 99.9%), Precision (SMOTE: 99.7%, undersampling: 98.8%, oversampling: 99.7%, GAN: 99.9%), Recall (SMOTE: 98.1%, undersampling: 94.9%, oversampling: 95.2%, GAN: 99.9%), F1-Score (SMOTE: 98.1%, undersampling: 94.7%, oversampling: 95.1%, GAN: 99.9%), ROC-AUC (SMOTE: 96%, undersampling: 95%, oversampling: 95.5%, GAN: 100%)
Leong, W. Y. et al.[33]	Identity theft, payment fraud, account takeover, credit card fraud, phishing	Logistic Regression, Decision Trees, Random Forest, Neural Networks, CNN, RNN, Isolation Forest, Autoencoders	Accuracy (LR: ~91%, RF: ~95%, SVM: ~90%, LSTM: ~97%, Autoencoder: ~82%), Precision, Recall, F1-Score,

Reference	Types of Financial Fraud in Digital Payment Systems	ML and DL Models	Metrics
			AUC (LSTM: 0.98, RF: 0.96), curvas precision-recall, matrices de confusión
El Youbi, R. et al.[34]	Electronic payment fraud, credit card fraud, unauthorized transactions, phishing	DNN, LSTM RNN, Logistic Regression, KNN, Random Forest, CNN, Deep Reinforcement Learning + ANN	Accuracy: 99.72%, AUC: 97.43%, Precision (fraud): 96.0%, Recall (fraud): 93.8%, F1-Score (fraud): 94.9%, Precision (no fraud): 99.8%, Recall (no fraud): 99.9%, F1 (no fraud): 99.8%, ROC-AUC: 0.999, PR-AUC: 0.913, Average Precision: 0.913, Confusion Matrix: TN=14,855, FP=17, FN=1, TP=127
Al Lawati, H. M. R. et al. [35]	Card fraud (skimming, CNP, counterfeit cards, loss/theft), payment fraud, phishing, collusion with merchants	CNN, ADASYN + Mutual Information + SelectKBest, EDDM, ADWIN, Random Forest, XGBoost, LightGBM, SVM, KNN, Decision Tree, J48, K-means, GRU	Accuracy (Credit Card: 100%, Real: 100%, Spam: 99.34%), Precision (Credit Card: 100%, Real: 100%, Spam: 100%), Recall (Credit Card: 100%, Real: 100%, Spam: 98.69%), F1-Score (Credit Card: 100%, Real: 100%, Spam: 99.34%), ROC-AUC (Credit Card: 100%, Real: 100%, Spam: 99.34%), Drift Detection Rate (Credit Card: 100%, Real: 100%, Spam: 99.34%)
Pavlova, O. et al.[36]	Money laundering, drop accounts, cryptocurrency fraud (Bitcoin)	GNN, GCN, DNN, Random Forest, Logistic Regression, MLP, CNN, KNN, LASSO, Gradient Boosting, Elastic Net	Accuracy: 93%, Recall: 88%, F1-Score: 90%, Precision-Recall AUC: valores altos según la curva (Figura 5), Confusion Matrix con TP, TN, FP, FN (Figura 4). La Precision-Recall curve muestra buen balance pero Precision más baja que Recall
Iqbal, S. et al.[37]	Credit card fraud, online transaction fraud	Random Forest, XGBoost, SHAP, LIME	RF: Accuracy 0.9996, Precision 0.8909, Recall 0.9423, F1 0.9159, ROC-AUC 0.9979, CV-F1 0.9998. XGB: Accuracy 0.9995, Precision 0.8776, Recall 0.9556, F1 0.9149, ROC-AUC 0.9997, CV-F1 0.9998
Renuga Devi, R. et al.[38]	Credit card fraud, real-time fraudulent transactions, clustered fraud patterns (coordinated attacks or organized fraud), detection of suspicious communities (cardholders, merchants, and compromised devices)	GNN (Graph Attention Networks), RL (Deep Q-Network), GAN, RNN (GRU, LSTM), SVM, Random Forest, XGBoost, Autoencoders, Restricted Boltzmann Machines, CART	AUROC 0.872, AP 0.683, Recall 0.85, Precision 0.83, F1 0.839, Balanced Accuracy 0.916, MCC 0.54, FPR 0.08, Latency 42ms/batch, Throughput 12,000 tx/s
Černevičienė, J. & Kabašinskas, A.[39]	General fraud detection (including credit card fraud, detection of suspicious transactions, electronic payment fraud, and P2P loan fraud)	ANN, XGBoost, Random Forest, SHAP, LIME, LightGBM, CNN, LSTM, Autoencoders, Gradient Boosting, Decision Trees, Logistic Regression, KNN, SVM, frameworks multi-enfoque	SLR cualitativa. 138 artículos, 397 autores, 80% publicados 2020-2022, China (33), Italia (17), Alemania (11), coautoría internacional 10%

IV. Research Questions (RQs) and Components

The following table summarizes the most relevant references from the 33 studies screened for each research question. Priority was given to articles that directly address each research question, to avoid an excessive number of references per row (Table VII).

TABLE VII. Research Questions, Titles, and References

Question Types	Question Title	References
RQ1	Machine learning algorithms used to detect financial fraud and anomalies in digital payment systems.	[29],[30], [35], [37], [41], [43], [14]
RQ2	Deep learning algorithms used to detect financial fraud and anomalies in digital payment systems.	[31], [34], [38], [40], [6],[53], [58]
RQ3	Comparison of machine learning and deep learning models with traditional rule-based or statistical methods.	[32], [17], [43], [16], [23],[14]
RQ4	Improvements in the interpretability of alerts while maintaining accuracy, recall, F1-score, and a low false positive rate.	[17], [37], [39],[41], [42], [44], [48]
RQ5	Evidence on real-time models with XAI to improve interpretability without compromising performance.	[29], [31], [35], [38], [41], [52], [57]

A. Bibliometric Research Figures

Bibliometric analysis complements the systematic review by providing a visual overview of the trends, relationships, and clusters present in the selected studies. In this case, the figures show how topics related to real-time anomaly detection, the use of machine learning and deep learning, explainable artificial intelligence, and the prevention of financial fraud in digital payment systems are organized. The interpretation is presented in a formal manner, while striving to maintain clear and natural wording so that it can be integrated directly into the final document.

B. Word Cloud

Fig. 2: In the word cloud, the most prominent terms are financial fraud, machine learning, deep learning, anomaly detection, and digital payments. This aligns with the selected articles, as the vast majority focus on how to identify suspicious transactions using machine learning models.

Fig. 2. Word cloud highlighting the dominant concepts in the field under study.

Concepts related to XAI, financial transactions, and interpretability also appear. Their presence indicates that several studies aim not only to improve detection but also to explain why a transaction was deemed risky. Thus, the figure highlights the most important themes of our review.

C. Scientific Collaboration Network

Fig. 3: The scientific collaboration network exhibits a structure composed of several small groups and a few more prominent collaboration hubs, indicating that scientific output on financial fraud detection using AI is distributed across relatively independent communities. This characteristic is understandable given that the topic encompasses diverse fields such as machine learning, deep learning, cybersecurity, fintech, blockchain, and digital payments. The groups with the highest density suggest the existence of teams engaged in ongoing collaboration and with more established lines of research.

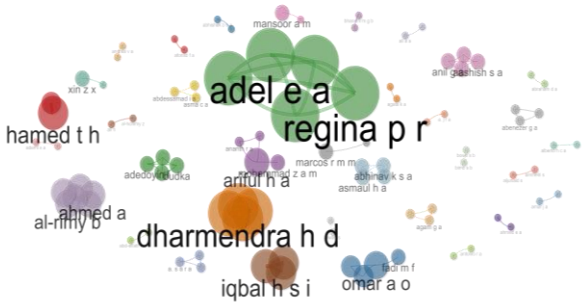

Fig. 3. Scientific collaboration network identified in the analyzed documents.

D. Conceptual Structure Map

Fig. 4: The map identifies three groups of topics. The green section includes support vector machines, SHAP, real-time fraud detection, and card transactions. In these studies, the focus is not only on detecting a suspicious transaction but also on understanding why the model flagged it and how long it takes to do so.

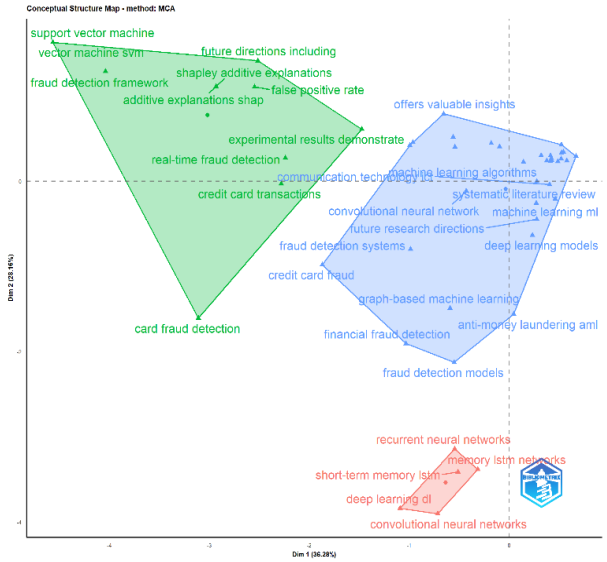

Fig. 4. Concept map generated using multiple correspondence analysis.

The blue area includes machine learning, convolutional networks, graph models, financial fraud, and money laundering. The articles in this group compare different ways of identifying transactions that could be fraudulent.

The red group includes deep learning, recurrent neural networks, LSTM, and CNN. These models are used when fraudulent behavior depends on multiple transactions or relationships that are not easily recognized. Looking at all three groups, the map reveals that the review is primarily divided among explainability, fraud detection, and deep models.

E. Thematic Map

Fig. 5: In the figure, machine learning, artificial intelligence, finance, blockchain, fintech, and fraud detection appear among the most prevalent topics. This is because they recur in several of the analyzed articles. Deep learning and federated learning appear in another section of the map. Meanwhile, document examination, digital twin, metaverse, privacy, and security compliance are less prevalent within the analyzed dataset. A similar pattern is observed for ensemble learning, class imbalance, generative AI, and large language models, which do not yet have the same prominence as the central topics. The position of each group reveals that some research areas already have more studies, while others still appear less frequently.

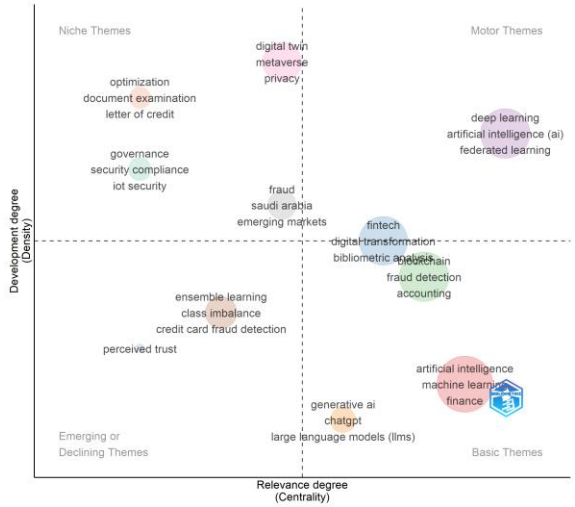

Fig. 5. Thematic map based on the centrality and density of the identified topics. (Source: Prepared by the author based on bibliometric analysis in Bibliometrix.)

V. DISCUSSION

The review shows that rule-based systems are still useful when fraud follows known patterns. The problem arises when those patterns change, or new forms of fraud emerge, because these systems are less adaptable. For this reason, the most recent studies increasingly rely on machine learning and deep learning models. Even so, the results do not allow us to identify a single model as the best in all cases.

For RQ1, Random Forest, XGBoost, Support Vector Machine, Logistic Regression, and Isolation Forest are among the most commonly used algorithms. In several studies, they achieve competitive results, although accuracy may not be very representative when fraudulent transactions are much less frequent than normal ones. In these situations, metrics such as recall, F1-score, ROC-AUC, and the false positive rate allow for a better evaluation of the model's performance.

In RQ2, architectures such as LSTM, CNN, GNN, GRU, and autoencoders were identified. These techniques can analyze more complex relationships and transaction sequences, but they also require more resources and tend to be more difficult to interpret. This can become a limitation when the model is used in a financial environment where an alert must be processed and understood quickly.

RQ3 revealed that traditional methods retain the advantage of being easy to interpret, although they are more difficult to adapt to changes in fraudulent behavior. Mill et al. point out that the increase in the volume of information and the emergence of new forms of fraud make it necessary to supplement these systems with machine learning techniques. However, a more complex model does not necessarily guarantee a better result.

In RQ4, SHAP and LIME make it possible to show which variables carried the most weight in an alert. However, this does not mean that the explanation is necessarily useful to the analyst. Diaz et al. indicate that there is still little empirical evidence on how AML specialists use these explanations in real-world settings[59]. Hosawi and Stone also caution that an unclear explanation can increase cognitive load or lead to overconfidence in the system[60].

Finally, RQ5 shows that there are still limitations to evaluating XAI in real-time fraud detection scenarios. Mill et al. indicate that factors such as false positives, class imbalance, concept drift, and real-time analysis should be considered together [61]. It is not enough to measure the algorithm's speed; it is also necessary to consider how much time the analyst needs to understand the alert and make a decision.

VI. CONCLUSION

Based on the reviewed studies, it was found that machine learning and deep learning can help detect fraud that rule-based systems alone do not always recognize. Machine learning models are generally easier to implement and explain, while deep learning models can identify more complex relationships among transactions.

It also became clear that high accuracy alone does not guarantee a good outcome. In this type of problem, it is important to know how many instances of fraud the model detects, how many false positives it generates, and whether it can respond quickly.

XAI techniques can help explain why a transaction was flagged as suspicious. However, several studies have not demonstrated whether these explanations actually assist the analyst in making a decision. Another limitation is that many studies use public or synthetic data, so it cannot be guaranteed that the same performance will be achieved in a real bank or payment platform.

Based on the review, the combination of machine learning, deep learning, and XAI can be useful for improving fraud detection. However, further testing with real data, larger transaction volumes, and the involvement of financial specialists

is still needed. This would make it possible to verify whether the models perform well outside of laboratory tests and whether their results can be put to practical use.

Fusion of Large Language Model and Knowledge Graph for Intelligent Power-System Q&A

Zijie Meng, Xinlei Cai*, Lizhou Jiang, Kai Dong, Bingzhao Zhu, Junhong Guo
Power Dispatching and Controlling Center of Guangdong Power Grid Company Limited,
Guangzhou, Guangdong 510000, China

***Abstract*—Intelligent question-answering (Q&A) models are needed for modern power systems that can provide accurate, reliable, and explainable answers to engineers and operators. Conventional Q&A systems cannot always understand the question semantically or combine domain knowledge, and stand-alone Large Language Models (LLMs) can generate hallucinated or non-grounded answers. To tackle these challenges, this research introduces a fusion model that combines the power of LLMs with a Power Knowledge Graph (PKG) for intelligent power-system question answering. The proposed approach integrates LLMs' ability to understand language with that of structured knowledge representation by PKGs. First, z-score normalization is used to normalize the operational parameters, such as voltage, current, temperature, and load. After that, Bidirectional Encoder Representations from Transformers (BERT) is used to obtain semantic relations and domain-specific elements from textual data related to the power system. The PKG stores fault, operational, and maintenance knowledge, and a knowledge-enhanced retrieval mechanism extracts relevant information and adds it to the LLM prompt to boost the accuracy of reasoning and diminish hallucination. The model is assessed with the following tasks: Fault Type Identification, Environmental and Operational Causation, and Maintenance and Recovery Decision. The proposed Python-based implementation achieves BERT Score F1 values of 71.5%, 69.2%, and 67.8%, Faithfulness Scores of 64.8%, 61.5%, and 59.7%, and Hallucination Rates of 18.6%, 21.4%, and 24.1%, respectively. The results validate the proposed model's efficiency in intelligent power-system decision support through semantic consistency, factual accuracy, and context relevance.**

Keywords*—*Large language model; intelligent question answering; knowledge graph reasoning; smart grid, power systems; knowledge management

I. INTRODUCTION

Power systems are now highly interconnected and intelligent infrastructures enabling large-scale electricity generation, transmission, distribution, and consumption [1]. The complexity of power systems operations has risen dramatically due to the addition of renewable energy resources, distributed generation, smart meters, and automated control technologies [2]. Therefore, it is essential for power engineers and system operators to have efficient knowledge services that can deliver accurate information to ensure system operation, equipment maintenance, and fault diagnosis [3]. Intelligent question-answering (Q&A) systems have been identified as a key tool for enhancing knowledge accessibility and aiding in decision-making in power systems [4].

*Corresponding author.

Smart grids are being scaled up, and a wide variety of power equipment (generators, transformers, substations, transmission lines, and protection devices) is recording large amounts of operational and maintenance data [5]. The efficient use of this knowledge is critical for ensuring system reliability, maintaining continuous operation, and streamlining the process of fault recovery [6]. Traditional power-system Q&A approaches are mostly based on rules for retrieval and/or keyword-matching, but these have a known lack of semantic understanding, poor contextual reasoning, and limited adaptability to complex technical questions [7]. The constraints limit their ability to provide clear and understandable answers in dynamic operational contexts.

With recent advancements in LLMs, performance on natural language understanding and reasoning in context has proven promising for intelligent question-answering applications [8]. However, conventional LLMs may generate hallucinated responses, lack specific domain knowledge, have poor explainability, and are thus unsuitable for critical applications in power systems. Fortunately, a PKG can effectively represent the knowledge associated with power systems, which includes information on equipment, operating procedures, maintenance history, and fault occurrence [9]. Power System Faults Dataset. The proposed methodology enhances answer correctness, consistency, and explainability of the Q&A system by combining PKG with LLMs.

With the development of intelligent power system fault diagnosis and Q&A, knowledge graph-based models have been increasingly applied to improve structured knowledge retrieval and reasoning. An intelligent model for fault retrieval based on knowledge graphs was proposed by [10] for power communication equipment, with F1-scores of 81.7% and 87%, respectively, with multi-layer encoding and graph convolution. It demonstrated that it could effectively represent the semantics of a graph, but it had a heavy reliance on fault-specific data quality requirements. Table I presents a comparison of existing power-system fault analysis and decision-support methods.

Based on this motivation, this research suggests that LLM-PKG can be fused to realize intelligent power-system Question and Answer (Q&A). The model utilizes Knowledge-Enhanced Retrieval techniques to retrieve relevant entities, relationships, and operational records from the PKG and to incorporate them into the reasoning process of the LLM. Experimental assessment shows increased accuracy of answers, relevance to context, explanation, and answer consistency, and reduction of hallucination.

TABLE I. COMPARISON OF EXISTING METHODS FOR POWER-SYSTEM FAULT ANALYSIS AND KNOWLEDGE-BASED DECISION SUPPORT

Ref	Main Objective	Method	Results	Limitation
[11]	Fault analysis in Industrial IoT	Multi-Entity Knowledge Joint Extraction (MEKJE) with jointly trained models	F1-score: 78.6%	Limited generalization
[12]	Knowledge utilization for recommendation systems	Cross-domain knowledge graph embedding	Improved prediction accuracy	Scalability and computational complexity
[13]	Automatic electric-power fault knowledge extraction and Q&A	BERT–BiLSTM–CRF + electric power fault knowledge graph	Improved Chinese entity extraction and Q&A	Limited multilingual adaptability
[14]	Equipment fault-diagnosis named entity recognition	RoBERTa–BiLSTM–CRF (RBC)	F1-score: 94.98%	Limited dataset
[15]	Power-system fault detection and reasoning	Random Forest + knowledge reasoning	Accuracy: 90%	Small-scale IEEE 14-bus simulation limits real-world applicability
[16]	Power knowledge retrieval and inference	RPKR-GNN with GNN, user-intent fusion, and knowledge inference	Improved power-knowledge retrieval and reasoning	Limited explainability and scalability
[17]	Reliable LLM-based decision support for smart-grid operations	Locally hosted LLMs	Local LLMs outperformed standard LLMs in identifying unauthorized operations.	LLM hallucination and insufficient domain-specific knowledge grounding
[18]	Improve retrieval-augmented generation (RAG) accuracy and retrieval efficiency for complex queries.	Query complexity classification, keyword retrieval, semantic rules, and natural language inference (NLI)-based relevance checking.	On HotpotQA, accuracy improved by 9.4% and F1 by 16.14% over Adaptive-RAG.	Depends on keyword rules, custom training data, and NLI quality.
[19]	Improve retrieval and generation for complex multi-hop queries.	Domain-specific Knowledge Graph (KG) + Large Language Model (LLM) using entity extraction, path finding, query decomposition, semantic path ranking, and context aggregation.	Outperformed RAG and GraphRAG, especially for 5–6-hop queries, with strong directness.	Limited generalizability across domains.
[20]	Improve multi-hop reasoning over knowledge graphs.	Question-Directed Reasoning with Relation-Aware Graph Attention Network (QRGAT) using relation-aware GAT and reasoning graphs.	Improved Hits@1 by 2.3% on WebQuestionsSP and 3.6% on ComplexWebQuestions over NSM+h.	Computationally complex for multi-layer graph reasoning.
[21]	Improve online power-grid fault diagnosis and decision support.	Time-series density maps + Residual Network (ResNet) for equipment and fault classification.	Accurately identifies faulty equipment and fault type for online diagnosis.	Mainly designed for power-grid fault data; generalization may be limited.

Based on these investigations, this research observes that knowledge graphs provide structured knowledge representation and reasoning, whereas LLMs provide strong semantic understanding and natural-language generation. However, without combination, the reliable, interpretable, and consistent knowledge base still fails. The knowledge extraction approach in examination [16] uses the powerful ability of Graph neural networks to retrieve the most related facts from large corpora, the knowledge retrieval method also fails due to problems with explanation and scalability. Investigation [17] presents an LLM-based system, the smart grid knowledge management approach, but because LLMs can hallucinate, which brings down trust and reliability, and no domain knowledge is grounded in the models. Therefore, combining LLM and PKG is a potential solution for creating accurate, explainable, and intelligent power system Q&A systems. From an electrical engineering point of view, the proposed framework should support structured power-system knowledge and provide intelligent decision support. In contrast to existing question-answering systems based on languages, the proposed approach captures information about electrical operating conditions, equipment state, fault events, environmental conditions, and maintenance actions in the form of a structured PKG. These electrical relationships are then applied as proof in the framework for fault interpretation and the generation of maintenance-related responses. Thus, the contribution can be seen not only as LLM-based Q&A but as an intelligent information and decision-support model for power system fault analysis.

The proposed LLM–PKG combines structured power knowledge from the domain, while avoiding reliance on text retrieval or graph querying. Conventional RAG only retrieves the most relevant textual passages, while the proposed scheme retrieves structured triples representing equipment, operating variables, environmental conditions, faults, equipment states, and maintenance actions in the power system. Retrieval is based on BERT for power-domain entity identification and a one-hop neighborhood expansion performed in the power domain, followed by ranking candidates based on semantic similarity and graph-based electrical relationship preservation. The retrieval process differs from general GraphRAG methods by first using BERT to identify entities in the power domain, then applying the one-hop neighborhood expansion in the power domain, and subsequently ranking the candidate triples by semantic similarity while also retaining the graph-based electrical relationship information. The PKG is not meant to be the only system supporting a Q&A component of a knowledge graph; it is meant to be used as a fact-based system to provide evidence for an LLM that provides a natural language response in context. To this end, the contribution involved a task-specific combination of power-domain entity/relation extraction, structured retrieval of PKGs, relevance training of the search results provided to the LLM, and knowledge-guided LLM language generation of fault and cause analysis, as well as of maintenance/recovery options.

II. Power-System Problem Formulation

A. Electrical Operating Variables

Electrical, environmental, and equipment-condition variables such as voltage, current, power load, temperature, wind speed, fault duration, downtime, component health, and maintenance status determine the power-system operating state. Voltage and current define an electrical operating condition, and power load defines the level of loading of the power equipment or network. The temperature indicates thermal stress and overheating situations, while wind speed and weather conditions indicate environmental disturbance which may lead to equipment problems. Equipment condition and recovery information include component health, fault duration, downtime, and maintenance status. The proposed PKG and knowledge-grounded LLM for fault diagnosis and decision support rely on these variables as the electrical evidence.

B. Electrical Fault-Causality Representation

Faults in power systems are expressed in terms of causality relationships between electrical operating conditions, environmental conditions, equipment situations, events resulting in a potential fault, and maintenance needs. For instance, if the power load is increased, this can lead to higher current and thermal stresses; this might increase the temperature and reduce the material performance. Adverse weather, like windstorms or thunderstorms, can also add to electrical equipment and so increase the chances of fault occurrence. These dependencies are represented as triples of entity–relation–entity in the proposed PKG, which enables the LLM to rely on electrical evidence to deduce the relation, in addition to language-based evidence.

C. Electrical Fault-State Representation

The operating condition of the power system, along with the relevant electrical, environmental, and component-health parameters, is mapped in a fault-state vector to characterize the condition systematically and reliably for fault identification, as presented in Eq. (1):

$$X = [V,\ I, P, T, W, H, D_f,\ D_o] \quad (1)$$

where, V denotes the voltage, I is the current, P is the power load, T is the temperature, W is the wind speed/weather condition, H is the component health, D_f is the fault duration, and D_o is the downtime.

The electrical fault state is represented in Eq. (2) as a function of the observed operating state and structured power-system knowledge:

$$F = f(X, G) \quad (2)$$

where, F denotes the identified fault state, and G represents the PKG. For operator decision support, the generated response is formulated by Eq. (3):

$$Y = g(Q, X, G) \quad (3)$$

where, Q is the user query, and Y is the knowledge-grounded engineering response.

III. Methodology

The proposed methodology consists of sequential phases for developing an intelligent power-system Q&A model by integrating an LLM with a PKG. The model utilizes the Power System Faults Dataset as the foundational knowledge source and extends it through structured knowledge representation and retrieval-enhanced reasoning. As illustrated in Fig. 1, the Overall Architecture of the proposed LLM–PKG model for Intelligent Power-System Q&A.

A. Data Collection

The proposed model is based on the Power System Faults Dataset (https://www.kaggle.com/datasets/ziya07/power-system-faults-dataset) that is obtained from Kaggle, which is used as a main knowledge source for intelligent power-system Q&A. There are 506 fault records, including operational, environmental, maintenance, and recovery data, such as voltage, current, power load, temperature, wind speed, weather conditions, component health, fault duration, and downtime. 80% of the records are used for training and 20% for testing. To ensure that the data partition is reproducible, the value 42, which is the same for all runs, is used as a fixed random seed. The evaluation looks at three Q&A tasks: Fault Type Identification, Environmental and Operational Causation, and Maintenance and Recovery Decision. Table II presents the categories of the dataset for structured fault reasoning: Fault Type Identification, Environmental and Operational Causation, and Maintenance and Recovery Decision. Sample Q&A pairs are presented in Table III for the purpose of replicably providing a benchmark of performance for the provided fault detection and decision support to be further compared and studied.

TABLE II. Power System Fault Dataset Category Overview

Category	Key Features Used	Fault Focus
Fault Type Identification	Voltage, Current, Power Load, Component Health	Line Breakage, Transformer Failure, Overheating
Environmental & Operational Causation	Temperature, Wind Speed, Weather Condition, Fault Duration	Weather-induced faults and operational triggers
Maintenance & Recovery Decision	Maintenance Status, Component Health, Downtime, Duration	Recovery urgency and maintenance prioritization

TABLE III. Representative Q&A Pairs from the Power Fault Dataset

Category	Question	Answer
Fault Diagnosis	What fault occurred in record F002?	The recorded fault was Transformer Failure, with faulty component health and 5 hours of downtime.
Environmental and Operational Analysis	What factors contributed to the overheating fault in F003?	The fault was associated with high temperature (35°C) and windstorm conditions, leading to component overheating.
Maintenance and Recovery Decision	What maintenance action is required for a transformer failure under faulty health status?	Immediate inspection and corrective maintenance are required to restore system stability and reduce downtime.

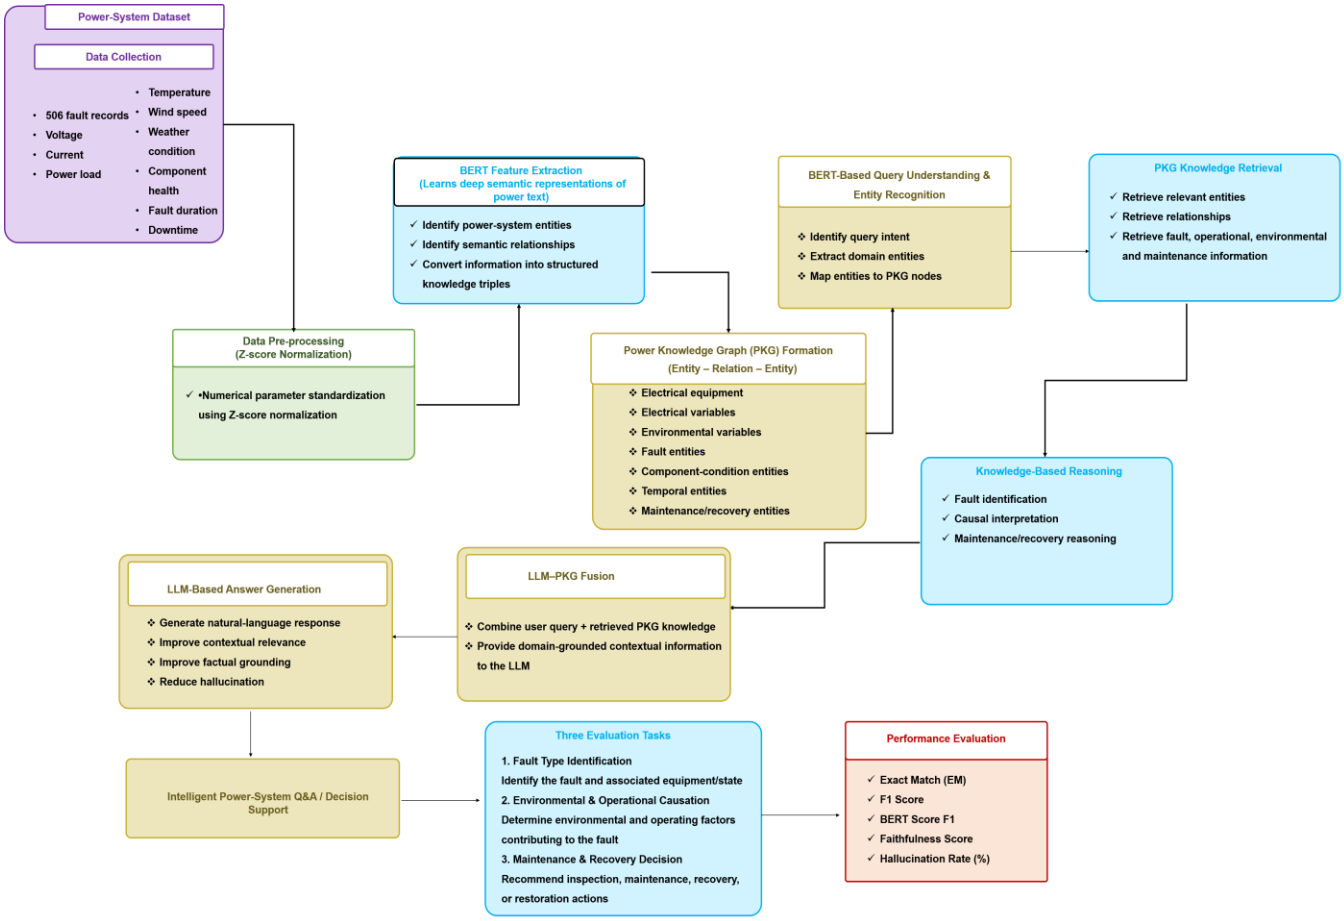

Fig. 1. Overall architecture of the proposed LLM–PKG fusion model for intelligent power-system Q&A.

The question–answer dataset is created from structured information in the 506 power-system fault records. For each of the following categories of semantic reasoning, questions were designed: fault diagnosis, electrical-state analysis, environmental and operational causation, maintenance and recovery, fault-duration and operational assessment, and LLM-based decision support. Each cluster of reasoning has the appropriate number of pairs of questions: 87, 85, 84, 83, 83, and 84 pairs of questions for the six thinking clusters. Each question has a fault record and structured PKG evidence associated. Answers to the ground truth questions are produced directly from the factual data attributes and relationships from the source records, such as downtime, maintenance status, fault type, equipment/component condition, electrical variables, environmental variables, fault duration, answers from the recovery requirements, and answers from the source records. The questions created are evaluated against the source record to make sure there is enough supporting information for each question to derive a deterministic source answer. Before assessing the question, the question is excluded from the examination if it has been duplicated or is unclear or not presented with the source record. The final reference answers are thus based on the original power-system records and associated PKG facts. These questions are coupled together in a question-answer set, which is subsequently applied in evaluating the accuracy of lexical matching, semantic similarity, factual grounding, and hallucination.

B. Data Pre-processing

This technique comes in handy for preprocessing and making heterogeneous numerical representations uniform before entity and relation extraction. Operating variables like voltage, current, power load, temperature, wind velocity, fault length, and time outage could range and have significantly varying numerical scales between different types of sensors. While these parameters can be utilized in the subsequent knowledge extraction process, their local scales can be different, so to scale down influence differences, they should be normalized using z-scores to convert them to a common scale, which allows for comparison of the same systems and easier representation of entities and relations in the power system. The transformation is defined in Eq. (4), where a normalized fault parameter is calculated based on its original value, the mean, and the standard deviation of the fault records. This normalization process helps maintain consistency among data and offers a stable numeric foundation for building the proposed PKG:

$$X = \frac{Z-\mu}{\sigma} \tag{4}$$

where, X is the normalized fault parameter value, and Z is the original operational parameter value, μ is the mean value of the same fault parameter, and σ is the standard deviation of the same fault parameter for all fault records. This normalization helps to maintain data consistency and to analyze and extract

knowledge from the faults that may occur within the proposed LLM-PKG system.

C. Power Knowledge Graph Construction

The PKG contains different interacting elements and relationships among the elements of electrical equipment, operating conditions, environment, fault events, and maintenance actions. The main entities are electrical equipment, fault types, electrical parameters, environmental conditions, component health types, maintenance types, and recovery conditions as shown in Table IV. These entities have causal, operational, spatial, temporal, and maintenance dependencies, known as relations. Power-System LLM–PKG Data Fusion Architecture integrating multi-modal operational data, Knowledge Graphs, and LLM-based reasoning is depicted in Fig. 2.

TABLE IV. ENTITY CATEGORIES AND REPRESENTATIVE ENTITIES IN THE POWER KNOWLEDGE GRAPH

Entity category	Representative entities
Electrical equipment	Transformer, transmission line, substation, relay, generator
Electrical variables	Voltage, current, power load
Environmental variables	Temperature, wind speed, weather
Fault entities	Line breakage, transformer failure, overheating
Condition entities	Component health, maintenance status
Temporal entities	Fault duration, downtime
Decision entities	Inspection, corrective maintenance, recovery

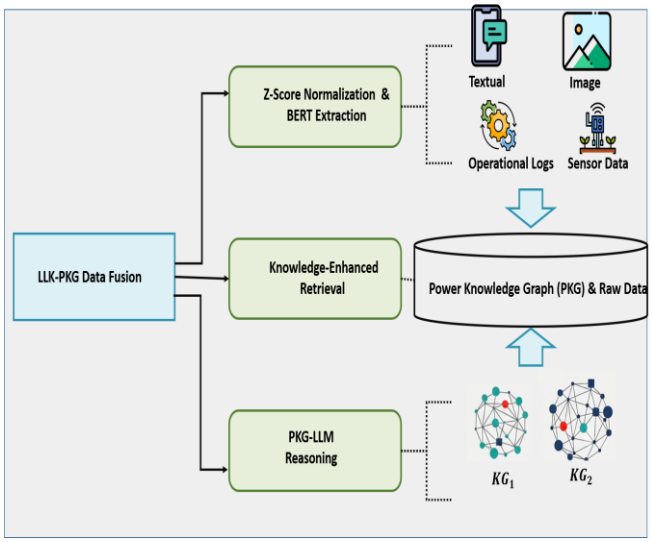

Fig. 2. Power-system LLM–PKG data fusion architecture.

The PKG is built based on the power-system fault records that have been normalized and deduplicated. The 506 normalized and deduplicated power-system fault records are used to build the PKG. It produces 1,248 distinct nodes, 1,836 entity-relationship-entity triples, 1,836 specific entity relationships, and 24 specific relation types. The types of nodes are electrical equipment, electrical variable, environmental, fault type, component, temporal, or maintenance or recovery decision. Relations express causal, operational, spatial, temporal, and maintenance dependencies. BERT will encode user query as a list of domain entities relevant to that query, mapping domain entities to the corresponding PKG nodes. The neighborhood system is then executed in a one-hop fashion to create potential candidate triples that are related to the extracted nodes. To rank candidate triples, the query representation is compared with representations of the triples, based on cosine similarity; thereafter, any duplicate triples are filtered out, and the top 5 triples are provided to the LLM as instructive and factual context. The process is dynamically linked to the query understanding process, the graph retrieval process, and the process of generating answers from the knowledge base.

The extracted entities are sorted based on their functional roles in the domain of power systems. Electrical equipment entities are physical objects like transformers, lines, substations, relays, and generators, while electrical and environmental variables are measurable operating conditions. Fault, condition, temporal, or decision entities offer more information on abnormal equipment health, fault duration, downtime, inspections, maintenance, and recovery. Finally, those entity pairs are translated into subject–relation–object triples and added to the PKG. This structured representation allows for enabling the connection of semantically relevant but different textual information by providing explicit semantic relations instead of handling only textual language. The resulting PKG can then be used as a knowledge layer when mapping queries to the graph and for evidence retrieval in the following step.

D. BERT-Based Power Entity and Relation Extraction

BERT is employed for extracting power-system entities and their semantic relationships from textual power-domain datasets. BERT is selected due to its bidirectional contextual learning capability, which enables effective understanding of technical terminology, operational dependencies, and fault-related semantics in power-system documents. The BERT input representation is composed of three embedding layers:

1) Token embedding: It transforms power-system textual tokens into dense vector representations. These embeddings capture domain-specific terms such as transformers, relays, substations, and fault types.

2) Input: The input to the BERT model consists of a linear sequence of tokens derived from the pre-processed power-system corpus. Special tokens [CLS] and [SEP] are added to mark the beginning and separation of input sequences.

3) Segment embedding: It distinguishes multiple sentence segments, which is useful for identifying inter-sentence relationships in fault reports and maintenance logs.

4) Position embedding: It preserves the sequential order of words in power-system text, enabling the model to understand the structural dependencies among entities and actions.

Using contextual embeddings, BERT extracts power-system entities and relations, converting fault, location, operational, environmental, maintenance, and temporal information into structured knowledge triples for PKG.

The semantic extraction module extracts power-system entities and relations from textual descriptions of the power system and user queries using BERT-base-uncased. The contextual BERT representation is then input to a token-classification output layer to perform entity classification. After the identification of entities, entity pairs are candidates in the considered textual context and then categorized based on the power-system relation inventory defined. The extracted entity–relational information is coded as structured triples (head entity, relation, tail entity) and added to the PKG. The same BERT representation process is used during the query processing stage for domain entity identification and to aid in their mapping to the respective nodes in the PKG. The final answer generation is then left to BERT. It is designed to deliver meaning to natural-language queries and to link them to the structured knowledge of the power system. The LLM then gets the evidence retrieved by the PKG and produces the completed natural-language result.

E. User Query Processing and Entity Recognition

In this phase, the proposed model receives natural language queries related to power-system faults, operational conditions, and maintenance decisions. The query is processed using BERT-based semantic analysis to understand user intent, capture contextual information, and identify domain-specific entities and relationships. The extracted entities are then aligned with the corresponding nodes in the PKG, enabling accurate knowledge retrieval and supporting subsequent reasoning and response generation.

F. Contextual Query Models

To illustrate the query understanding process, representative contextual Q&A examples derived from the power fault dataset are presented in Fig. 3 and Fig. 4. These examples demonstrate how fault records are transformed into structured contextual inputs for semantic interpretation. The contextual representation enables BERT to capture fault-specific dependencies, operational conditions, environmental influences, and maintenance-related information from user queries. This process supports effective entity recognition and improves the alignment between user queries and Power Knowledge Graph entities for accurate knowledge retrieval and reasoning.

Context 1: Fault record F002 reports a Transformer Failure at coordinates *(34.056, -118.245)* under rainy weather conditions. The transformer operated at 1800 V, 180 A, and 45 MW load with a recorded temperature of 28°C. The component health status was marked as Faulty, with a fault duration of 3 hours and a total downtime of 5 hours. Maintenance history indicates the component was previously serviced.
Question: Which operational parameter indicates that the transformer failure was likely associated with equipment degradation rather than thermal overload?
Answer: The moderate operating temperature (28°C) combined with the Faulty health status suggests the failure was caused by internal equipment degradation rather than excessive thermal stress.
Question: Why does the downtime exceed the fault duration in F002?
Answer: The longer downtime (5 hrs) compared to the fault duration (3 hrs) indicates additional time was required for fault isolation, transformer inspection, and restoration of grid connectivity.

Fig. 3. Contextual query examples for power fault analysis for fault diagnosis and operational analysis.

Context 2: Fault F003 records an Overheating event at (34.0525, -118.244) during windstorm conditions. The system operated at 2100 V, 230 A, and 55 MW load. The temperature reached 35°C, and the component health was classified as Overheated. The fault persisted for 4 hours, resulting in 6 hours of downtime.
Question: Which combination of parameters most strongly indicates thermal stress as the primary cause of failure?
Answer: The elevated temperature (35°C), high power load (55 MW), and Overheated component condition collectively indicate thermal stress as the dominant fault-driving factor.
Question: How could windstorm conditions contribute to overheating despite not being a direct thermal source?
Answer: Windstorm conditions can introduce mechanical stress and cooling instability, reducing heat dissipation efficiency and increasing the probability of sustained thermal accumulation in the component.

Fig. 4. Contextual query examples for power fault analysis for environmental and thermal fault reasoning.

G. LLM-PKG for Intelligent Power-System Question Answering

The proposed LLM-PKG model integrates structured knowledge retrieval with language generation for intelligent power-system question answering. After query entity recognition, relevant knowledge triples are retrieved from the PKG and combined with the user query as contextual input to the LLM. This hybrid retrieval-reasoning mechanism improves answer accuracy, contextual relevance, and explainability, and reduces hallucinations through domain-grounded response generation. The proposed model employs Llama-3.1-8B-Instruct (8 billion parameters), a decoder-only Transformer LLM, for knowledge-grounded answer generation, while BERT-base-uncased is used for entity and relation extraction and query understanding. The LLM is used in pretrained form without additional domain-specific pretraining. For each query, BERT identifies relevant entities, which are mapped to PKG nodes. A two-stage graph-neighborhood and semantic retrieval method is then applied, using cosine similarity between query and triple embeddings. The top 5 relevant triples (K=5) are retrieved and inserted into a structured prompt containing the task instruction, user query, and retrieved PKG evidence. The PKG constructed from the 506 fault records contains 1,248 nodes, 1,836 edges, 24 relation types, and 1,836 unique triples. Since the LLM is used without fine-tuning, training epochs and learning rate are not applicable to the LLM. During inference, the temperature is set to 0.2, with a maximum generation length of 256 tokens. The implementation uses Python 3.11, PyTorch 2.3.1, and Transformers 4.44.2, and experiments are performed on an NVIDIA RTX 4090 (24 GB), Intel Core i9-13900K CPU, and 64 GB RAM. A fixed random seed of 42 is used to ensure reproducibility.

The fusion process includes four consecutive steps: Query interpretation, evidence retrieval in the graph database, contextual fusion, and response generation. The first is the BERT query processor, which detects user intents, entities, and relationships. Second, the identified entities are mapped onto corresponding nodes in PKG, and their graph neighborhoods are searched to get related knowledge triples. Third, recovered triples are reduced and structured into contextual evidence with the original query. Lastly, the query-evidence context is given to the LLM for answer generation, where the instruction is tiled.

Finally, the query-evidence context is presented to the LLM for answer generation, with an instruction tiled around it. This design decouples the structured knowledge retrieval from the natural-language generation and enables the LLM to rely on explicitly available evidence from the power system for response generation. Language understanding and generation in LLMs should therefore remain unchanged, with the aim of enhancing the factual grounding via the fusion mechanism.

1) Power Knowledge Graph (PKG) retrieval and reasoning: After query entity recognition, the extracted entities are mapped to their corresponding nodes in the PKG to retrieve relevant structured knowledge. The retrieval process explores entity–relation connections associated with fault events, operational parameters, environmental conditions, and maintenance records. This is followed by semantic reasoning on extracted knowledge triples to infer fault causes, operating dependencies, and maintenance needs. This process enhances context understanding, ensuring the generated response is based on knowledge in power systems. The constructed PKG contains 1,248 unique entities (nodes), 24 relation types, and 1,836 unique entity–relation–entity triples represented by 1,836 directed edges. The graph was constructed from the 506 power-system fault records after entity normalization and duplicate removal. The entities include electrical equipment, electrical variables, environmental conditions, fault types, component conditions, temporal information, and maintenance/recovery decisions. For each query, the identified entities are mapped to corresponding PKG nodes, and their connected relations and triples are retrieved to provide domain-specific evidence for LLM-based reasoning.

To ensure a repeatable knowledge-retrieval approach, the suggested LLM–PKG strategy involves the semantic retrieval phase based on a query, the neighborhood expansion in the retrieved graph, and the relevance-based triple selection. The recognized entities and the representation of the query are fed into the retrieval system after the query is processed using BERT. Both the textual description and the semantic embedding of each PKG entity and each PKG relation are used. Both the query embedding and the embeddings for candidate entity–relation–entity triples are compared with cosine similarity in Eq. (5):

$$S(q, t_i) = \frac{\mathbf{q} \cdot \mathbf{t}_i}{\|\mathbf{q}\| \|\mathbf{t}_i\|} \quad (5)$$

where, (q) denotes the user-query representation and $\mathbf{t}_i$ denotes the semantic representation of the $i - th$ knowledge triple. A higher cosine-similarity value indicates greater semantic relevance between the query and the corresponding PKG triple. There are two steps in the retrieval process. The entities in the query are first matched to the review nodes corresponding to the entities in PKG, and candidate triples are extracted that have a connection with these nodes by a 1-hop graph traversal. Second, the candidate triples are ordered by the cosine-similarity score. Only the top-K (K is set by the user) highest-ranked triples are stored in order to avoid irrelevant information being passed to the LLM. The proposed implementation assumes that K=5; that is, it supplies at most five knowledge triples to the LLM that are relevant to the same query. All triples are left in if fewer than 5 satisfy the relevance criterion. Semantic similarity is the main criterion for determining the final selection score, leaving the graph relationship criterion for power-system reasoning unchanged. So, the triple is chosen if it meets both conditions: 1) it is connected with at least one query-relevant entity or its graph neighborhood and 2) it meets a high enough similarity score compared to other candidate triples. Triples are deleted unless they represent duplicates, and semantically redundant triples are removed prior to the final top-(K) selection. This approach involves minimizing the contextual data provided to the LLM while keeping the electrical, environmental, fault, and maintenance connections pertinent to the query.

The retrieval process can be summarized as follows: 1) receive the natural-language query; 2) recognize domain entities and query intent with BERT; 3) match the recognized entities to the PKG nodes; 4) conduct a one-hop neighborhood expansion to get candidate triples; 5) produce semantic representations for the query and candidate triples; 6) calculate the similarity of the query with candidate triples based on cosine similarity; 7) rank the candidate triples by the cosine similarity score in descending order; 8) filter duplicate or redundant triples; 9) use the top five triples as the knowledge context input to the LLM to generate the answer. The retrieved triples are then appended to the original query to follow a prompt template as outlined in 3.7.2. This retrieval mechanism acts as a direct link between understanding the query, the graph-based retrieval of evidence, and reasoning with the LLM. For instance, if a query about transformer overheating is issued, the overload retrieval will return triples related to the transformer equipment along with temperature, overheating, component health, weather, and maintenance actions, but not unrelated power-system entities such as circuit breakers or an index. This results in the LLM only being given a subset of the evidence relevant to each particular query, thereby increasing the relevance of the material and minimizing the likelihood of unsupported generation.

Only the graph evidence most closely related to the semantic content of the query should be retained during the retrieval stage. Once entity recognition is complete, the retrieved anchors are nodes of the corresponding PKG. Their neighbouring triples give the evidence for the candidates in the form of descriptions of equipment states, fault conditions, environmental influences, temporal characteristics, and maintenance actions. Finally, the retrieved evidence is ranked by semantic similarity between the query representation and candidate triples. Top-ranked triples are kept as knowledge in context, because redundant triples are meant to be stripped away to reduce repetition of context and unnecessary details. This retrieval approach minimizes the information that the LLM receives in the graph and focuses the response on the most relevant facts within the world of the power system.

2) Large Language Model (LLM)-based answer generation: The retrieved knowledge triples after retrieval and inference are supplemented with the user query as input for generating answers by the LLM. The LLM is able to produce accurate, context-aware, and explainable responses based on the natural language query combined with the structured PKG

context. This knowledge-guided generation enhances semantic understanding and mitigates hallucination by embedding domain-specific evidence. The proposed model uses Llama-3.1-8B-Instruct, with 8 billion parameters, as the LLM for knowledge-grounded answer generation. The model follows a decoder-only Transformer architecture and is used in its pretrained, instruction-tuned form without additional fine-tuning on the power-system dataset. The 506 power-system fault records are used to construct the PKG and generate the knowledge-grounded Q&A context, rather than being used for additional LLM pretraining. BERT is used separately for power-system entity/relation extraction and query understanding. The top 5 relevant PKG triples are retrieved using semantic similarity and appended to the query as contextual evidence. The instruction requires the LLM to answer using the retrieved power-system facts and avoid unsupported information. Since the LLM is not further fine-tuned, training epochs, learning rate, and fine-tuning method are not applicable. During inference, the temperature is set to 0.2, the maximum generated length is 256 tokens, and deterministic decoding is used to improve reproducibility. Thus, the LLM functions as the final knowledge-grounded response generator, while the PKG supplies the domain-specific factual evidence.

To evaluate the generated answers, the 20% test set is compared to the corresponding reference answers in the Power System Faults Dataset. Exact Match (EM) indicates verbatim accuracy of the generated answer and the reference. F1 is used to assess the accuracy of generated answers on a token-by-token basis. BERT Score F1 is the version of BERT that compares answers based on contextual representations. Faithfulness measures how consistent the responses are with the retrieved PKG evidence, while Hallucination Rate measures the percentage of responses that include information that is unsupported or incorrect. All comparison variants use the same testing subset, reference answers, retrieval settings, and evaluation criteria as are utilized for the proposed LLM–PKG model. The scores obtained are then averaged across the assessed test set on each of the three Q&A scenarios, quantifying the correctness of the answers, semantic similarity, factual grounding, and answering behavior of hallucinated answers.

Llama-3.1-8B-Instruct (8B parameters), pretrained in an instruction-tuned fashion, has been used for the implementation without fine-tuning. BERT-base-uncased is used alone for entity and relation extraction, and for query understanding. Power-System does not, therefore, update the parameters of the LLM, but rather its records are mapped to structured, evidence-of-expertise power-system instances, as well as question–answer instances associated with knowledge. Given a query, BERT finds entities that are relevant to the query, aligns the entities by mapping them to the nodes in PKG, and expands the one-hop neighborhood for formulating candidate triples. Corresponding to the query representation, a group of top 5 (K=5) triples is returned, with the highest-ranking one according to cosine similarity between the query and the corresponding triple representations. The LLM is provided with a structured prompt that consists of the following three parts: 1) an instruction that asks the LLM to respond in a relevant way that can be supported with evidence; 2) the original user query; and 3) the retrieved PKG triples. The answer must be limited to the information provided in the Power System Supplies and does not include statements of facts that are not supported by the information provided. To evaluate a model for inference, they set the temperature to 0.2 and the maximum generation length to 256, and set the decoding method to deterministic to be reproducible. No further fine-tuning, optimization, or further training epochs are applied, both on the LLM and during the preprocessing. It is implemented on an NVIDIA RTX 4090 (24 GB memory), an Intel Core i9-13900k (CPU), and 64 GB of RAM with Python 3.11, PyTorch 2.3.1, and Transformers 4.44.2. In the experimental implementation, a random seed of 42 is fixed throughout the implementation. The cross-entropy training loss is not applied to the LLM in the proposed experimental setting, as is the norm with the LLM in isolation. The generation stage is thus handled as inference, where a pre-trained instruction-tuned model is conditioned on the retrieved PKG evidence. The cross-entropy loss function is used to optimize the LLM during training, measuring the difference between the probabilities of the tokens generated by the LLM and the actual target sequence as shown in Eq. (6):

$$K = -\sum_{i=1}^{m} \log P\left(x_j | y, x_1, x_2, \dots, x_{j-1}\right) \qquad (6)$$

where, K denotes the cross-entropy loss; m is the total answer length, y represents the knowledge-augmented input (user query + PKG facts), x_j is the jth generated token, log denotes the logarithmic function measuring prediction confidence, and $\log P\left(x_j | y, x_1, x_2, \dots, x_{j-1}\right)$ is the conditional probability of generating the next answer token.

H. Electrical Fault Diagnosis and Decision-Support

This retrieved knowledge in turn is leveraged to make three engineering decisions: fault identification, causal interpretation, and maintenance/recovery recommendation. The query is initially converted into electrical bodies and working parameters. The relevant PKGs are then retrieved to look for supporting evidence. This LLM then uses the retrieved electrical evidence and the user question to formulate the final response. The response obtained is then compared with the fault information and the decision requirements. The proposed model thus couples machine measurements and equipment conditions to structured fault knowledge and natural-language decision support.

IV. Results

The experimental evaluation aimed to determine the language-based reasoning capability and assess the electrical fault-diagnosis capability of the proposed LLM–PKG model. This evaluation focuses on fault identification; causal factors associated with the environment and operation; and decision-making on maintenance and recovery. Moreover, measures of semantic similarity and knowledge-grounding, the performance in electrical fault diagnosis is assessed with the application of classification-oriented measures. The Power System Faults Dataset is then statistically analysed and validated to assess its structural quality and appropriateness for intelligent power-system question answering. The pairs of Q&A were then analyzed in a rule-based system using Python, where the results

were grouped into three categories: Fault Type Identification, which includes fault detection, category, and location; Environmental and Operational Causation, which classifies environmental and operational factors that cause faults; and Maintenance and Recovery Decision, which identifies corrective actions, maintenance planning, and restoration of systems. The distribution of the dataset by category, shown in Table V and Fig. 5, is a well-balanced distribution that supports the different aspects of the fault reasoning and decision-making process.

TABLE V. DISTRIBUTION OF QUESTION CATEGORIES ACROSS THE POWER SYSTEM FAULTS DATASET

Question Category	Fault Type Identification (%)	Environmental & Operational Causation (%)	Maintenance & Recovery Decision (%)
Diagnostic Reasoning	38.2	12.4	8.6
Causal Analysis	14.5	41.3	9.2
Operational Assessment	21.8	28.6	14.1
Maintenance Planning	6.4	4.8	39.5
Recovery Evaluation	5.1	3.9	21.4
Decision Support	14.0	9.0	7.2

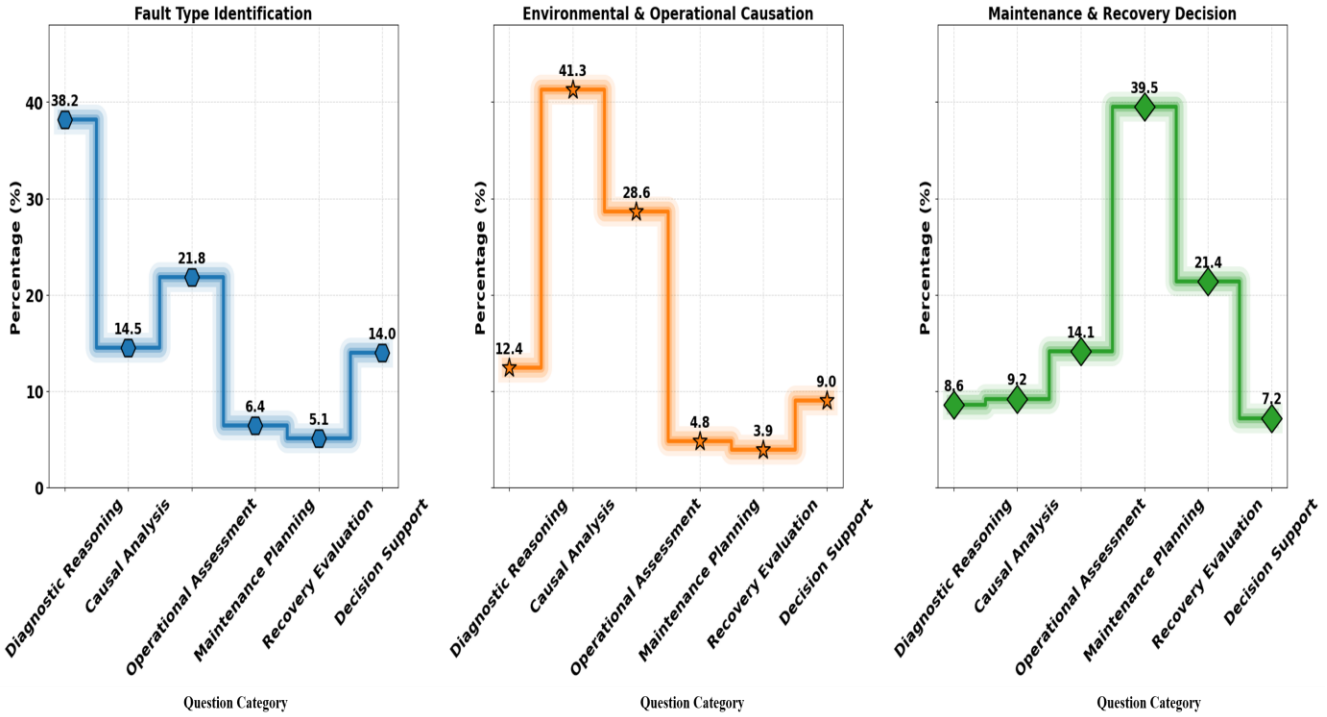

Fig. 5. Category-wise distribution of power-system fault reasoning tasks.

The dataset exhibits a well-balanced distribution across six defined reasoning categories. The questions generated from the texts were clustered into six clusters of semantic reasoning, based on the dominant information content and reasoning requirements of queries. There are a total of 87, 85, 84, 83, 83, and 84 pairs of Q&A generated in the six clusters, respectively, for a total of 506 pairs across all six clusters. Overall cluster proportions varied from 16.27% to 17.26%, suggesting a reasonably even balance of types of questions within the clusters that focused on fault diagnosis, electrical-state analysis, environmental and operational causes, maintenance and recovery, duration of fault, and operational decision support using LLM.

Table VI summarizes the properties of the dataset, and Fig. 6 outlines the Semantic Network of the principal entities related to power system faults. Power system fault diagnosis, electrical system state analysis, power system condition evaluation, power system maintenance management, power system fault loss assessment, and fault analysis on decisions supported by LLM are the six main categories of questions on which the Power System Faults Dataset displays an even distribution. Such a distribution of question types allows rich reasoning abilities for fault diagnosis, maintenance planning, fault repair, system restoration, and operation decisions in the power system context. The generated question set was grouped into six semantic reasoning clusters according to the dominant information and reasoning requirements of the queries. The cluster sizes were relatively comparable, indicating a balanced distribution of question types.

TABLE VI. DISTRIBUTION OF CLUSTER ID ACROSS THE POWER SYSTEM FAULTS DATASET

Cluster ID	Size (Fault Records)	Top Defining Terms	Sample Query
Cluster 1	87	fault type, transformer failure, line breakage, overheating, fault location, component health	What type of fault occurred in F002, where was it located, and what caused it?
Cluster 2	85	voltage, current, power load, electrical parameters, electrical state	How did voltage, current, and power load conditions contribute to the fault event in F001?
Cluster 3	84	weather condition, rainy, snowy, thunderstorm, windstorm, environmental factors	Which weather conditions contributed to transformer overheating in F003?
Cluster 4	83	maintenance status, scheduled, pending, completed, maintenance actions, recovery process	What is the maintenance status of the affected component, and what actions are required after the fault?
Cluster 5	83	fault duration, downtime, outage duration, system availability, recovery time	How long did the fault last, and what was the resulting downtime of the system?
Cluster 6	84	LLM-based intelligent Q&A, fault diagnosis answer, fault interpretation, risk interpretation, operational decision support	What operational decisions are recommended based on the diagnosed fault and associated risks?
Total	506	—	—

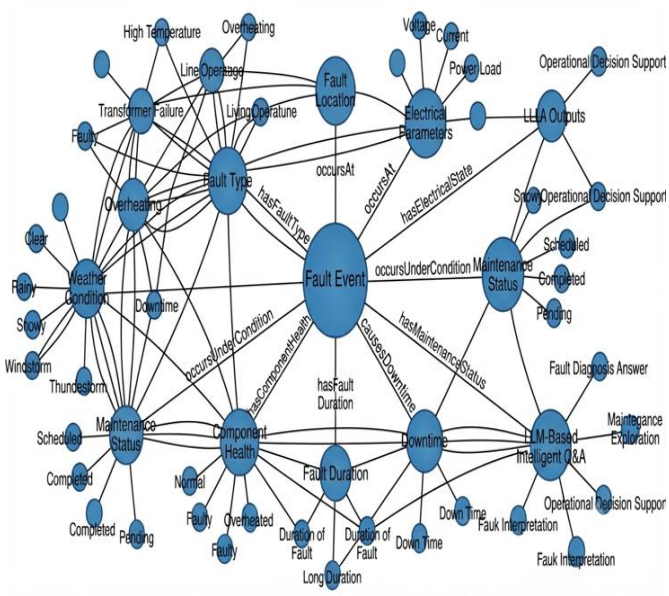

Fig. 6. PKG representation of thematic fault clusters and entity relationships.

A. Performance Evaluation

The performance of the novel proposed fusion model LLM-PKG is assessed using three functional areas: Fault type detection; Causation and origin environment and operations; and support and decision making for operation and maintenance. Both lexical and semantic analysis of output metrics, and measures for Knowledge grounding and for hallucination evaluation.

1) Exact Match (EM): Measures whether the generated answer exactly matches the reference answer after normalization. It is defined as shown in Eq. (7):

$$EM = \frac{1}{N}\sum_{i=1}^{N} \mathbb{I}\,(\hat{y}_i = y_i) \tag{7}$$

where, N is the number of evaluated questions, $\hat{y}_i$ is the generated answer, y_i is the ground-truth answer, and $\mathbb{I}(\cdot)$ is an indicator function. It assigns a value of one only when the prediction completely matches the reference.

2) Token-level F1-score: Evaluates partial lexical overlap between generated and reference answers. Precision (P), recall (R), and F1 are calculated as given in Eq. (8)-(10):

$$P = \frac{|T_{\hat{y}} \cap T_y|}{|T_{\hat{y}}|} \tag{8}$$

$$R = \frac{|T_{\hat{y}} \cap T_y|}{|T_y|} \tag{9}$$

$$F1 = \frac{2PR}{P+R} \tag{10}$$

where, $T_{\hat{y}}$ and T_y represent the predicted and reference token sets, giving partial credit when the response contains only part of the expected information.

3) BERTScore: Measures contextual semantic similarity using the RoBERTa-large pretrained checkpoint as the contextual encoder. Pairwise cosine similarities between candidate token x_i and reference token y_j are calculated. The final BERTScore is reported as Eq. (11):

$$F1_{BS} = \frac{2P_{BS}R_{BS}}{P_{BS}+R_{BS}} \tag{11}$$

This accommodates technically correct power-system answers that use alternative wording while preserving semantic meaning. $2P_{BS}$ specifies the BERTScore precision. R_{BS} denotes BERTScore recall. $F1_{BS}$ represents the harmonic mean of precision and recall, indicating the overall contextual semantic similarity between the predicted and reference answers.

4) PKG-Based Faithfulness Score (FS): Serves as the primary measure of factual grounding for the LLM–PKG architecture. Generated answers are decomposed into atomic claims ($C = \{c_1, c_2, \ldots, c_m\}$) and compared against retrieved PKG facts ($K = \{k_1, k_2, \ldots, k_r\}$). Claim-level faithfulness is calculated using Eq. (12).

$$FS = \frac{N_{supported}}{N_{claims}} \times 100 \tag{12}$$

where, $N_{supported}$ is the number of supported claims and N_{claims} is the total number of claims. High scores indicate statements regarding fault types, equipment conditions,

environmental factors, or maintenance actions are directly supported by PKG evidence.

5) Hallucination Rate (HR): Quantifies unsupported content generated by the LLM shown in Eq. (13):

$$HR = \frac{U}{A} \times 100 \quad (13)$$

where, U is the number of unsupported factual answer units and A is the total number of factual answer units. A lower rate indicates better grounding.

The Faithfulness Score (FS) represents the ratio of factual claims, stated in the answer generated by the model, that are backed up by the retrieved evidence/items from the PKG. Each answer is broken down into individual pieces of factual information (fingers) such as: fault type, equipment condition, environmental factor, operational condition, or recommended maintenance action. A claim is faithful if there exists evidence in the retrieved PKG triples or the related source record to the claim. The Faithfulness Score is therefore equal to the ratio of the number of claims that get supported and the total number of factual claims.

The Hallucination Rate is the percentage of factual statements that cannot be substantiated with the evidence from the PKG retrieved, or the corresponding source record. There is a possibility that one or more variables of the unsupported claim may be incorrect: the fault classified as the fault type which is not the true cause; the operating condition which is not the true cause; an environmental cause not observed in the evidence; a maintenance recommendation which is not supported by the available power-system data. Therefore, a lower HR means a more solid basis of facts.

In addition to automated grounding measures, domain-expert assessment is used because numerical and semantic text measures are not sufficient to determine if the response is technically correct with respect to decision-making in power systems. Each answer needs to be evaluated by a specialist for its factual accuracy, relevance to the specific electrical circumstance for which the inquiry was made, consistency among the retrieved evidence, and engineering suitability of the suggested actions. The expert assessment considers and reports on linguistic similarity without also reporting on technical content and validity of the domain-specific content, which are reported separately from it. The results of all three tasks are shown in Table VII.

TABLE VII. DISTRIBUTION OF QUESTION CATEGORIES ACROSS LLM-PKG-BASED POWER SYSTEM FAULT DATASET

Metric	Fault Type Identification	Environmental & Operational Causation	Maintenance & Recovery Decision
EM	62.4%	58.7%	55.9%
F1 Score	68.1%	65.3%	63.4%
BERT Score F1	71.5%	69.2%	67.8%
Faithfulness Score	64.8%	61.5%	59.7%
Hallucination Rate	18.6%	21.4%	24.1%

The proposed model gets the best score in Fault Type Identification because fault types have a structured and clear pattern; its performance decreases slightly in Environmental and Operational Causation due to a complex system because of the dependency on various factors (e.g., weather, load). The scores in Maintenance and Recovery Decision tasks are lower as the need for high-order deduction across various system characteristics increases; the consistently good results in BERTScore F1 scores (ranging from 67.8% to 71.5%) confirm a high semantic similarity to ground truth; Faithfulness scores in these tasks confirm the excellent effect of PKG fact grounding. The hallucination rate (ranging from 18.6% to 24.1%) shows a relatively low rate thanks to knowledge-graph fusion. To assess the contribution of the main elements of the suggested LLM–PKG fusion framework, an ablation study was carried out. The whole model was contrasted with variations that did not include PKG retrieval and reasoning, BERT-based semantic extraction, Z-score normalization, or an LLM-only baseline. The findings in Table VIII show that eliminating these elements increases hallucination while decreasing answer accuracy, fidelity, and semantic similarity. Specifically, a greater performance loss results from the elimination of PKG retrieval and reasoning, underscoring the need for domain-grounded knowledge for trustworthy power-system Q&A and decision support.

TABLE VIII. ABLATION ANALYSIS OF LLM–PKG COMPONENTS FOR POWER-SYSTEM Q&A

Model / Variant	Z-score	BERT Extraction	PKG Retrieval & Reasoning	LLM Fusion	EM (%)	F1 (%)	BERTScore F1 (%)	Faithfulness (%)	Hallucination (%)
Rule-based Q&A	✗	✗	✗	✗	43.5	49.1	52.8	55.6	34.2
PKG-only retrieval	✗	✗	✓	✗	46.8	52.4	56.7	57.2	31.6
LLM-only baseline	✗	✗	✗	✗	51.2	57.6	61.5	53.8	28.1
Conventional RAG	✓	✓	✗	✓	56.7	62.5	66.1	59.3	23.7
Without PKG retrieval/reasoning	✓	✓	✗	✓	54.6	60.8	64.3	56.9	25.3
Without BERT extraction	✓	✗	✓	✓	58.9	64.2	67.8	60.7	21.8
Without Z-score normalization	✗	✓	✓	✓	59.8	65.4	69.1	61.9	20.7
Full LLM–PKG	✓	✓	✓	✓	62.4	68.1	71.5	64.8	18.6

The advancement of intelligent power system fault diagnosis and Q&A systems leverages KG-based reasoning as a means to enrich structure information retrieval and enhance explainability. Numerous works prove that KG-augmented

models achieve high accuracy in the task of fault retrieval and entity-relation extraction from the domain-specific query based on KG, but struggle with generalization capability, dependence on labeled data quality, and scalability issues in real-world large, complex power grid scenarios [14]. KG embedding and KG-reasoning models can further obtain satisfactory results regarding prediction performance; however, this comes with computational expense and lower efficiency in massive knowledge contexts [13].

Smart grid operation with LLMs makes considerable improvements in reasoning efficiency but is deficient in hallucination and shallow-grounded structured domain knowledge to guarantee safe decision-making. For this reason, the LLM-PKG fusion model is designed by fusing context-language modeling with structured knowledge graphs that enhance the factual grounding of predictions and their inferential logic correctness. Extensive experiments verify the model's robust effectiveness across all benchmarks that reflect semantic understanding, strengthen knowledge grounding, boost response faithfulness, and mitigate hallucination. The obtained results validate and prove the effectiveness of the proposed framework, LLM-PKG, in providing truthful and trustworthy answers to intelligent question answering in a power system with context. The model performs well in fault type identification with fixed pattern and relatively poor performance in complex logical inference with dependent variables as multiple factors, respectively. Several limitations also existed in terms of limitations of data scale, extraction noise in the construction of PKG, and insufficient temporal inference abilities. Future directions involve real-time and scalable applications, graph learning, and multi-modality. The proposed model is designed to be a tool for the decision-making process of power-system engineers and operators. It offers a natural language user interface to which one can pose questions on conditions for the electrical operation, on faults, on the environment, and on maintenance. The PKG now structures electrical evidence, and the LLM is used to interpret and generate the evidence to be formulated into a response. The model thus does not stand alone as a protection or control tool, but is designed to be advisory in nature.

V. Conclusion

With the gradual development of the power system, the research and application of intelligent Q&A models have become more and more important in the field of power system fault diagnosis and effective operation decision support. Traditional methods are difficult to reason with and lack structured reasoning ability, and standalone LLMs have limitations in factually grounded reasoning and hallucination. To overcome these limitations, the proposed LLM–PKG fusion model combines z-score normalization, BERT-based entity and relation extraction, and Power Knowledge Graph-guided retrieval to boost knowledge-driven reasoning. The experimental results for all tasks (Fault Type Identification, Environmental and Operational Causation, and Maintenance and Recovery Decision) are 71.5%, 69.2%, and 67.8%, respectively, with the Hallucination Rate of <25% for all of them (18.6%, 21.4%, and 24.1%). The results demonstrate that structured graph knowledge, alongside LLM reasoning, has a substantial impact on the semantic consistency, factual correctness, and explainability of questions and answers within a power system. The electrical fault-analysis experiments illustrate how the model can link operating measurements to environmental conditions, structure, and equipment states, and incorporate fault knowledge and natural-language decision support. The model would serve as a practical basis for intelligent fault diagnosis and smart grid decision support, and future research involves real-time data integration, temporal reasoning, and the scaling of graph learning for widespread use.

Adapting Ephemeral ECC Authentication for Decentralized Web 3.0: A Threat Model and Security Analysis

Adarsh S V Nair*, Rathnakar Achary
Alliance School of Advanced Computing, Alliance University, Bengaluru, India

***Abstract*—Web 3.0 shifts control of digital identity and data away from centralized platforms, moving authentication onto resource-constrained end-user devices, wallets, and smart contracts. RSA and ElGamal are computationally expensive at the key sizes required for adequate security, making them a poor match for this setting. This study presents a user-centric Web 3.0 authentication framework combining Elliptic Curve Cryptography with an ephemeral Elliptic Curve ElGamal (ECEG) character-encoding scheme, building on an ephemeral-encoding design for constrained IoT devices and its subsequent hash/XOR authentication extension. Unlike that prior design, the mutual-authentication step here binds each party to its long-term key through digital signatures and replaces static-key ECEG transport with a two-ephemeral-key ECEG transport, providing an erasure-conditional forward-secrecy property that the prior design lacks. We define a Dolev-Yao threat model with an in-scope/out-of-scope adversary boundary, an assumption-based security analysis, a formal-verification specification, and a decentralized-identifier/verifiable-credential mechanism binding long-term public keys to claimed identities, addressing the identity-binding gap that otherwise limits man-in-the-middle resistance without a common certificate authority. A protocol-level operation count and a complexity comparison against RSA are reported without claiming empirical superiority. We situate the framework against its closest prior IoT-oriented work and active 2025–2026 literature on ECC- and blockchain-based decentralized authentication. Recent 2026 analyses have reduced estimates of the quantum resources needed to solve the elliptic-curve discrete logarithm problem underlying secp256k1-style curves; we give a post-quantum outlook against current NIST migration guidance. The evaluation remains analytical rather than empirical; formal verification and hardware benchmarking remain necessary before production deployment.**

Keywords*—Elliptic curve cryptography; decentralized authentication; Web 3.0 security; privacy-preserving authentication; self-sovereign identity; decentralized identifiers; verifiable credentials; forward secrecy; formal verification; resource-constrained devices; post-quantum cryptography

I. Introduction

The development of the World Wide Web is generally described in three overlapping phases. Web 1.0 was a static medium in which users were essentially passive consumers of information provided by publishers. Web 2.0 swung the pendulum towards participation, allowing for social interaction and user-generated content, but then conversely centralized data, identity, and economic value in the hands of a few large platforms. Web 3.0 is best understood as a correction to this concentration: a computing paradigm that uses blockchain infrastructure, cryptographic identity primitives, and peer-to-peer protocols to return control of data and digital identity to the people who created it.

This change of control does not remove the need for security; it moves it. In Web 2.0, a central identity provider can enforce authentication policy, patch vulnerabilities, and revoke compromised credentials for its users. In a decentralized environment, this burden falls on end-user devices, wallets, and smart contracts, which usually have limited computational power, memory, and energy budgets. Decentralized identity technologies such as Decentralized Identifiers (DIDs), Self-Sovereign Identity (SSI), and Zero-Knowledge Proofs (ZKPs) give individuals cryptographic control of credentials without a centralized issuing authority. These mechanisms are attractive because they minimize third-party trust, but they also raise the bar for the cryptographic building blocks that underpin them: authentication must be robust enough to withstand active adversaries, yet lightweight enough to run on constrained hardware such as embedded wallets, IoT gateways, and mobile edge devices participating in decentralized applications.

This tension has practical consequences that are visible in the attack landscape that has grown alongside Web 3.0. Social-engineering attacks such as rug pulls, Sybil attacks, and phishing trick users into giving up credentials or authorizing malicious transactions, and weak or spoofable authentication is a direct contributor to several of these: if the link between a user and their cryptographic identity can be spoofed, replayed, or intercepted, an attacker can impersonate a legitimate party or enrol duplicate identities under someone else's claimed identity. Smart contracts are self-executing and largely immutable once deployed, which makes them susceptible to logic errors and reentrancy attacks, and cryptojacking silently hijacks computing power for unauthorized mining; these two threats are primarily software-security and resource-abuse problems rather than authentication failures, and the framework proposed here does not address them (Section X). Strengthening the authentication layer is therefore not a complete defense for Web 3.0 but a necessary precondition for the identity-dependent parts of its security promises [1].

Public-key cryptosystems such as RSA and ElGamal have been the standard building blocks for mutual authentication between distributed entities for decades, but their computational profile, dominated by large-modulus modular exponentiation,

*Corresponding author.

and their reliance on large keys make them poorly suited to resource-constrained devices operating within decentralized networks. Elliptic Curve Cryptography (ECC) is an alternative that provides comparable security with a much smaller key size, resulting in less computation time, a smaller memory footprint, and lower communication overhead. These properties make ECC a natural candidate for authentication in Web 3.0 settings, provided that the protocol built around it is designed with the specific trust assumptions of decentralized environments in mind.

This study presents a user-centric authentication framework for Web 3.0 that uses Elliptic Curve Cryptography together with an ephemeral Elliptic Curve ElGamal (ECEG) character-encoding scheme, a two-ephemeral-key ECEG parameter transport, and a digital-signature-based mutual authentication step. The ephemeral ECEG character encoding builds on the encoding concept originally proposed for constrained IoT devices by Baccouri et al. [2], and the goal of binding the resulting encoding parameters to an authenticated exchange builds on that group's own subsequent extension of the idea, which transports the encoding parameters inside an ECEG ciphertext under the recipient's static public key and confirms them with a hash-and-XOR exchange chained to the previous session's parameters, verified with the Scyther tool and benchmarked against RSA [3]. As Section II-D discusses in detail, this study departs from [3] at the protocol level as well as the application level: mutual authentication here rests on digital signatures over each party's long-term key rather than on the hash-and-XOR confirmation of [3], and the encoding parameters are transported under a fresh, per-session ephemeral key rather than under the recipient's static public key. Under the stated erasure assumption, this removes the static-key forward-secrecy limitation of [3] (Section VI-D). The present study's contribution is therefore both this protocol-level adaptation and the Web 3.0-specific threat model, requirements analysis, and identity-binding mechanism built around it, for the setting in which two entities may share no prior relationship and no common certificate authority. The contributions of this work are summarized as follows.

- A review of the authentication and identity-management challenges specific to decentralized Web 3.0 architectures, linking them to concrete attack patterns reported in the literature.
- An explicit, requirement-driven threat model for Web 3.0 peer-to-peer authentication, together with an honest positioning of this work relative to its closest prior art (Section II-D).
- A Web 3.0-oriented adaptation of an existing ECEG character-encoding scheme [2,3], replacing its static-key encoding transport with a two-ephemeral-key ECEG exchange and its mutual-authentication step with digital signatures over each party's long-term key, reanalyzed for the trust assumptions of self-sovereign, peer-to-peer Web 3.0 identity. The adaptation is designed to operate without exposing long-term private keys and provides an erasure-conditional forward-secrecy property that the prior static-key design lacks.
- An informal, assumption-based security analysis against eavesdropping, man-in-the-middle, replay, and impersonation attacks – with man-in-the-middle resistance stated explicitly as conditional on authenticated public-key binding rather than as an unqualified guarantee – together with a concrete formal-verification plan (Section VI-F) that specifies the exact queries needed to move from an informal argument to a machine-checked one.
- A concrete decentralized-identifier/verifiable-credential (DID/VC) mechanism (Section VI-F) for binding long-term public keys to claimed identities, closing the residual key-to-identity binding gap that otherwise limits man-in-the-middle resistance in a peer-to-peer setting with no common certificate authority.
- A computational complexity comparison between RSA and ECC, checked against the current NIST SP 800-57 equivalence table, together with an honest discussion of the limits of the present analytical-only evaluation and concrete directions for hardware-based validation.
- A post-quantum outlook (Section IX) that situates the proposed ECC-based framework against the rapidly narrowing 2025–2026 quantum resource estimates for solving the elliptic-curve discrete logarithm problem, and against current NIST migration guidance for algorithm deprecation.

The remainder of this study is organized as follows. Section II reviews related work on public-key and elliptic-curve-based authentication for constrained and decentralized systems, and positions this work relative to its closest prior art. Section III introduces the mathematical preliminaries of elliptic curve cryptography used throughout the study. Section IV defines the threat model and security objectives. Section V presents the proposed authentication framework in detail. Section VI gives the security analysis, including the formal-verification plan. Section VII studies computational complexity relative to RSA. Section VIII discusses the results. Section IX gives a post-quantum outlook. Section X discusses limitations and future work, and Section XI concludes the study.

II. Related Work

A. Public-Key Cryptography as a Baseline for Authentication

Traditionally, public-key cryptosystems such as RSA and ElGamal have been used to achieve mutual authentication between distributed entities, where the security of the scheme rests on the difficulty of factoring large integers or computing discrete logarithms in large multiplicative groups. These systems require key sizes of two to four thousand bits or more for an adequate security margin, and the modular exponentiation operations involved are computationally intensive. This overhead is manageable on servers and general-purpose computers, but becomes a bottleneck on the memory- and energy-constrained devices common in Internet of Things (IoT) deployments, and increasingly in Web 3.0 client software such as wallets and decentralized-application agents. This limitation motivates the search for cryptographic primitives that realize similar security with a smaller computational footprint.

B. Elliptic Curve Cryptography for Constrained and Decentralized Systems

Elliptic Curve Cryptography is increasingly the preferred choice for constrained environments because it offers security comparable to RSA with much shorter key lengths, owing to the higher per-bit strength of the Elliptic Curve Discrete Logarithm Problem (ECDLP). ECC has been used for authentication in resource-constrained settings in a large body of work. Dinarvand and Barati [4] proposed an efficient and secure ECC-based RFID authentication protocol; Lamrani Alaoui et al. [5] proposed a highly efficient ECC-based authentication protocol for RFID tags under similarly tight resource constraints. Noori et al. [6] extended this line of work to the healthcare Internet of Things with an ECC-based mutual authentication scheme for RFID-enabled medical devices, and Sowjanya et al. [7] designed an ECC-based authentication scheme specifically for the Internet of Medical Things. Khan et al. [8] proposed a secure framework combining authentication and encryption with an improved ECC construction for IoT-based medical sensor data, illustrating the recurring role of healthcare IoT as a proving ground for lightweight ECC protocols.

ECC authentication using smart cards and multi-factor schemes has also been heavily explored. Kumari et al. [9] proposed a smart-card-based mutual authentication protocol named ESEAP, and a related work by the same group [10] proposed a secure user authentication protocol based on ECC. Li et al. [11] proposed a robust and energy-efficient authentication protocol for the industrial Internet of Things, while Panja et al. [12] combined ECC with fingerprint biometrics to strengthen user binding. Ramasamy et al. [13] proposed an ECC-secured one-time-password scheme for mobile commerce; Sadri and Asaar [14] designed an anonymous two-factor authentication protocol for IoT applications with emphasis on user privacy; Elias et al. [15] implemented a one-time-password system on top of ECC key exchange; and Kaur et al. [16] proposed a two-factor authentication framework for cloud computing based on the same underlying elliptic-curve operations. A common observation across these contributions is that identity-based and certificate-based ECC schemes can fail either because they lack user anonymity, or because the authentication step itself remains vulnerable to replay and impersonation if ephemeral values are reused or predictable a gap this work directly addresses by using fresh ephemeral parameters on a per-session basis.

On the implementation side, Islam et al. [17] proposed high-performance ECC processors with unified point addition on twisted Edwards curves, and Basu Roy and Mukhopadhyay [18] presented a high-speed implementation of ECC scalar multiplication over prime fields for generic Montgomery curves, both demonstrating that the scalar multiplication at the heart of ECC can be realized efficiently even on constrained hardware. Lara-Nino et al. [19] provide a comprehensive survey of elliptic-curve lightweight cryptography that catalogs the design trade-offs between security margin, key size, and implementation cost that motivate the present work. The most directly related prior work is that of Baccouri et al. [2], who proposed an ephemeral encoding scheme in which plaintext characters are mapped onto curve points using randomly generated ephemeral parameters rather than a fixed, exchanged lookup table. The framework proposed in this study builds on that ephemeral-encoding idea; Section II-D discusses in detail how it relates to that group's own subsequent extension of the same idea into a full authentication protocol [3].

The field has remained active through 2025 and into 2026. Prakash and Ramesh [20] proposed a decentralized ECC-based authentication scheme with a dynamic difficulty-adjustment mechanism for IoT networks, correctness argued with BAN logic and evaluated against replay and man-in-the-middle attacks, architecturally the closest 2025 comparator to the framework proposed here. Liu et al. [21] introduced EdenDID, an edge-computing and blockchain-based decentralized identity system for Web3 applications that binds a human user, wallet address, and physical device together specifically to resist Sybil attacks on Web3 wallets, and Le et al. [22] combined blockchain smart contracts with AI-driven document recognition and Merkle-tree-based access control for decentralized identity management. These 2025 contributions confirm that ECC-based and blockchain-based decentralized authentication remains a fast-moving area, which strengthens the case, developed in Section II-D, for differentiating this study's contribution narrowly and explicitly rather than on the underlying cryptographic primitives alone.

C. Blockchain, Identity, and Verification

Beyond point-to-point authentication, several works consider the broader decentralized identity and trust ecosystem in which such protocols operate. Achary et al. [1] proposed an integrated blockchain model for personally identifiable information systems, examining how blockchain-based identity management can mitigate the social-engineering and identity-theft risks characteristic of Web 3.0 platforms, and a related study [23] investigated the integration of ECC with the Constrained Application Protocol (CoAP) to secure resource-constrained IoT communication, a combination architecturally close to the decentralized, low-power devices targeted here. A related blockchain-enabled IoT logistics system for high-value shipment tracking [52] similarly pairs a smart contract with blockchain-based access control, illustrating the same decentralized-trust pattern applied to a supply chain rather than an authentication setting, and a multi-authentication smart-locker design [53] combines several authentication modalities in a deployed IoT system; both are system-level rather than protocol-level contributions, but they reinforce the point that authentication should be evaluated alongside privacy mechanisms and deployment cost rather than through key-size comparisons alone. Zheng et al. [24] proposed a blockchain-based lightweight authentication and key-agreement scheme for the Internet of Vehicles, illustrating how ECC-style lightweight authentication is increasingly paired with distributed ledgers rather than centralized authentication servers. Formal verification of such protocols is itself an active area: Cremers [25] developed Scyther, a tool for the automated verification of security protocols, and Blanchet [26] developed ProVerif, based on the applied pi calculus; both tools are used to motivate the formal-verification plan of Section VI-F. Finally, K. K. G. V. et al. [27] explored machine-learning-based anomaly detection for cloud data, a complementary line of defense that could, in future work, be layered on top of the authentication mechanism

proposed here to flag statistically anomalous authentication attempts rather than only individually valid or invalid ones.

Within the same domain, Kanjanapruthipong and Boonkrong [28] proposed a blockchain-based decentralized authentication paradigm for closed environments, with security argued using Gong–Needham–Yahalom (GNY) logic rather than the Dolev–Yao-style symbolic verification pursued here, illustrating the range of formal approaches the field currently uses. Recent systematization work has also matured: a companion comparative survey [29] in this journal analyzes the scalability, security, and feasibility trade-offs between centralized and decentralized identity management, and a 2026 systematization of knowledge [30] organizes the open challenges of self-sovereign digital identities across a broad cross-section of the recent literature.

D. Positioning Relative to the Closest Prior Art

The protocol most closely related to the one proposed here is the lightweight authentication scheme of Baccouri et al. [3], which extends their own earlier ephemeral-encoding proposal [2] by exchanging the ephemeral encoding parameters (α, β) inside an ECEG ciphertext C encrypted under the recipient's static public key, sending C together with a hash value h1 in the first message and returning a hash-and-XOR confirmation CH1 = h3 ⊕ h1 whose hash input includes the previous session's encoding parameters; the resulting protocol is verified with the Scyther tool — checking secrecy, liveness, weak agreement, non-injective agreement and synchronization, and commitment to the exchanged values — and benchmarked against RSA on a C implementation across 8-, 64-, and 256-bit inputs. At the level of the cryptographic mechanism, that scheme and the framework proposed in this study therefore share the ephemeral ECEG character-encoding step of [2]; the mutual-authentication mechanism itself differs, since [3] authenticates via a hash-and-XOR confirmation that depends on state carried over from the previous session rather than via digital signatures over the current transcript, and transports the parameters under a static recipient key rather than the two-ephemeral-key ECEG transport used here (Section V-C). Table I sets these differences out message by message. Based on the openly available full text of [3], that protocol is designed and evaluated for classical IoT and wireless-sensor-network deployments between two devices provisioned in advance, and it does not address the specific trust assumptions of Web 3.0: there is no notion of a self-sovereign, wallet-held identity, no discussion of decentralized identifiers, and no attempt to reason about anonymity in the sense required by self-sovereign identity systems.

The contribution of the present study relative to [3] operates at two levels. At the protocol level, mutual authentication here rests on digital signatures over each party's long-term key combined with a two-ephemeral-key ECEG transport of the encoding parameters (Section V-C), replacing the static-key ECEG transport and previous-session-chained hash/XOR confirmation of [3], and providing an erasure-conditional forward-secrecy property that [3] does not have (Section VI-D). At the requirements level, the contribution is: 1) an explicit, requirement-driven threat model formulated for the trust assumptions of decentralized Web 3.0 identity, where the two parties may share no prior relationship and no common certificate authority (Section IV); 2) a concrete decentralized-identifier/verifiable-credential mechanism for binding long-term public keys to claimed identities (Section VI-D), together with an accompanying discussion of anonymity, pseudonymity, and forward secrecy framed in self-sovereign-identity terms rather than device-provisioning terms (Section VI-E); and 3) a concrete, ready-to-execute formal-verification plan with explicit secrecy and injective-agreement queries (Section VI-F), intended to be carried out as direct follow-up work. Readers should treat the ephemeral ECEG character-encoding step of Section V-B as a design pattern inherited from [2] and [3]; the signature- and two-ephemeral-key-ECEG-based mutual-authentication mechanism built around it (Section V-C), the Web 3.0-specific requirements analysis, the identity-binding mechanism, and the verification plan are this study's own contribution, summarized in Table I.

TABLE I. MESSAGE-LEVEL AND TRUST-MODEL DIFFERENCES BETWEEN THE CLOSEST PRIOR SCHEME [3] AND THE PROTOCOL OF SECTION V

Aspect	Baccouri et al. [3]	This study (Section V)
ECEG character encoding	Ephemeral (α,β) encoding of [2]	Retained unchanged; inherited, not claimed as new
Parameter transport	ECEG ciphertext C under recipient's static public key	ECEG ciphertext (C_1, C_2) under recipient's fresh per-session ephemeral point R_b
Message 1	C, h1	C, N_A, σ_A = Sign_{k_A}(hash(C ‖ N_A ‖ Q_A ‖ Q_B ‖ R_b))
Message 2	CH1 = h3 ⊕ h1 (hash input includes previous session's parameters)	N_B, σ_B = Sign_{k_B}(hash(M ‖ N_A ‖ N_B ‖ Q_A ‖ Q_B))
Authentication primitive	Hash and XOR	Schnorr/BIP-340 signatures over the current transcript
First-session bootstrap	Depends on previous-session state	Stateless per session; valid signature required regardless of history
Replay protection	Session chaining	Fresh 128-bit nonces + bounded replay cache
Forward secrecy	Not provided (static-key transport)	Provided conditionally if A erases i,r and B erases r_b after single use (Section VI-D)
Identity binding	Devices provisioned in advance	DID/VC binding check before the handshake (Section VI-B)
Added per-session cost	—	+1 ephemeral point, +2 signature ops, +2 verifications (Table VI); not claimed lighter than [3]
Validation	Scyther-verified; RSA benchmark	Analytical; verification plan (Section VI-F) and benchmarking pending

E. Research Gap

The literature makes two things clear: 1) ECC is well suited to authentication on constrained devices because of its favorable security-to-key-size ratio; and 2) ephemeral, non-repeating cryptographic parameters are important for resisting replay and impersonation. What is comparatively unexplored, as Table II summarizes, is the combination of these two properties analyzed against the specific trust requirements of Web 3.0 identity management, where authentication must also support user-

controlled, self-sovereign identity without a centralized issuing or verifying authority. Existing ECC-based authentication schemes, including the closest prior art discussed in Section II-D, are analyzed for classical IoT, RFID, or wireless-sensor-network environments rather than for the decentralized application and wallet interactions of Web 3.0. The framework proposed in this study targets that gap. This remains true of the most recent 2025–2026 literature identified during the preparation of this revision (Table II): the closest 2025 comparators [20,21,28] each address either dynamic difficulty adjustment, blockchain-level decentralized authentication, or Sybil-resistant wallet binding, but none combines ephemeral character-level ECEG encoding with a signature- and two-ephemeral-key-ECEG-based mutual-authentication handshake analyzed against a Web 3.0-specific threat model, which is the specific combination this study targets.

TABLE II. SUMMARY OF REPRESENTATIVE ECC-BASED AUTHENTICATION SCHEMES

Ref.	Target Domain	Core Mechanism	Noted Limitation
[4,5]	RFID	ECC-based mutual authentication for tags	Tight tag-side resource budget limits protocol complexity
[6–8]	Healthcare IoT / IoMT	ECC authentication and encryption for sensor data	Emphasis on confidentiality; limited anonymity guarantees
[9,10]	Smart-card authentication	ECC-based mutual authentication with smart cards	Card loss/cloning risk; anonymity depends on card security
[12]	Biometric authentication	ECC combined with fingerprint features	Requires biometric sensing hardware
[13,15]	OTP-based authentication	ECC key exchange for one-time-password generation	OTP channel itself can be a phishing target
[14]	IoT two-factor authentication	Anonymous two-factor protocol	Second factor adds device/hardware dependency
[2]	IoT messaging	Ephemeral ECC/ECEG character encoding (no authentication handshake)	No explicit mutual authentication handshake
[3]	IoT / wireless sensor networks	Ephemeral ECEG encoding + hash/XOR confirmation chained to previous session; Scyther-verified; RSA-benchmarked	Targets classical IoT/WSN; no Web 3.0/SSI trust model or DID/VC binding
[20]	IoT networks (decentralized)	ECC + dynamic difficulty adjustment; BAN-logic proof	No ephemeral character-encoding layer; not Web 3.0/SSI-specific
[28]	Closed blockchain environments	Blockchain-based decentralized authentication; GNY-logic proof	ECC used only for validator-node key agreement, not for end-user authentication
[21]	Web 3.0 wallets / DePIN	Edge computing + blockchain identity binding human, wallet, and device	Targets Sybil resistance specifically; no ephemeral encoding or signature-based parameter-transport handshake
This work	Web 3.0 / decentralized identity	Ephemeral ECEG encoding + signature/two-ephemeral-key ECEG mutual authentication and DID/VC binding, adapted to an explicit Web 3.0-oriented threat model	Forward secrecy added over [3]; evaluated analytically; formal verification and hardware benchmarking pending (Section X)

III. ELLIPTIC CURVE CRYPTOGRAPHY

Anonymity is an essential requirement for authentication in open networks, especially where the privacy of the interacting parties must be protected. Early designs for mutual authentication in public-key cryptosystems such as RSA and ElGamal relied on resource-intensive modular exponentiation and a separate infrastructure for certificate management. Fig. 1 illustrates how steeply this modular-exponentiation cost grows with key size under a naive-multiplication model. This combination is difficult to justify on devices with limited processing power, memory, or battery capacity, which motivates the use of Elliptic Curve Cryptography as a lighter-weight alternative with an equivalent security guarantee.

An elliptic curve over a finite field $\mathbb{F}p$ is formally the set of points (x, y) that satisfy $y^2 = x^3 + ax + b$, together with a distinguished point at infinity that serves as the identity element. The points on the curve form an Abelian group under a geometrically defined addition rule. In this group, scalar multiplication is repeated addition of a base point G to itself: $k \cdot G = G + G + \cdots + G$ (k times). Fig. 2 plots the real points of a representative curve of this form to illustrate the group law geometrically.

The security of ECC rests on the computational hardness of the Elliptic Curve Discrete Logarithm Problem (ECDLP): given the base point G and a point $Q = d \cdot G$, computing the scalar d is believed to require time exponential in the bit-length of the curve's order for well-chosen curves, with respect to the best algorithms currently known. This asymmetry easy to compute Q from d, hard to invert lets ECC bind a private key to a publicly verifiable value without disclosing the key itself. In this work, the elliptic-curve key pair is generated as follows.

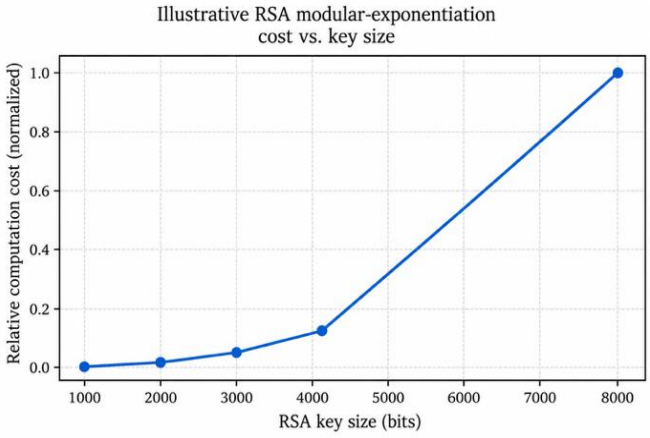

Fig. 1. Illustrative relative computation cost of RSA modular exponentiation as key size grows (naive-multiplication asymptotic model; not a measured benchmark).

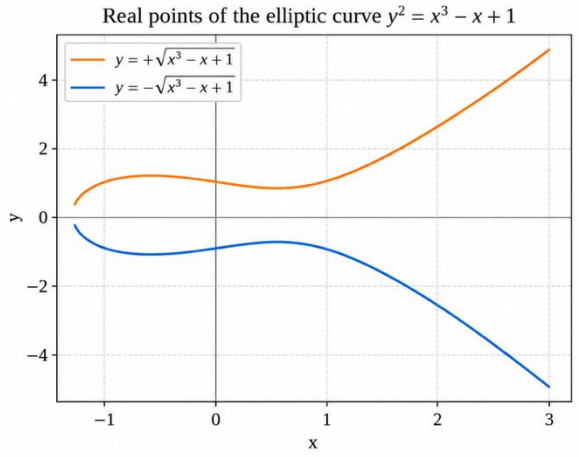

Fig. 2. Real-plane plot of the elliptic curve $y^2 = x^3 - x + 1$ (illustrative example of the group law; not the deployment curve, which is secp256k1).

Private key (d): a randomly chosen integer in the interval [1, n − 1], where n is the order of the base point G.

Public key (Q): computed as Q = d·G, a point on the curve.

The Elliptic Curve Integrated Encryption Scheme (ECIES) is a widely used hybrid construction that combines an ephemeral ECC key-agreement step with symmetric encryption and authentication. It is introduced here only as background context for the general pattern of ephemeral-key-plus-transport constructions; the protocol proposed in Section V is an ElGamal-based (ECEG) construction, not an implementation of ECIES itself. Fig. 3 compares the same RSA/ECC asymptotic costs at equal operand length, complementing the key-size-equivalent comparison of Fig. 4.

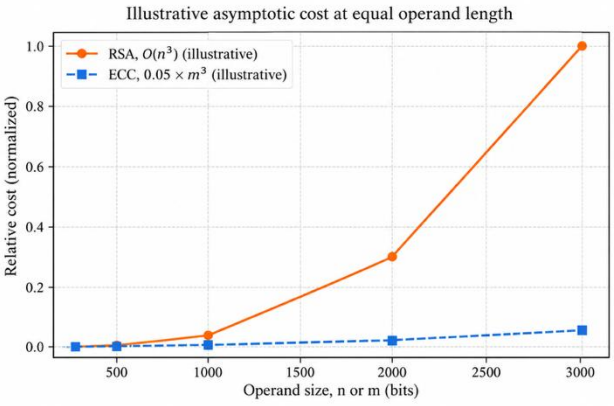

Fig. 3. Illustrative asymptotic cost of RSA and ECC at equal operand length (naive-multiplication model).

Encryption is performed by the sender using the recipient's public key Q, as follows.

- The sender generates an ephemeral private key r and the corresponding ephemeral public key R = r·G.
- The sender computes the shared point S = r·Q and derives a shared secret byte string from it, typically the x-coordinate of S.
- A key derivation function (KDF) is applied to the shared secret to produce symmetric keys: K_{enc} for encryption and K_{mac} for integrity.
- The plaintext is encrypted with an authenticated symmetric cipher, such as AES-GCM or AES-CBC combined with HMAC, using K_{enc}.
- A message authentication code is computed over the ciphertext and any associated header data using K_{mac}.
- The tuple (R, ciphertext, MAC) is transmitted to the recipient.

Decryption, performed by the recipient using the private key d, mirrors this process.

- The recipient computes the shared point S′ = d·R.
- K_{enc} and K_{mac} are derived from S′ using the same KDF and parameters used by the sender.
- The MAC is verified; the protocol aborts if verification fails.
- The ciphertext is decrypted with K_{enc} to recover the plaintext.

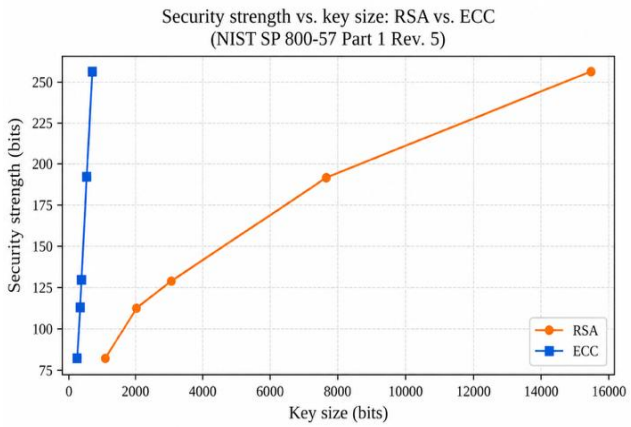

Fig. 4. Security strength versus key size for RSA and ECC, following NIST SP 800-57 Part 1 Rev. 5 [31].

As Fig. 4 illustrates, the security level obtainable per bit of key length is markedly higher for ECC than for RSA: a 256-bit ECC key (curve P-256, used here only as the NIST reference point for security-strength equivalence – the proposed protocol itself uses secp256k1, Section V-A) offers a security level comparable to a 3072-bit RSA key, both corresponding to a 128-bit security strength. This disparity widens further at higher security levels: at the 256-bit security level, a curve with a field size of 512 bits or more (e.g., P-521) is comparable to an RSA key of roughly 15360 bits, which is the central efficiency argument for adopting ECC on the resource-constrained devices considered in this study, and is analyzed quantitatively in Section VII. This comparison is a purely classical one: it assumes an adversary restricted to conventional computation. Section IX revisits the comparison under a quantum adversary, where the picture changes substantially, and situates both curves against NIST's current post-quantum migration guidance [32].

IV. Threat Model and Security Requirements

The proposed framework is evaluated under a Dolev–Yao-style adversary model [33], in which the attacker fully controls the communication channel: messages can be observed, intercepted, modified, replayed, or forged, but the attacker cannot break the underlying cryptographic hard problem; that is, the attacker cannot efficiently solve the ECDLP for the deployed curve parameters, nor invert the hash function used in the protocol. The attacker does not have access to the long-term private keys of legitimate parties and cannot read a device's protected key storage. This classical Dolev–Yao adversary is consistent with the attack surface reported in a recent systematic review of Web 3.0 cybersecurity incidents [34], which documents network-level interception, replay, and impersonation alongside Sybil attacks and phishing as recurring threats to decentralized systems. A quantum-capable adversary, who could in principle solve the ECDLP efficiently, is outside this classical threat model and is treated separately in Section IX. Under the classical model, the framework is designed to satisfy the following security requirements, which also structure the analysis in Section VI.

1) Mutual authentication: Both communicating entities should be able to verify each other's identity before any application data is exchanged.

2) Confidentiality: The character mapping and any plaintext exchanged should be unreadable to any party other than the intended recipient.

3) Integrity: any modification of the exchanged parameters or of the ciphertext during transmission must be detectable.

4) Resistance to replay: protocol messages captured in a previous session should not be reusable to impersonate a legitimate party in a new session.

5) Resistance to man-in-the-middle attacks: an adversary positioned between the two parties should not be able to establish independent, undetected sessions with each, provided the parties' long-term public keys are authentically bound to their claimed identities (Section VI-B); absent that binding, this requirement reduces to key-possession authentication rather than identity authentication (Section VI-B).

6) Pseudonymity and unlinkability: the protocol should not leak information that lets an observer link protocol messages to a real-world identity beyond what the parties intentionally disclose (pseudonymity), and, more strongly, should not let an observer tell whether two sessions involve the same party (unlinkability). As Section VI-E makes precise, this protocol targets pseudonymity by design — protocol messages carry curve points and digests, not identity attributes — but does not by itself provide unlinkability, since the long-term public keys Q_A and Q_B are reused, and hence observable, across sessions.

7) Ephemeral-session freshness: the encoding parameters used to authenticate each session should be freshly generated and distinct from those of any other session, rather than static, reusable secrets.

8) Forward secrecy: later compromise of a party's long-term private key should not allow an adversary to recover the encoding parameters, and hence the message-key material, of previously completed sessions.

9) Public-key-to-identity binding: because the protocol targets parties with no common certificate authority, an explicit external mechanism (Section VI-B) must bind each long-term public key to its claimed identity; absent that binding, mutual authentication establishes only that a peer holds a particular private key, not that the key belongs to a particular real-world or wallet identity.

Sections IV and X already draw several of the distinctions above individually; Table III collects them into a single in-scope/out-of-scope boundary for the Web 3.0-specific adversary conditions raised in the discussion of related work (Section II).

TABLE III. In-Scope and Out-of-Scope Adversary Capabilities

Adversary Class	Treatment in This Study
Network (Dolev–Yao)	In scope: full control of the channel (intercept, modify, replay, inject, block); cannot break ECDLP or invert the hash (Section IV).
Endpoint/wallet compromise (malicious wallet software, key exfiltration)	Out of scope for Sections VI-A – VI-D; partially mitigated by explicit ephemeral-key erasure (Section VI-D) but not modeled as an active capability.
Signing-request substitution / malicious dApps	Out of scope; assumed handled by wallet-level user-interface security, not by this protocol.
Phishing / social engineering	Out of scope (Section X).
Smart-contract vulnerabilities (reentrancy, logic errors)	Out of scope; an application-layer concern distinct from the authentication protocol.
Public blockchain linkability of long-term keys	Partially in scope: acknowledged as a residual pseudonymity limitation (Section VI-E), not defended against as a network-adversary capability.
Quantum adversary (Shor's algorithm)	Out of scope for the classical analysis of Sections IV - VIII; treated separately in Section IX.

V. Proposed Authentication Framework

The main operation in the proposed framework is elliptic-curve scalar multiplication. In a decentralized Web 3.0 network, two entities must authenticate each other before any data exchange takes place, and the authentication step itself must be resilient to active attacks such as man-in-the-middle interception and eavesdropping-based replay. The framework presented below is designed for constrained devices; whether it is lightweight in practice remains an empirical question requiring implementation-level benchmarking.

A. System Parameters and Key Generation

The proposed framework targets secp256k1 as its deployment curve, consistent with its use throughout the Web3/blockchain wallet ecosystem discussed in Section IX; the standardized domain parameters for secp256k1 are used directly rather than being restated here. In general, the elliptic curve E over a finite prime field is defined by the domain parameters T = (p, a, b, G, n, h), where p describes the underlying finite field, a and b define the shape of the curve, $G = (x_G, y_G)$ is the base

point, n is the order of G (the smallest positive integer such that $n \cdot G$ is the point at infinity), and h is the cofactor, $h = \#E(\mathbb{F}p)/n$, where $\#E(\mathbb{F}p)$ is the total number of points on E over $\mathbb{F}p$. The curve used in this work is cubic and is given by

$$y^2 + a_1xy + a_3y \equiv x^3 + a_2x^2 + a_4x + a_6 \pmod p \quad (1)$$

For $p > 3$ prime, the curve in Weierstrass form is

$$y^2 \equiv x^3 + ax + b \pmod p \quad (2)$$

where, $a, b \in \mathbb{F}p$ and $4a^3 + 27b^2 \neq 0$. This condition ensures that the curve is nonsingular. Each participant generates a private key k_A as a random integer and computes the corresponding public key $Q_A = k_A \cdot G$. The other participant similarly generates k_B and $Q_B = k_B \cdot G$, and the two public keys are exchanged over the (possibly adversarial) channel.

In addition to their long-term key pairs, B generates a fresh, single-use ephemeral key pair for each session: a scalar r_b and the corresponding point $R_b = r_b \cdot G$. R_b is published alongside Q_B during this same parameter-exchange step (its binding to B is subject to the same external-identity assumption as Q_B itself, Section VI-B). This per-session ephemeral point, rather than the long-term Q_B, is what the ECEG transport of Section V-C encrypts to, which is what gives the protocol forward secrecy (Section VI-D); B discards r_b once it has been used to recover a single message, so a later compromise of B's long-term key k_B does not expose past sessions' encoding parameters. In an interactive deployment, B generates R_b on demand for each new session; in a deployment where B must be able to receive a first message while offline, B instead publishes a small batch of one-time R_b values in advance and discards each one after its first use, following the same one-time-prekey pattern used in Signal's X3DH handshake.

This study adopts Schnorr signatures over secp256k1 (BIP-340 [44]) for $\mathrm{Sign}_k(\cdot)$ in Section V-C, rather than leaving the signature primitive unspecified: SHA-256 as the hash function, tagged hashes for domain separation between the different hash uses in the protocol, and a 64-byte fixed-size signature encoding. Nonces are generated deterministically from the signing key and message following BIP-340's synthetic-nonce procedure [44] (optionally mixed with fresh auxiliary randomness for side-channel hardening), the same deterministic-nonce principle standardized for ECDSA in RFC 6979 [45], which removes the catastrophic key-exposure risk that a biased or repeated per-signature random nonce creates in ECDSA-style schemes, and sidesteps ECDSA's $(r, -s)$ malleability without requiring a separate canonical-encoding rule. All received points — Q_A, Q_B, R_b, and any signature-carried commitment — are validated on receipt: each is checked to satisfy the curve equation, to differ from the point at infinity, and to lie in the correct order-n subgroup, following standard curve-point validation practice (SEC 1 [46]; NIST SP 800-186 [47]), before being used in any further computation.

B. Ephemeral ECEG Character Encoding

Before encryption, the plaintext message is processed using an Elliptic Curve ElGamal (ECEG) style encoding, extending the ephemeral mapping approach of [2]. Rather than exchanging a fixed lookup table between the 8-bit byte alphabet and points on the curve, each character is mapped, character by character, to a curve point using the scalar-multiplication relation

$$E_k = (\alpha \cdot k + \beta) \cdot G \quad (3)$$

where, k denotes the byte value (0–255) of the character being encoded, and α and β are two session-specific byte values jointly agreed upon by the sender and receiver during the encoding phase described below. Requiring a raw curve-point coordinate to already fall in (0, 255) is not usable on a 256-bit curve: both coordinates of a random point land in that range with probability on the order of 2^{-496}, making rejection sampling computationally infeasible. The sender therefore derives α and β from an ephemeral point with a hash-based key-derivation step, then re-encodes them as a curve point before transport (Section V-C requires a curve point, not an arbitrary integer pair), as follows.

Step 1: pick a random integer i.

Step 2: compute the ephemeral elliptic-curve point

$S = i \cdot G = (X_S, Y_S)$, where G is the generator point of the selected curve.

Step 3: derive the encoding parameters with a key-derivation function applied to the point's coordinates: $(\alpha, \beta) = \mathrm{Trunc}_{16}(\mathrm{hash}(X_S \,\|\, Y_S))$, i.e., take the first 16 bits of $\mathrm{hash}(X_S \,\|\, Y_S)$ and split them into two bytes α and β. If $\alpha = 0$, the sender discards the derived pair and regenerates i until $\alpha \neq 0$, ensuring that the byte-to-point mapping remains injective over the 256-byte alphabet.

Step 4: combine the two bytes into a single 16-bit integer $m = 256 \cdot \alpha + \beta$, and encode m as a curve point $M = \mathrm{EncodeToPoint}(m)$ using the integer-to-point technique of Koblitz [41]: for $j = 0, 1, 2, \ldots$, form the candidate x-coordinate $x = m \cdot K + j$ for a fixed public padding constant K chosen so that $m \cdot K$ stays far below p, and stop at the first j for which $x^3 + ax + b$ is a quadratic residue mod p, setting y to a square root of $x^3 + ax + b \bmod p$. Decoding reverses this: recover $m = \lfloor x / K \rfloor$ from M's x-coordinate, then split it back into $\alpha = \lfloor m / 256 \rfloor$ and $\beta = m \bmod 256$. Because roughly half of the field elements are quadratic residues, encoding succeeds within the first few values of j with overwhelming probability.

Only M – not α and β directly – is ever placed on the curve or on the channel; α and β themselves remain ordinary 16-bit integers used solely to build M, to form the signature input used in Section V-C, and to build the byte-to-curve-point mapping table. Because that reduction is only 16 bits wide, α and β are not by themselves a cryptographically strong secret – at that size they would be brute-forceable if ever exposed on their own. Their practical protection instead comes from the fact that they are only ever transported inside the authenticated ECEG ciphertext M of Section V-C, never sent in the clear; this trade-off is stated here explicitly rather than left implicit.

C. Signature- and Two-Ephemeral-Key ECEG-Based Mutual Authentication

Once α and β are generated and encoded as the curve point M of Section V-B, they must be transported to B and confirmed by both parties before either side uses them, without ever placing

(α, β) or M on the channel unencrypted, and with each party's authorship of its own messages bound to its long-term key pair rather than to any state carried over from a previous session. Every symbol below is defined once and used consistently with Fig. 5.

A picks a fresh ephemeral scalar r and forms the ECEG transport of M under B's per-session ephemeral point R_b (Section V-A) rather than under B's long-term Q_B: $C_1 = r \cdot G$, $C_2 = M + r \cdot R\_b$, $C = (C_1, C_2)$. A also generates a fresh, single-use session nonce N_a and computes a signature $\sigma\_a = \mathrm{Sign}_{k_A}(\mathrm{hash}(C \parallel N\_a \parallel Q_A \parallel Q_B \parallel R\_b))$ under its own long-term private key — binding the specific R_b used into the signed transcript so that a later substitution of R_b during the key-exchange step cannot go undetected — then sends (C, N_a, σ_a) to B. B first checks that N_a has not been seen before, rejecting the message as a replay if it has, and verifies σ_a against Q_A; if either check fails, B aborts before doing any further work on C, in particular before performing the ECEG decoding.

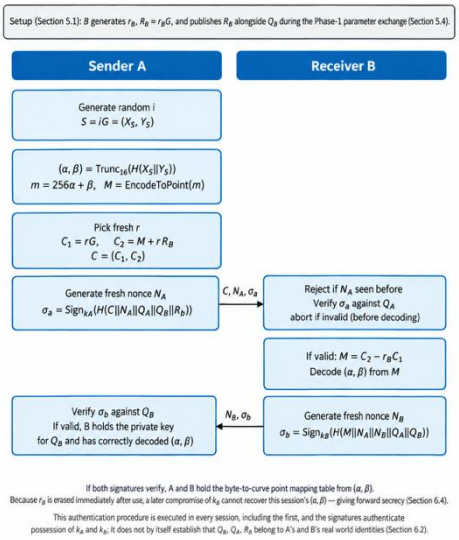

Fig. 5. Signature- and nonce-based mutual authentication and encoding parameter transport between sender A and receiver B.

If both checks succeed, B recovers $M = C_2 - r\_b \cdot C_1$ using the ephemeral scalar r_b generated for this session (Section V-I), then immediately erases r_b — the step that gives the protocol forward secrecy (Section VI-D), since nothing derivable from B's long-term key k_B can later reconstruct r_b or M — and decodes (α, β) from M as in Section V-B. B then generates its own fresh nonce N_b and computes $\sigma\_b = \mathrm{Sign}_{k_B}(\mathrm{hash}(M \parallel N\_a \parallel N\_b \parallel Q_A \parallel Q_B))$, and sends (N_b, σ_b) to A. A verifies σ_b against Q_B; if verification succeeds, A concludes that whoever holds the private key for Q_B received and correctly decoded (α, β), and both sides finalize the byte-to-curve-point mapping table used for subsequent character-by-character encryption.

This design authenticates each party as the holder of the long-term private key corresponding to its public key, in every session including the first: unlike a design that relies on shared history from a previous session, a valid signature cannot be produced without k_A or k_B regardless of whether A and B have interacted before, so it does not have the bootstrapping gap that a history-dependent check would have on a first encounter. It does not by itself establish that Q_A or Q_B belongs to the real-world identity it is claimed to represent; that binding is the external identity layer discussed in Section VI-B, but it does rule out an adversary who has not compromised either long-term key from completing the handshake under a false claim to already hold one of these keys. Freshness and replay-resistance rest on the per-session nonces N_a, N_b, which B and A each check against a short-lived record of recently used values, rather than on synchronized state carried over from a previous session; this also avoids the resynchronization problems (e.g., after a device restart or an interrupted session) that a previous-session-dependent design would otherwise create.

Both nonces are generated as 128-bit values from a cryptographically secure random-number generator, giving a collision probability across k sessions on the order of $k(k-1)/2 \times 2^{-128}$ by the birthday bound — negligible for any realistic session count. Each party retains a replay cache of nonces it has already seen and evicts each entry a fixed window after first recording it (tens of seconds to a few minutes, matching the round-trip tolerance conventionally used for challenge–response freshness, e.g., in Kerberos), so the cache size stays bounded by the message-arrival rate rather than growing without bound over the life of a long-lived identity; a replayed message that arrives after its originating entry has already been evicted is accepted as if fresh only if the underlying nonce happens to collide with a genuinely new one, which the birthday bound above rules out. After a restart, a party simply begins from an empty cache; a validator or wallet backend spanning multiple nodes shares this cache (or replicates it with bounded staleness) across nodes so that a replay accepted at one node is rejected at the others.

D. Protocol Execution

The protocol runs in three phases, as shown in Fig. 6. First, the shared elliptic-curve domain parameters are agreed upon by sender A and receiver B; long-term public keys Q_A and Q_B are exchanged, and B additionally generates and publishes a fresh, session-specific ephemeral point R_b (Section V-A); the binding of Q_A, Q_B, and R_b to A's and B's real-world identities is treated as an external assumption rather than established by this exchange itself, as discussed in Section VI-B. Second, the ephemeral encoding procedure of Section V-B is performed to produce α and β, which are transported under R_b rather than under B's long-term key and mutually confirmed using the signature- and nonce-based handshake of Section V-C; this step proves that each party holds the private key for its claimed long-term public key, in addition to confirming that B correctly recovered (α, β), and at the end of this stage both parties share the same session-specific encoding parameters, B has erased r_b (Section VI-D), and neither has exchanged the full byte-to-curve-point mapping table itself. Third, A encrypts the message character by character with the derived mapping and sends it to B as ciphertext; B has already recovered and decoded (α, β) in the previous phase and uses the resulting byte-to-curve-point mapping table to recover the original plaintext character by character.

This design reduces the risk of replay attacks, since authentication in each session depends on encoding parameters that combine fresh randomness with values distinct from any previous session; resistance to man-in-the-middle substitution

additionally requires the public-key binding discussed in Section VI-B. Even if an adversary intercepts the ciphertext components during transmission, recovering B's private key k_B, and, separately, recovering B's per-session ephemeral scalar r_b, from the intercepted values is computationally infeasible under the ECDLP hardness assumption discussed in Section VI, since the ephemeral points i·G, R_b = r_b·G, and the ciphertext component $C_1 = r \cdot G$ reveal only curve points, not the underlying scalars i, r, r_b, or k_B. The session's encoding attributes α and β are a different case, addressed in Section VI-A: at only 16 bits, they are not ECDLP-hard on their own, and are protected instead by never being sent except inside the encrypted transport M of Section V-C.

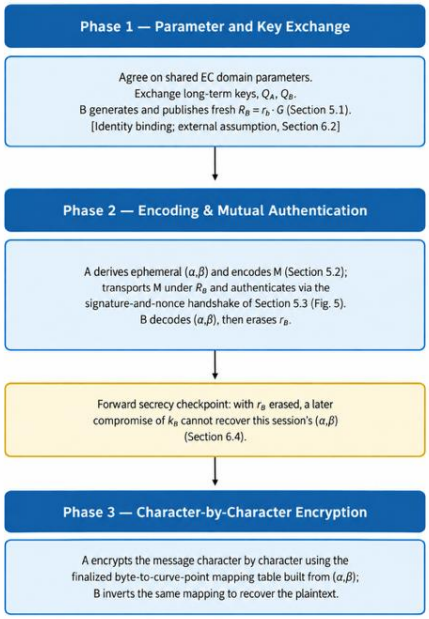

Fig. 6. End-to-end execution flow of the proposed ECEG authentication framework, including per-session signature verification.

VI. Security Analysis

This section gives an informal, assumption-based analysis of the protocol with respect to each requirement identified in Section IV. The analysis rests on the Dolev–Yao adversary model [33] and on the standard assumptions that the ECDLP is computationally hard for the chosen curve parameters and that the ECEG transport is IND-CPA secure under the relevant group assumption (e.g., DDH), while the hash function used in the signature inputs is preimage- and collision-resistant. Section VI-F then specifies a concrete plan for replacing this informal argument with a machine-checked one.

A. Resistance to Eavesdropping

An adversary eavesdropping on the channel sees only public curve points – e.g., Q_A, Q_B, ciphertext components, and hash/signature outputs. Recovering the long-term or ephemeral private scalars k_A, k_B, r_b, or i from these observations requires solving the ECDLP, which is assumed computationally infeasible for curves of appropriate size. The 16-bit pair (α, β) is a different matter: at only 2^{16} possible values it is not itself ECDLP-hard, and would be recoverable by exhaustive search from even a single known plaintext/ciphertext pair under a fixed encryption key. Its confidentiality therefore rests entirely on the semantic security (IND-CPA) of the ECEG transport that carries it — specifically, on the pair (r, R_b) never repeating across sessions (Sections V-A, V-C) — rather than on the small parameter space itself being hard to search; framed differently, the 16-bit encoding provides no obfuscation-level security on its own and should not be read as doing so. Because r and R_b are both freshly generated per session and never reused, each transport instance is independently randomized, so an eavesdropper who cannot invert the transport does not obtain (α, β) directly, and passive monitoring does not reveal the mapping used for the actual message.

B. Resistance to Man-in-the-Middle Attacks

The signature step of Section V-C means a man-in-the-middle adversary cannot forge a valid session on behalf of A or B without the corresponding long-term private key k_A or k_B: substituting tampered values for C, N_a, or N_b causes signature verification to fail, and the session aborts before either party acts on the forged data. What this check cannot do is establish that Q_A or Q_B belongs to the real-world identity it is claimed to represent in the first place. If an adversary presents its own key pair as Q_B at the very start of the exchange – before any signature has been exchanged – and A has no independent way to confirm that this Q_B is genuinely B's, A can complete a validly signed handshake with the adversary under the adversary's own key. This residual gap is a binding problem between identity and public key, not a weakness in the signature or key-transport steps themselves; closing it requires the external identity layer described next.

A concrete instantiation of this external identity layer, rather than an abstract placeholder, is available using the W3C Decentralized Identifier (DID) Core [42] and Verifiable Credential Data Model [43] standards, and integrates directly into the parameter exchange of Section V-D rather than sitting alongside it as a separate system. Each party publishes its long-term public key as the verification method of a DID document — for instance, under the did: key method, which encodes the public key directly in the identifier and needs no registry lookup, or under a ledger-anchored method such as did:ethr when linkage to an existing wallet address is required. A credential issuer that the verifying party already trusts (a prior counterparty, an organization, or any other chosen trust anchor) signs a verifiable credential attesting that a given DID controls a given real-world or wallet identity. During the exchange of Q_A, Q_B, and R_b in Section V-D's first phase, each party additionally presents its DID document and this credential; the peer checks the credential's issuer signature and confirms that the DID document's verification method matches the presented public key before proceeding to the signature-and-key-transport steps of Section V-C. This binds the specific public key used later in the handshake to a checked identity claim up front, rather than accepting whichever key arrives first, closing the substitution gap described above; the pattern of folding a DID/VC presentation directly into an existing handshake, rather than treating it as a separate protocol layer, follows the approach recently described for integrating DIDs and verifiable credentials into the TLS handshake [50].

This mechanism does not remove every trust assumption — it shifts the question from "is this public key really B's" to "is

this credential issuer trustworthy and is its signature currently valid," the same reduction any certificate- or credential-based scheme makes — but the resulting trust anchor is a credential issuer or prior relationship chosen by the parties themselves rather than a centralized certificate authority, consistent with the self-sovereign-identity setting motivating this study (Section I). Formally analyzing the combined system — the DID/VC presentation step together with the signature-and-key-transport handshake of Section V-C, as a single verified protocol rather than as two independently analyzed components — is identified as follow-up work in Section 10.

C. Resistance to Replay Attacks

Each session includes a fresh, single-use nonce (N_a from A, N_b from B, Section V-C), and both the signature and the confirmation checks are computed over values that include these nonces. An adversary who records a complete protocol transcript from one session and replays it in a later session presents a nonce that the recipient has already seen, so B's nonce check (or A's, for the return message) rejects it before any signature verification or ECEG decoding is attempted. Because this check happens first, a replayed message is cheap to reject; a flood of freshly-constructed but invalidly-signed messages is more expensive, since it still costs a signature verification per message, and defending against that kind of resource-exhaustion load is outside the assumption-based analysis in this section – rate limiting or a lightweight pre-filter would be needed in a production deployment (Section X).

D. Forward Secrecy and Key Compromise

Because α, β, the ephemeral scalar i used to derive them, and the per-session ephemeral scalars r and r_b (Section V-A, V-C) are all generated freshly for each session, none of them is a deterministic function of the long-term private keys k_A or k_B alone, so a device that is captured while offline does not thereby leak the encoding parameters of past sessions from its stored long-term key material. Unlike the static-key ECEG transport used in [3] and in an earlier draft of this protocol, the transport of Section V-C encrypts (α, β) under B's per-session ephemeral point $R_b = r_b \cdot G$ rather than under B's static Q_B, and B erases r_b immediately after using it to recover a single message. Consequently, an adversary who has recorded C_1 and C_2 from a past session and later obtains B's long-term private key k_B gains no advantage in reconstructing that session's r_b, since r_b is chosen independently of k_B and is not recoverable from R_b under the ECDLP hardness assumption; without r_b, the adversary cannot compute $r_b \cdot C_1$ and so cannot recover (α, β) from the recorded transcript. The protocol therefore provides forward secrecy against later compromise of a long-term private key, conditional on B genuinely erasing r_b after each session's single use — an explicit key-erasure assumption stated here rather than left implicit, and one that a production implementation must enforce (e.g., by zeroing the scalar's memory immediately after the single point multiplication that consumes it) for the property to hold in practice. This conditional guarantee, together with its formal counterpart in the verification plan of Section VI-F, replaces the unconditional absence of forward secrecy that an earlier, static-key version of this design would have inherited from [3]. The same forward-secrecy guarantee also requires A to erase its session-specific scalars i and r after the session completes; retaining either scalar would allow recovery of past session material from recorded data. Accordingly, the erasure condition is a protocol-state requirement for both parties, not only for B.

E. Anonymity and Residual Risks

The protocol limits what an on-path observer can learn about the identities involved in a given exchange, since the exchanged values are curve points and hash digests rather than identity attributes. Full anonymity in the sense used by self-sovereign identity systems, however, also depends on how public keys are bound to real-world identities at the application layer, for instance, through the decentralized-identifier/verifiable-credential mechanism integrated into the exchange in Section VI-B, which establishes identity binding but does not by itself change what an observer of the resulting public keys can infer. This distinction matters specifically for the Web 3.0 setting targeted here (Section II-D): unlike a provisioned IoT device with a fixed operator-known identity, a Web 3.0 wallet's long-term public key may itself be linkable across sessions through blockchain analysis even if this protocol's ephemeral parameters are not. Reasoning about that residual linkability is an application layer concern outside this study's scope, but it should be addressed jointly with the SSI layer in any deployment. The analysis in this section is informal rather than a machine-checked proof; Section VI-F identifies automated protocol verification as an important next step before the protocol is considered ready for production deployment.

F. Formal Verification Specification and Reproducibility Artifact

Sections VI-A – VI-E give an informal, assumption-based argument. To move beyond that argument, this subsection specifies a concrete formal-verification model and its required security queries, precisely enough to be encoded in Tamarin [54] as a supplementary reproducibility artifact without further design decisions. No such encoding has yet been produced or executed, and accordingly no machine-checked verification result is claimed in this study; preparing and running that encoding is identified as the immediate next step in Section X.

1) Adversary model: The standard Dolev–Yao network adversary of Section IV, in full control of the network and able to intercept, block, modify, replay, and inject messages, and able to compromise any number of protocol sessions but not the internal state of an honest party during a session, nor the long-term private keys k_A, k_B.

2) Tool and primitives: The specification below abstracts the two-ephemeral-key ECEG transport using a symbolic shared-point relation, rather than attempting to encode concrete secp256k1 point arithmetic. It treats the hash function as one-way and digital signatures through the verifier's signature primitives. Because the protocol no longer includes an XOR operation, the resulting model would not require XOR equational reasoning. Tamarin [54] is used as the reproducibility target; Scyther [25] remains relevant as the tool used to verify the closest prior art [3].

3) Protocol encoding: The roles of A and B are encoded as two processes exchanging exactly the messages of Section V-D, with fresh session-specific values (i, r, r_b) declared using

the tool's freshness construct so that each session uses independent randomness, while the long-term private keys k_A, k_B remain persistent across sessions, and with r_b scoped so the process has no further access to it once it has been used for a single decryption, modeling the explicit erasure required by Section VI-D.

Queries.

- Secrecy of α, β, r_b, k_A, and k_B: the adversary process must never derive these values, regardless of how many sessions run concurrently.
- Injective agreement (correspondence) between A and B on the tuple of session-specific values (α, β, R_b, and the session identifier), so that every session in which A completes with B corresponds to a distinct completed session of B with A — the standard formalization of both mutual authentication and replay resistance, with R_b included so that a substitution of the ephemeral point between phases is itself caught as a disagreement.
- Forward secrecy under long-term key compromise: secrecy of α and β from an already-completed session even after both parties' long-term private keys are revealed to the adversary once the session has ended, directly encoding the erasure-conditional guarantee argued informally in Section VI-D, rather than treated as an optional strengthening as it would have been for the earlier static-key design.
- Expected deliverable: A machine-checked verdict verified, or a concrete attack trace for each query above, together with the tool version and the model source, to be released as a supplementary artifact. Executing this plan and reporting its outcome, whichever it is, is identified in Section X as the immediate next step before the protocol can be considered validated beyond the assumption-based argument given in Sections VI-A – VI-E.

G. Security-Claim Summary

Table IV records, for each property discussed in Sections 6.1–6.6, the strongest claim this study makes and the assumption or limitation on which it rests. It is intentionally conservative: properties that depend on external identity binding or on an unexecuted validation step are marked conditional or not claimed rather than folded into an unqualified security statement.

TABLE IV. SECURITY-CLAIM SUMMARY FOR THE PROTOCOL OF SECTION V

Property	Status	Basis and limitation
Key-possession authentication	Claimed	Schnorr signatures over the current transcript (Section V-C); assumes uncompromised long-term keys and point validation (Section V-A).
Identity authentication	Conditional	Holds only after the DID/VC binding check of Section VI-B; depends on the chosen credential issuer / DID method.
MITM resistance	Conditional	Signatures block tampering after key selection; initial key substitution is prevented only by the identity binding of Section VI-B.
Replay resistance	Claimed	Fresh 128-bit nonces checked against a bounded replay cache (Section V-C); requires the stated cache window.
Confidentiality of (α,β)	Claimed	Rests on IND-CPA security of the ECEG transport with fresh (r, R_b) per session (Section VI-A); the 16-bit values are not secrets in themselves.
Forward secrecy	Conditional	Requires erasure of i and r by A and r_b by B after the session (Section VI-D).
Pseudonymity	Claimed	Messages carry curve points and digests, not identity attributes (Section VI-E).
Unlinkability/anonymity	Not claimed	Long-term keys, DIDs, and wallet addresses remain linkable across sessions (Sections IV, VI-E).
Machine-checked verification	Not claimed	Verification plan specified (Section VI-F); no verifier run reported in this study.
Empirical lightweight performance	Not claimed	Analytical operation count only (Table VI); no latency, energy, memory, or throughput measurements performed.
Post-quantum security	Not claimed	Classical ECC only; migration path outlined in Section IX.

VII. COMPUTATIONAL COMPLEXITY ANALYSIS

The efficiency analysis in this section separates generic RSA/ECC complexity from the protocol-level costs of the proposed scheme. The generic comparison is intended to show the security-to-key-size relationship; it is not a substitute for implementation-level benchmarking.

A. RSA Modular Exponentiation

The main computation of RSA is the modular exponentiation $c = m^e \bmod N$. Its cost under repeated squaring depends on n, the bit length of the modulus N (an upper bound on the number of modular multiplications), and M(n), the cost of a single big-integer multiplication or modular reduction. The total cost of modular exponentiation is therefore roughly $O(M(n)\cdot n)$. School-book multiplication gives $M(n) = O(n^2)$ and hence a rough bound of $O(n^3)$; more advanced algorithms such as Karatsuba or FFT-based multiplication improve the constant, and the exponent on M(n), but the dependence on n remains large, and n must typically be 2048 bits or more to reach an acceptable security level.

B. ECC Scalar Multiplication

The main computation in ECC is scalar multiplication $Q = k\cdot P$, realized through repeated point additions and doublings. Its cost depends on m, the bit length of the field elements used to

represent coordinates (the number of point operations is proportional to m), and M(m), the cost of one field multiplication. This gives a total scalar-multiplication cost of order O(M(m)·m), a bound of similar form to O(m³) under naive field multiplication. The key difference is that m can be substantially smaller than n while still achieving the same security level, as Table V shows, which reduces key representation and can reduce the cost of corresponding public-key operations; actual runtime and energy benefits depend on implementation, hardware, and library choices and are not measured here. Values follow NIST SP 800-57 Part 1 Revision 5 [31].

TABLE V. COMPARABLE SECURITY LEVEL: ECC KEY SIZE VERSUS RSA KEY SIZE

Security Level (bits)	ECC Field Size (bits)	RSA Key Size (bits)
256	512+	15,360
192	384–511	7,680
128	256–383	3,072
112	224–255	2,048
80	160–223	1,024

As Table V and Fig. 7 show, the RSA key size is 3072 bits for a 128-bit security level, while the corresponding ECC key size is only 256 to 383 bits. The difference widens further at higher security levels: a 256-bit security level requires an RSA key of roughly 15,360 bits, versus an ECC key of 512 bits or more. Under the naive-multiplication model, both schemes have cost growing with the cube of the key length, but the ECC key length required grows much more slowly than the RSA key length required as the target security level increases. This supports the use of ECC where storage and communication overhead matter, but it does not establish lower end-to-end runtime for the complete protocol; that requires empirical measurement.

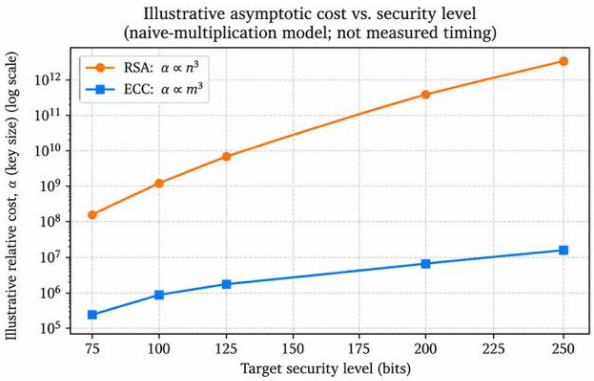

Fig. 7. Illustrative asymptotic cost of RSA and ECC as a function of target security level.

C. Protocol-Level Operation Count and Communication Cost

The comparison in Sections VII-A – VII-B evaluates generic RSA and ECC operations rather than the protocol proposed in Section V itself. Table VI instead counts, directly from the specification of Sections V-A – V-D, every EC scalar multiplication, signature operation, hash evaluation, message, and byte of state that one completed session requires of each party.

TABLE VI. PER-SESSION OPERATION COUNT FOR THE PROTOCOL OF SECTION V

Operation (per completed session)	A	B
EC scalar multiplications, total (handshake, incl. Schnorr)	6	5
Byte-to-point table construction (one-time per session)	256	256
Signature generations	1	1
Signature verifications	1	1
Explicit SHA-256 hash/KDF evaluations (protocol)	2	1
Messages sent (handshake only)	1	1
Bytes transmitted (handshake only)	≈ 146 B	≈ 80 B
Long-term key state	k_A + Q_B	k_B + replay cache

The scalar-multiplication total breaks down as follows: for A, i·G (encoding, Section V-B) + r·G + r·R_b (Section V-C) + 1 scalar multiplication for generating σ_A + 2 for verifying σ_B (Schnorr verification counted conservatively as two scalar multiplications in the unbatched verification equation) = 6. For B, r_b·G (Section V-A) + r_b·C₁ (Section V-C) + 1 scalar multiplication for generating σ_B + 2 for verifying σ_A = 5. These totals therefore include the elliptic-curve work performed inside the Schnorr signature operations; the signature-generation and signature-verification columns in Table VI report those operations separately for clarity. An implementation using multi-scalar-multiplication techniques can reduce verification cost. The 256-entry byte-to-point table is built once per session and then reused for every character of the message by table lookup, so its construction cost is independent of message length L rather than growing with it. Persistent state is dominated by the 32-byte long-term private key on each side; B additionally holds a bounded replay cache (Section V-C). Table VI's message and byte counts cover only the cryptographic authentication phase and exclude Phase-1 domain/key exchange and DID/VC presentation overhead.

A separate communication cost, not included in the handshake byte count in Table VI, is the bandwidth expansion of the character-level ECEG encryption in Section V-D's third phase: each plaintext byte is represented on the wire as a full secp256k1 curve point, 33 bytes compressed or 65 bytes uncompressed, a 33× to 65× expansion over the one byte of plaintext it carries. A conventional hybrid alternative — using the already-established per-session shared point r·R_b (Section V-C) to key a symmetric authenticated cipher such as AES-GCM or ChaCha20-Poly1305 for the bulk message, as Section III describes for ECIES — would instead add only a small constant-size tag (typically 16 bytes) regardless of message length, with no per-character point encoding. This study retains character-level ECEG encoding because it is the specific mechanism inherited from [2,3] that the threat model and verification plan of Sections IV and VI-F are built around; a deployment that prioritizes bandwidth over continuity with that

prior design should instead use the hybrid AEAD construction for the bulk message while keeping the ECEG-over-two-ephemeral-key transport of Section V-C for the (α,β) handshake itself.

Published implementation-level benchmarks corroborate the direction, though not the exact magnitude, of the efficiency argument above: Hammi et al. [48] propose a lightweight ECC-based mutual authentication scheme for IoT and report it as computationally and communication-efficient relative to prior IoT authentication schemes on constrained hardware, in the same general direction as the asymptotic argument of Sections VII-A – VII-B, though that study does not benchmark against RSA directly; Li and Hu [49] report a fresh ECC-based IoT authentication and key agreement protocol reducing computational overhead by more than 37% and communication cost by more than 5% relative to prior schemes, using a per-session operation-count methodology similar in spirit to Table VI. Neither benchmark is of the protocol proposed in this study, so they are cited as external corroboration of the general ECC-efficiency direction rather than as a substitute for the hardware benchmarking identified as future work in Section X.

VIII. Discussion

The analyses of Sections VI and VII lead to two complementary conclusions. From a security standpoint, tying authentication to ephemeral, session-unique parameters instead of static secrets, and grounding that design in the ECDLP hardness assumption, is intended to make eavesdropping and replay harder for an adversary limited to the Dolev–Yao model of Section IV, without requiring a common certificate authority; resistance to man-in-the-middle interception additionally depends on the public-key binding discussed in Section VI-B. From an efficiency standpoint, the asymptotic and key-size comparisons in Section VII support the well-known ECC security-to-key-size advantage, though actual end-to-end performance depends on implementation, hardware, and library choices not measured here.

These security and representation-size properties are complementary rather than independent: the relatively small ECC keys and points make per-session ephemeral operations practical to consider on constrained devices, while the actual cost of the proposed ECEG encoding and signature-based handshake remains an empirical question. The security properties described in Section VI therefore should not be inferred from key-size ratios alone.

As discussed in Section II-B, the framework's relationship to the closest prior art [3] is best understood as an adaptation at two levels rather than a wholesale new cryptographic mechanism: both protocols inherit the same ephemeral ECEG character-encoding step from [2], rather than a static, exchanged lookup table or a static identity-bound key exchange as in several of the RFID and smart-card schemes reviewed in Section II [4,5,9,10]. Beyond that shared encoding step, however, the two protocols diverge: [3] transports the encoding parameters under a static recipient key and confirms them with a hash-and-XOR value chained to the previous session, whereas this study authenticates each party with digital signatures over its long-term key and transports the encoding parameters under a fresh per-session ephemeral key (Section V-C), which is what closes the forward-secrecy gap identified in Table I. What this study adds on top of that protocol-level change is the explicit threat model, the pseudonymity/unlinkability analysis, the concrete DID/VC identity-binding mechanism (Section VI-B), and the verification plan needed to argue that the resulting design is appropriate specifically for Web 3.0 peer-to-peer interactions, where the two interacting parties may have no previously established trust relationship and no common certificate authority.

IX. Post-Quantum Outlook

The security analysis in Section VI and the efficiency case in Section VII both rest on a classical adversary: one that cannot efficiently solve the Elliptic Curve Discrete Logarithm Problem (ECDLP). A quantum adversary running Shor's algorithm can, in principle, solve the ECDLP in polynomial time, and 2025–2026 has seen rapid, concrete progress in estimating exactly how many quantum resources that would take for the curve sizes relevant to Web 3.0. This section situates the proposed framework against that fast-moving picture, states plainly what it implies for the protocol proposed here, and outlines a migration path consistent with current NIST guidance.

A. The Narrowing Quantum Resource Gap for ECDLP

TABLE VII. Successive 2020–2026 Estimates of the Logical Qubits Needed to Solve the 256-Bit Elliptic-Curve Discrete Logarithm Problem on a Prime-Field Curve

Source	Year	Venue / Status	Logical Qubits (256-bit curve)
Häner et al. [PQCrypto 2020]	2020	Peer-reviewed (PQCrypto 2020)	≈ 2124
[35]	2026	Peer-reviewed (PRX Quantum 2026)	< 1200–1450
[36]	2026	Peer-reviewed (EUROCRYPT 2026)	≈ 1193
[37]	2026	Preprint (arXiv)	≈ 1333
Häner et al. [51]	2026	Preprint (IACR ePrint / arXiv)	≈ 1450 (19,397 physical qubits; ~25.7 days)

Table VII summarizes successive 2026 reductions in the estimated number of logical qubits needed to solve the 256-bit ECDLP on a prime-field curve such as secp256k1, the curve family underlying most Web3 wallets and curves in the same security class as those discussed in this study. Babbush et al. [35], a Google Quantum AI, Ethereum Foundation, and Stanford collaboration, reported that Shor's algorithm for this problem can execute with either fewer than 1200 logical qubits and fewer than 90 million Toffoli gates, or fewer than 1450 logical qubits and fewer than 70 million Toffoli gates, running in minutes on fewer than half a million physical qubits at a 10^{-3} error rate. Chevignard, Fouque, and Schrottenloher [36], published in the peer-reviewed EUROCRYPT 2026 proceedings, independently reduced the estimate to roughly 1193 logical qubits, below the qubit count separately estimated for factoring 3072-bit RSA; Luo et al. [37] independently reduced the earlier estimate of roughly 2124 qubits reported by Häner et al. to about 1333. None of these results has been demonstrated on physical hardware at the required scale, but the direction is unambiguous: multiple independent groups converged on roughly the same 1200–1450-qubit range within a few months of each other in

2026, down from the prior benchmark of over 2100 qubits. A September 2026 estimate by Häner et al. [51] translates a comparable logical-qubit count into a physical-hardware figure for a trapped-ion architecture: roughly 19,397 physical qubits solving the same problem in approximately 25.7 days, down from prior trapped-ion estimates of 1.2 to 9.4 million physical qubits. As preprints or very recent results, these figures should be read as a fast-moving direction rather than a settled number; the recommendation in Section IX. C is unaffected by exactly which proves most durable.

Figures are as reported by each source; none has been demonstrated on physical quantum hardware at the scale required, and estimation methodology differs slightly across sources.

B. Implications for this Framework

The framework proposed in this study is, like essentially all currently deployed Web 3.0 authentication and wallet infrastructure, built entirely on classical ECC and therefore offers no protection against a sufficiently capable quantum adversary: such an adversary could recover a party's private key k_A or k_B from its public key, and could therefore forge the mutual-authentication handshake of Section V-C outright, independent of the ephemeral, session-unique design that protects against the classical replay and man-in-the-middle attacks analyzed in Section VI. A further, distinct risk is "harvest-now, decrypt-later": an adversary who records protocol transcripts or on-chain public keys today could decrypt or forge against them retroactively once a cryptographically relevant quantum computer exists, which matters specifically for long-lived Web 3.0 identities that are expected to remain valid for years. It is important to be precise about what current estimates do and do not show: no cryptographically relevant quantum computer capable of running these circuits exists today, and the qubit counts in Table VII, while dropping quickly, remain roughly three orders of magnitude beyond current hardware. The risk this section addresses is therefore one of migration planning, not of an immediate break.

C. Standards Guidance and a Migration Path

NIST finalized the first three post-quantum cryptography standards in August 2024: FIPS 203 (ML-KEM, a module-lattice key-encapsulation mechanism), FIPS 204 (ML-DSA, a module-lattice digital signature scheme), and FIPS 205 (SLH-DSA, a stateless hash-based digital signature scheme) [38]. NIST Internal Report 8547 (initial public draft) sets out a migration timeline in which algorithms providing 112-bit classical security, including RSA-2048 and ECC P-256, are to be deprecated after 2030 and disallowed after 2035, with the same disallowance date applying to higher-strength classical public-key algorithms including the curves discussed in this study [32]. Read against that timeline, the ECC-based framework proposed here remains an appropriate near- and medium-term choice, consistent with current NIST guidance, but it is not a long-term end state.

A practical migration path, consistent with how the wider field is approaching this problem, is a hybrid construction rather than a wholesale redesign: retaining the ephemeral ECEG encoding and signature-based handshake of Section V for their efficiency and their resistance to classical replay and man-in-the-middle attacks, while wrapping the long-term key-establishment step in a post-quantum key-encapsulation mechanism such as ML-KEM, so that an adversary must break both the classical and post-quantum components to succeed. Recent quantum-resistant self-sovereign-identity frameworks [39,40] establish precedent for this pattern by layering NIST-standardized post-quantum primitives onto a decentralized identity architecture; designing and evaluating a concrete hybrid variant of the present framework along these lines, rather than merely outlining the path as this section does, is identified as future work in Section X.

X. Limitations and Future Work

The evaluation in this study is analytic rather than empirical: the security discussion in Section VI is an informal argument based on standard cryptographic hardness assumptions rather than a machine-checked proof, and the efficiency discussion in Section VII is based on asymptotic complexity and established key-size equivalences rather than measured execution time on physical hardware. This limitation directly implies five concrete directions for follow-up work.

1) Formal verification of the protocol. The plan of Section VI-F should be encoded in Tamarin [54] and run against the documented queries for mutual authentication, replay resistance, secrecy, and erasure-conditional forward secrecy. The present manuscript reports no machine-checked verdict because that encoding has not yet been produced or executed.

2) Formal and empirical validation of the identity-binding mechanism. The DID/VC binding of Section VI-B is specified concretely but has not been analyzed as part of a single verified system together with the signature-and-key-transport handshake of Section V-C, nor implemented against a live DID method (e.g., did: key or did:ethr) to measure the latency and message-size overhead the credential-presentation step adds to the base handshake of Table VI.

3) Hardware benchmarking. To confirm the asymptotic gains of Section VII under practical operating conditions rather than theoretical bounds, the protocol should be implemented on representative resource-constrained platforms, such as microcontroller-class IoT devices or embedded wallet hardware, with measured wall-clock execution time, memory usage, and energy consumption, reported against the same curve parameters and RSA baseline used by the closest prior art [3] to allow a direct, like-for-like comparison rather than a comparison of asymptotic bounds alone.

4) Integration with anomaly detection. The authentication layer could be supplemented with a separate anomaly-detection mechanism, such as the machine-learning-based approach studied for cloud data in [27], to recognize statistically unexpected authentication patterns, for example, an unusually high number of failed handshakes even when each individual attempt is cryptographically valid.

5) Hybrid post-quantum migration. As Section IX discusses, a concrete hybrid variant of the protocol that wraps the long-term key-establishment step in a NIST-standardized post-quantum key-encapsulation mechanism such as ML-KEM

[38] should be designed and evaluated, following the precedent of recent quantum-resistant self-sovereign-identity frameworks [39,40], so that the protocol's classical efficiency advantages are retained in the near term without leaving it exposed once quantum resource estimates such as those in Table VII are realized in hardware.

The present framework addresses authentication and identity binding only. It does not address smart-contract-level vulnerabilities such as reentrancy or logic errors, nor the social-engineering component of attacks such as rug pulls, which rely on manipulating user decisions rather than defeating the cryptographic layer. These are complementary areas of defense that remain necessary for a complete Web 3.0 security posture and are outside the scope of the authentication mechanism proposed here. Finally, as Section VI-E notes, full anonymity in the self-sovereign-identity sense also depends on the application-layer binding between public keys and real-world identity, which this protocol does not itself provide and which should be addressed jointly with a DID/verifiable-credential layer in any deployment.

XI. Conclusion

This study presented an authentication framework for decentralized Web 3.0 environments, built around Elliptic Curve Cryptography, an ephemeral Elliptic Curve ElGamal encoding scheme, and a mutual-authentication handshake that combines digital signatures over each party's long-term key with a two-ephemeral-key ECEG transport of the encoding parameters. The framework was evaluated against an explicit Dolev–Yao threat model with an explicit in-scope/out-of-scope adversary boundary (Table III); the informal security analysis indicates resistance to passive eavesdropping, replay, and, conditional on ephemeral-key erasure, later compromise of a long-term key, attributable to session-unique ephemeral parameters bound by the hardness of the Elliptic Curve Discrete Logarithm Problem. Resistance to man-in-the-middle substitution additionally requires the authenticated binding between long-term public keys and identities that Section VI-B supplies through a concrete decentralized-identifier/verifiable-credential mechanism. A protocol-level operation count and a computational complexity comparison against RSA, checked against the current NIST SP 800-57 equivalence table, showed the ECC security-to-key-size advantage while making clear that complete-protocol runtime, energy, and bandwidth performance remain to be established experimentally.

As Section II-D makes explicit, the ephemeral ECEG character-encoding step builds directly on prior work [2,3]; this study's own contribution is the protocol-level replacement of that prior work's static-key parameter transport with a signature-and-two-ephemeral-key-ECEG construction, together with the explicit Web 3.0-specific threat model, the DID/VC identity-binding mechanism, the requirements analysis, and the concrete formal-verification plan of Section VI-F built around it. Section IX further situated the framework's classical ECC foundation against the rapidly narrowing 2025–2026 quantum resource estimates for the elliptic-curve discrete logarithm problem — including a September 2026 physical-hardware estimate of roughly 19,397 qubits — and against current NIST post-quantum migration guidance, concluding that the framework remains an appropriate near- and medium-term choice but should be extended with a hybrid post-quantum key-establishment step ahead of the 2030–2035 deprecation horizon. Because the present evaluation is analytical, the five next steps identified in Section X — formal protocol verification, hardware-based benchmarking, anomaly-detection integration, hybrid post-quantum migration, and formal/empirical validation of the identity-binding mechanism — are necessary before the framework can be considered validated for production deployment. Subject to that validation, the proposed approach offers a practical building block for strengthening authentication and mitigating identity theft, phishing, and unauthorized access in self-sovereign, user-centric Web 3.0 identity ecosystems.

Automated Generation of Arabic Procedural Court Orders in the Moroccan Legal Context

Saliha Yassine, Mohammed Essoujaa, Mustapha Esghir, Ouafaa Ibrihich
Faculty of Sciences, Mohammed V University in Rabat, Laboratory MIA-SI, Rabat, Morocco

***Abstract*—Automating the drafting of legal documents can reduce repetitive judicial workload and support procedural efficiency in e-Justice systems. However, Arabic legal text generation remains underexplored, particularly for Moroccan procedural court orders, which are characterized by highly structured language and recurring legal formulations. This study compares retrieval-based and transformer-based approaches for generating Moroccan procedural court orders using a corpus of 4,098 authentic orders collected from 2020 to 2025. Three approaches are evaluated: a TF-IDF-based Template Baseline, AraBART, and AraT5. A random stratified split and a stricter template-disjoint evaluation are used to assess both performance and generalization. Under the random split, the Template Baseline achieves the highest BLEU score (87.39), followed by AraBART (77.33) and AraT5 (51.88). In contrast, under the template-disjoint setting, AraBART outperforms the Template Baseline, achieving BLEU scores of 68.00 and 63.67, respectively, with a statistically significant difference ($p = 0.004$). These findings demonstrate that retrieval-based generation can benefit from repeated legal templates, whereas AraBART achieves better performance under the template-disjoint setting when exact templates are absent. The results highlight the importance of evaluation design and corpus structure when selecting generation approaches for standardized legal documents. A conceptual hybrid strategy combining retrieval, neural generation, and human validation is proposed for future e-Justice applications.**

Keywords*—Arabic legal NLP; legal text generation; moroccan procedural court orders; retrieval-based generation; AraBART; AraT5; e-Justice

I. Introduction

The rapid digitalization of judicial systems has increased interest in Artificial Intelligence (AI) and Natural Language Processing (NLP) technologies for supporting judicial document drafting and administrative procedures. In Morocco, procedural court orders constitute an essential component of judicial administration, supporting routine legal procedures such as payment orders, notifications, deposits, and other administrative decisions. Unlike judicial judgments, these documents are generally concise, highly structured, and frequently follow standardized legal formulations. Automating their drafting has the potential to improve document consistency, accelerate routine judicial procedures, and support the development of intelligent e-Justice services while allowing legal professionals to focus on more complex judicial tasks [24].

Recent advances in transformer-based models and large language models have significantly improved automatic text generation across numerous domains, including legal NLP [1]. Arabic generative models such as AraBART and AraT5 have demonstrated promising performance by leveraging large-scale pretraining and contextual language representations. However, applying these models to procedural legal documents presents a unique challenge. Because many procedural court orders contain recurring legal expressions and standardized templates, it remains unclear whether computationally intensive neural generation models consistently provide advantages over simpler retrieval-based approaches. Consequently, selecting the most appropriate generation paradigm depends not only on the model architecture but also on the intrinsic characteristics of the legal corpus.

Existing research on legal text generation has primarily focused on judgment summarization, legal question answering, statute retrieval, and general legal document drafting, with most studies conducted for English- or Chinese-language legal systems. Arabic legal NLP remains comparatively underexplored, particularly for generative tasks involving authentic judicial documents. Although recent Arabic transformer models, including AraBART and AraT5, have achieved encouraging results across several natural language generation tasks, their effectiveness for generating procedural court orders has received little attention. Furthermore, previous studies rarely examine how corpus repetitiveness influences the comparative performance of retrieval-based and neural generation methods in highly standardized legal domains.

This observation reveals an important research gap. To the best of our knowledge, no prior study has reported a systematic comparison of retrieval-based and transformer-based generation for Moroccan procedural court orders while explicitly analyzing the influence of corpus repetition on model selection. Addressing this question is particularly important because highly repetitive legal corpora may favor retrieval-based methods when relevant templates are available in the retrieval database, whereas neural generation models may achieve better performance when exact decision templates are absent from the training data. Understanding this trade-off is essential for designing efficient, reliable, and practically deployable legal text generation systems for Moroccan courts and other legal environments characterized by standardized procedural documents.

To address this research gap, this study presents a comprehensive comparative study of retrieval-based and transformer-based approaches for generating Moroccan procedural court orders. Rather than assuming that increasingly complex neural models always produce superior results, this work investigates how corpus characteristics, particularly the degree of textual repetition, influence the effectiveness of different generation paradigms.

The main contributions of this study are summarized as follows:

- Use and systematic characterization of a corpus comprising 4,098 authentic Moroccan procedural court orders from 2020 to 2025, representing a systematically described dataset for Arabic legal text generation in this domain.
- Comprehensive comparative evaluation of a TF-IDF-based Template Baseline, AraBART, and AraT5 using complementary automatic evaluation metrics, enabling a systematic assessment of retrieval-based and transformer-based generation methods.
- Corpus repetition analysis demonstrating how the degree of textual repetition affects the relative performance of retrieval-based and transformer-based generation across different evaluation settings.
- A conceptual hybrid generation strategy derived from the experimental findings, recommending retrieval-based generation for highly repetitive cases and transformer models for more diverse drafting scenarios under human supervision, providing guidance for future intelligent e-Justice systems.

The remainder of this study is organized as follows. Section II reviews related work on Arabic legal NLP and legal text generation. Section III describes the proposed methodology, including corpus construction, preprocessing, generation models, and evaluation metrics. Section IV presents and discusses the experimental results. Finally, Section V concludes the study and outlines directions for future research.

II. Related Work

Legal Natural Language Processing (Legal NLP) has rapidly evolved from rule-based systems to transformer-based architectures, enabling significant advances in legal document classification, information extraction, judgment prediction, and text generation. Among these tasks, legal text generation has recently attracted increasing attention because of its potential to support judicial drafting, reduce repetitive workload, and improve the efficiency of e-Justice systems.

Domain-specific pre-training has proven effective across various legal NLP applications. LEGAL-BERT [2], which builds upon the BERT architecture [20], achieves strong performance for European court judgment prediction, while Zhong et al. [3] examined the application of NLP methods to several tasks in the Chinese legal system. Large-scale legal datasets such as CAIL2018 [16] have further supported research on judgment prediction. In legal text generation, Feijo et al. [4] demonstrated the feasibility of GPT-2 for automatic contract generation in Brazilian law. In the Arabic NLP domain, AraBERT [5] established a strong baseline for Arabic language understanding, whereas AraBART [6] and AraT5 [7] introduced transformer-based sequence-to-sequence architectures that have shown promising performance in Arabic text generation and summarization tasks. AraBART is grounded in the BART architecture [17] and AraT5 in the T5 text-to-text framework [18], both building on the foundational Transformer architecture [21]. Bidirectional Arabic pretraining models such as ARBERT and MARBERT [22] and comprehensive Arabic NLP resources [25] have further supported the development of these models.

Retrieval-based and case-based approaches have also been explored as alternatives to fully generative systems, particularly in domains where documents exhibit strong structural regularities. Such approaches can preserve established domain-specific formulations by reusing previously validated outputs. However, their effectiveness for Moroccan procedural court orders in Arabic has not been systematically compared with neural generation models.

More recently, large language models and retrieval-enhanced generation have further expanded the potential of legal text generation. General-purpose LLMs such as GPT-3 [23] and Llama 2 [8] and retrieval-augmented generation frameworks [9] illustrate the growing trend toward combining knowledge retrieval with neural generation. Dedicated benchmarks such as LegalBench-RAG [10] and Arabic-specific models such as AceGPT [11] further demonstrate the breadth of this research landscape. Although these approaches are promising, their application to highly standardized Arabic procedural court orders remains largely unexplored. Table I summarizes representative studies in Legal NLP and Arabic text generation. Existing research has mainly focused on legal judgment prediction, legal document classification, contract generation, and general-purpose Arabic text generation. However, the automatic generation of Moroccan procedural court orders has not yet been systematically investigated. Moreover, previous studies have not examined how corpus repetitiveness influences the relative effectiveness of retrieval-based and transformer-based generation approaches. To address this gap, the present work investigates how corpus repetitiveness influences the comparative performance of retrieval-based and transformer-based generation, providing practical guidance for designing efficient Arabic legal text generation systems for highly structured legal domains.

TABLE I. Representative Studies in Legal NLP and Arabic Text Generation

Study	Domain	Task	Main Method
Chalkidis et al. [2]	EU courts	Judgment prediction	LEGAL-BERT
Zhong et al. [3]	Chinese legal system	Multiple legal NLP tasks	Legal NLP methods
Feijo et al. [4]	Brazilian law	Contract generation	GPT-2
Antoun et al. [5]	Arabic NLP	Text classification	AraBERT
Kamal et al. [6]	Arabic NLP	Text generation	AraBART
Nagoudi et al. [7]	Arabic NLP	Text generation	AraT5
Sulea et al. [12]	French law	Legal classification	SVM + TF-IDF
Medvedeva et al. [13]	ECHR	Decision prediction	Linear SVM + textual n-grams

Although transformer-based models have demonstrated strong performance in Arabic text generation, their application to highly repetitive procedural legal documents raises a methodological question: whether generative flexibility provides a genuine advantage when valid judicial formulations

are already available in historical records. Retrieval-based approaches preserve established legal formulations and can reduce the risk of generative deviations at low computational cost, but they are limited in their ability to generate formulations unseen in the training corpus. Transformer-based approaches offer greater generative flexibility and can adapt to novel inputs, but remain exposed to hallucination and semantic deviation. This trade-off motivates the use of TF-IDF character n-gram retrieval, rather than a purely generative approach, as a baseline for highly standardized procedural court orders.

III. METHOD

A. Dataset

We compiled a corpus of 4,098 authentic Moroccan procedural court orders issued by first-instance courts between 2020 and 2025. The corpus was previously used for a classification study of Moroccan procedural court orders [26]; the present work addresses a distinct research question focused on automatic text generation and the comparative analysis of retrieval-based and transformer-based approaches. Each document consists of two main sections: faits (procedural facts describing the legal request) and décision (the judicial ruling issued by the court). In this study, the faits section serves as the input to all generation models, while the corresponding décision is used as the reference output during training and evaluation. Table II summarizes the main characteristics of the corpus. The corpus covers four procedural categories representing the most frequent types of procedural court orders handled by Moroccan first-instance courts.

TABLE II. CORPUS STATISTICS

Statistic	Value
Total documents	4,098
Training set	3,278 (80%)
Validation set	410 (10%)
Test set	410 (10%)
Average facts length (characters)	323
Average decision length (characters)	159
Number of procedural categories	4
Global repetition rate (training set)	64.0%
Random seed	42

To ensure a fair, reproducible, and representative evaluation, the corpus was partitioned using a stratified 80/10/10 split, resulting in 3,278 training documents, 410 validation documents, and 410 test documents. Stratification preserves the distribution of procedural categories across all subsets, while a fixed random seed (42) ensures the reproducibility of the data partition. Because the corpus contains repeated judicial formulations, the random stratified split may place identical decision formulations in both the training and test sets. This setting reflects the intended retrieval scenario but may favor retrieval-based methods on highly standardized cases. To address this limitation, an additional template-disjoint evaluation was conducted. Decision texts were grouped by their exact string content after normalizing whitespace, and a group-based split (scikit-learn's GroupShuffleSplit) was used to ensure that all documents sharing an identical decision formulation were assigned entirely to the same subset (training, validation, or test), thereby preventing any decision string from appearing in more than one split.

This evaluation provides a more stringent assessment of generalization beyond previously observed judicial templates. The resulting template-disjoint partition contained 3,364 training documents, 354 validation documents, and 380 test documents.

B. Corpus Analysis: Repetition Structure

A preliminary analysis of the training corpus reveals a global repetition rate of 64.0%, corresponding to 1,180 unique judicial decisions among 3,278 training documents. In this study, a repeated decision refers to an identical judicial ruling appearing in multiple procedural court orders after whitespace normalization. The repetition rate was computed by comparing unique decision texts within each procedural category, providing a quantitative measure of the degree of standardization in judicial drafting.

Fig. 1 illustrates the distribution of procedural categories in the training set, while Table III summarizes the corresponding repetition rates, showing that rejection orders exhibit the highest repetition (89.9%), followed by validation-of-warning orders (75.9%). In contrast, payment orders show considerably greater textual diversity, with a repetition rate of only 27.0%.

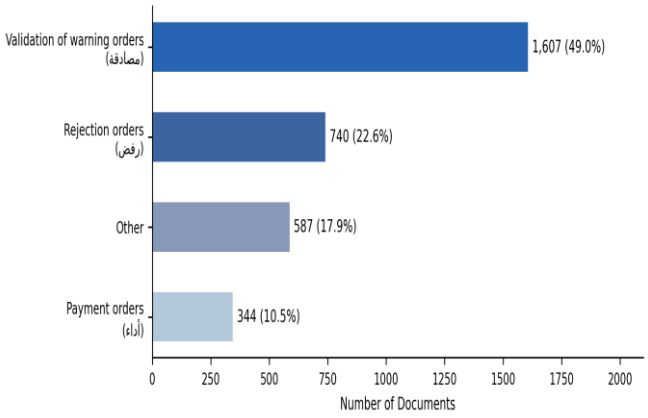

Fig. 1. Distribution of procedural court order categories in the training set (n = 3,278).

TABLE III. REPETITION ANALYSIS OF THE TRAINING CORPUS BY PROCEDURAL CATEGORY

Category	Documents	Unique Decisions	Repetition Rate (%)
Validation of warning orders (مصادقة)	1,607	388	75.9%
Rejection orders (رفض)	740	75	89.9%
Payment orders (أداء)	344	251	27.0%
Other	587	466	20.6%
Total (training set)	3,278	1,180	64.0%

These observations indicate that corpus repetition is a key factor in selecting an appropriate generation paradigm and

motivate the inclusion of a retrieval-based Template Baseline in the comparative evaluation.

Rejection orders exhibit the highest repetition rate (89.9%), reflecting the highly formulaic nature of procedural refusals under Moroccan procedural law. Validation-of-warning orders (75.9%) follow a similarly standardized structure. This observation explains the strong performance of the Template Baseline.

C. Systems

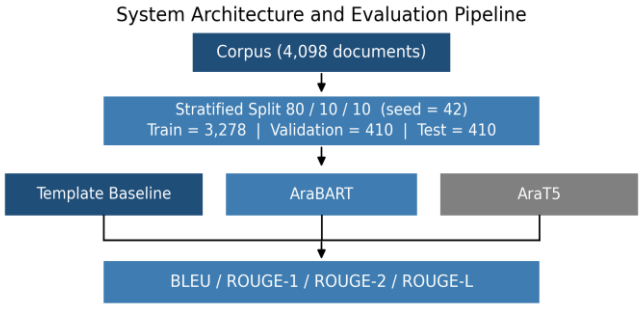

Fig. 2. Experimental framework for retrieval-based and transformer-based generation of Moroccan procedural court orders.

Fig. 2 illustrates the main experimental framework used for the random-split evaluation. An additional template-disjoint evaluation was conducted as described in Section III-A. Three complementary approaches were evaluated: a retrieval-based Template Baseline, AraBART, and AraT5. The retrieval-based system represents a non-neural approach that exploits the high repetition rate of procedural court orders, whereas AraBART and AraT5 represent neural sequence-to-sequence architectures capable of generating more flexible judicial texts.

1) Template baseline: For each test document, the most similar training document is retrieved using TF-IDF with character n-grams (3–5) and cosine similarity. The retrieved document's judicial decision is then returned as the generated output. Character n-grams were selected because they are more robust than word-based representations for Arabic text, effectively handling morphological variations, affixes, spelling differences, and tokenization inconsistencies while preserving lexical similarity between highly repetitive legal documents. This approach requires no neural training and directly exploits the standardized nature of procedural court orders.

2) AraBART: We fine-tuned moussaKam/AraBART [6], a BART-based sequence-to-sequence model [17] pre-trained on approximately 70 GB of Arabic text. AraBART was selected because it provides an Arabic sequence-to-sequence architecture designed for text generation and has demonstrated strong performance on Arabic generation tasks. The faits section is provided as input, while the corresponding décision is generated as output, with both input and output sequences limited to 128 tokens.

3) AraT5: We fine-tuned UBC-NLP/AraT5-base-title-generation [7], an Arabic adaptation of the T5 text-to-text framework [18]. AraT5 was included as a complementary Arabic text-to-text baseline for comparison with AraBART. Although this checkpoint was originally developed for title-generation tasks, it was included here as a complementary Arabic T5 baseline to assess its transferability to procedural legal text generation. The same input-output configuration and maximum sequence length were used to ensure a fair comparison with AraBART. A preliminary experiment with mT5-small [19] did not produce coherent Arabic judicial text and was therefore excluded from the main comparison; this result should not be interpreted as a general limitation of the mT5 architecture.

D. Hyperparameters

The hyperparameters used for fine-tuning AraBART and AraT5 are summarized in Table IV. To ensure a fair comparison between both transformer models, identical training settings were adopted whenever applicable while maintaining computational feasibility on the available hardware.

TABLE IV. TRAINING HYPERPARAMETERS

Parameter	AraBART	AraT5
Pre-trained model	moussaKam/AraBART	UBC-NLP/AraT5-base-title-generation
Training epochs	3	3
Batch size	8	4
Max input/output length (tokens)	128 / 128	128 / 128
Learning rate	5×10^{-5}	5×10^{-5}
Warmup steps	100	100
Precision	fp16	fp16
Hardware	Kaggle T4 GPU	Kaggle T4 GPU
Optimizer	AdamW	AdamW

E. Evaluation Metrics

The generated judicial decisions were evaluated using the BLEU [14] and ROUGE [15] metrics, which are widely adopted for automatic text generation evaluation. BLEU measures modified n-gram precision with a brevity penalty by comparing the generated text with the reference decision, whereas ROUGE evaluates recall-based lexical overlap. Specifically, ROUGE-1, ROUGE-2, and ROUGE-L were computed to assess unigram, bigram, and longest common subsequence similarity, respectively.

Because retrieval-based and neural generation models exhibit different generation behaviors, multiple evaluation metrics were employed to provide a comprehensive assessment. BLEU is particularly informative for highly repetitive legal documents where exact lexical matching is expected, while ROUGE captures partial lexical overlap when generated texts differ from the reference, complementing BLEU in cases where exact n-gram matching is limited.

Because Arabic is morphologically rich, BLEU and ROUGE may underestimate semantic similarity when equivalent legal expressions differ only in their morphological or orthographic forms. Therefore, these metrics are interpreted jointly with the qualitative analysis presented in Section IV-C to provide a more comprehensive evaluation of generation quality.

IV. Results and Discussion

A. Quantitative Comparison of Generation Models

TABLE V. Performance Comparison on 410 Test Documents

Method	BLEU	ROUGE-1	ROUGE-2	ROUGE-L
Template Baseline	**87.39**	**21.30**	**15.29**	**21.14**
AraBART	**77.33**	**20.01**	**13.92**	**20.01**
AraT5	**51.88**	**19.00**	**12.81**	**19.00**

Table V summarizes the quantitative performance of the three evaluated generation approaches on the 410-document test set. The retrieval-based Template Baseline achieves the highest overall performance, obtaining a BLEU score of 87.39, followed by AraBART (77.33) and AraT5 (51.88). Similar performance trends are observed across the ROUGE metrics, where the Template Baseline consistently outperforms both transformer-based models.

Statistical significance analysis: To assess whether the observed differences between the generation approaches were statistically significant, a paired bootstrap analysis was conducted over the 410 test documents using 2,000 bootstrap replications. The analysis was performed on document-level BLEU scores, with each comparison using the same test documents for both methods. The Template Baseline significantly outperformed AraBART, with a mean BLEU difference of 10.07 points (95% CI: [7.74, 12.34], $p < 0.001$). Similarly, the Template Baseline significantly outperformed AraT5 by 35.51 BLEU points (95% CI: [32.59, 38.38], $p < 0.001$). AraBART also significantly outperformed AraT5, with a difference of 25.45 BLEU points (95% CI: [23.03, 27.66], $p < 0.001$). These results confirm that the observed performance differences are statistically significant under the present test-set configuration.

The results under the random split initially show a strong advantage for the Template Baseline, which is consistent with the highly repetitive nature of Moroccan procedural court orders. However, the template-disjoint evaluation provides a more stringent test of generalization and reverses this ranking, with AraBART achieving a significantly higher BLEU score than the Template Baseline. This contrast indicates that the apparent superiority of retrieval-based generation under the random split is partly associated with the availability of repeated decision formulations across the training and test sets. Since many judicial decisions follow standardized legal formulations, retrieving the most similar precedent frequently produces an output that closely matches the reference decision. Consequently, retrieval-based generation can be particularly effective for highly standardized procedural court orders when sufficiently similar validated precedents are available in the retrieval corpus.

Among the evaluated checkpoints, AraBART achieves higher BLEU, ROUGE-1, and ROUGE-L scores than the selected AraT5 checkpoint (UBC-NLP/AraT5-base-title-generation), while AraT5 obtains a slightly higher ROUGE-2 score than AraBART under the template-disjoint setting; this discrepancy may partly reflect checkpoint mismatch rather than a general architectural disadvantage of AraT5.

Under the random split, the Template Baseline achieves the highest scores, while the relatively small differences in ROUGE-1 (21.30 vs. 20.01) and ROUGE-L (21.14 vs. 20.01) indicate that transformer models may generate expressions that differ lexically from the reference text. This observation highlights the complementary roles of BLEU and ROUGE in evaluating legal text generation, particularly when comparing retrieval-based and neural generation approaches.

B. Template-Disjoint Evaluation

To assess the generalization of the evaluated approaches beyond repeated decision templates, an additional template-disjoint evaluation was conducted. In contrast to the initial random stratified split, the template-disjoint protocol prevents documents sharing an identical decision string from being assigned to different subsets. The resulting test set contains 380 documents and provides a more stringent assessment of model generalization to decision formulations not represented in the training set. The AraBART and AraT5 models were re-trained using the corresponding template-disjoint training set, while the Template Baseline retrieved candidate decisions only from that same training set.

The results reveal a substantially different performance pattern from that obtained under the random split. As shown in Table VI, AraBART achieved the highest BLEU score (68.00), followed by the Template Baseline (63.67) and AraT5 (39.89). AraBART also obtained higher ROUGE-1, ROUGE-2, and ROUGE-L scores than the Template Baseline, indicating better lexical overlap with the reference decisions under the template-disjoint setting.

TABLE VI. Template-Disjoint Evaluation on 380 Test Documents

Method	BLEU	ROUGE-1	ROUGE-2	ROUGE-L
Template Baseline	**63.67**	**19.37**	**8.99**	**19.20**
AraBART	**68.00**	**26.32**	**16.54**	**26.32**
AraT5	**39.89**	**25.61**	**17.09**	**25.61**

The difference between the two evaluation settings is particularly informative. Under the random split, the Template Baseline achieved a BLEU score of 87.39 compared with 77.33 for AraBART. Under the template-disjoint split, however, AraBART outperformed the Template Baseline by 4.33 BLEU points. This contrast indicates that retrieval-based generation benefits substantially from the presence of repeated decision formulations across the training and test sets, whereas AraBART achieves better performance when exact decision templates are excluded from the training data.

To determine whether this difference was statistically significant, a paired bootstrap analysis with 2,000 replications was performed on document-level BLEU scores using the same 380 test documents for each method. AraBART significantly outperformed the Template Baseline, with a BLEU difference of 4.33 points (95% CI: [1.60, 6.95], $p = 0.004$). The Template Baseline also significantly outperformed AraT5 by 23.78 BLEU

points ($p < 0.001$), while AraBART significantly outperformed AraT5 by 28.11 BLEU points ($p < 0.001$). These results confirm that the advantage of AraBART over the retrieval-based baseline under the template-disjoint setting is statistically significant.

Overall, the template-disjoint evaluation provides complementary evidence to the random-split results. Rather than indicating that one generation paradigm is universally superior, the two-evaluation settings show that the relative performance of retrieval-based and generative approaches is strongly influenced by the degree of template overlap between training and test data.

Table VII focuses on the Template Baseline and AraBART, the two approaches selected for qualitative comparison, to illustrate the contrast between retrieval-based and neural generation. AraT5 is not included because it obtained lower BLEU, ROUGE-1, and ROUGE-L scores than AraBART across the two evaluation settings, although it slightly outperformed AraBART in ROUGE-2 under the template-disjoint setting. Table VII presents representative examples illustrating the qualitative behavior of the retrieval-based Template Baseline and AraBART on held-out test documents. While automatic metrics quantify overall performance, these examples illustrate the different behaviors of retrieval-based and transformer-based generation.

The Template Baseline frequently retrieves judicial decisions that are identical or nearly identical to the reference text, reflecting the high level of standardization observed in Moroccan procedural court orders. In the second and third examples, the retrieved decisions exactly match the reference output. In the first example, only a minor morphological agreement variation, المطلوب instead of المطلوبة, is observed, while the underlying procedural action remains unchanged.

In contrast, AraBART generally generates fluent and grammatically well-formed judicial text, but it may introduce semantic deviations. As illustrated in the first and third examples, the generated decisions preserve the overall legal intent while using alternative legal expressions. However, the second example shows that AraBART may also generate a different judicial action (validation of the warning) instead of the expected notification of the warning, leading to a legally inappropriate output despite its linguistic fluency.

Overall, the qualitative analysis complements the quantitative results reported in Table V and illustrates the behavior of the two approaches under the random-split setting. Retrieval-based generation can produce highly faithful outputs when sufficiently similar precedents are available, whereas transformer-based generation provides greater linguistic flexibility but may remain susceptible to semantic deviations in legally sensitive contexts.

To complement the illustrative examples in Table VII, all 410 test documents were automatically classified into seven output categories by comparing each prediction with its reference decision, using text similarity, judicial-action keywords, and monetary-amount comparison. This automatic, similarity-based classification is not equivalent to expert legal review, but it provides a systematic, corpus-wide complement to the qualitative examples above. Table VIII summarizes the results for AraBART and the Template Baseline.

TABLE VIII. SYSTEMATIC ERROR ANALYSIS ACROSS THE RANDOM-SPLIT TEST SET

Output Category	AraBART	Template	Description
Exact match	30.5%	60.7%	Output identical to the reference
Lexical variation	26.1%	8.8%	Alternative phrasing, meaning preserved
Morphological variation	23.4%	10.7%	Minor difference (agreement, punctuation)
Numerical substitution	9.8%	13.2%	Amount (and sometimes identity) differs from reference
Procedural omission	2.4%	1.2%	Expected amount or element missing
Semantic deviation	0.2%	0.5%	Different judicial action (e.g., validation instead of notification)
Other/major deviation	7.6%	4.9%	Differences not classified above

A closer analysis of AraBART's outputs further reveals that 9.8% of test documents were automatically categorized as involving numerical or beneficiary-identity substitution. In several cases, recurring names or amounts were observed across different inputs, suggesting that the model may sometimes rely on frequently observed patterns rather than fully conditioning its output on the input facts. This observation requires further expert validation and should therefore be interpreted as an indication rather than a definitive causal explanation. Although automatic metrics such as BLEU and ROUGE do not necessarily distinguish this type of error from a minor lexical variation, it may constitute a materially more serious risk in a judicial deployment context, reinforcing the need for systematic human validation before any generated decision is adopted in practice.

D. Practical Implications and Recommended Generation Strategy

The combined experimental results demonstrate that no single generation approach is universally optimal for Moroccan procedural court orders; performance depends substantially on the availability of repeated templates and the evaluation setting.

For highly standardized procedural categories, where sufficiently similar and validated precedents are available, retrieval-based generation can be particularly suitable. By retrieving an existing precedent, the Template Baseline preserves the original judicial wording and can achieve strong quantitative performance without requiring computationally intensive neural inference. However, the template-disjoint evaluation shows that this advantage does not necessarily extend to cases where exact decision templates are absent from the training data.

For procedural categories exhibiting greater textual diversity, transformer-based models offer increased linguistic flexibility by generating decisions from the procedural facts; however, their outputs require legal validation, as semantic deviations may occur. Among the evaluated transformer models, AraBART achieves the highest BLEU, ROUGE-1, and ROUGE-L scores in the template-disjoint evaluation, while AraT5 obtains a slightly higher ROUGE-2 score than AraBART, making AraBART the preferred neural alternative when retrieval-based generation is less appropriate.

Based on the complementary results obtained under the random and template-disjoint evaluation settings, we propose a conceptual hybrid generation strategy for future practical e-Justice applications, illustrated in Fig. 3. Retrieval-based generation should be employed when a sufficiently similar precedent is identified with high confidence. In contrast, a transformer model such as AraBART may be preferable when exact templates are unavailable. In all cases involving low-confidence retrievals or legally sensitive decisions, human validation remains essential before the generated text is adopted in judicial practice.

The present study is limited to Moroccan procedural court orders and therefore does not establish cross-jurisdictional generalizability. Differences in legal terminology, procedural rules, document structure, and drafting conventions may substantially affect model performance in other jurisdictions. Future studies should evaluate the proposed methodology on procedural legal corpora from other Arabic-speaking jurisdictions. Due to the legal and privacy constraints associated with judicial documents, the full corpus cannot be publicly released.

A further limitation concerns the absence of systematic human evaluation by legal professionals. The qualitative analysis presented in Table VII and the automatic error categorization in Table VIII provide complementary evidence, but they cannot replace expert assessment of legal correctness, semantic fidelity, and procedural appropriateness. A future study should involve legal experts and report inter-annotator agreement to provide a more rigorous human-centered evaluation.

The study also does not provide a systematic quantitative analysis of computational cost, including training time, inference latency, and memory consumption. Such measurements should be incorporated in future experiments to provide a more complete assessment of deployment feasibility.

Although the present study focuses on Moroccan procedural court orders, the proposed strategy may also be applicable to other legal domains characterized by varying levels of textual standardization. Future work may investigate adaptive systems capable of automatically selecting the most appropriate generation paradigm according to corpus characteristics and retrieval confidence.

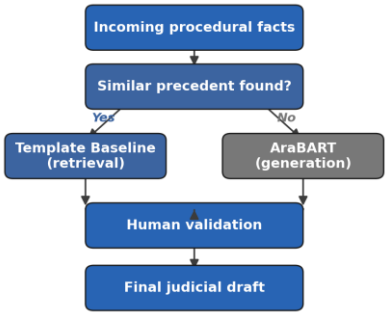

Fig. 3. Conceptual hybrid generation strategy recommended for Moroccan procedural court orders.

V. Conclusion

This study presented a comparative study of retrieval-based and transformer-based generation for Moroccan procedural court orders. Using a corpus of 4,098 authentic Moroccan procedural court orders, we compared a retrieval-based Template Baseline with two Arabic sequence-to-sequence models, AraBART and AraT5, under complementary evaluation settings.

Under the random stratified split, the Template Baseline achieved the highest BLEU score (87.39), reflecting the strong repetition present in the corpus. However, the additional template-disjoint evaluation produced a different result: AraBART achieved a BLEU score of 68.00 compared with 63.67 for the Template Baseline, and the 4.33-point difference was statistically significant ($p = 0.004$). This contrast demonstrates that retrieval-based performance is strongly influenced by the presence of repeated templates across training

and test data, whereas AraBART achieves better performance under the template-disjoint setting.

These findings show that no single generation paradigm is universally optimal. Retrieval-based generation is advantageous when reliable and sufficiently similar precedents are available, while transformer-based generation may be advantageous when the required formulations are not directly represented in the retrieval corpus. The evaluation protocol itself therefore plays an important role in determining the apparent effectiveness of each approach.

Beyond the quantitative comparison, this study shows that the effectiveness of a generation approach depends on the degree of textual repetition within the target corpus. Retrieval-based generation is particularly suitable when sufficiently similar and validated precedents are available, whereas transformer-based models provide greater flexibility and may be advantageous when exact legal formulations are not represented in the retrieval corpus. Based on these findings, we propose a conceptual hybrid generation strategy, intended as a practical guideline that combines retrieval-based generation, neural text generation, and human validation to support future e-Justice applications; this strategy has not yet been implemented or empirically evaluated as an integrated system.

Future work will investigate retrieval-confidence estimation, automatic selection between retrieval-based and neural generation, and human-in-the-loop validation. Recent developments in legal retrieval-augmented generation [10] and Arabic large language models such as AceGPT [11] also provide promising directions for extending the proposed strategy. The proposed strategy will additionally be evaluated on other categories of Moroccan legal documents to assess its generalizability.

VI. Declaration on Generative AI

Generative AI tools were used for language refinement and editorial assistance during manuscript preparation. The authors critically reviewed and validated the resulting text and remain fully responsible for the scientific content, methodology, results, and conclusions of this work.

***Abstract*—Rice is a vital crop for global food security, but its productivity is frequently threatened by diseases and pests, necessitating rapid and accurate detection. This study presents a semi-supervised deep learning approach to automate the classification of ten categories of rice leaf conditions, including seven diseases, two pests, and a healthy class. Field images were acquired using a custom solar-powered ESP32-CAM- based Internet of Things (IoT) edge node. To leverage unlabeled data and minimize manual annotation costs, the dataset was structured with 744 expert-labeled images and 10,249 unlabeled images. An initial Convolutional Neural Network (CNN) model was trained using the 744 expert-labeled images to generate pseudo-labels for the 10,249 unlabeled images. The combined labeled and pseudo-labeled dataset was subsequently partitioned into 80% training, 15% testing, and 5% validation sets to train the final transfer learning-based CNN and Support Vector Machine (SVM) models. Under the evaluated configurations, the CNN achieved higher performance than the SVM baseline, with an accuracy of 82.9%, precision of 83.0%, recall of 82.9%, F1-score of 0.829, and Matthews Correlation Coefficient (MCC) of 0.798, whereas the evaluated SVM configuration achieved an accuracy of 23.7%. These findings demonstrate the efficacy of combining low-cost IoT edge acquisition with semi-supervised deep learning for scalable, real-time crop disease monitoring in precision agriculture.**

I. Introduction

Rice is one of the main staple foods that significantly contributes to global food security, especially in Asian countries, including Indonesia. About 480 million tons of rice are produced each year, with China and India accounting for more than 50% of the total production [1], [2]. Rice is not only important for meeting the caloric needs of the people but also plays a role in supporting the economy and social stability, providing jobs for millions of farmers[3], [4]. Sometimes, rice plants get sick or are eaten by bugs, and this can make it hard to grow enough rice. Among these diseases and pests are Brown Spot (BS), Hispa (Pest), Bacterial Leaf Blight (BLB), Blast, Sheath Blight (SB), Dead Heart (Pest), Bacterial Panicle Blight (BPB), Tungro, and Bacterial Leaf Streak (BLS). Diseases and pests can lead to major losses and put the long-term success of rice farming at risk [5]–[9]. It is important to spot pest and disease problems early so you can act quickly and control them effectively, thereby minimizing losses and maintaining rice productivity amidst existing challenges [8], [10], [11]. Conventional methods for detecting diseases in rice generally require the expertise of trained specialists, are subjective, and cannot be widely or scalably applied. In the context of modern agriculture, this leads to delays in responding to disease outbreaks and results in significant losses for farmers [12], [13]. As a solution, the development of computer vision technology offers new opportunities to improve accuracy and efficiency in real-time disease detection, becoming an integral part of precision agriculture systems. The two main streams in this technology are: 1) the classic machine learning approach that uses handcrafted feature extraction, such as color, texture, and shape, accompanied by the use of classifiers like Support Vector Machine (SVM); and 2) the deep learning approach that allows models to learn features end-to-end without requiring manual intervention for feature extraction [14], [15]. Recent research shows that deep learning methods, especially convolutional neural networks (CNNs), can improve disease detection capabilities with high accuracy, reaching over 97% [16], [17]. This approach not only improves efficiency but also has the potential to save crops and enhance the sustainability of rice production by providing faster and more accurate detection of various diseases such as Leaf Blight, Brown Spot, and Blast [13], [18]. With the implementation of these techniques, it is expected that farmers will be better prepared to face disease threats, thereby maintaining food security more effectively[19], [20].

Against this practical context, the present study investigates a semi-supervised workflow that combines a limited expert-labeled set with a substantially larger pool of unlabeled field images for rice leaf disease and pest classification. The study integrates IoT-based field image acquisition using an ESP32-CAM node with CNN-based pseudo-label generation and compares the resulting CNN classifier with an SVM reference classifier across ten rice leaf condition classes. The objective is to evaluate a practical classification workflow for variable and imbalanced field imagery while reducing dependence on exhaustive expert annotation.

The remainder of this study is organized as follows. Section II reviews related work; Section III describes the materials and methods; Section IV presents the experimental results; Section V discusses the findings and deployment implications; and Section VI concludes the study and outlines future work.

*Corresponding author.

II. Background and Related Work

Semi-supervised learning (SSL) has recently emerged as an effective strategy for reducing the heavy annotation burden in agricultural computer vision, leveraging abundant unlabeled imagery alongside a small expert-labeled set. Reported applications span crop classification from satellite image time series [21], UAV-based maize seedling monitoring and counting [22], [23], multi-class weed detection and robotic weed management [24], [25], pixel-level and panoptic crop segmentation [26], [27], region-of-interest monitoring in vertical farms [28], and plant counting in aerial images under domain shift [29], with several pipelines approaching fully supervised accuracy while using only 5–30% of labeled data [21], [22], [23], [24], [25], [29], [30]. Within plant pathology specifically, SSL and self-training have improved disease and pest recognition: a lightweight self-training CNN achieved near-supervised accuracy for real-time jute leaf disease classification [31]; a semi-supervised one-stage detector raised mean average precision for maize leaf disease at low labeling ratios [32]; memory-based mutual learning produced robust pest detection from small labeled fractions [33]; and pseudo-labeling with consistency regularization (the Wheat Teacher detector) together with collaborative SSL enabled accurate wheat-head detection and wheat-lodging segmentation [34], [35].

A consistent finding across this literature is that the reliability of pseudo-labels governs SSL success; high-confidence pseudo-labels yield large gains, whereas unfiltered or erroneous labels propagate noise and can erode accuracy [32], [33], [36], [37]. Accordingly, several safeguards have been proposed: ambiguity-aware rejection of uncertain predictions [36], dynamic pseudo-label allocation with adaptive loss thresholds [34], iterative correction of noisy annotations [38], knowledge-distillation-based and one-shot pseudo-labeling demonstrated even for livestock video and animal identification [37], and depth-informed, almost-unsupervised pseudo-labeling for dense crop segmentation [39], [40]. Where the deployment domain differs from the training domain (different crops, growth stages, or imaging conditions), semi-supervised and semi-self-supervised domain adaptation, few-shot learning, and self-training improve cross-domain robustness [29], [30], [41], [42]. Collectively, these studies establish SSL with curated pseudo-labels rather than naive self-training as the practical route to scalable field analytics under limited supervision.

Despite this progress, two gaps motivate the present study. First, the very high accuracies, frequently exceeding 97%, reported for CNN-based rice-disease classification are predominantly obtained on curated, class-balanced secondary datasets captured under controlled conditions [43], [44]; images acquired in situ by low-cost IoT edge devices instead exhibit variable illumination, viewpoint, occlusion, and pronounced class imbalance, which substantially depress real-world performance consistent with the 82.9% accuracy obtained here on field-captured data. Second, most agricultural SSL studies target UAV or satellite imagery and crops other than rice, and few couple edge-based IoT image acquisition with a pseudo-label-driven semi-supervised workflow on a single, real field dataset. This study addresses both gaps by pairing a solar-powered ESP32-CAM acquisition node with a pseudo-labeling CNN that converts 10,249 unlabeled field images into usable training signal, and by benchmarking it against a handcrafted-feature SVM under realistic, imbalanced field conditions.

Research on plant disease classification using Support Vector Machine (SVM) has shown good accuracy, especially on limited and controlled datasets [12], [20]. SVM is often effective in classifying and detecting diseases because of its ability to separate data classes with an optimal decision boundary. However, a significant drawback of this approach is its dependence on the limited quantity and quality of training data, which does not always represent real-world conditions. On the other hand, the use of Convolutional Neural Networks (CNNs) in rice disease detection has shown superior performance, especially when using large datasets consisting of balanced labeled images from online repositories [45], [46]. Nevertheless, this approach tends to be less effective when applied to field datasets with more variable conditions. Previous studies generally focused only on balanced labeled data and did not consider challenges such as class imbalance and environmental variability caused by data acquisition through the Internet of Things (IoT). Current research clearly still lacks systematic comparisons between the two approaches, SVM and CNN, on real field datasets with unique characteristics, namely, limited labeled data (744) and abundant unlabeled data (10,249). This creates additional challenges for effective and efficient disease detection and highlights the need for further research to develop methodologies that can address these weaknesses in rice farming contexts [45], [46], [47]. This study makes a significant contribution to understanding and managing rice diseases by providing a comprehensive field dataset consisting of 744 labeled and 10,249 unlabeled data points, covering 10 classes of rice leaf conditions. The dataset was acquired through IoT technology, enabling more representative data collection aligned with dynamic field conditions [12], [46]. Furthermore, this research systematically compares traditional approaches (SVM with handcrafted feature extraction) and modern approaches (semi-supervised CNN) in limited data scenarios. This approach aims to enhance understanding of each method's strengths and weaknesses in a realistic context [13], [48]. Additionally, the study investigates the effectiveness of using unlabeled data by applying semi-supervised learning techniques, which aim to improve CNN model performance in rice disease detection. This method offers great potential to maximize available data and address the common issue of limited labeled data faced in previous research [49], [50]. Finally, the study provides recommendations for optimal architecture and strategies for field implementation based on IoT, intended to assist farmers in detecting and managing rice diseases efficiently and effectively. With support for integrating this technology, it is hoped that this research can contribute not only to increased agricultural yields but also to overall food security [14], [51], [52]

III. Materials and Methods

In this study, rice disease and pest classification on leaves was conducted using deep learning approaches based on Convolutional Neural Networks (CNN). The dataset used consists of 10,249 unlabeled images and 744 images labeled by experts. These images were obtained directly from the field using IoT devices that enable real-time monitoring of rice leaf conditions in agricultural environments. The types of diseases and pests classified include Brown Spot (disease), Hispa (pest),

Bacterial Leaf Blight (disease), Blast (disease), Sheath Blight (disease), Dead Heart (pest), Bacterial Panicle Blight (disease), Bacterial Leaf Streak (disease), and Tungro (disease), with varying numbers of images. Representative examples of the ten classes are shown in Fig. 1.

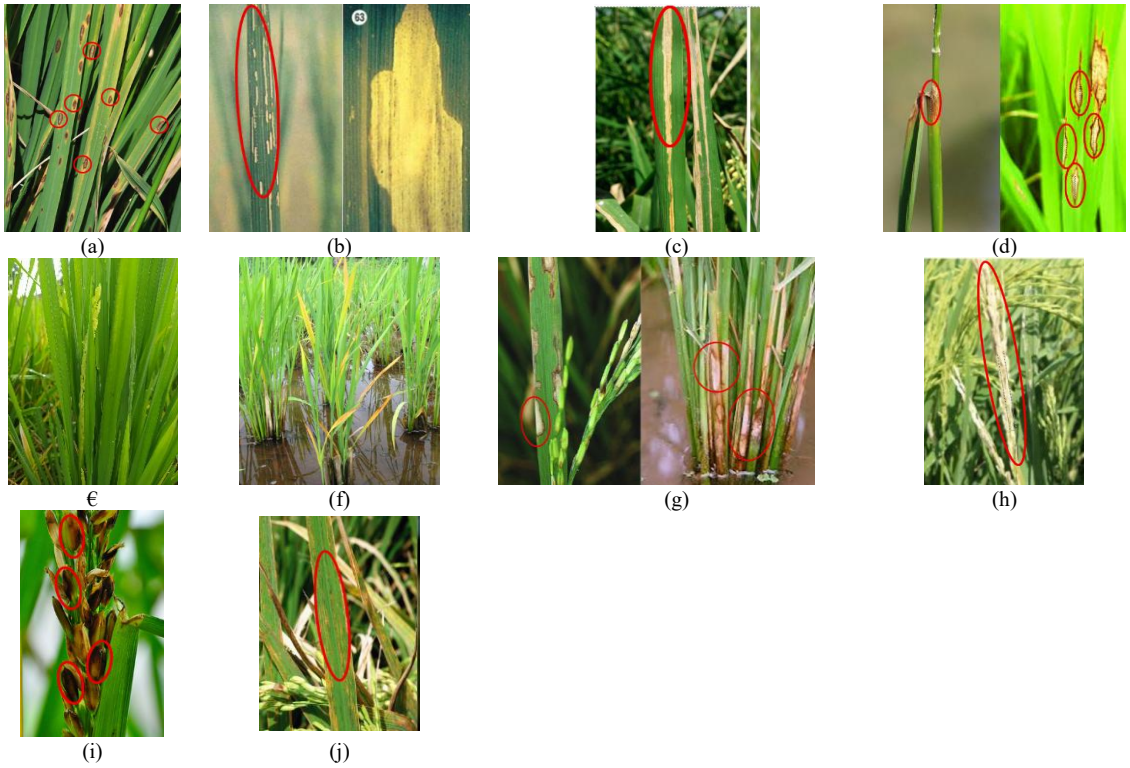

Fig. 1. Samples of the rice leaf diseases and pests dataset: (a) Brown Spot; (b) Hispa; (c) Bacterial Leaf Blight; (d) Blast; (e) Normal; (f) Tungro; (g) Sheath Blight; (h) Dead Heart; (i) Bacterial Panicle Blight; and (j) Bacterial Leaf Streak.

The collected data comprise images of rice leaves obtained from the field using IoT devices, totaling 10,249 unlabeled images and 744 labeled by experts. From this data, the dataset is divided into two groups: training data (learning dataset) and performance data (performance dataset). In the training dataset, the process is carried out gradually until a trained model is produced. The model is then tested to measure accuracy using performance data. If the accuracy meets the standard, the model is finalized. If not, other methods are applied until satisfactory performance is achieved. This methodology aims to continuously optimize the rice leaf disease and pest classification model by improving accuracy. The overall research workflow is summarized in Fig. 2.

This flowchart diagram illustrates the research methodology for classifying rice leaf diseases and pests using CNN and SVM. The process begins with data collection, preprocessing (normalization and augmentation), followed by data splitting. Two models are selected, CNN and SVM, and trained using the data. A semi-supervised approach is used for unlabeled data. After training, the models are evaluated based on accuracy, precision, recall, and F1 score, and then the best model is used to predict unlabeled rice leaf images. The final stage involves applying the model for real-time field prediction of diseases and pests.

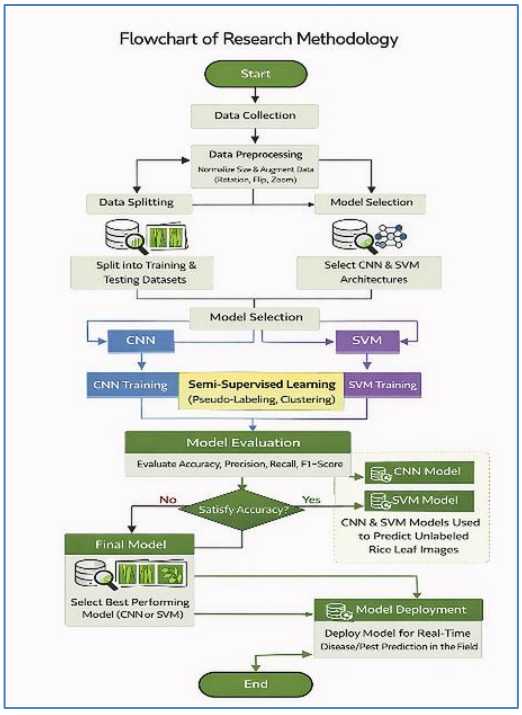

Fig. 2. Flowchart of research methodology.

A. Data Acquisition and IoT Setup

The ESP32-CAM module attracts attention in agricultural IoT because it is inexpensive, has integrated Wi-Fi, and has enough resolution to monitor plant diseases [53]. Combined with ultrasonic sensors for distance measurement, servo motors for precise positioning, and GPS modules for geotagging, the ESP32-CAM-based system offers an affordable solution for automatic field image acquisition [54]. Table I summarizes the specifications of the IoT components used.

TABLE I. IOT NODE COMPONENT SPECIFICATIONS

Components	Specifics	Function
ESP32-CAM	ESP32-S dual-core 240MHz, 4MB PSRAM, Wi-Fi	Main controller and camera
Camera OV2640	2MP, resolution 1600×1200	Filming
Sensor HC-SR04	Distance 2- 400 cm, accuracy ±3mm	Distance measurement
Servo MG90S (2)	Torque 2.2 kg·cm, 0-180°	Pan and tilt control
GPS NEO-6M	Accuracy 2.5m, update rate 5Hz	Geotagging
Buzzer 5V	85dB, 10cm	Field operator alert
Solar Panel	20W polycrystalline	Main resources
Battery	12V 12Ah lead-acid	Power storage
Regulator LM2596	Step-down 12V to 5V	Power regulation
Module TP4056	Charging with protection	Battery management

Fig. 3 illustrates the hardware assembly and pin connections of the IoT node. The ESP32-CAM is connected to the GPIO pins, and Fig. 4 shows the process of capturing images of rice leaves in the field.

Fig. 4. Photographing in the rice field.

B. Dataset and Ground Truth:

In this study, the dataset [55] used is divided into two main parts, namely Labeled Data and Unlabeled Pool. The Labeled Data consists of 744 images that were verified by three experts from the Faculty of Agriculture, Universitas Jenderal Soedirman (UNSOED), Purwokerto, Indonesia: Prof. Ir. Totok Agung Dwi Haryanto, M.P., Ph.D. (Plant Breeding); Woro Sri Suharti, S.P., M.P., Ph.D. (Plant Pathology); and Dr. Endang Mugiastuti, S.P., M.P. (Plant Pathology). Each image is classified into a category of disease or pest on rice leaves, with details available in Table II.

TABLE II. DISTRIBUTION OF RICE LEAF DISEASE CLASSES IN THE LABELED DATASET

Disease Class	Number of Images	Class classification
Bacterial Leaf Blight	85	Diseases
Brown Spot	120	Diseases
Blast	83	Diseases
Sheath Blight	59	Diseases
Tungro	50	Diseases
Normal	72	Normal
Dead Heart	56	Pests and Diseases
Bacterial Panicle Blight	53	Diseases
Bacterial Leaf Streak	50	Diseases
Hispa	116	Pests and Diseases
Quantity	744	

Meanwhile, the Unlabeled Pool contains 10,249 raw images taken directly from the field. These images do not yet have expert-assigned class labels and cover a variety of conditions, including different rice plant varieties, growth stages, lighting conditions, and viewing angles. In the semi-supervised workflow, this pool is processed by the initial teacher CNN to obtain predicted class labels. The prediction output is then converted into the class-label field and combined with the expert-labeled data before the final train/test/validation partition is created. Representative samples from the unlabeled image pool are shown in Fig. 5.

Fig. 5. Unlabeled data.

C. Pre-Processing Data

In the data preprocessing stage, all images in the dataset are resized to suit the needs of each model. Images for the Convolutional Neural Network (CNN) model are resized to 224x224 pixels, while images for feature extraction with Support Vector Machine (SVM) are reduced to 227x227 pixels.

D. Convolutional Neural Network

Semi-supervised CNN is a machine learning approach that combines labeled and unlabeled data to train object detection and classification models in images. The model is trained with a small amount of labeled data to learn initial representations, then optimized with unlabeled data through the creation of pseudo-labels. The main challenge is errors in pseudo-labels, which can reduce accuracy if not handled properly [56].

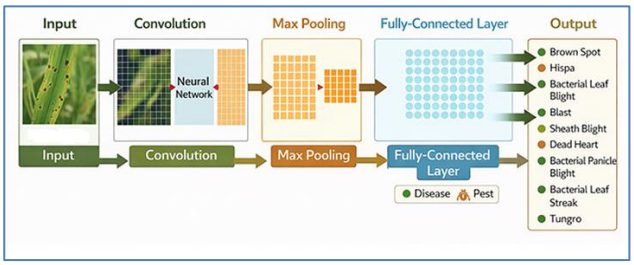

Fig. 6. CNN workflow.

Fig. 6 illustrates the process of classifying rice leaf diseases and pests using a CNN, starting from an input image measuring 224x224 pixels. The image is processed through convolution to extract features such as texture and shape, then through max pooling to reduce dimensions while preserving key features. The features are then classified as Brown Spot, Hispa, and others via a fully connected layer, enabling the system to automatically detect rice plant diseases and pests, thereby assisting agricultural management. CNN utilizes the convolution process to divide the image into small parts, extract numerical features through encoding, and use down-sampling (max pooling) to reduce the array size, which speeds up training and decreases layer complexity. At the end of the convolutional network, there is an evaluation section used to measure the system's performance. The model is optimized using the categorical cross-entropy loss, while its classification performance is assessed using Accuracy, Precision, Recall, F1-score, and the Matthews Correlation Coefficient (MCC), as defined in Equations (1)–(6). Here, TP, TN, FP, and FN denote the true positives, true negatives, false positives, and false negatives, respectively; N is the number of observations and K is the number of classes.

$$\text{Accuracy} = \frac{\sum_{k=1}^{K} \text{TP}_k}{N} \tag{1}$$

$$\text{Precision} = \frac{\text{TP}}{\text{TP} + \text{FP}} \tag{2}$$

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}} \tag{3}$$

$$\text{F}_1 = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{4}$$

$$\text{MCC} = \frac{\text{TP} \times \text{TN} - \text{FP} \times \text{FN}}{\sqrt{(\text{TP} + \text{FP})(\text{TP} + \text{FN})(\text{TN} + \text{FP})(\text{TN} + \text{FN})}} \tag{5}$$

$$L = -\frac{1}{N} \sum_{i=1}^{N} \sum_{k=1}^{K} y_{i,k} \log(\hat{y}_{i,k}) \tag{6}$$

The initial preprocessing stage of rice leaf data involves configuring and collecting data to train a CNN model. Out of 10,993 IoT images, 744 are validated and labeled by plant experts across 10 categories, while 10,249 images form the unlabeled pool used for semi-supervised learning. After training on the 744 expert-labeled images, the initial CNN is applied to the 10,249 unlabeled images in the Predictions Data widget. The predicted class output is passed through the Edit Domain ("Edit Label") widget to standardize it as the target class variable, producing the pseudo-labeled pool used in the subsequent combined-data stage. For comparison, the study also employs Support Vector Machine (SVM) as a conventional reference classifier using handcrafted features and the fixed configuration listed in Table V, including a sigmoid kernel. Evaluation is performed using confusion matrices and metrics including accuracy, precision, recall, F1-score, and MCC.

To preserve separation in the final evaluation stage, the expert-labeled and pseudo-labeled data are concatenated before the final-model split. The first stratified Data Sampler, using a fixed seed, allocates 80% of the combined pool to training. From the remaining 20%, a second stratified sampler allocates 75% to testing, corresponding to 15% of the complete pool, while the remaining 5% is reserved for validation. Consequently, the final CNN and SVM are trained only on the 80% training partition, while the 15% test and 5% validation partitions remain non-overlapping hold-out subsets.

E. Support Vector Machine

Support Vector Machine (SVM) is a machine learning algorithm used in classification and regression analysis. This algorithm belongs to the category of supervised learning, which means it requires labeled data for training. SVM is well-known for its ability to find the optimal hyperplane that separates classes in the feature space with the maximum margin between data points from two different classes. The basis of SVM is the search for a hyperplane that separates two classes of data. This hyperplane can be viewed as a line (in two dimensions), or a plane (in three dimensions), and the model aims to maximize the margin, which is the distance between the closest data points of each class. The data points closest to the hyperplane are called support vectors, which are crucial points because they determine the position of the hyperplane [56], [57].

IV. RESULT

The data preparation process is implemented to ensure consistency across the entire dataset. A total of 10,993 rice leaf images are used, consisting of 744 labeled images validated by experts and 10,249 unlabeled field images taken through IoT devices (Fig. 8). The labeled dataset includes 10 different classes, including 7 disease categories (bacterial leaf blight, bacterial leaf streak, bacterial panicle blight, blast, brown spot, sheath blight, and tungro), 2 pest categories (dead heart and hispa), and 1 healthy class (normal). The 744 expert-labeled images are first used to train the initial CNN model, which subsequently generates predictions for the 10,249 unlabeled field images. After label assignment, the resulting data are combined with the expert-labeled dataset for final model development. The combined dataset is then partitioned using stratified sampling into 80% training, 15% testing, and 5% validation subsets. The reported performance metrics therefore correspond to this predefined stratified hold-out evaluation.

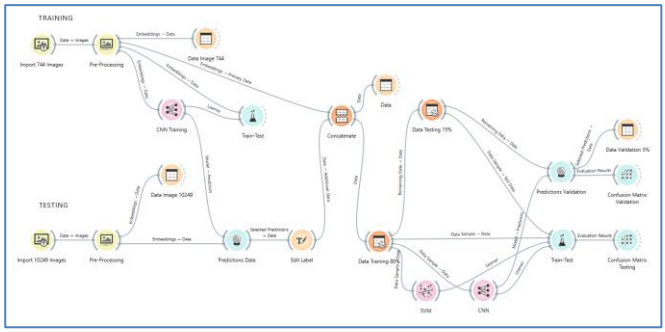

Fig. 7. Result of model development using graphical data mining application.

Based on the workflow in Fig. 6, the classification procedure consists of an initial teacher-model and pseudo-labeling stage followed by final model development and evaluation. In the first stage, the 744 expert-validated images are processed through pre-processing and feature extraction to train the initial CNN, which is then used to predict labels for the 10,249 unlabeled field images. The prediction output is standardized as the class variable through the Edit Label step and then concatenated with the expert-labeled data. Only after this label-assignment stage is the combined dataset divided into 80% training data, 15% testing data, and 5% validation data. The final CNN and SVM models are evaluated using confusion matrices and performance measures including accuracy, precision, recall, F1-score, and MCC (Fig. 7).

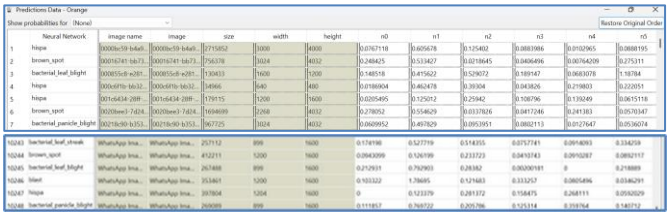

Fig. 8. Image labeling process of 10,993 images.

A. Convolutional Neural Network

CNN Training serves as an initial model that functions as a 'teacher' before the final model is created. Starting with the expert-labeled rice leaf images, the CNN learns visual patterns from the disease and pest classes and is then used in the Predictions Data widget to assign pseudo-labels to the unlabeled image pool. The predicted class output is standardized through the Edit Label widget and combined with the expert-labeled data through the Concatenate widget. The combined pool is then divided into 80% training, 15% testing, and 5% validation using the sequential stratified samplers. The 5% validation partition contains 549 images and is used for the confusion-matrix analysis in Fig. 9, whereas the 15% test partition is used for the summary performance metrics reported in Table IV. CNN Training therefore functions as the teacher stage for expanding the available training signal before the final CNN and SVM evaluation.

Details of the training configuration for the CNN model from the Graphical Data Mining Application are shown in Table III.

TABLE III. DETAILS OF THE TRAINING LAYERS FOR THE CNN

No	Parameters	Value
1	Neuron in Hidden Layer	200,100
2	Activation	ReLu
3	Solver/Optimizer	Adam
4	Regulation optimizer	0,001
5	Iteration	500

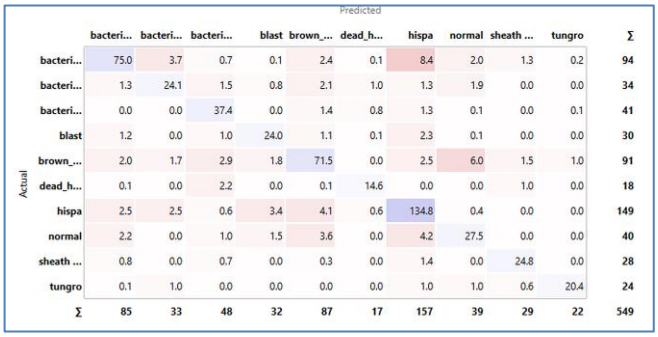

Fig. 9. CNN validation confusion matrix 5%.

The confusion matrix shown in this analysis illustrates the detailed performance of the Convolutional Neural Network (CNN) model in classifying ten categories of rice leaf conditions, including seven types of diseases, two types of pests, and one healthy class. In the matrix, the actual labels are shown by rows and the model predictions by columns, while the main diagonal represents correctly assigned class membership. The matrix is calculated on the 5% validation partition of the combined dataset, comprising 549 images. This validation partition is distinct from the test partition used for the summary performance metrics reported in Table IV.

The CNN confusion matrix indicates comparatively strong class-level recall for Hispa (90.5%) and Bacterial Leaf Streak (91.2%), followed by Sheath Blight (88.6%) and Dead Heart (81.1%). In contrast, Tungro showed the lowest recall at 52.2%, with a notable tendency to be confused with Sheath Blight. Bacterial Panicle Blight and Brown Spot achieved class-level recall of 65.1% and 73.7%, respectively. The matrix also indicates overprediction of Hispa and underprediction of

Tungro. Overall, most classes showed comparatively strong recall, while some classes, particularly Tungro, remained more challenging. These class-wise confusion patterns indicate that visually similar symptoms continue to be an important source of classification error and motivate further improvements through additional representative samples and data augmentation.

TABLE IV. RESULTS OF THE DEVELOPED MODEL CNN

No	Result	Value on Data Testing (%)
1	Accuracy	82,9
2	Precision	83
3	Recall	82,9
4	F1-Score	0,829
5	MCC	0.798

Table IV summarizes the performance of the Convolutional Neural Network (CNN) model for classifying 10 categories of rice leaf conditions (7 diseases, 2 pests, and 1 healthy class) on the final combined-data test partition defined by the 80% training, 15% testing, and 5% validation split. The separate 5% validation partition, comprising 549 images, is used for the confusion-matrix analysis in Fig. 9. The reported metrics include accuracy, precision, recall, F1-score, MCC, and AUC. The CNN achieved an AUC of 0.985, indicating strong discriminative capability across the evaluated classes.

B. Support Vector Machine

Pre-processing methods for the SVM and CNN models follow the same scheme as the workflow diagram that shows the data splitting details. The data is grouped into ten folders according to the rice disease class names, including Bacterial Leaf Blight and Blast. Images are converted into a format readable by the model after being resized using the pre-processing widget in Orange, and visual features are extracted through an Image Embedding method based on Inception v3. For initial CNN training, 744 labeled images are used, generating predictions for 10,249 unlabeled images through pseudo-labeling. All labeled data are then combined into approximately 11,000 images. For final model development, the combined dataset is partitioned into training (80%), testing (15%), and validation (5%) subsets used by both the CNN and SVM evaluation workflows in Orange Data Mining. The SVM shows lower performance than the CNN under the evaluated configuration, as reflected by CA, F1, Precision, Recall, and MCC, with higher prediction errors especially in visually similar classes such as Blast and Brown Spot. The performance of both models can be viewed through the Confusion Matrix. Details of the SVM configuration from the Graphical Data Mining Application in Fig. 10 are shown in Table V.

TABLE V. SVM MODEL CONFIGURATION

No	Parameters	Value
1	SVM Cost	1,0
2	Regression loss epsilon	0,10
3	Kernel	Sigmoid
4	SVM optimizer tolerance	0,0010
5	SVM Iteration Limit	100

Fig. 10. SVM validation confusion matrix 5%.

The SVM confusion matrix shows limited class-wise performance across the 10 rice leaf categories. Hispa achieved the highest class-level recall at 42.8%, while several other classes showed substantially lower recall, and Bacterial Leaf Blight and Blast were rarely classified correctly. These patterns are consistent with the overall SVM results in Table VI and indicate that the evaluated SVM configuration had difficulty separating visually similar disease and pest classes.

TABLE VI. RESULTS OF THE DEVELOPMENT MODEL SVM

No	Result	Value on Data Testing (%)
1	Accuracy	23,7
2	Precision	27,6
3	Recall	23,7
4	F1-Score	25,5
5	MCC	15,1

This study compares CNN and SVM for rice leaf image classification. The SVM is trained and evaluated using the same final combined-data split described above, with 80% allocated to training, 15% to testing, and 5% to validation. On the test partition, the SVM achieved an AUC of 0.761 and an accuracy of 23.7%. The F1-Score of 0.255 indicates prediction imbalance, and the MCC of 0.151 reflects limited agreement between predicted and actual classes under the evaluated configuration.

V. DISCUSSION

A. Performance Comparison of CNN and SVM Classifiers

This study compares the CNN and SVM implementations evaluated for classifying rice leaf diseases and pests. The CNN achieved an AUC of 0.985, classification accuracy (CA) of 82.9%, F1-score of 0.829, precision of 83.0%, recall of 82.9%, and an MCC of 0.798. Under the specified SVM configuration, the corresponding testing accuracy was 23.7% with an MCC of 0.151. The SVM confusion matrix shows frequent misclassification, particularly for disease classes with overlapping visual symptoms such as Blast and Brown Spot. Accordingly, the comparison in this study is interpreted as the performance of the two implemented configurations on the same field-acquired dataset, rather than as an exhaustive assessment of all possible SVM parameterizations.

B. Annotation and Computational Trade-Offs

While the CNN model offers high accuracy, it requires a substantial labeled dataset to initialize training. In this study, the

training of the initial "teacher" CNN utilized 744 expert-labeled images to generate pseudo-labels for the 10,249 unlabeled images. In terms of workflow constraints, expert manual annotation of the entire 10,993-image dataset represents a significant bottleneck in terms of time and cost. The SVM model presents a simpler alternative that does not require GPU acceleration for inference. However, traditional SVMs face scaling limitations as the size of the training feature space grows, leading to high training complexity, even though their final testing (inference) time remains negligible. Under the configurations evaluated in this study, the semi-supervised CNN provided the stronger classification performance. Future work may broaden the benchmark by examining alternative SVM parameterizations together with other classifiers such as Random Forest, K-Nearest Neighbors (KNN), and additional deep learning architectures.

C. Impact of Semi-Supervised Learning on Class Imbalance

A key finding in this study is the interaction between Semi-Supervised Learning (SSL) and the class imbalance inherent in the labeled dataset (Table II). The majority class (Brown Spot) contains 120 images, whereas minority classes (Tungro and Bacterial Leaf Streak) contain only 50 images each. In self-training workflows, this imbalance presents a risk of confirmation bias because the pseudo-label assignments are generated by a model initialized from the same imbalanced expert-labeled distribution. As a result, class preferences learned during the teacher stage can be propagated into the pseudo-labeled pool and subsequently influence the combined-data training stage.

This behavior provides a plausible explanation for the lower class-level recall of Tungro (52.2%) and its recurring confusion with Sheath Blight, which shares visually similar yellowing symptoms. Conversely, Hispa tended to be overpredicted. These patterns are consistent with the general risk that pseudo-labeling can reinforce initial class preferences when visually overlapping classes are present. Future implementations could therefore consider class-aware pseudo-label selection and human-in-the-loop review of uncertain cases before final model retraining.

D. Proposed Field Deployment Architecture and Real-Time Farmer Notification Pipeline

To illustrate how the classification framework could be extended into a practical precision agriculture service, a real-time data integration and notification architecture is proposed. In this architecture, the ESP32-CAM IoT edge node deployed in the field would perform image acquisition and geotagging via the NEO-6M GPS module, and the captured images could be transmitted to a cloud-based server through a local Wi-Fi gateway or cellular network such as 4G/5G. The computational task of running the trained transfer learning CNN model could then be handled by the cloud server. When a disease or pest is detected, the classification result, GPS coordinates, and timestamp could be stored in a Firebase Realtime Database.

In the proposed farmer-facing layer, database updates could trigger an automated webhook to send a push notification or instant message through services such as the WhatsApp Business API. The notification could link to a lightweight mobile dashboard displaying:

- The classified disease or pest type.
- A confidence score and the captured leaf image.
- The exact geographic location of the affected crop to facilitate targeted pesticide application or physical intervention.

Such a cloud-to-mobile pipeline would allow farmers to access the classification results without requiring specialized technical knowledge or high-performance local computing devices, and could support rapid, localized responses to pest and disease outbreaks.

VI. Conclusion

This study investigated rice leaf disease and pest classification using a semi-supervised Convolutional Neural Network (CNN) workflow and a Support Vector Machine (SVM) reference classifier. The CNN used 744 expert-labeled images to generate labels for 10,249 unlabeled field images, after which the combined dataset was used for final model development. Under the configurations evaluated in this study, the CNN achieved 82.9% accuracy compared with 23.7% for the SVM baseline, while also providing a practical mechanism for exploiting the large unlabeled image pool. These results support the use of the semi-supervised CNN workflow for the field-image classification setting examined here. Future work may extend the comparison to additional classifier configurations and architectures, apply data-augmentation strategies, and explore lighter CNN models and more advanced semi-supervised techniques for resource-limited deployment. Future studies may complement this hold-out evaluation with repeated or cross-validation-based assessment across additional field datasets.

Acknowledgment

The author would like to express sincere gratitude to Universitas Ahmad Dahlan for providing academic support and guidance during the preparation of this research. The author also gratefully acknowledges Universitas Amikom Purwokerto for providing scholarship support during the doctoral study. Appreciation is extended to the doctoral program supervisors and lecturers for their valuable insights, constructive feedback, and encouragement throughout the development of this study. This work was conducted as part of the author's doctoral academic activities in the field of deep learning and IoT-based agricultural disease detection.

***Abstract*—This study presents a controlled proof-of-concept comparison of Genetic Algorithm (GA) and Particle Swarm Optimization (PSO) for automated daily meal-plan generation. The evaluation is deliberately restricted to the data available in the current prototype: a 24-item Japanese-style food database, one nutritional profile, one random seed (42), 100 iterations, and an equal population/swarm size of 60. Both optimizers use the same scalarized fitness function that combines nutrient-target adherence, penalties for constraint violations, and a food-diversity bonus. In the representative run, GA achieved a final fitness of 5.15 compared with 4.92 for PSO and reached its plateau by generation 14, whereas PSO reached its final value near iteration 75. The GA solution had a daily cost of ¥980, while the PSO solution had a lower daily cost of ¥650. Both solutions remained within the specified macronutrient tolerance bounds. These results reveal a configuration-specific trade-off: GA produced a higher scalar fitness and earlier convergence, whereas PSO produced a lower-cost plan and smaller deviations for several macronutrients. Because the experiment uses a single profile and a single random seed, the findings are descriptive and should not be interpreted as statistical evidence of general algorithmic superiority.**

***Keywords*—Automated meal planning; genetic algorithm; particle swarm optimization; constrained combinatorial optimization; personalized nutrition; computational intelligence**

I. Introduction

Personalized meal planning can be formulated as a computational decision problem in which nutritional adequacy, dietary restrictions, user preferences, and affordability must be considered simultaneously. Recent artificial-intelligence-based meal-planning studies have explored reinforcement learning and hybrid optimization to tailor food recommendations to individual needs and preferences [1], [2]. Population-based optimization has also been applied to nutrition- and budget-aware menu generation, including maternal nutrition planning [3].

From an optimization perspective, meal planning is a constrained combinatorial search problem because food choices are discrete and multiple criteria must be satisfied at the same time. Contemporary diet-optimization studies show that mathematical models can balance nutritional adequacy with affordability, acceptability, food waste, and other practical objectives [4], [5], [6], [7]. Population-based metaheuristics such as GA and PSO are therefore attractive when the search space is discrete or mixed, the objective is nonlinear, and feasibility is controlled through penalties or decoding rules [7], [8].

This study makes four contributions within the scope of the available prototype data. First, it formulates four-meal daily planning as a constrained combinatorial optimization problem over a 24-item food database. Second, it implements GA and PSO under matched computational settings and a common scalarized fitness function so that differences are not caused by different objective definitions. Third, it contrasts an integer-based GA representation with a continuous latent-space PSO representation that is decoded into discrete food selections. Fourth, it provides a descriptive head-to-head comparison using final fitness, convergence behavior, daily cost, and macronutrient deviations. The scope is intentionally limited to one user profile and one random seed; therefore, the study evaluates the behavior of the two implementations under a controlled configuration rather than claiming population-level or statistically generalizable superiority.

The remainder of this study is organized as follows. Section II reviews recent work on GA, PSO, and computational meal planning. Section III defines the decision variables, constraints, and fitness function. Section IV describes the system architecture, Sections V and VI present the algorithm design and implementation, Section VII specifies the experimental configuration, and Section VIII reports the descriptive results. Section IX discusses the observed trade-offs and limitations, followed by the conclusion and future research directions.

II. Research Background and Related Work

A. Genetic Algorithm (GA)

GA is an evolutionary optimization technique that improves a population of candidate solutions through selection, crossover, mutation, and survival mechanisms. Recent reviews emphasize that representation, fitness design, crossover, mutation, and diversity preservation strongly influence search behavior and convergence [7], [9], and the same body of work shows that GA and PSO performance is sensitive to control-parameter choices such as mutation/inertia settings and population size [11]. For the present meal-planning problem, a direct integer representation is appropriate because candidate solutions are constructed from discrete food identifiers grouped into meal slots.

*Corresponding author.

B. Particle Swarm Optimization (PSO)

PSO is a population-based swarm-intelligence method in which particles update their positions using their own best-known position and the best position discovered by the swarm. Although PSO is naturally defined in continuous space, it has been widely adapted to constrained, discrete, and application-specific optimization through customized encodings and decoding mechanisms [8]. In this study, each continuous particle position is interpreted as a food-selection strength and is decoded into a discrete meal plan.

$$v_i(t+1) = \omega\, v_i(t) + c_1 r_1 (pbest_i - x_i(t)) + c_2 r_2 (gbest - x_i(t)) \quad (1)$$

where, ω is the inertia weight controlling the exploration-exploitation balance, c_1 and c_2 are the cognitive and social acceleration coefficients, and r_1 and r_2 are uniformly distributed random scalars. For the discrete meal-selection task, the continuous position vector is not used directly as the final plan; instead, it is decoded by selecting the highest-strength eligible foods for each meal.

C. Related Work

Recent computational nutrition research has moved beyond static rule-based recommendation toward optimization and adaptive decision support. Authors in [1] used reinforcement learning to generate personalized meal plans with an emphasis on user acceptance. Authors in [2] combined PSO and simulated annealing with analytic hierarchy process weighting for personalized meal planning under multiple user-specific criteria. Authors in [3] compared several population-based optimizers, including GA and PSO, for pregnancy menu planning using nutritional requirements and food budget as optimization considerations.

Other recent diet-optimization studies demonstrate that food planning can be framed around multiple practical constraints. Authors in [4] incorporated nutrition, cost, package sizes, and food waste into a mathematical meal-planning model, while [5] optimized diet structures to improve nutritional adequacy while accounting for affordability and environmental implications. Authors in [6] further showed that nutritional requirements can materially constrain optimized healthy eating patterns. The present study is narrower in scope than these works: it does not model a population, weekly planning, sustainability, or clinical outcomes. Instead, it isolates a controlled GA-versus-PSO comparison for a four-meal daily plan using the same 24-food database, the same scalar fitness function, the same population size, and the same iteration budget. This controlled design supports implementation-level comparison, while the single-profile and single-seed scope limits statistical generalization.

III. Problem Formulation

A. Decision Variables

A daily meal plan is represented as a set of four meals $M = \{breakfast, lunch, dinner, snack\}$. Each meal $m \in M$ contains a subset of food items $Fm \subseteq F$ from the food database F, where, $|F| = 24$. Each food item $f \in F$ is characterized by its nutritional content per serving (kcal, protein, fat, carbohydrates), unit price (JPY), food category, and allergen list.

B. Constraints

The following constraints must be satisfied:

- Nutrient bounds: target caloric intake within ±10%, protein within +20%/−15%, fat within ±20%, carbohydrates within +15%/−15%.
- Allergen exclusion: no food item containing a user-specified allergen may appear in any meal.
- Dislike exclusion: explicitly disliked food IDs are permanently excluded.
- Budget constraint: the total daily cost $\sum price(f)$ must not exceed the daily budget (default: ¥1,500).
- Meal structure: each meal may contain 1–4 food items drawn from meal-appropriate categories (e.g., grains, proteins, vegetables, dairy).

C. Fitness Function

A single scalar fitness value is used to rank candidate meal plans. The objective combines nutritional adequacy, penalties for constraint violations, and a diversity reward. Accordingly, the present implementation is a scalarized multi-criteria optimization model rather than a Pareto-based multi-objective optimizer.

$$F(plan) = Snut - Cviolation + \lambda \cdot diversity(plan) \quad (2)$$

The nutrient score $Snut = \frac{\Sigma j\, wj}{(1 + devj)}$ rewards proximity to nutritional targets, where $devj = max(0, actualj - ubj, lbj - actualj)$ represents the out-of-bound deviation for nutrient j and wj is its weight; protein is weighted 1.5× in the current implementation. Constraint penalties subtract $Callergen$ = 100 for an allergen violation, $Cdislike$ = 10 for each disliked item, and 0.05 × overage for a budget violation. The diversity term is $\lambda \cdot log(1 + uniquefoods)$, with λ = 0.3. Because all components are aggregated into one fitness value, the reported fitness should be interpreted according to this specific weighting and penalty structure.

IV. System Architecture

The prototype uses a backend-centric architecture (Fig. 1). A RESTful POST /plan endpoint receives a user-profile JSON payload containing nutritional targets, dietary constraints, and the selected optimizer (GA or PSO). The optimization engine executes server-side and returns a structured meal plan, per-food nutritional information, total cost, and optimizer-trace metadata. Both optimizers access the same food database and the same fitness engine, which keeps the comparison focused on the search mechanisms rather than on different data or objective functions.

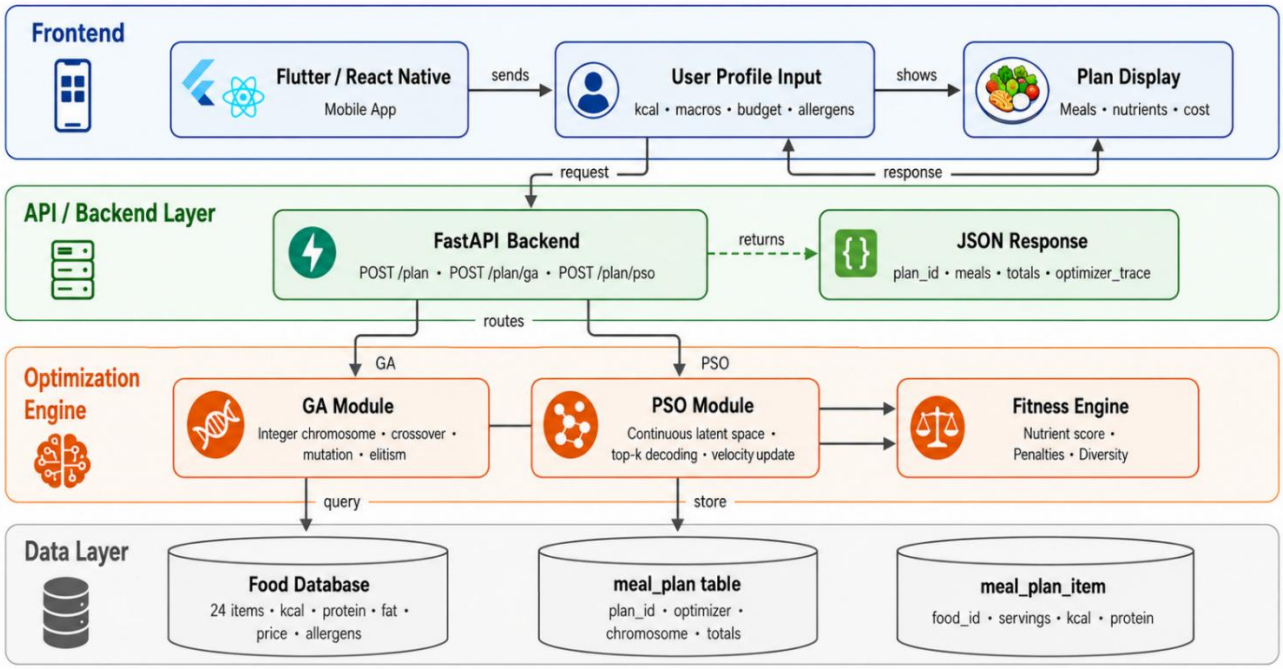

Fig. 1. System architecture of the automated daily meal-planning prototype. The frontend captures the user profile and displays the generated plan; the FastAPI backend routes requests to either the GA or PSO module; and both optimizers use the same fitness engine and data layer.

Table I summarizes the prototype components. Flutter/React Native is used for the frontend, FastAPI handles JSON-based communication, GA and PSO provide alternative optimization engines, and a lightweight SQLite/JSON food store contains the nutritional, price, category, and allergen attributes required by the fitness function.

TABLE I. SYSTEM COMPONENT OVERVIEW

Layer	Component	Responsibility
Frontend	Flutter / React Native	User profile input; plan display
API	FastAPI (Python)	POST /plan endpoint; JSON I/O
Engine	GA / PSO modules	Combinatorial meal search
Data	Food DB (SQLite/JSON)	Nutritional facts; allergen flags

V. ALGORITHM DESIGN

A. GA Encoding and Operators

Each GA chromosome is an integer-keyed meal matrix. The genome is divided into four meal slots, each containing a variable-length list (1–4) of food IDs drawn from the meal-appropriate subset of the food database. Initialization randomly samples valid foods per meal, ensuring allergen compliance. The key operators are:

1) Selection: tournament selection with k = 3 candidates, choosing the individual with the highest fitness.

2) Crossover: for each meal slot, one parent's foods are inherited with probability 0.5 (uniform crossover at the meal level).

3) Mutation ($rate\ pm = 0.15$): per meal, randomly replace a food with another valid food, insert an additional food ($if\ |meal| < 4$), or remove a food ($if\ |meal| > 1$).

4) Elitism: the top 10% of individuals are carried forward unchanged to the next generation. This rate follows a commonly used default in the GA literature rather than a value selected through tuning for the present problem, and it is one of several factors that may contribute to GA's faster observed convergence, since preserving the fittest individuals each generation directly protects incremental fitness gains from being lost to crossover or mutation. Its individual contribution relative to selection pressure and mutation rate was not isolated in this study.

B. PSO Encoding and Decoding

Each PSO particle is a real-valued vector $x \in [0,1]^N$, where $N = 24$ is the number of foods. Component xi represents the selection strength of food i. At each iteration, particle positions are decoded into discrete meal plans by selecting, for each meal m, the top- k foods ($k \in \{1,2,3\}$ sampled uniformly) whose selection strengths are highest among the meal-appropriate, allergen-free food pool. Velocity updates follow the standard inertia-weight PSO equation with $\omega = 0.7$, $c_1 = c_2 = 1.5$.

The two representations determine meal size through different mechanisms. In GA, the number of foods per meal changes only through insertion and deletion mutations acting on an already-instantiated meal. In PSO, meal size is instead re-sampled at every iteration, since k is drawn uniformly from {1, 2, 3} independently for each meal each time a particle is decoded. This introduces a source of per-iteration randomness in PSO's meal construction that has no counterpart in GA's representation. Consequently, the two optimizers are matched in population/swarm size, iteration budget, random seed, and fitness function, but not in the decoding-level stochasticity of meal length; the comparison should accordingly be read as

controlled at the level of computational budget and objective function rather than as a fully matched search-space representation.

VI. Implementation

Both algorithms are implemented in Python 3 without external optimization libraries so that the encoding, operators, decoding rules, and fitness calculations remain explicit in the prototype code. The implementation consists of approximately 300 lines organized into the following modules:

1) Food database: A list of 24 food items (Japanese-style) with nutritional profiles, prices, allergen flags, and meal-category labels.

2) Fitness engine: A shared function computing the multi-component fitness score used by both GA and PSO without modification.

3) GA module: GeneticAlgorithm class with configurable population size, number of generations, mutation rate, and elite ratio.

4) PSO module: PSO class with configurable swarm size, iteration count, inertia weight, and cognitive/social coefficients.

The algorithmic settings used for the representative comparison are shown in Table II.

TABLE II. Hyperparameter Settings used in the Representative Experiment

Parameter	GA	PSO
Population/Swarm size	60	60
Iterations/Generations	100	100
Mutation rate (pm)	0.15	-
Elite ratio	10%	-
Inertia weight (ω)	-	0.70
Cognitive Coeff. (c_1)	-	1.50
Social Coeff. (c_2)	-	1.50
Random seed	42	42

Algorithm 1 presents a representative excerpt of the GA chromosome initialization used in the prototype.

Algorithm 1: GA Chromosome Initialization

```
def _init_individual(self) -> MealPlan:
    return MealPlan(meals={mt: random_meal(mt, self.profile, random.randint(1,3))
for mt in MEAL_STRUCTURE })
```

VII. Experimental Setup

The controlled experiment uses one test profile: 2,000 kcal/day, 90 g protein, 60 g fat, 250 g carbohydrates, a ¥1,500 daily budget, and shellfish as an allergen restriction. Both implementations use seed 42, 100 iterations, and an equal population/swarm size of 60. The best-so-far fitness is recorded at each iteration. Because only one seed is available, all numerical results are descriptive single-run observations rather than estimates of expected performance.

The comparison uses final scalar fitness, plateau iteration, daily cost, and deviations from the calorie, protein, fat, and carbohydrate targets. These measures are reported directly from the available seed-42 execution and are interpreted descriptively within the scope of the prototype.

VIII. Results

Under the configured single run (seed 42), GA and PSO generated the following best daily meal plans:

GA Optimal Menu (Fitness: 5.15)

Meal Details:

Breakfast: Salmon, Tofu, Banana, Apple

Lunch: Rice, Bread, Spinach, Broccoli

Dinner: Soba Noodles, Pork Miso Soup, Chicken Breast, Cabbage

Snacks: Orange, Almonds, Rice Ball, Milk

Total: 2,045 kcal / Protein: 106g / Cost: ¥980

PSO Optimal Menu (Fitness: 4.92)

Meal Details:

Breakfast: Bread, Pork Loin, Soba Noodles

Lunch: Miso Soup, Bread

Dinner: Miso Soup, Bread, Pork Loin

Snacks: Rice Ball, Milk, Orange Total: 2,027 kcal / Protein: 94g / Cost: ¥650

Implementation characteristics relevant to interpretation of the results are summarized as follows:

- GA encoding: integer food identifiers organized by meal slot.
- PSO encoding: continuous food-selection strengths in [0,1] decoded to the highest-ranked eligible foods.
- Shared fitness function: scalar combination of nutrient adherence, constraint penalties, and food diversity.
- GA operators: tournament selection, meal-level uniform crossover, replacement/insertion/deletion mutation, and elitism.
- PSO update: inertia, personal-best attraction, and global-best attraction followed by discrete meal decoding.

For seed 42, GA achieved the higher final scalar fitness (5.15 versus 4.92). This comparison describes the configured execution only and is interpreted together with convergence behavior, daily cost, and macronutrient deviations rather than as evidence of universal algorithmic superiority.

A. Convergence Behavior

Fig. 2 shows the best-so-far fitness trace over 100 iterations for the representative run. GA starts at 3.28, reaches 5.09 by generation 10, and plateaus at 5.15 by generation 14. PSO starts at 3.67, reaches 4.88 by iteration 10, and improves to its final value of 4.92 near iteration 75, as shown in the full-resolution

curve in Fig. 2. Table III samples only four checkpoints (iterations 1, 10, 25, and 100) for brevity; it does not include a point at iteration 75, so readers should consult Fig. 2 for the exact location of PSO's late-stage increase. Relative to each algorithm's own final plateau in this run, GA required about 5.4 times fewer iterations than PSO (14 versus 75) to reach its final value. This pattern is consistent with the direct discrete GA representation and meal-level recombination implemented in the prototype and is interpreted only within the current configuration. Table III reports representative fitness values at selected iterations and complements the full convergence trace in Fig. 2. Macronutrient-target adherence is examined separately in Fig. 3.

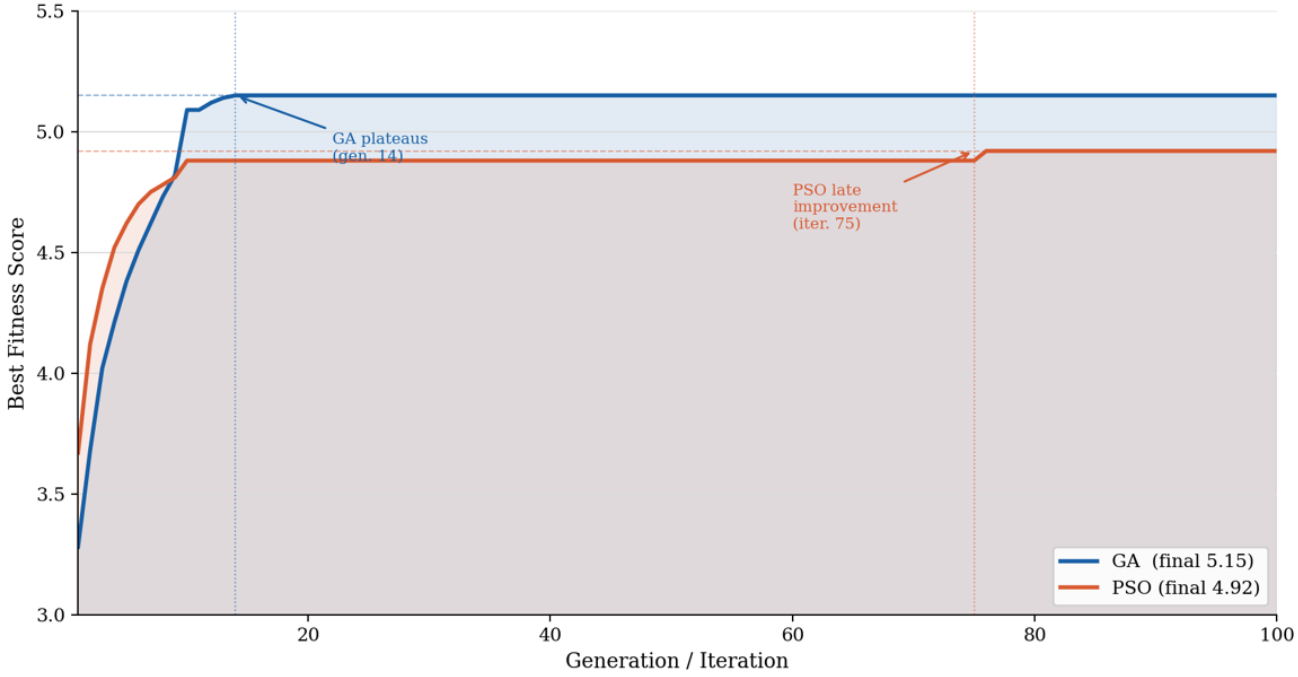

Fig. 2. Representative best-fitness convergence curves for seed 42 over 100 iterations. GA plateaus at 5.15 by generation 14, whereas PSO's fitness plateaus at 4.88 and then increases again near iteration 75, reaching its final value of 4.92. The figure is descriptive of this single run and is not an averaged convergence profile.

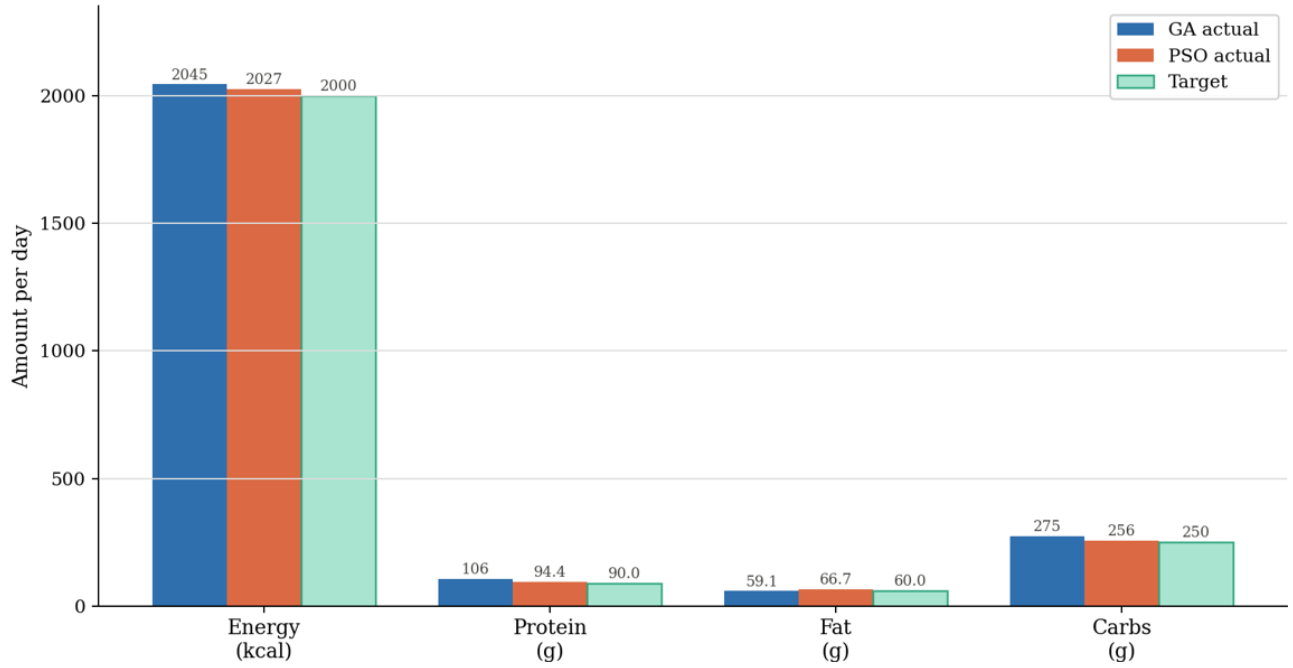

Fig. 3. Macronutrient totals for the representative GA and PSO best plans compared with the daily targets. The plotted values correspond to the single seed-42 experiment.

TABLE III. REPRESENTATIVE CONVERGENCE TRACE FOR SEED 42

Iteration	GA Fitness	PSO Fitness
1	3.28	3.67
10	5.09	4.88
25	5.15	4.88
100	5.15	4.92

These four checkpoints were chosen for brevity and do not include iteration 75, near which PSO's fitness rises from 4.88 to its final value of 4.92; this transition is visible in the full-resolution trace in Fig. 2.

B. Nutrient Accuracy

Fig. 3 compares the macronutrient totals of the best GA and PSO plans with the specified targets. The GA plan provides 2,045 kcal, 106.1 g protein, 59.1 g fat, and 275.0 g carbohydrates, corresponding to deviations of +2.3%, +17.9%, −1.5%, and +10.0%, respectively. The PSO plan provides 2,027 kcal and 94.4 g protein and, according to Table IV, shows smaller deviations than GA for energy, protein, and carbohydrates, while GA is closer to the fat target. Both plans remain within the tolerance bounds encoded in the current fitness formulation.

C. Summary

Representative final fitness and daily cost are GA = 5.15 / ¥980 and PSO = 4.92 / ¥650. Table IV consolidates the raw head-to-head metrics used in the subsequent discussion.

TABLE IV. DESCRIPTIVE HEAD-TO-HEAD COMPARISON FOR ONE PROFILE AND SEED 42

Metric	GA	PSO
Final fitness	5.15	4.92
Convergence generation	~14	~75*
Daily cost (¥)	980	650
Caloric accuracy ($\Delta kcal$)	+45 (+2.3%)	+27 (+1.4%)
Protein accuracy (Δg)	+16.1 (+17.9%)	+4.4 (+4.9%)
Fat accuracy (Δg)	−0.9 (−1.5%)	+6.7 (+11.2%)
Carbohydrate accuracy (Δg)	+25 (+10.0%)	+5.8 (+2.3%)

*PSO's convergence generation is read from the full-resolution trace in Fig. 2. Table III samples only iterations 1, 10, 25, and 100 for brevity and does not itself include a point at iteration 75.

IX. DISCUSSION

A. Advantages of GA for Meal Planning

The earlier GA plateau observed in Fig. 2 is consistent with the representation used in this prototype. Integer chromosomes directly encode discrete food selections, and meal-level crossover can preserve and recombine partial meal structures. Genetic-algorithm performance is known to depend strongly on representation, selection, crossover, mutation, and parameter settings rather than on the algorithm label alone [7], [9]. A more directly comparable meal-planning study by [3] evaluated GA together with PSO, duck swarm algorithm (DSA), and whale optimization (WO) on a 55-food maternal menu-planning problem. That study reported statistically different fitness behavior among the evaluated optimizers. The present experiment likewise shows different GA and PSO behavior in the representative run, with GA reaching a higher final fitness and an earlier plateau. However, the fitness formulations, objective directions, datasets, and experimental protocols differ across the two studies. Their numerical fitness values should therefore not be compared directly.

B. Advantages of PSO for Budget Efficiency

PSO produced a best plan costing ¥650 compared with ¥980 for GA, a reduction of approximately 33.7%, while remaining within the encoded nutritional tolerance bounds. It also achieved smaller deviations for energy, protein, and carbohydrates in the reported solution. This trade-off is relevant to recent personalized nutrition research, where cost and nutritional criteria are often optimized jointly rather than treated as a single performance dimension [2], [5]. For example, [2] showed that a hybrid PSO-Simulated Annealing approach could improve the accuracy of standard PSO when optimizing consistency in an AHP-based personalized meal-planning framework. This illustrates that PSO performance can change substantially with hybridization and problem representation. More broadly, the systematic review by [8] emphasizes that PSO behavior is sensitive to parameter settings, variants, and the balance between exploration and exploitation. Thus, the lower-cost solution obtained here should be interpreted as a configuration-specific result of the continuous latent representation, top-k decoding rule, and current fitness weights, rather than as evidence that PSO generally produces cheaper meal plans.

C. Comparison with Recent Meal-Planning Studies

The present study occupies a narrower but complementary position relative to recent AI-based meal-planning research. Amiri et al. [1] combined reinforcement learning and collaborative filtering and evaluated their approach on a large recipe-and-user-interaction setting, explicitly targeting user acceptance, preference, and nutritional adequacy. By comparison, the current prototype uses a 24-item food database and a single static nutritional profile, with no feedback loop or learned preference model. Its contribution is therefore not adaptive personalization, but a controlled implementation-level comparison of two population-based optimizers under the same food data, constraints, population size, iteration budget, and scalar fitness function.

The observed tension between GA's higher scalar fitness and earlier convergence and PSO's lower cost also reflects the broader multi-criteria nature of diet optimization. Liu et al. [5] demonstrated that diet optimization at a much larger scale requires simultaneous consideration of nutrition, affordability, acceptability, and environmental consequences. Dussiot et al. [6] separately showed that realistic nutrient requirements, particularly micronutrient constraints, can materially alter feasible optimized diets. These studies reinforce two implications for the present results. First, no single metric should be treated as sufficient evidence of overall meal-plan quality. Second, the apparent preference between GA and PSO may change when additional criteria such as micronutrients, portion sizes, acceptability, or longer planning horizons are introduced. Direct numerical benchmarking against these studies would be inappropriate because their decision variables, objectives, datasets, and evaluation protocols differ substantially from those used here.

D. Limitations

This study has several important limitations. First, the food database contains only 24 Japanese-style items, which limits the search-space diversity and does not represent a comprehensive real-world food catalog. Second, only one nutritional profile and one random seed (42) are evaluated. The study therefore reports descriptive single-run results rather than mean performance, standard deviation, or significance testing across repeated runs, and the findings should not be read as statistically generalizable. Established nonparametric methodologies for comparing stochastic optimizers across repeated runs, such as the Wilcoxon signed-rank test, are available for this purpose and are recommended for future multi-seed replication [12]. Third, portion sizes are fixed at one serving per selected item, preventing continuous portion adjustment. Fourth, the fitness function models calories and three macronutrients but not micronutrients, meal timing, clinical conditions, or longitudinal variety. Fifth, neither GA's operator settings (mutation rate, elite ratio, tournament size) nor PSO's coefficients (inertia weight, cognitive and social coefficients) were tuned or subjected to a parameter-sensitivity analysis. Both GA and PSO performance are known to depend strongly on such settings [7]–[9], [11], so the reported comparison reflects one arbitrarily chosen configuration per algorithm rather than each algorithm's best achievable performance. Sixth, the manuscript does not report the wall-clock or computational runtime of the two optimizers, even though runtime is a practically relevant dimension for comparing population-based metaheuristics and has been highlighted in prior GA–PSO comparisons [10]. These limitations define the present work as a focused proof-of-concept comparison and should be considered when interpreting the reported GA–PSO trade-offs.

X. Conclusion

This study presents a controlled proof-of-concept comparison of GA and PSO for automated four-meal daily planning using a common 24-food database, identical population/swarm size, an equal iteration budget, and the same constraint-aware scalar fitness function. Both algorithms produced meal plans that satisfied the encoded macronutrient tolerance bounds within the representative execution.

For the single profile and seed 42, GA achieved the higher final fitness (5.15 versus 4.92) and reached its final plateau earlier (generation 14 versus iteration 75, per the full-resolution trace in Fig. 2). PSO, however, produced the lower-cost plan (¥650 versus ¥980) and smaller deviations from the energy, protein, and carbohydrate targets.

Accordingly, the present evidence supports a configuration-specific trade-off rather than a universal recommendation of one optimizer. Under the current scalar fitness, GA is preferable when the emphasis is on the reported fitness value and convergence behavior, whereas the PSO solution is attractive when lower cost and closer matching of several macronutrient targets are prioritized. The conclusions are intentionally confined to the available prototype data and the representative seed-42 execution.

XI. Future Research Directions

Future research may extend the present proof-of-concept by enlarging the food database to represent a broader set of realistic food choices and by allowing serving sizes to vary rather than remaining fixed at one portion per selected item. Methodological extensions may also combine discrete food selection with continuous portion-size optimization or adopt Pareto-based multi-objective optimization when nutrient deviation, cost, and diversity are treated as separate competing objectives. The nutritional scope may be broadened from calories and macronutrients to relevant micronutrients, while longer planning horizons could support weekly or monthly menus with cross-day variety and meal-timing constraints. Further application-oriented work may additionally consider multiple nutritional profiles and domain-expert or user assessment to examine the practical usefulness of the generated meal plans.

***Abstract*—ICT projects in the Malaysian public sector continue to experience failure, especially in outsourced application system projects. In striving to overcome this issue, the government is leading a significant push toward the digitization of public services. In previous studies, the challenges of ICT implementation have been analyzed from the perspective of project, system, and technology management. However, the focus in these studies is typically on challenges that occur within the system. There is limited concern for the outsourcing of public services. Specifically, this study focuses on the critical factors of vendor-related failure in ICT projects in the Malaysian public sector. The study employed an interview-based approach in which eight experienced ICT practitioners involved in project implementation, procurement, governance, and vendor management participated in purposefully selected, semi-structured interviews. Data were analyzed by thematic coding of interview transcripts. Each percentage reported represents the frequency of the reference within its own HOPT-FIT domain rather than a total share across all four domains. The findings were that vendor ineffectiveness, lack of project management, problems with requirements and risk management, as well as issues of knowledge transfer and effective governance, technology, and project management were the dominant factors contributing to ICT project failure. The research further confirmed that ICT project failure is multifaceted and occurs due to the integration of challenges in the human, organizational, process, and technology domains throughout the project lifecycle. deficiencies in technology, as opposed to upstream weaknesses in human capability and process governance. This demonstrates the study's finding that human and process-related capabilities are the dominant factors contributing to the failure of outsourced ICT projects, with Technology (the biggest of these factors, technical difficulties, 75%) recording the highest percentage in a single domain. Through this study, providing the first empirical evidence on the failure of ICT projects due to vendors, I offer contributions to the body of knowledge in information systems and provide practical advice for improving the procurement of goods and services and the assessment of vendors. The results lay the foundation for the development of a vendor selection tool that aims to decrease the risk of failure of public sector projects in Malaysia and increase the chances of succeeding on the public sector digital initiatives.**

***Keywords*—ICT project; ICT project failure; project management; ICT procurement; vendor characteristics; information systems**

I. Introduction

Information and Communication Technology (ICT) drives economic growth, restructures industries, and reforms public services [1]. Today, governments use ICT application systems to offer better services, increase efficiency, build transparency, and aid evidence-based decision-making [2], [3]. The development of digital technology has made ICT infrastructures and application systems essential to deliver public services [3], [4]. Consequently, governments [5] have dedicated more resources to ICT projects to ensure that the government's digital services are effective and on par with the needs of its citizenry.

In Malaysia [6], ICT is critical for public sector transformation. Government agencies perform a myriad of ICT activities, including the development of application systems, digital service delivery projects, and initiatives for cybersecurity, systems integration, and the modernization of ICT infrastructure [6], [7]. Such initiatives are expected to improve organizational performance and remove bureaucratic bottlenecks to improve the quality and efficiency of public services [8], [9]. Thus, the successful implementation of ICT projects is vital [3] to ensure public investments produce the expected operational, organizational, and societal benefits. From an Information Systems (IS) perspective, project success is more than completing a project within time, cost, and scope constraints [10]. Instead, [11] for an ICT implementation to be successful, there has to be a congruence of the organization's objectives, business processes, and the needs of system users, and the organization's capacities [11], [12]. If vendors lack the required capabilities to support this alignment, the resulting systems will fail to provide the expected value to the organization.

Consequently, [13] argued that generic IS outcomes such as system quality and implementation outcomes, in addition to the quality and impact of services, information, and user satisfaction, are all reliant upon vendor performance. Therefore, the vendor selection process [14] should embrace an element of consideration beyond a procurement function and should reflect an IS strategic function, as it may determine the success or failure of an ICT project implementation.

Although there are advancements in digital technology and project management systems, failure of ICT projects is still

prevalent globally[15] and is still a major issue. Many publications [16], [17] have reported issues associated with ICT projects in terms of delays, budget overruns, increasing work requirements, declining quality, and seldom complete project refusals. The challenges of ICT project implementation include technological uncertainty, continually changing needs of the users, resistance of the organization, and the many kinds of stakeholders [18]. As a result, these factors ultimately lead to the failure [17] of many ICT projects despite ample planning and substantial effort. According to [17], the outcomes of ICT project failures extend beyond financial losses. Unsuccessful projects [18] tend to cause operational inefficiencies, lower user satisfaction, service disruptions, reputational damage, and missed organizational benefits [8], [14], [18]. In the public sector, these issues are particularly significant because when projects fail [19], it directly impacts how public services are provided, how well the government performs, and the level of trust from the public [11].

The Malaysian public sector faces similar issues [20]. Reports [21] and Auditor General reports [22] have identified problems with ICT project governance due to issues such as poor planning, inadequate requirements management, weak governance, limited stakeholder engagement, and deficient risk management [23]. These initiatives also face system integration issues [13] as well as vendor performance issues [8], [13]. A number of high-impact ICT projects have experienced delays in implementation, extended deadlines, increased costs, and poor functionality before they were made available for operational use [23]. The challenges of project governance and procurement processes are inadequate to manage the key success factors of these projects [20], [23].

Though a lot of work has been done looking at ICT project failure in general, a few notable gaps in the existing research remain. First, most of the existing research concentrates heavily on challenges like project management issues, organizational problems, and technological risks [16], [24], [25], while relatively fewer studies look at factors related to outsourcing as determinants of project failure [14]. Second, most research studies [14] examine project failure after implementation problems have already occurred rather than how risks start forming during the procurement and vendor selection stages. Third, few studies examine outsourced ICT project breakdowns through an IS lens within Malaysia's government sector [20], [26]. Finally, most current procurement studies focus mainly on compliance, financial assessment, and procurement efficiency, offering little theoretical grasp of how vendor characteristics [28] impact long-term ICT project results [27], [28].

Therefore, this study aims to understand how vendor traits lead to ICT project failures in Malaysia's public sector. In particular, the research intends to identify the factors related to outsourcing failures [13] and build an empirical basis to develop a better framework for selecting vendors for ICT application system projects. This study addresses gaps in the existing research and supports Malaysia's digital transformation as it also strengthens procurement theory and practice within the public sector and the IS. Understanding the main causes of failures in ICT projects is still of major concern to both researchers and practitioners [13], [29].

This section has been organized as follows: Section II describes some theories on the factors behind ICT project failures, as described in previous studies. Section III describes the methodology of this study, including a qualitative research approach and semi-structured interviews. Section IV provides empirical data and theoretical findings. Finally, Section V describes the conclusions drawn from the research.

II. THEORETICAL FINDINGS

Many governments spend an enormous amount of money on digital tools and services in efforts to develop more effective and transparent processes and communicate with their citizens more. Despite these investments, ICT project failures remain a major issue [30] in both developed and developing countries [30], [31], [32]. Various research papers have noted that numerous ICT projects end up failing, and failed implementation [32], [33] of ICT projects can be attributed to inadequate planning and initiation, insufficient budget allocation, insufficient training [34], lack of qualified personnel, poor communication to reach their goals, inefficient government practices, inadequate functionality, and unmet government expectations [35], [36]. Focusing on giving users a good experience helps increase efficiency in work. Without focused attention [48], system faults will eventually hold back overall business operations.

Additionally, studies [30] show that several factors lead to the failure of ICT projects, such as the lack of understanding of the domain agency, shortages of human resources, and poor management of stakeholder engagement [37], [38]. Referring to [39], automation projects in this sector frequently face major obstacles, leading to delays, cost overruns, and in some instances, complete failures. Moreover, the consequences of ICT project failures extend beyond financial losses [16], [17]. This leaves a gap in the systematic investigation [21] of vendor-related critical factors of failure in ICT projects. Vendor performance reliability [40] directly impacts project failure. Addressing this gap will help strengthen procurement decisions [10] and establish a foundation for successful outcomes of future government digital initiatives in [19]. Fig. 1 below shows outsourced ICT project failure factors as insights obtained from the literature.

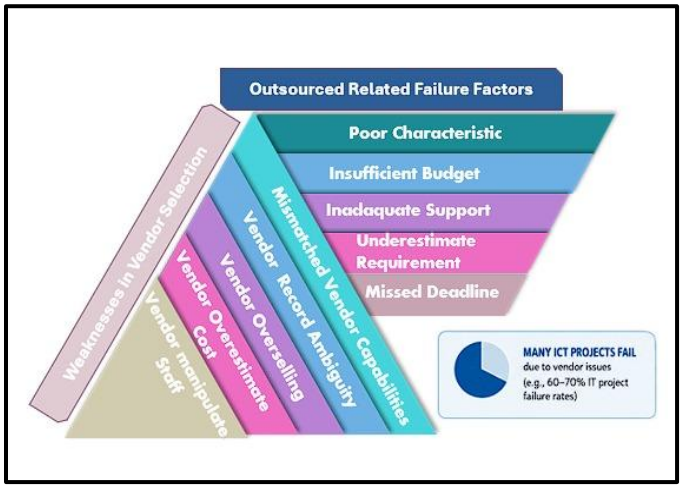

Fig. 1. Outsourced ICT project failure factors.

In Malaysia, public sector digital initiatives [41] have expanded significantly over the past decade. However, project assessments and performance audits [42] continue to report recurring implementation issues, including delayed project delivery, escalating costs, technical difficulties, integration difficulties, incomplete system functionality, and limited realization of expected benefits [13]. A lack of experience and skills related to implementation is another reason noticed for the failure of ICT projects [43]. These recurring challenges suggest that understanding the critical factors contributing to ICT project failures remains an important area of investigation, particularly in projects implemented through outsourcing arrangements.

Although numerous studies have employed various models with multiple dimensions to explore ICT projects, minimal attention has focused on the vendor's perspective. Thus, for this study, a basic human, organization, process, and technology (HOPT) have been employed as a baseline to reveal the critical failure factors in public sector ICT projects: insights from outsourced digital initiatives in Malaysia.

The increasing dependency on outsourcing has changed the implementation landscape [44] of ICT projects within the public sector. External vendors are frequently engaged to provide specialized expertise, system development services, infrastructure support, maintenance activities, and technological solutions. However, outsourcing introduces risks [44], [45] that may significantly influence project outcomes.

There are many state-of-the-art studies that explore these outsourced ICT project risks. Researchers [46] employed information, technology processes, objectives and values, staffing and skills, management systems and structures, and other resources (ITPOSMO) models to explore risks in ICT development projects. Besides, studies conducted by [47] also utilized ITPOSMO to identify gaps in e-Government implementation.

The ITPOSMO model was used by [48] and [49] in the research to evaluate the gaps between the designs realized applications, while [50] used it to identify design gaps and assess the success or failure of a statistical IS. Another opinion [48] also indicates that the ITPOSMO model is used to assess how well an IS performs in the delivery of public services and to identify areas requiring improvement to enhance employee satisfaction. Similarly, [46] reveals issues related to Enterprise Architecture (EA) implementation by breaking the factors into HOPT-FIT.

According to [51], the human, organization, and technology dimensions are essential to evaluating health information systems (HIS) implementation; [52] stated that this led to the development of a HOT-FIT model designed for HIS evaluation based on the IS success model. The HOPT-FIT model is most relevant [53] to this research due to the interrelated dimensions of human, organization, process, and technology, where each factor from the four aspects influences the others in determining the success or failure of ICT project implementation.

Based on research by [54], human involvement plays a crucial role in implementing ICT projects. The human-related dimension represents one of the most frequently reported causes of ICT project failure. The success of outsourced ICT projects depends heavily on the knowledge, skills, experience, communication abilities, and commitment of vendor personnel. Incompetency and inadequate technical expertise often limit a vendor's ability [55] to understand business requirements, develop effective solutions, and respond to implementation challenges. The organizational dimension is just as important as the human dimension, as it affects how ICT projects are steered, handled by top management, and aligned with project strategic goals. Organizations today rely on IS to carry out and streamline their business processes [56]; thus, an organization's performance relies heavily on three main factors: the quality of data in the system, user satisfaction, and the needs of the organization using the system in its everyday tasks. Poor governance structures have frequently led to project failure by slowing down decision-making processes and restricting effective project management [57].

Authors in [25] stated that process dimension is also commonly listed as key drivers of ICT project failure, as stated in. Proper execution of a project depends on clearly defined processes from initial planning of requirements, management of risks, quality checks, and ongoing monitoring. Successful implementation calls for clear processes during initial project planning, requirements tracking, risk accountability, quality checking, and project tracking; insufficiencies in these processes usually increase the uncertainty and risk of project implementation. Technology still plays a key role in shaping the results of ICT projects, especially in more complex digital transformation scenarios. Vendors must have the technical ability to build, connect, and maintain complex IS. A lack of technical expertise frequently leads to skills deficiency, implementation issues, system faults, integration problems, and reduced system performance. The dimensions and factors related to this HOPT-FIT model are depicted in Table I.

TABLE I. DIMENSION VS FAILURE FACTORS

Dimension	Failure Factors	Citation
Human	Shortage of qualified personnel, poor communication to achieve their intended objectives, incompetency of technical skills, lack of experience and skills.	[35], [33], [36], [43], [58], [34]
Organization	Human resource shortage and ineffective stakeholder involvement, delayed project delivery, financial losses	[33], [36], [59], [41], [19]
Process	Poor understanding of domain agencies, integration difficulties, ineffective government practice, inadequate functionality, unmet government expectations, poor communication, and delayed project delivery	[60], [42], [41], [13], [31], [32], [35], [32], [39]
Technology	Technical difficulties, incomplete system functionality, system defects, reduced system performance, poor system quality	[8], [42], [41], [13], [20], [61]

Table I integrates findings from various researchers and shows that the failures inherent in outsourced ICT projects are not the result of simple technical shortcomings. Instead, they result from the interrelated dimensions of people, processes, and organizations. From the human dimension, most studies point to the lack of skilled staff, poor communication, inadequate technical know-how, and lack of project experience as main factors contributing to poor collaboration, weak decision-making, and poor problem-solving in implementation. From the

organizational side, an inadequate number of staff, insufficient customer participation, late delivery of projects, and loss of funds reflect how the organization's capacity and governance contribute to a vendor's inability to fulfill projects successfully. Also, from the process side, poor understanding of government departments' needs, inefficient government processes, integration difficulties, defective systems, slow communication, and late project delivery and unmet expectations reflect that deficiencies in project management, requirements engineering, and procurement remain primary factors leading to project failure. From the technology perspective, technical difficulties, incomplete system functionality, system defects, reduced system performance, and poor system quality are frequently associated with implementation challenges that undermine system reliability and operational effectiveness.

Collectively, these studies indicate that outsourced ICT project failure results from the interaction of human capability, organizational readiness, implementation processes, and technological quality. However, most existing studies examine these factors during project implementation or post-implementation, while limited attention has been given to integrating them as vendor-related evaluation criteria during the procurement and tenderer selection stage. This gap provides the theoretical motivation for the present study to investigate critical vendor-related failure factors and to support the development of a comprehensive Tenderer Selection Specification Framework for outsourced ICT projects in the Malaysian public sector.

III. METHODOLOGY

This study adopted a qualitative research approach to obtain in-depth information on critical ICT project failure factors. This approach was conducted [24] to ensure certainty through interviews with experts in ICT project management Malaysia public sector [12], [24]. This method is appropriate to examine experts' opinions and suggestions on current failure factors that may lead to the risk of application system development failure [13].

To improve content validity, the interview protocol [62] was developed based on the collection of factors and domains through a comprehensive review and found in the related works [63], [64], [65] and was reviewed by academic experts and experienced practitioners before preliminary data collection to refine the instrument and obtain useful suggestions [67]. Feedback gathered [66] in the review process was used to make sure clarity, readability, and relevance in the final interview tool.

Semi-structured interviews [67] were chosen as the main data collection method because they allow participants to describe comprehensive experiences, views, and ideas about ICT project failures. This method helps to elicit detailed expert feedback [68] from their experiences linked to vendor behavior and project results.

The research was conducted in relation to ICT application system projects implemented in Malaysian public sector organizations [13], [69]. The public sector was chosen because government agencies keep encountering implementation problems [19], [70] despite major investments in digital transformation initiatives. Moreover, most ICT application system projects in the public sector are usually carried out through outsourcing agreements, so vendor performance is a key factor in whether the project succeeds or fails [71], [72], [73].

A purposive sampling approach [65] was used to find participants with a lot of experience in ICT project implementation, procurement management, project governance, and vendor management activities. Eight experts were selected according to predetermined inclusion criteria. First, participants needed ample professional experience in ICT project management or ICT application system implementation [74], [75]. Second, participants needed direct involvement in outsourced [13] ICT projects in the public sector. Third, participants needed hands-on experience with project planning, procurement, vendor assessment, project governance, system development, or project monitoring. Finally, participants needed to occupy more senior roles so they could offer a strategic and operational viewpoint on the failures of ICT projects [12], [65], [76].

The selected experts represented diverse professional backgrounds, including deputy ICT directors, project managers, leading PMO and PMO teams (project monitoring office), procurement officer [7]. This diversity ensured comprehensive coverage of technical, managerial, organizational, and procurement perspectives relevant to vendor-related project failures [74]. Table II below shows the expert selection criteria applied in the Malaysian public sector.

Data analysis was performed using thematic content analysis. Interview transcripts were transcribed verbatim and coded manually, with each mention of a failure factor tagged to its corresponding HOPT-FIT dimension (Human, Organization, Process, or Technology). The percentage reported for each factor represents the proportion of coded references to that factor relative to the total coded references within its own domain and therefore reflects the relative salience experts placed on that factor within each dimension rather than its share of the overall interview data across all four domains combined. To strengthen the credibility and consistency of the coding process, the coding scheme and factor categorization were independently reviewed by two academic experts, and disagreements were resolved through discussion until consensus was reached. Given the purposive and highly experienced nature of the eight participants (15–25 years of relevant experience across diverse public-sector domains), data collection continued until no new failure factors emerged from successive interviews, indicating that thematic saturation had been reached within the scope of this exploratory study. Nonetheless, the relatively small, purposively sampled group of participants is acknowledged as a limitation of this study, and this is addressed further in Section V.

As shown in Table II, the interview sessions were conducted based on the theoretical findings established in Section II, which provided the basis for identifying research questions and confirmed that this research topic is suitable within the information system field. Table II presents the expert selection criteria adopted to ensure the credibility and relevance of the qualitative findings. Eight experts (EX1–EX8) were selected based on a set of predefined criteria, including at least 15 years of professional experience in ICT project management, system development, procurement, or ICT governance. All

selected experts had considerable involvement in Malaysian public sector ICT projects and substantial experience in outsourcing evaluation, contract management, procurement processes, or the implementation of outsourced ICT projects. The selected experts also held strategic, managerial, or technical decision-making positions and had a deep understanding of the challenges related to the implementation of ICT application systems and IT projects. Participants were chosen to reflect different areas of the public sector, spanning digital services, enforcement, public security, public order, health management, and natural resources. These participants had between 15 and 25 years of professional experience, allowing them to provide valuable, authentic, and situational explanations of the critical failures experienced on outsourced public sector ICT projects in Malaysia.

TABLE II. EXPERT SELECTION CRITERIA

Experts (EX)	Experience	Position	Agency (Domain)
EX1	25 years	Deputy Director, Project Management Unit	Digital services
EX2	21 years	Deputy Director, IT Department	Enforcement
EX3	20 years	Chief Assistant Director, IT Department	Public security
EX4	20 years	Chief Assistant Director, IT Department	Public order
EX5	18 years	Assistant Director, IT Department	Health management
EX6	17 years	Assistant Director, IT Department	Enforcement
EX7	15 years	Assistant Director, IT Department	Natural resources
EX8	17 years	Deputy Director, Project Management Unit	Digital services

IV. EMPIRICAL FINDINGS

While Section II synthesized failure factors identified in prior literature to build the theoretical foundation of this study, this section presents the empirical findings derived directly from the eight expert interviews conducted for this research. The analysis of data obtained from the expert interviews revealed critical failure factors that affect the outcomes of outsourced ICT projects in the Malaysian public sector, and these empirical findings are mapped back to the theoretical findings from the literature review discussed earlier. The critical failure factors were categorized into four main domains based on the HOPT-FIT model, namely Human, Organization, Process, and Technology (HOPT).

The analysis showed that outsourced ICT projects in the public sector in Malaysia have complex failures due to the interconnectedness of different factors. The first of these is the Human domain. Insufficient communication, lack of skills, experience, and competency, as well as a lack of specialized skills and knowledge, have all been factors in project failures. The Organization domain noted issues of capacity, particularly around challenges with human resources, stakeholder inclusion, and financial shortages resulting in delayed project delivery. Among the challenges in the Process domain, the study noted poor understanding of government agency requirements, insufficient government practices, difficulties with integration, insufficient system functionality, and challenges with unmet government expectations. Technology domain issues included incomplete systems and technical problems. These findings suggest that all ICT project failures have to do with people, their organization, and the process of implementation, and the capabilities of technology, giving a full account of user-related failure factors in outsourced public sector ICT projects. The following is a comprehensive breakdown for each domain.

A. Human Domain

According to all eight experts, communication breakdown and insufficient project experience are the biggest issues in the Human domain, each contributing approximately 30% of the coded references within this domain. The results show that vendor-to-government agency communication is one of the primary causes of miscommunication during the business requirements clarification process. Poor communication causes delays, misaligns stakeholders, and results in ambiguous solutions to project issues. Similarly, project experience on the vendor's side is just as important; without experience, a vendor cannot anticipate risks during implementation, manage public sector requirements, or handle the fluctuation of project requirements. Other causal factors (approximately 15%) included incompetence, reflected in a lack of professional knowledge and poor problem-solving. Performance-related issues (approximately 13.5%) included poor commitment and inconsistency in the delivery of assigned projects. Inadequate technical expertise (approximately 11.5%) affects a vendor's ability to provide reliable and sustainable ICT solutions. Collectively, these findings show that human capacity remains one of the main obstacles to project success and vendor performance. Fig. 2 illustrates the factors identified by all experts under the Human domain.

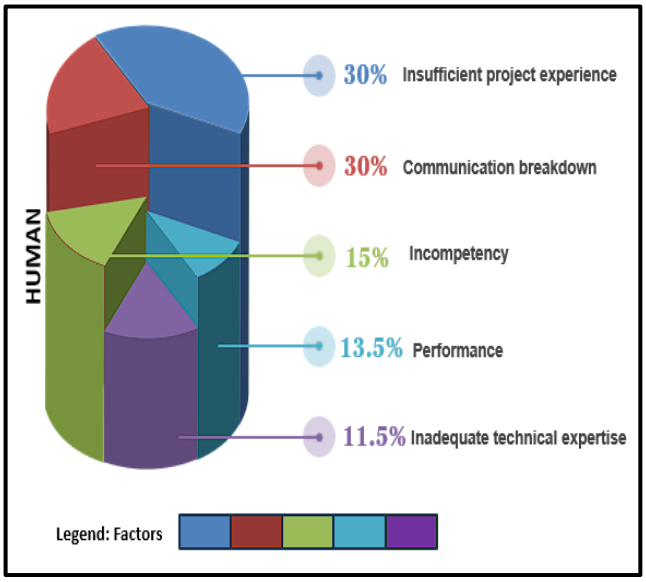

Fig. 2. Human factors related.

B. Organization Domain

According to the experts, 50% of participants identified human resource issues as the biggest organizational constraint, while the remaining 50% identified financial breakdown as the biggest constraint. Insufficient human resources among vendors means there are not enough skilled resources to carry

out the project, resulting in an overburdened workforce, reduced productivity, and delays in project activities. Financial breakdown means that a vendor lacks the financial reserves to support the project, retain skilled employees, or cover financial gaps in the required technologies and sustain the project. These constraints adversely affect the operational resilience of a vendor and its ability to deliver contracted outcomes as expected. Fig. 3 indicates the factors selected by the experts.

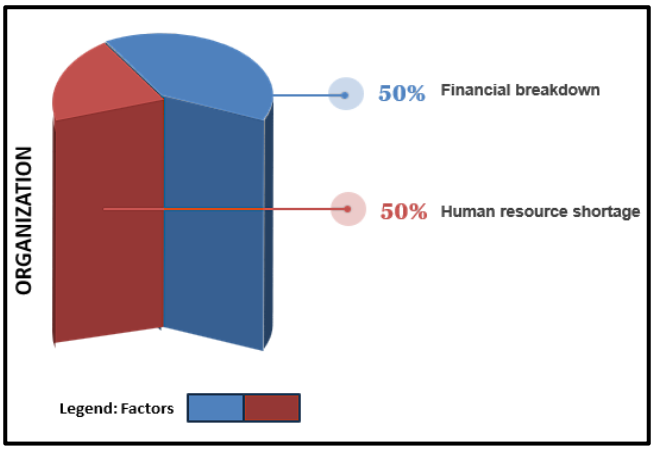

Fig. 3. Organization factors related.

C. Process Domain

The Process domain indicated that communication breakdown continued to be the most important process factor, at 40% of coded references, indicating that poor communication affects not only people but the project management process itself. Poor communication leads to issues in identifying requirements, engaging stakeholders, managing change, and coordinating the project. Additionally, long project completion times (20%), deficient government operating practices (20%), and poor understanding of government agency requirements (20%) show that issues in planning and governance, coordination of procurement, and management of requirements continue to negatively affect the effectiveness of project implementation. The results in Fig. 4 show that ineffective project processes lead to increasing risks in project cost, time, and quality.

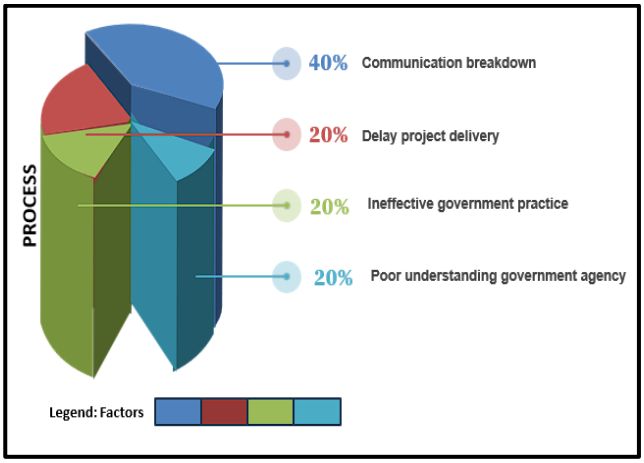

Fig. 4. Process factors related.

D. Technology Domain

Technology domain experts unanimously agreed that the biggest technological challenge for outsourced ICT projects is technical difficulties, accounting for 75% of coded references within this domain. This challenge is characterized by the integration of multiple systems, compatibility issues between software components, and insufficient infrastructure, along with the complexity and implementation challenges of the systems that lead to delays and compromise system effectiveness. Second, poor system quality (13.5%) reflects weaknesses in system functionality, reliability, and performance. Although Technology issues were reported less frequently overall than Human and Organizational issues, the experts indicated that many of the technological challenges are caused by deficiencies in the planning and governance of communication and project execution, rather than by the technology itself — reinforcing that the Human and Process domains are the primary root causes underlying downstream technical shortcomings. Fig. 5 illustrates the Technology domain factors identified by the experts.

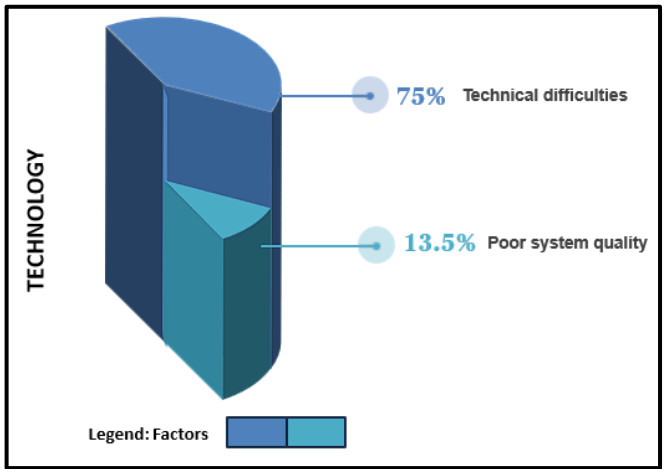

Fig. 5. Technology factors related.

The findings show how complex and interrelated the critical failure factors can be in outsourced public sector ICT projects. Weaknesses in one domain can easily affect the other domains and adversely affect a project by causing delays, budget overruns, low-quality systems, user dissatisfaction, and unmet organizational goals. These findings support the notion that for a vendor to improve its capability, there should be an equally strong focus on all elements within the human domain, the organization, the process, and the level of technical preparedness demanded across the full spectrum of the ICT project lifecycle.

The critical failure factors identified in this study provide insight into the challenges associated with the implementation of outsourced ICT projects, despite the large public commitment to digital transformation endeavors. Communication was the most critical factor across the Human and Process domains, highlighting the negative effects that ineffective collaboration between vendors and government agencies has had, and continues to have, on planning, requirements management, decision-making, and the ultimate implementation of the project. Restrictions facing organizations, primarily a lack of financial and human resources, increase the challenges vendors

face in delivering projects. Inadequate planning and execution along the governance dimension of the project are typically the root causes of malfunctions, as opposed to deficiencies in technology itself. The cumulative effect of these problems leads to delays in project completion and consequent cost overruns, poor-quality systems and services, and increased user dissatisfaction, as the organization's intended benefits are not achieved. This supports the claim that ICT failure is a multidimensional issue, and that evaluating each vendor component — people, organizational capacity, implementation process, and technical skill — is crucial. Using empirical evidence from practitioners, this study describes the challenges of outsourcing public sector digital projects and guides adjusting procurement, vendor evaluation, and project management frameworks for government services to support the success of future ICT undertakings.

V. Conclusion

This study on outsourced ICT projects in the Malaysian public sector focused on the primary vendor-related failure factors. From the interviews with ICT specialists, it was found that project failure may be attributed to a combination of human, organizational, process, and technology factors, in the absence of adequate synthesis of vendor capability across all four domains. It was found that the way a vendor synthesizes its capabilities will ultimately affect project outcomes. From an active public sector perspective, a lack of adequate communication, a lack of competency and organizational readiness, inadequate capacity for project execution, and a lack of adequate technical capabilities negatively affect digital strategies. These factors can result in poor system quality, user dissatisfaction, cost overruns, delayed project completion, and an inability to achieve intended outcomes and benefits.

This study adds value to the existing literature on ICT project failure by focusing on outsourced digital initiatives in Malaysia and will be of interest to academia. It will also be of interest to the public sector in proposing a more complete assessment of vendors and in extending risk management approaches across the project lifecycle. This study focuses on the failure of outsourced ICT projects and aims to improve procurement and project management practice. It should be noted that the findings are based on a purposively sampled group of eight experts within the Malaysian public sector, and while thematic saturation was observed within this group, further research involving a greater variety of stakeholders across the public sector is necessary to validate and extend these findings, improve strategies for mitigating the risk of ICT project failure, and enhance the success of future digital transformation initiatives.

Empowering Educators to Develop Augmented Reality Applications by Integrating Computational Thinking and Experiential Learning

***Abstract*—Augmented reality (AR) promises rich, immersive experiences in learning, yet many educators lack the technical expertise to develop AR content independently. Existing authoring environments often emphasise functionality over instructional design, leaving educators reliant on pre-built resources that seldom match their learning goals. This study proposes EduCATE-AR, a template-based authoring model that integrates Experiential Learning (EL) and Computational Thinking (CT) to embed pedagogies directly into a modular-based authoring approach. Using a three-phase design science research approach, pedagogical principles were mapped onto AR authoring workflows to develop the model. A template-based editing environment was then constructed based on these mappings, and its use was evaluated through a mixed-methods study involving a focus group with educators. Quantitative results based on the Technology Acceptance Model (TAM) indicated strong perceived usefulness and intention to use, particularly among educators without prior AR development experience. Qualitative findings further highlighted the model's value in reducing technical barriers and supporting pedagogical structuring, while also revealing the need for improved extensibility and subject-specific flexibility. Collectively, the proposed model is a valuable addition to AR instructional design by empowering educators as content creators to develop pedagogically aligned AR applications with greater autonomy.**

***Keywords*—Augmented reality; content creation; instructional design; template-based authoring; experiential learning; computational thinking**

I. Introduction

With the advancement of technologies, digital-native learners are expecting visually rich and interactive educational content, pushing educators to adopt more engaging instructional strategies. Among the possible technologies, Augmented Reality (AR) particularly stands out for its ability to overlay real-world environments with dynamic digital content, offering immersion in the learning experiences [1-4] to improve motivation and interests [5-9]. While AR is often accessed through mobile devices and marker-based tracking [10, 11], its adoption tends to prioritise engagement. Learners may initially be engaged; however, feature-driven applications can result in superficial engagement, lacking the depth required for sustained knowledge acquisition [12]. Hence, a critical challenge persists: how can AR experiences be designed to achieve not only engagement but also pedagogically meaningful learning?

Developing AR applications in education is not without its limitations. Studies in AR authoring often emphasise technical capabilities in interactivity but pay less attention to pedagogical structuring, which places usability barriers and limits educators' involvement in shaping meaningful AR learning experiences [13-15]. The disconnection of pedagogical relevance in AR content is a concern echoed in recent reviews of AR adoption in education [16]. Although approaches like inquiry-based and situated learning have been constantly explored within AR [17-19], there is limited integration of structured pedagogies like Experiential Learning (EL) and Computational Thinking (CT) in providing support for AR design that emphasises both reflective thinking and systematic problem-solving.

Integrating these structured pedagogies can provide a foundation for enhancing the educational impact of AR [20] by moving beyond surface-level engagement toward deeper learning outcomes. EL supports reflective learning through a cycle of experience, reflection, conceptualisation, and application [21-23], which aligns naturally with AR's immersive potential. CT, on the other hand, fosters essential cognitive skills through processes such as pattern recognition, decomposition, abstraction, and algorithmic reasoning [24-26], providing a valuable approach for designing logic-driven AR learning tasks. Although EL and CT have been applied separately in AR learning environments [24, 27, 28], their combined potential within a unified AR content creation framework remains largely unexplored.

To address these challenges, this study proposes a template-based authoring model designed for educators with limited technical expertise. The model integrates EL and CT principles directly into the AR content creation workflow, embedding pedagogical structure into modular templates. The study employed a focus group methodology to evaluate the model's pedagogical alignment and usability, gathering feedback through open-ended reflections and Technology Acceptance Model (TAM)-based questions. Specifically, the research investigates: 1) how EL and CT can be systematically mapped into an AR authoring model (RQ1), 2) how prior AR development experience influences educators' perceptions of

*Corresponding author.

the model (RQ2), and 3) which features are most valued, and what refinements are considered necessary for effective adoption (RQ3).

The remaining sections of this study have been structured in the following manner. Section II provides a review of related work on AR applications in education and their pedagogical underpinnings. Section III outlines the research design, introduces the proposed template, and defines participant recruitment, focus group procedures, and data analysis approach. Sections IV and V present the findings and discussion from the focus group discussions, examining educators' reflections on pedagogical needs, perceived challenges, and opportunities for AR content creation. Finally, Section VI provides the conclusion, which shows the study's limitations and directions for future research.

II. Related Works

The potential of AR to enhance learners' engagement and encourage positive learning attitudes has received considerable attention in the field of education. Even though current studies are largely centered on demonstrating AR's advantages for learners, a growing body of literature is starting to shift towards the involvement of educators as primary creators of AR content. Despite this shift, much of the existing literature leans towards the technical capability of authoring tools, or their usability from a technical perspective [13, 29], omitting clear guidance on aligning AR activities with learning objectives.

A. Authoring Environment for AR Content Creation

AR authoring environments vary widely in both their level of technical abstraction and the extent of pedagogical support they offer, as depicted in Table I. Three recurring patterns emerge from the literature. Firstly, based on authoring style, visual editing environments help in lowering the entry barrier for educators [24, 30, 31]. Template-based editing can also accelerate content reuse [32, 33], yet in practice, most of these tools often produce static overlays with limited adaptability. As for pedagogy integration, it is explicitly seen in ExposAR [24], where learners are engaging in CT concepts during AR activities. However, none of the reviewed authoring environments systematically integrates the EL cycle to guide lesson sequencing. Moreover, since engagement with AR content is deemed important [34, 35], many authoring tools still offer restricted interactivity, missing opportunities for real-time manipulation and learner-driven exploration [36-38].

Gaps in AR authoring environments become more apparent when they are seen to reduce programming load on educators, but are mostly still privileging technical usability over a structured, theory-driven approach to AR design. For instance, Paper Trail [37] and WebArt [36] offer immersive experiences with tangible artefacts and web-based capabilities, respectively, but their main focus remains on interaction mechanics and visual augmentation, rather than on embedding a pedagogical framework into the flow of activities. Therefore, this investigation addresses the need to provide educators with a low-effort, high-guidance AR content creation process that integrates EL and CT while preserving the learner-driven interactivity that mobile AR affords. The EduCATE-AR model addresses this shortfall by embedding pedagogical concepts drawn from EL and CT directly into each authoring step.

B. Integration of Experiential Learning and Computational Thinking in AR Content

EL involves a continuous four-stage cycle that facilitates knowledge construction through experience and application [42]. AR can strengthen this cycle by providing immersive environments, real-time feedback, and interactive content [21, 43, 44], hence connecting hands-on activities with cognitive learning [45]. CT, by contrast, is a series of cognitive processes that uses approaches comparable to those applied in computing [25, 26, 46]. When applied within AR, CT enables structured problem-solving through tasks such as programming sequences, as demonstrated in the ARQuest game [47]. Together, EL and CT provide a strong pedagogical foundation for AR content, where EL fosters experiential and reflective learning, while CT instils logic and structured reasoning. Their integration transforms AR into a meaningful instructional medium that supports both cognitive growth and hands-on engagement. As noted by Ramli et al. [48], effective AR pedagogy must address the what, why, and how of learning. Hence, the first two are outlined in Table II, whereas the how is clarified through the EL-CT alignment presented in this study.

Researchers have noted persistent inconsistencies between technological capabilities and instructional objectives, resulting in AR applications that may capture students' attention but fall short in promoting deep learning [12, 16, 49]. While EL and CT have demonstrated value in AR, they are rarely embedded within authoring tools, creating a technological–pedagogical

gap that can limit the educational usefulness of AR applications among educators [12]. Moreover, studies have shown that AR adoption is shaped by factors beyond technical features. The MARAM model by Koutromanos et al. [50] extends TAM to incorporate dimensions such as perceived usefulness, ease of use, facilitating conditions, and self-efficacy, highlighting their influence on AR adoption by educators.

TABLE II. THEORETICAL GROUNDING OF EXPERIENTIAL LEARNING AND COMPUTATIONAL THINKING IN AR

Approach	Explanation		Ref.
Experiential Learning	What	A learning theory that promotes active knowledge construction through immersive and interactive AR activities, allowing learners to engage directly with simulated environments.	[51, 52]
	Why	Enhance motivation and engagement in AR by enabling learners to explore digital representations of real-world phenomena, make personal discoveries, and reflect on their experiences within the AR space.	[28, 42, 43]
Computational Thinking	What	A cognitive approach to solving problems in digital contexts.	[25, 26, 46, 53]
	Why	Fosters critical thinking skills and 21st-century competencies through structured, logic-based learning in interactive environments.	[25, 54]

Hence, by integrating EL and CT into a single template-based design, this study responds directly to calls for pedagogically aligned AR design while preserving ease of use for educators. It underpins the investigation of how the authoring model supports pedagogical mapping, its acceptance across varying levels of background expertise, and how users identify helpful features and areas for improvement, ensuring that the model meets educators' needs and further advances the AR's potential for adoption.

III. METHODOLOGY

The study followed a three-phase design science research sequence that progresses from solution design to artefact construction and empirical evaluation, as illustrated in Fig. 1. Phase 1 encompasses the authoring model that maps EL phases with complementary CT skills to mobile AR interactions, thereby addressing RQ1. Phase 2 translated the model design into the form of a working authoring template, demonstrating the feasibility of implementing the EL-CT alignments for AR content creation. Phase 3 gathered educators' perceptions through a focus-group study, generating evidence for RQ2 and RQ3. Consistent with design science research, in which empirical evaluation may take the form of satisfaction and perception-based feedback [55]. The study's evaluation was scoped to perceived usefulness and usability prior to performing any classroom-based effectiveness assessment. This practice ensures that each research question is examined at the stage most suited to its focus and that later insights remain anchored in the established conceptual groundwork.

A. Alignment of Experiential Learning and Computational Thinking in AR Content

The EduCATE-AR model is grounded in EL, comprising four phases, which are Concrete Experience (CE), Reflective Observation (RO), Abstract Conceptualisation (AC), and Active Experimentation (AE). Each phase is paired with a CT practice and a cognitive task: 1) Pattern Recognition (PR) and Identifying for CE, 2) Abstraction (AB) and Interpreting for RO, 3) Decomposition and Relating for AC, and (4) Algorithmic Thinking (AL) and Sequencing for AE, as presented in Fig. 2. Table III details how each module's AR interaction supports its cognitive task, where the complexity of that cognition is shaped by the learning activity's design. For instance, at CE, scale-and-rotate can range from recognising a single feature to a more complex spatial analysis across various viewpoints. Tap-to-reveal in RO enables the retrieval of a single contextual annotation, extending to drawing connections across several related details. In AC, scale-and-rotate similarly supports viewing an individual component in isolation, though it can equally demand reasoning about how multiple components function together. Drag-and-drop at AE is capable of simple recall through reordering pre-labelled steps, up to inferring the correct sequence through procedural reasoning.

TABLE III. AR CONTENT DESIGN BASED ON THE LEARNING MODULES

Cognitive-based Module	AR Interaction	Learning Objective in AR
Identifying	Two-finger (scale-and-rotate)	*LO1:* Learners observe and explore virtual objects in the AR environment to identify recurring features and build initial familiarity.
Interpreting	One-finger (tap-to-reveal)	*LO2:* Learners extract meaning from their prior observations by accessing contextual annotations on virtual objects that highlight important features.
Relating	Two-finger (scale-and-rotate)	*LO3:* Learners break down AR content into individual components for inspection to understand their functions and relationships within the overall concept.
Sequencing	One-finger (drag-and-drop)	*LO4:* Learners test their ordered actions in a new scenario and observe the outcome.

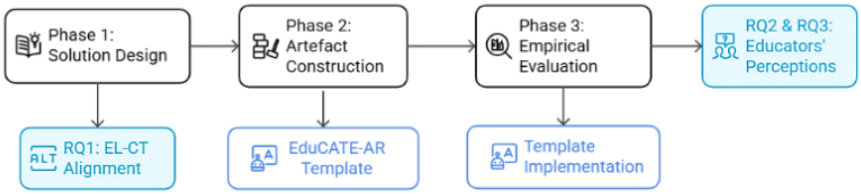

Fig. 1. Research design of the study.

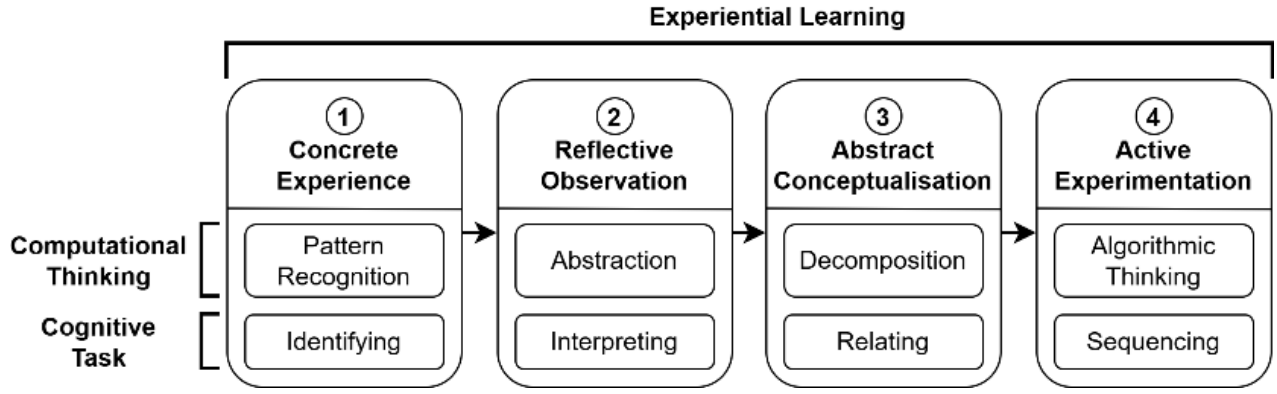

Fig. 2. Experiential learning and computational thinking mapping with cognitive task.

B. Design of the Proposed Authoring Model

As depicted in Fig. 3, the EduCATE-AR model integrates EL phases, CT practices, cognitive tasks, and AR interactions into a template-based authoring flow, addressing RQ1 by demonstrating how these elements can be systematically embedded in content creation. The template layer contains four sequential modules, one per EL phase (CE→RO→AC→AE), each pairing its CT practice, cognitive task, and AR interaction as detailed in Table III. Educators assemble lessons by selecting these modules and configuring their content, while the template handles the technical implementation of each AR interaction.

This template design is realised in Unity. Each of the four modules is packaged as a prefab, which is a ready-made object bundle containing its own scripts, components, and behaviours, as shown in Fig. 4, so it can be placed into a scene and used directly, without being rebuilt each time. Each prefab is linked to a physical marker, a printed image that the AR camera can recognise. When the camera detects a marker, Vuforia identifies it and triggers Unity to load the matching prefab, rendering its AR content at that location in the real-world scene. Once the content appears, Leap Touch captures the learner's gesture, such as rotating, tapping, or dragging, to support interaction with the AR content.

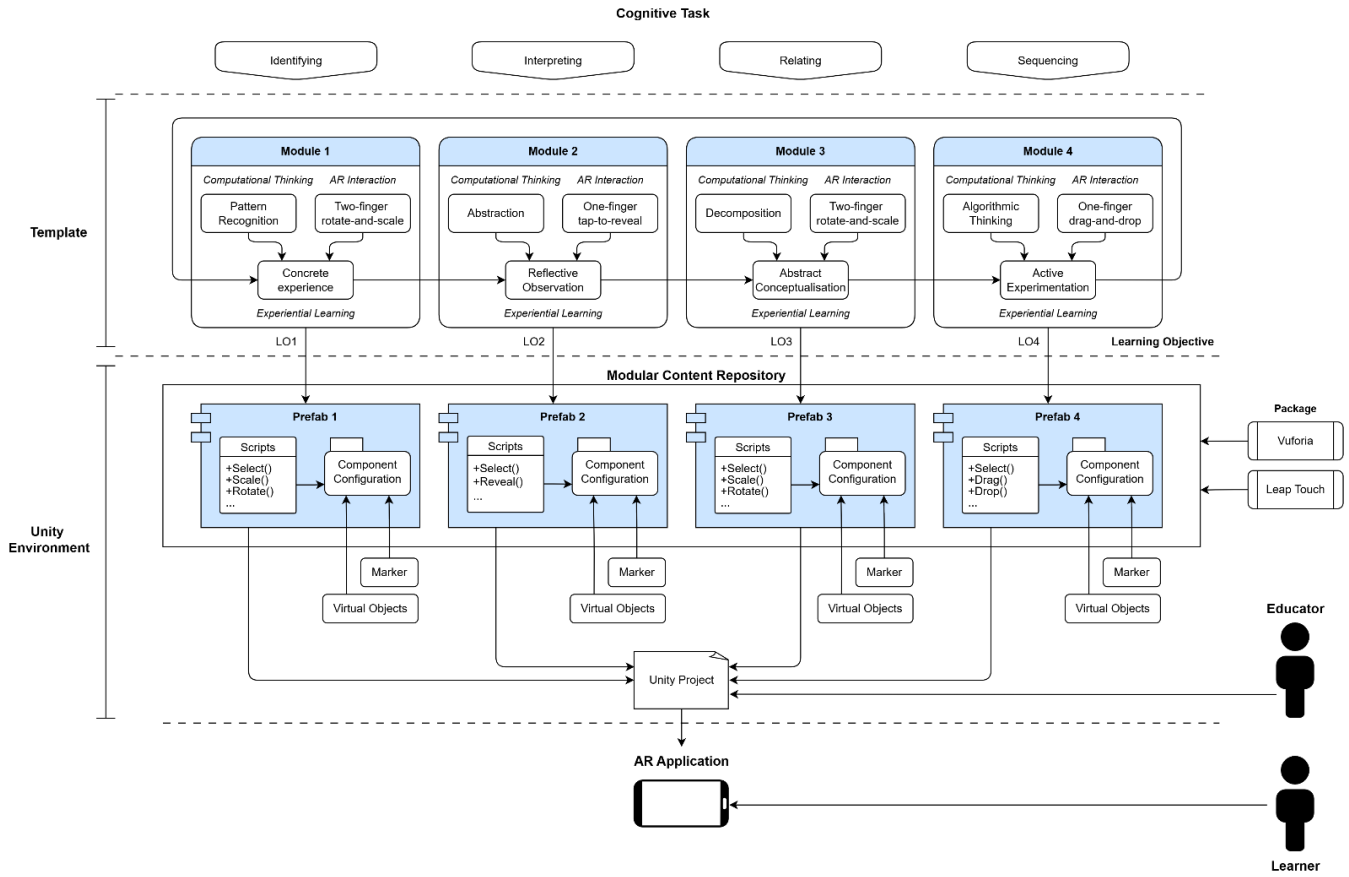

Fig. 3. EduCATE-AR model for template-based AR content creation.

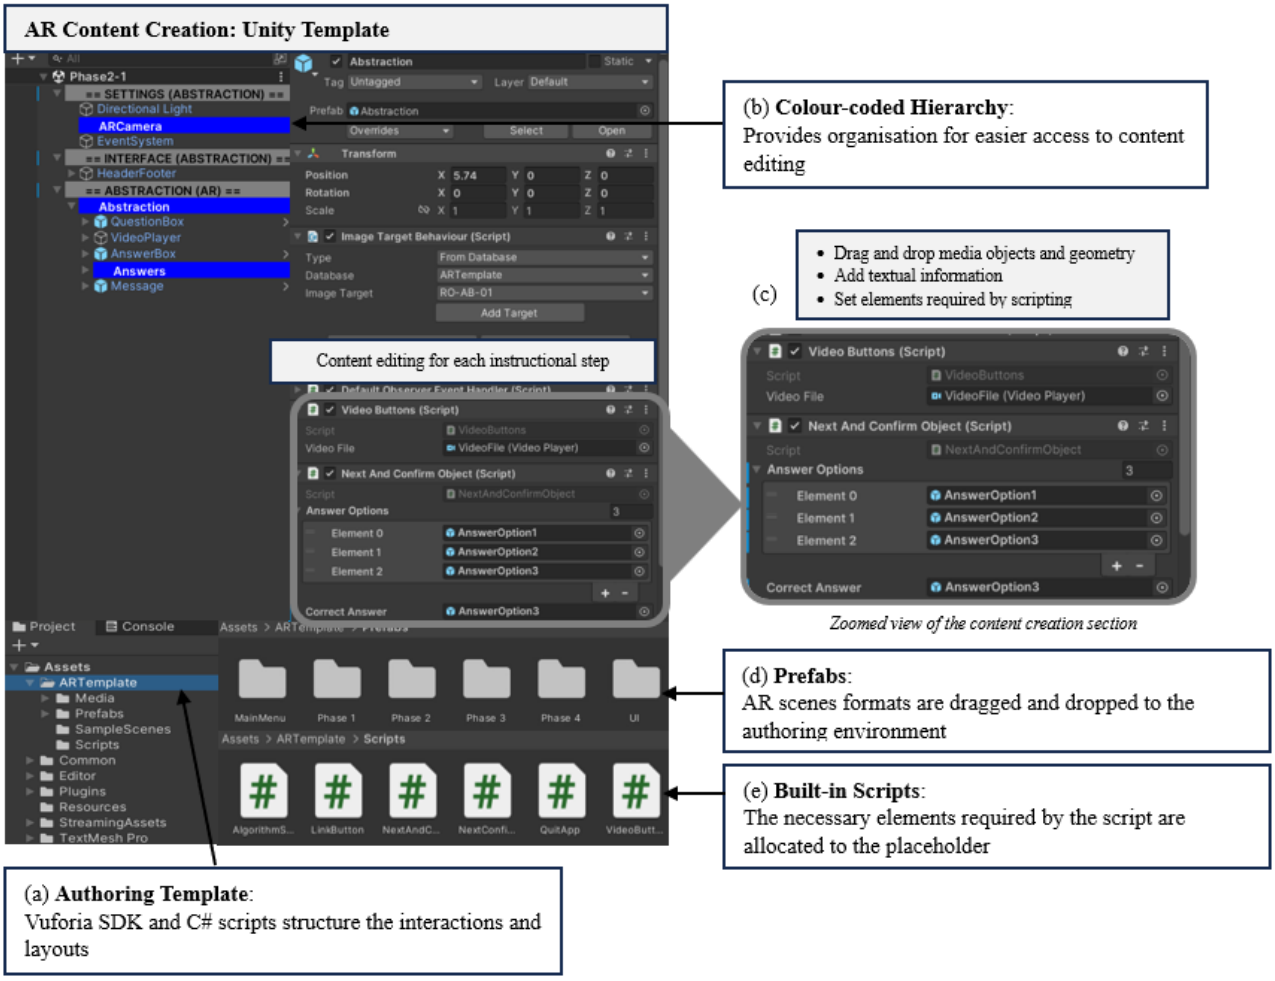

Fig. 4. EduCATE-AR template for educational AR content creation.

Each module in the model is realised as one of four prefabs, matched to its EL phase, CT practice, and cognitive task. Prefab 1 (CE-PR, Identifying) enables open exploration, where learners scale and rotate a virtual object from different angles to spot recurring visual features. Prefab 2 (RO-AB, Interpreting) supports sense-making from those observations, where learners tap to reveal contextual annotations that explain what they are looking at. Prefab 3 (AC-DC, Relating) supports component-level inspection, allowing learners to scale and rotate individual parts of a more complex object to see how each part relates to the whole. Prefab 4 (AE-AL, Sequencing) supports applied problem-solving by providing learners with drag-and-drop elements to be placed in the correct order for testing their understanding in a new scenario. Together, this prefab structure keeps the EL-CT sequence embedded in the authoring process rather than in code, so educators build lessons by selecting and configuring these prefabs instead of programming them directly.

C. Experimental Design and Implementation

This study adopted a focus group evaluation of the EduCATE-AR template. Educators' experiences were examined using TAM [56] and thematic analysis of open-ended reflections, providing a comprehensive view of usability, pedagogical fit, and perceived instructional value [20].

TABLE IV. DISTRIBUTION OF EDUCATORS' DEMOGRAPHIC PROFILE

Demographic (N = 18)	Category	Frequency	Percentage (%)
Gender	Male	5	27.78
	Female	13	72.22
Age	30 - 34	8	44.44
	35 - 39	7	38.89
	40 - 44	1	5.56
	45 - 49	2	11.11
Teaching Subject / Discipline	Computing	11	61.11
	Science	2	11.11
	Language	3	16.67
	Business	2	11.11
AR Development Experience	Experienced	5	27.78
	Non-experienced	13	72.22

1) Participants: Eighteen educators, consisting of school teachers and university lecturers, participated voluntarily and were selected through an open invitation. All participants provided informed consent and were anonymised using unique

identifiers. As shown in Table IV, most participants were female (72.22%) and aged between 30 and 39 (83.33%). The majority taught Computing (61.11%), but most did not have prior AR development experience (72.22%). Based on their profiles, this group was able to offer perspectives from both technical and non-technical backgrounds. A sample size of 18 educators is appropriate for a focus group-based study, as thematic insights are commonly achieved with approximately 12 to 18 participants [57, 58] and prior studies employing similar designs in educational technology contexts have used similar or smaller samples [59, 60].

2) Procedure: A workshop was conducted to introduce participants to key AR concepts, CT and EL pedagogies, and essential Unity workflows. This was followed by hands-on training using the EduCATE-AR template (Fig. 5), where educators created an AR application focused on geometric shapes. The session was facilitated to help them through content development, including sequencing AR modules across EL stages and embedding the corresponding CT practices, so each authoring step targeted a clear learning objective.

Fig. 5. Educators using the EduCATE-AR template during AR content creation.

3) Measurements and variables: A mixed-methods approach was employed to evaluate how well the EduCATE-AR template aligns with educators' pedagogical and technical needs. Quantitative data were collected using an 11-item TAM-based questionnaire measuring Perceived Usefulness (PU), Perceived Ease of Use (PEU), and Intention to Use (ITU) on a 7-point Likert scale. Qualitative data were also gathered through two open-ended questions capturing participants' reflections and suggestions. Thematic analysis was conducted and triangulated with TAM findings to identify converging insights. Additionally, prior AR development experience was examined as a moderating factor influencing perceptions.

IV. Results

This section presents the quantitative and qualitative findings from the focus-group evaluation, covering educators' TAM-based perceptions and the thematic patterns identified in their reflections.

A. Educators' Perceptions Based on Technology Acceptance Model

Descriptive statistics were calculated for each TAM construct to evaluate participants' overall perceptions of the EduCATE-AR template. Internal reliability for all constructs was robust, with Cronbach's alpha values exceeding the recommended threshold: PU ($\alpha = 0.824$), *PEU* ($\alpha = 0.976$), and *ITU* ($\alpha = 0.925$), confirming the reliability of the instrument in capturing educators' perceptions towards the template. As shown in Table V, PU ($M = 6.694$, $SD = 0.425$) emerged as the highest-rated dimension, indicating strong educators' agreement regarding the template's relevance to pedagogical goals and facilitating the development of interactive AR content. This was followed by ITU ($M = 6.333$, $SD = 0.825$), suggesting that educators showed willingness to adopt the template in future practice. PEU received a slightly lower mean score ($M = 6.097$, $SD = 1.473$), reflecting varied individual experiences during template usage. This signals potential challenges in conceptual clarity for some educators, particularly those without prior exposure to Unity or AR development.

TABLE V. Mean (M), Standard Deviation (SD) and Cronbach's Alpha (α) for Items in TAM Constructs

Item	Question	*M*	*SD*	*α*
Perceived Usefulness		**6.694**	**0.425**	**0.824**
PU1	The template helps me create AR applications that meet my teaching goals.	6.611	0.502	
PU2	The template makes it easier to integrate pedagogies in my AR applications.	6.778	0.428	
PU3	The template improves the lesson quality of my AR applications.	6.611	0.608	
PU4	The template lets me create AR applications with interactive elements.	6.778	0.548	
Perceived Ease of Use		**6.097**	**1.473**	**0.976**
PEU1	Learning how to use the template is easy.	6.167	1.505	
PEU2	The template makes it easy to create AR applications with minimal effort.	6.278	1.447	
PEU3	The steps for building an AR lesson with the template are simple.	5.833	1.618	
PEU4	The interface and structure of the template are understandable.	6.111	1.530	
Intention to Use		**6.333**	**0.825**	**0.925**
ITU1	I am interested in using the template for future AR applications.	6.389	0.778	
ITU2	Given the opportunity, I will use the template in my teaching practice.	6.278	0.826	
ITU3	I will use the template to integrate pedagogies in my future AR applications.	6.333	1.029	

To evaluate whether perceptions differed based on educators' prior expertise in AR content creation, a Mann-Whitney U test was conducted for each TAM construct. Prior to group comparison, the Shapiro-Wilk test was used to assess

normality separately within each experience subgroup. As presented in Table VI, all three constructs showed significant deviation from normality within the non-experienced subgroup, while the experienced subgroup did not. Given the non-normality observed in the larger subgroup, non-parametric analysis was adopted for both comparisons.

TABLE VI. SHAPIRO-WILK TEST FOR NORMALITY OF TAM CONSTRUCTS

Variables	Group	Shapiro-Wilk		
		W	*df*	*p*
Perceived usefulness (PU)	Non-experienced	0.513	13	<.001
	Experienced	0.902	5	0.421
Perceived ease of use (PEU)	Non-experienced	0.689	13	<.001
	Experienced	0.894	5	0.377
Intention to use (ITU)	Non-experienced	0.658	13	<.001
	Experienced	0.828	5	0.135

TABLE VII. MANN-WHITNEY U TEST COMPARING TAM SCORES BASED ON EXPERTISE IN AR DEVELOPMENT

Variables	Expertise in AR	*N*	Mean Rank	Total Ranks	*U*	*p*	*r*
Perceived usefulness (PU)	Non-experienced	13	11.46	149.00	7.000	0.010	0.785
	Experienced	5	4.40	22.00			
Perceived ease of use (PEU)	Non-experienced	13	9.19	119.50	28.500	0.703	0.123
	Experienced	5	10.30	51.50			
Intention to use (ITU)	Non-experienced	13	11.04	143.50	12.500	0.046	0.615
	Experienced	5	5.50	27.50			

The application of the Mann-Whitney U test ensured the robustness of inferential comparisons and supported the integrity of the conclusions drawn about educators' differing levels of acceptance. Table VII reports that non-experienced participants give significantly higher scores for PU ($U = 7.000$, $p = 0.010$) and ITU ($U = 12.500$, $p = 0.046$) compared to experienced participants, while PEU did not significantly differ between groups ($U = 28.500$, $p = 0.703$), indicating a shared perception of usability irrespective of prior exposure to AR development. Given the smaller experienced subgroup (n=5), rank-biserial effect sizes were also computed for each comparison. ITU (r=0.615) and PU (r=0.785) showed large effects, suggesting these differences are unlikely to be due to chance from the small subgroup size, while PEU showed a negligible effect (r=0.123), consistent with its non-significant result. These findings indicate that non-experienced participants rated the template-based design more favourably than experienced participants, particularly on PU and ITU, reflecting strong initial acceptance among less technical users within this preliminary evaluation. Collectively, these findings reinforce the potential of the EduCATE-AR template, particularly for novice AR creators seeking simplified authoring pathways.

B. Thematic Insights from Educators' Reflections

Responses were manually coded using predefined categories mapped to TAM's three core constructs, which are PU, PEU, and ITU. Fig. 6 presents the thematic breakdown and frequency based on the qualitative educators' responses. In terms of PU, educators highlighted that the low technical barrier (f = 6) of the EduCATE-AR template made it suitable for non-programmers and novice AR content creators. One educator noted, "The template helps people who've never made an AR app before, especially for teachers who are not good with technical things", proving how the template opens up AR content creation to a broader, less technical audience. This reinforces its accessibility for educators who typically struggle with coding-based platforms. Pedagogical structuring (f = 4) was also appreciated for simplifying AR development. This was captured in remarks like, "All is suitable in the template and helps navigate my application well from one module to another", suggesting that the template's design included built-in sequences to support AR lesson progression. This aligns with the goal of helping educators structure their lesson content systematically. Moreover, some educators expressed a desire for scalability and expandability (f = 3), particularly with multimedia support. One respondent mentioned, "It's good for now, but I'd like to be able to add videos or maybe audio in future applications", signaling the potential of the template to support more immersive experiences if equipped with richer media capabilities. Also, the template was seen to accelerate development (f = 2), with the support of a comment, "Because it is easy to use the template, maybe I can make AR app faster". This suggests that the predefined structure in the template helped users move from concept to implementation quickly.

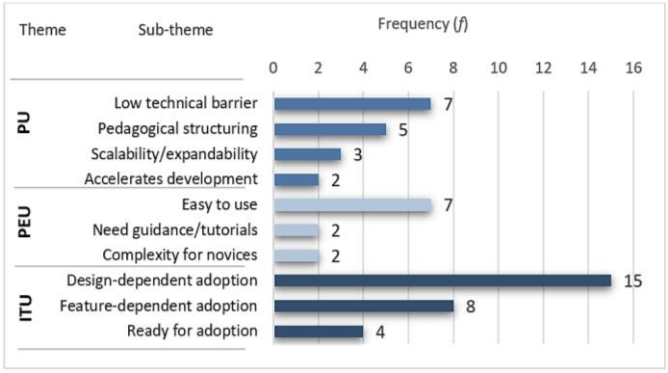

Fig. 6. Frequency of sub-themes across educators' responses.

Regarding PEU, the template's ease of use was the most cited benefit, with easy to use (f = 7) emerging as the dominant sub-theme. A participant remarked, "Everything inside the template is easy to understand and access," highlighting the structure and labelling of components in the template's hierarchy, which eases the process of AR content creation. Nevertheless, not all experiences were equally straightforward. Under need guidance or tutorials (f = 2), one educator suggested improvements, such as a step-by-step walkthrough. This was reflected in the sentiment that "The template is beneficial, but requires different paces among users," pointing to the necessity

of tailored guidance based on their experience levels. Additionally, complexity for novices (f = 2) surfaced through the same concern, suggesting that while the template is understandable for some, others may still find the authoring steps confusing without additional help.

Within the ITU construct, design-dependent adoption (f = 15) emerged as the most prevalent theme, with educators noting that although the template is promising, adoption depends on improved structure, layout, or navigational flow. One participant commented, "Maybe improve the hierarchy and visual layout of the template, so it can be easier to organize the content, especially if I can use it to apply speech or sensor inputs in AR", suggesting how usability limitations in the template's design can constrain adoption. Another group of educators expressed feature-dependent adoption (f = 8), emphasizing that their intent to use the template depends on the inclusion of more engaging, interactive functionalities. As one educator noted, "Add more interactions to make it more engaging", highlighting how richer media elements and interaction capabilities are essential for enhancing learners' attention. These reflections indicate that pedagogical value in AR content is often tied to the need for improved layout and content organisation, as well as expanding the template's interactive capabilities to better engage learners. In contrast, a smaller group of educators demonstrated readiness for adoption (f = 4), with no further requests for template improvement. This is shown in responses like "I think it's good to go for now. After I try to adapt it to my project, I'll see what else is needed", pointing to satisfaction with the template's features and potential willingness to adopt.

V. Discussion

A. Usability in AR Content Creation

Educators' experiences with the EduCATE-AR template underscored the central role of accessibility in AR content creation. Participants consistently highlighted that the template lowered the technical barrier, especially for those without programming experience. The drag-and-drop mechanics and visual organisation of the template, such as colour-coded hierarchies and prefab-based modules, allowed them to focus on content design rather than technical mechanics. This confirms prior findings that *simplified interfaces* enable broader participation in digital content authoring [13, 61]. While the majority of educators described the template as "easy to understand", a few expressed the need for more structured walkthroughs. These comments reflect a broader expectation among educators that authoring platforms should provide *facilitating conditions*, especially for those with minimal prior exposure to AR development. Offering in-app tutorials, visual cues, or sample scenes allows educators to build confidence and avoid trial-and-error inefficiency [50].

Notably, statistical analysis revealed that less experienced participants conveyed significantly higher scores for PU and ITU than their more experienced counterparts. This suggests that template-based editing with low technicalities may be particularly valuable for novice AR creators, providing a structured yet flexible environment that increases PEU. Interestingly, the absence of significant differences in PEU across experience levels further underscores the platform's universal usability. In particular, the ability to use pre-configured prefabs was seen to accelerate development, with educators noting that they could replicate and customise elements quickly, reducing preparation time. Hence, *fast content assembly* was highly valued for accelerating AR application development.

B. Structuring AR Content for Pedagogical Alignment

Beyond usability, participants underlined the importance of *pedagogical structuring* within the AR development process. Educators appreciated how the template supported lesson progression through built-in sequencing based on EL phases across content modules. As noted by one participant, "it helps navigate my application well from one module to another", indicating that this structuring was especially helpful in supporting clear lesson design, as educators were able to align AR content to predefined learning objectives. Prior work on AR environments has highlighted similar findings, where logical sequencing of authoring steps should reflect the instructional logic recognised by educators to reinforce conceptual clarity and instructional control [62].

However, some participants emphasised that pedagogical structuring must be responsive to subject-specific needs. While the EL and CT integration in the template was seen as generally effective, some educators noted that a uniform instructional framework may not always translate well across disciplines. For instance, one language educator noted that "using one pedagogy for all subjects may not be suitable, especially for activities involving pattern recognition or algorithms". A science educator raised a similar point, stating that "for subjects like science that have abstract concepts, using activities that focus only on computational thinking might not be suitable". These responses highlight a broader issue, indicating that although CT can be useful for procedural thinking and problem-solving in technical fields, the AR content design also needs to be adjusted in subjects where conceptual understanding or interpretive thinking is more important [63, 64]. This means that the authoring platform should support diverse interaction modes and pedagogies to ensure that AR content can be tailored to reflect the instructional logic of different disciplines.

Beyond subject-specific responsiveness, *scalability* also depends on how efficiently new content can be authored and reused as adoption grows. Because each module's scripts and component configuration are decoupled from any particular subject's content, similar interaction logic should be able to be reused across different virtual objects and markers without modifying the underlying template. This is consistent with how template-based editing has been shown to accelerate content reuse in AR authoring [33]. Scalability reduces the technical effort needed to extend the authoring template to new subjects. At larger scale, however, this would likely need to be paired with a shared library of ready-made content assets across common subject areas, an approach consistent with reusable learning object repositories that reduce the cost and effort of producing new educational content [32, 65], rather than requiring each educator to individually source and configure their own virtual objects.

Moreover, a few educators emphasised the importance of *content organisation* within the AR scene, reporting that purposeful placement of instructional elements should be

considered. This is derived from responses such as "improve the visual layout of the content". These insights affirm the necessity for content organisation in AR content design. This is linked with established cognitive load theory, which describes the importance of visual coherence in AR learning environments to avoid extraneous cognitive load [66]. While reducing cognitive distractions is valued by some participants, the significance of *multimedia support* was generally acknowledged to facilitate immersion in AR. Several educators mentioned the need for the integration of diverse media types in AR content to support different instructional methods. As an example, a language educator highlighted that audio is an essential element for demonstrating the sound of Arabic vocabulary. These observations are similar to results from prior studies, showing that embedding rich multimedia is key to improving learner satisfaction [66-68].

C. Towards Personalised Content Creation

Based on the responses collected, several participants appreciated the elements of personalisation and flexibility embedded in the template. As noted by one participant, "Everything inside the template is easy to understand and access, which makes it easier to know how to change the components inside the template." Another participant stated, "I can just switch the given element and use copy and paste with all the elements needed". The responses indicate that the template enables educators to personalise lessons by selecting the entry point in the EL cycle, pairing it with the corresponding CT practice, and configuring the AR interaction to embed. For instance, some educators might begin with an AR-based experience in Phase 1 (CE) and shift to a non-AR approach, such as written classroom exercises in Phase 2 (RO). This flexibility enables educators to design their own instructional content based on specific learning outcomes or teaching goals [69].

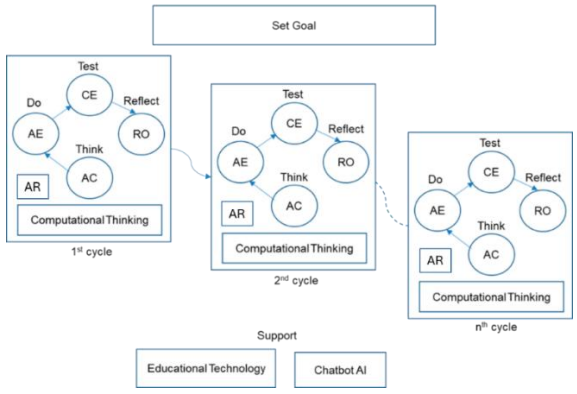

Fig. 7. Additional personalisation layer through Chatbot AI.

Extending this flexibility in content creation, Fig. 7 illustrates how an AI chatbot can add another layer of personalisation to AR content, as a virtual tutor. Since pedagogical agents with human-like assistance have been shown to aid learning [70], such integration can enhance support during the AC phase by providing on-demand explanations or addressing learners' queries with theoretical grounding. Thus, the authoring experience not only allows educators to tailor content flow based on pedagogies but also lays the groundwork for scaffolded and adaptive AR learning experiences, aligned with instructional intent and learner needs [71].

VI. Conclusion

This study investigated how a pedagogically structured integration of CT and EL can empower educators in creating AR learning content. By designing and evaluating the EduCATE-AR model, which operationalises CT principles through the EL cycle, this study demonstrated that educators, particularly those with limited technical expertise, can effectively participate in AR content authoring when supported by a theoretically grounded, template-driven model. The model's foundation in pedagogical mapping between computational logic practice and experiential learning design bridges technical and instructional barriers in AR creation. Quantitative results supported the model's practicality, with novice participants reporting significantly higher levels of PU and ITU. Meanwhile, thematic analysis revealed that the model's modularity and prefab-based design approach were especially valued, though participants also highlighted the need for expanded features and greater pedagogical flexibility to accommodate personalisation.

In terms of limitations, the study was conducted within a focused and relatively small participant group, and all evaluations occurred within a guided research setting rather than a classroom setting. As such, the observed acceptance and positive perceptions may reflect initial exposure rather than sustained integration. Moreover, the study focused primarily on educator perspectives, without directly measuring student learning outcomes or classroom impacts. In addition, the prototype version of the template, while functional, did not offer full customisability or extensibility beyond its prefab modules, which limits insights into more advanced usage scenarios.

Future research should extend these findings by examining how educator-authored AR content affects real classroom environments over time. Longitudinal studies could assess whether the initial motivation and intention to use translate into continued use and improved instructional outcomes. Future evaluations should also incorporate specialised instruments, such as cognitive load assessments, pedagogical alignment rubrics, or CT skill integration metrics, to more directly assess whether the EL-CT theoretical grounding achieves its intended instructional goals, beyond the acceptance-level evidence captured by TAM. Moreover, involving students in future evaluations will be crucial to understanding how educator-authored AR experiences affect engagement, comprehension, and knowledge retention. Expanding the AR authoring template design to support a wider range of pedagogical strategies will also help ensure broader applicability. In addition, performing a controlled comparative study with an existing AR authoring tool would help isolate the specific advantages of embedding EL and CT directly into the authoring workflow. Finally, incorporating adaptive features such as real-time guidance during authoring or AI-based design recommendations could further support educators in aligning their AR content with instructional goals. Such enhancements would not only deepen the educational impact of immersive technologies but also lay the foundation for more personalised, learner-centred AR experiences.

A Bidirectional Cross-Modal Attention Framework for Multimodal Sentiment Analysis

B S Harish, C K Roopa, M S Kendagannaswamy, T S Kaveri*
Department of Information Science and Engineering, JSS Science and Technology University, Mysuru 570006, Karnataka, India

***Abstract*—Multimodal sentiment analysis on social media data presents unique challenges due to label noise, modality conflicts, and class imbalance inherent in annotated image-text datasets. The proposed work presents CLIP-CrossFusion Net, a novel multimodal sentiment analysis framework that integrates the Contrastive Language-Image Pre-Training (CLIP) ViT-B/32 image encoder with a RoBERTa-Base text encoder through a bidirectional cross-modal attention mechanism. The proposed approach addresses three key challenges: 1) rich cross-modal feature interaction via bidirectional attention, 2) noisy label robustness through focal loss with label smoothing, and 3) class imbalance mitigation via targeted class weighting and Mixup augmentation. The study further proposes an extended variant with a colour feature branch, supervised contrastive loss, and deeper cross-modal attention layers. Using the proposed model, comprehensive experiments are conducted on both the MVSA-Multiple (19,600 image-text tweet pairs) and MVSA-Single (4,511 pairs) datasets. On MVSA-Multiple, the proposed model achieves 74.39% accuracy and a weighted F1 of 0.7497. On MVSA-Single, the proposed ensemble of three complementary model variants (base model, colour-contrastive variant, and RoBERTa-Large variant) achieved 75.66% accuracy and an F1 of 0.7517, outperforming strong baselines. These results demonstrate the effectiveness of cross-modal attention fusion combined with noise-robust training strategies for multimodal sentiment analysis.**

I. Introduction

Twitter, Instagram, and Weibo generate colossal quantities of multimodal content, posts in which opinions are conveyed in the form of text, images, and video simultaneously. Sentiment analysis of such content can be helpful in brand monitoring, tracking health and politics, as well as financial projections [1]. Text-only strategies are very good; however, they still lack what images are saying and the interaction between text and images.

Combining text and image processing (MSA) is more effective than either of the two, yet there are real challenges. Social media image-text pairs often contain conflicting sentiment, e.g., a tweet may contain a complaint, but the image will appear cheerful. To further complicate matters, the MVSA-Multiple dataset [2] has a lot of label noise, because of disagreements between its three annotators. The most difficult of all cases is the Neutral category, as the neutral sentiment is context-specific and can be misinterpreted as positive or negative.

As an extension of this work, this study introduces CLIP-CrossFusion Net, a new multimodal sentiment analysis model, which has three main contributions:

- A cross-modal attention process in both directions, with text and image features cross-attending in parallel so that each modality can influence the other to be reshaped and then fused.
- A noise-robust training method based on Focal Loss and class-balanced weights, label smoothing, and Mixup augmentation to deal with label noise in MVSA-Multiple and improve the performance of Neutral classes.
- Ablation experiments on variants of models in simple concatenation baselines and full cross-modal transformer architectures, and the way each component contributes to the final output.

The proposed MVSA-Multiple experiments achieve an accuracy of 74.39% and a weighted F1 of 0.7497, which is higher than strong baselines. The Neutral class F1, which is enhanced by the weighting of classes, improves from 0.59 to 0.63.

II. Related Work

A. Unimodal Sentiment Analysis

Sentiment analysis has a rich history dating back to lexicon-based approaches [3]. CNN-based [4] and LSTM-based [5] architectures improved performance, followed by attention mechanisms [6] and transformer-based models such as BERT [7] and RoBERTa [8]. However, unimodal approaches are fundamentally limited for social media content where images carry substantial sentiment information.

B. Multimodal Sentiment Analysis

Early multimodal approaches were based on the concatenation of simple features of CNN images and word embeddings [9]. Graph neural network models like MGNNS represented cross-modal relationships as graphs [10]. The D&R Net [11] was able to determine the cross-modal contrast as well as semantic correlation by decomposition and relational networks. CLMLF [12] used transformer-fusion CNN-supervised contrastive learning. MVSA-Single with cross-modal interaction fusion on SECIF [13] produced good results. ICCI [14] scored 79.33% on MVSA-Single by combining HSV colour cues with semantic features.

*Corresponding author.

Using VGG16, Mask-RCNN, BERT, WCNNE, and Dempster-Shafer theory, Biswas et al. [15] obtained 93.48% on MVSA-Multiple.

C. Vision-Language Pretraining

CLIP [16] proposed contrastive pretraining using 400M image-text pairs, and it trains a shared embedding space with impressive transfer properties. ViT [17] showed image recognition with pure transformer architectures, and DeiT [18] optimized vision transformers with distillation. Such models offer much more detailed representations than the conventional CNN encoders, which is why they are adopted into the proposed framework.

D. Cross-Modal Attention and Colour Features

Deep cross-modal attention was applied to two-stage feature fusion in DTN [19]. The SRC-Model [13] used bidirectional image-text interaction gating and MHA. MIGSIE [13] applied GNN-based text-guided multi-channel modules. ICCI showed that the colour cues presented by images are good sentiment indicators, which drives the colour feature branch. The main task of this work is to combine CLIP joint pretraining with explicit cross-modal attention and colour features.

III. Datasets

A. MVSA-Multiple Dataset

The MVSA-Multiple dataset [2] comprises 19,600 image-text pairs on Twitter that have been annotated by three human raters. The final joint label is obtained by majority voting, and the conflicting pairs are eliminated. It has a large class imbalance: Positive (42.0%), Negative (31.4%), Neutral (26.7%), and inherent label noise due to annotation disagreement. Fig. 1 shows the distribution of the classes in the train, validation, and test splits, with the positive class being predominant and the relatively low representation of the neutral category, which compels the class-weighting approach.

B. MVSA-Single Dataset

The MVSA-Single dataset is a set of 4,511 valid image-text pairs on Twitter (after filtering) annotated by one rater. The extreme imbalance of classes, Positive (59.5%), Negative (30.1%), Neutral (10.4%), is problematic with the neutral category. Hence, a typical 8:1:1 train/validation/test split with stratified sampling was applied. This extreme imbalance is depicted visually in Fig. 2, where positive samples are nearly 60% of the data and neutral samples are only 10.4%. Thus, correct Neutral classification is the most difficult on this dataset. Table I summarises the statistics of both datasets.

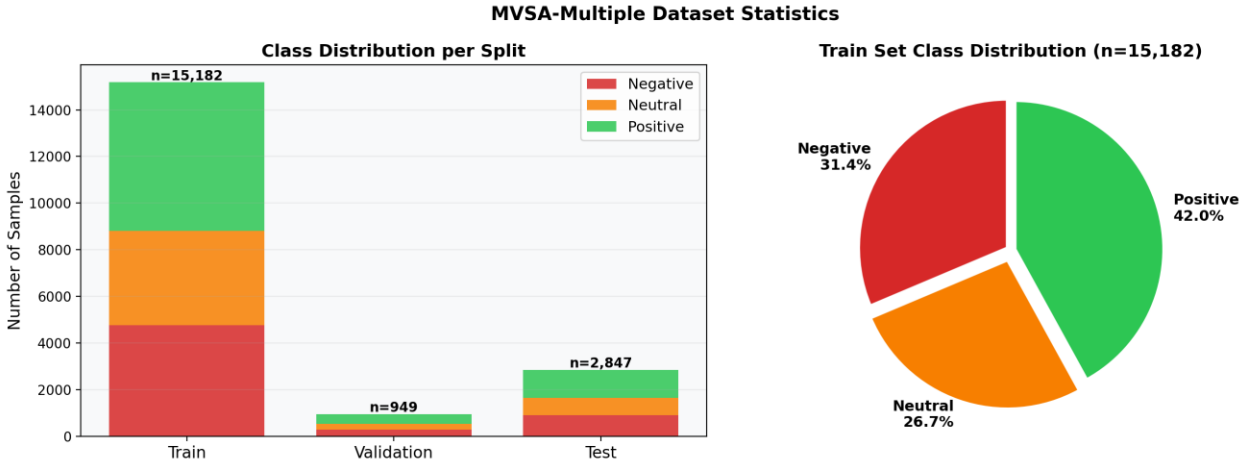

Fig. 1. MVSA-Multiple dataset class distribution across train, validation, and test splits.

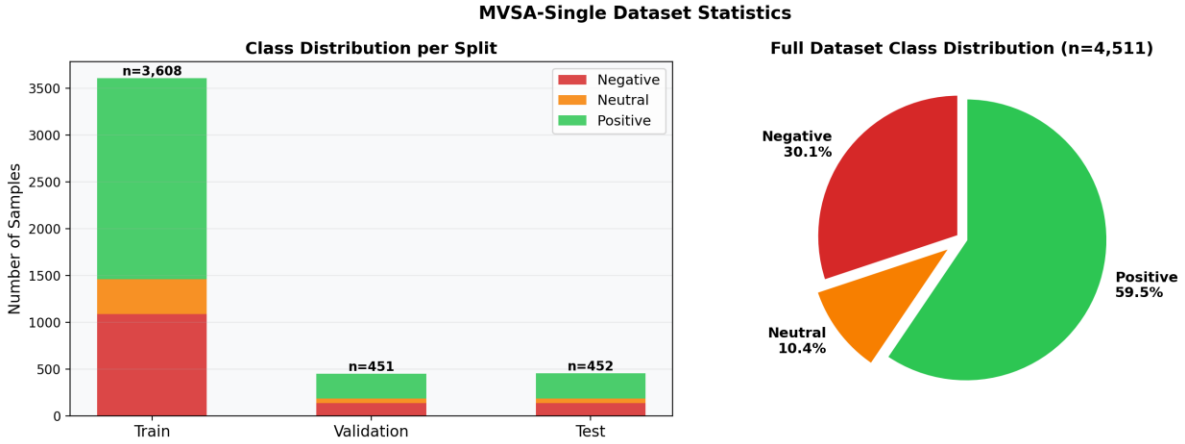

Fig. 2. MVSA-Single dataset class distribution. Severe positive dominance (59.5%) makes neutral classification challenging.

TABLE I. DATASET STATISTICS FOR MVSA-MULTIPLE AND MVSA-SINGLE (ANNOT. = NUMBER OF ANNOTATORS PER SAMPLE)

Dataset	Split	Neg	Neu	Pos	Total	Annot.	Split Ratio
MVSA-Multiple	Train	4,760	4,047	6,375	**15,182**	3	Pre-split
	Val	290	244	415	**949**		
	Test	893	759	1,195	**2,847**		
MVSA-Single	Train	1,086	376	2,146	**3,608**	1	8:1:1
	Val	136	47	268	**451**		
	Test	136	47	269	**452**		

IV. METHODOLOGY

CLIP-CrossFusion Net follows a dual-stream encoder architecture where text and image modalities are independently encoded, projected to a shared embedding space, refined through bidirectional cross-modal attention, and fused via a gated mechanism before classification. The extended colour-contrastive variant adds a colour feature branch that extracts HSV colour histograms from images and integrates them through additional cross-modal attention layers. Fig. 3 presents a complete overview of the architecture, depicting the dual-stream encoders, shared projection layers, bidirectional cross-modal attention module, gated fusion mechanism, and final three-class classifier.

A. Encoders

1) Image Encoder: CLIP ViT-B/32: The proposed approach employs the Vision Transformer ViT-B/32 component of CLIP [16], pretrained on 400 million internet-collected image-text pairs. The encoder produces a 512-dimensional embedding. All layers are frozen except the final two to four transformer blocks, which are fine-tuned with a small learning rate to adapt visual representations to sentiment-relevant features, as expressed in (1).

$$f_{img} = \text{CLIP}_{\text{ViT}}(x_{img}) \in \mathbb{R}^{512} \quad (1)$$

2) Text Encoder: RoBERTa-Base / RoBERTa-Large: For text encoding, RoBERTa-Base [8] is employed for the base, cross-modal attention, focal-loss, and colour-contrastive variants, or RoBERTa-Large for the large-encoder variant. Tweet text is tokenised to a maximum of 128 tokens. The [CLS] token is extracted as the sentence-level representation, as given in (2). The same selective fine-tuning strategy applies: all layers are frozen except the last two to four blocks.

$$f_{text} = \text{RoBERTa}([\text{CLS}], x_{text}) \in \mathbb{R}^{768} \text{ or } \mathbb{R}^{1024} \quad (2)$$

B. Modality Projection

Both modalities are projected to a common 256-dimensional space using separate projection heads with LayerNorm and GELU activation, as defined in (3) and (4).

$$p_{img} = \text{LayerNorm}(\text{GELU}(W_{img} \cdot f_{img})) \in \mathbb{R}^{256} \quad (3)$$

$$p_{text} = \text{LayerNorm}(\text{GELU}(W_{text} \cdot f_{text})) \in \mathbb{R}^{256} \quad (4)$$

C. Bidirectional Cross-Modal Attention

The core innovation is the bidirectional cross-modal attention module enabling each modality to attend to the other simultaneously, as formulated in (5) and (6) for the image-to-text and text-to-image directions, respectively. Two to three such layers are stacked for hierarchical cross-modal reasoning.

$$a_{img} = \text{LayerNorm}(p_{img} + \text{Dropout}(\text{MHA}(p_{img}, p_{text}, p_{text}))) \quad (5)$$

$$a_{text} = \text{LayerNorm}(p_{text} + \text{Dropout}(\text{MHA}(p_{text}, p_{img}, p_{img}))) \quad (6)$$

D. Colour Feature Branch

Inspired by ICCI [14], which demonstrated that colour information improves sentiment analysis, the extended variant introduces a dedicated colour branch. HSV colour histograms (32 bins each for the H, S, and V channels, giving a 96-dimensional feature) are extracted from each image and processed through a two-layer MLP, as given in (7) and (8). Bidirectional cross-modal attention between colour and image features, defined in (9) and (10), allows the model to leverage emotional colour cues.

$$c = \text{concat}(\text{hist}_H, \text{hist}_S, \text{hist}_V) / \Sigma \in \mathbb{R}^{96} \quad (7)$$

$$p_{colour} = \text{ColourBranch}(c) \in \mathbb{R}^{256} \quad (8)$$

$$p_{img} = \text{Attn}_{col \to img}(p_{img}, p_{colour}) \quad (9)$$

$$p_{colour} = \text{Attn}_{img \to col}(p_{colour}, p_{img}) \quad (10)$$

E. Gated Fusion

The base, cross-modal attention, and focal-loss variants use dual-stream gated fusion, while the colour-contrastive and large-encoder variants use triple-stream fusion including colour features, as expressed in (11)-(13). The fused representation is 512-dimensional for the dual-stream variants and 768-dimensional for the colour-contrastive variants.

$$\text{fused} = \text{concat}(a_{img}, a_{text} [, p_{colour}]) \quad (11)$$

$$\text{gate} = \text{Sigmoid}(W_{gate} \cdot \text{fused}) \quad (12)$$

$$z = \text{fused} \odot \text{gate} \quad (13)$$

F. Training Strategy

1) Focal loss with label smoothing: Standard cross-entropy fails on MVSA due to label noise and class imbalance. Focal Loss with label smoothing and class-balanced weights targeting the hard Neutral class is used, as given in (14).

$$L_{FL} = -\Sigma_i \, w_i \cdot (1 - p_i)^{\gamma} \cdot y_i^{smooth} \cdot \log(p_i) \quad (14)$$

Here $\gamma = 2.0$, label smoothing $\varepsilon = 0.1$, and class weights are [Neg: 1.2-1.5, Neu: 1.8-2.0, Pos: 1.0]. The Neutral class receives higher weight to improve recall. The focal term $(1 - p_i)^{\gamma}$ down-weights easy samples.

2) Supervised contrastive loss: The colour-contrastive variant adds a supervised contrastive loss term that pulls same-class embeddings closer while pushing different-class embeddings apart, improving class separation especially for the ambiguous Neutral class. The contrastive term and the combined objective are given in (15) and (16).

$$L_{contrast} = -\text{mean}_{anchors}\ [\ \Sigma(\text{positive pairs}) / \Sigma(\text{all pairs})\ ] \quad (15)$$

$$L_{total} = L_{focal} + \lambda \cdot L_{contrast}, \quad \lambda = 0.05 \quad (16)$$

3) Mixup augmentation: Mixup [20] is applied to the image modality with $\lambda \sim \text{Beta}(0.2, 0.2)$, creating mixed image-label pairs that prevent overly certain predictions on noisy labels.

4) Optimisation: AdamW [21] is used with layer-wise learning rates: encoders (3-5e-6) and fusion head (8e-5 to 1e-4). Training uses cosine annealing with 10% warmup, gradient clipping (max = 1.0), and gradient accumulation (steps = 2-4, effective batch = 64). Early stopping patience is 5-6 epochs on validation F1. The complete hyperparameter configuration of each model variant is listed in Table II.

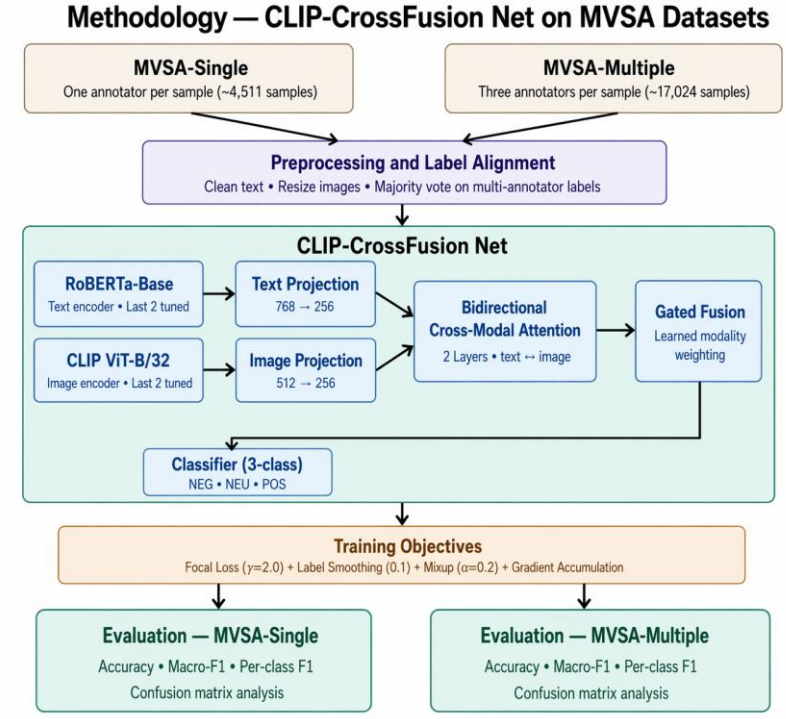

Fig. 3. CLIP-CrossFusion Net architecture: dual-stream encoders, projection, bidirectional cross-modal attention, gated fusion, and 3-class classifier.

TABLE II. HYPERPARAMETER CONFIGURATION PER MODEL VARIANT

Hyperparameter	Base / X-Attn / Focal	Colour + Contrastive	RoBERTa-Large Variant
Image encoder	CLIP ViT-B/32	CLIP ViT-B/32	CLIP ViT-B/32
Text encoder	RoBERTa-Base	RoBERTa-Base	RoBERTa-Large
Colour branch	No	Yes (96-dim)	Yes (96-dim)
Contrastive loss	No	Yes (w = 0.05)	Yes (w = 0.05)
Attention layers	2	3	3
Unfrozen layers	2	4	4
Focal loss γ	2.0	2.0	2.0
Class weights (Neg/Neu/Pos)	1.2 / 1.8 / 1.0	1.3 / 2.0 / 1.0	1.3 / 2.0 / 1.0
Hardware	T4 15 GB	T4 15 GB	T4 15 GB

G. Multi-Model Ensemble

For MVSA-Single, three complementary model variants are combined through weighted probability averaging, as given in (17). The base model provides strong text representations, the colour-contrastive variant adds colour information, and the RoBERTa-Large variant contributes larger text features. The optimal weights (base: 0.5, colour-contrastive: 0.4, RoBERTa-Large: 0.1) are determined by grid search on the validation set. Test-Time Augmentation (three transforms: original, horizontal flip, centre crop) is applied for each model before ensembling.

$$P_{ens} = 0.5 \cdot P_{base} + 0.4 \cdot P_{colour} + 0.1 \cdot P_{large} \quad (17)$$

V. EXPERIMENTS

A. Experimental Setup

All experiments use PyTorch with mixed-precision training (FP16) on an NVIDIA Tesla T4 (15 GB VRAM). For the MVSA-Multiple dataset, the predefined train/validation/test splits are used. For MVSA-Single, 8:1:1 stratified random splits are used. Accuracy and weighted F1-score are reported as primary metrics, consistent with prior work.

B. Baselines

- DeiT-Base + BERT-Base (Concat): primary strong baseline using concatenation fusion.
- ViT-Base + BERT-Base (Concat): Vision Transformer with BERT.
- Swin-Base + BERT-Base (Concat): Swin Transformer with BERT.
- RoBERTa-Large + CLIP ViT-L/14 (large-encoder baseline): larger encoders with gated fusion.
- CLIP ViT-B/32 + RoBERTa-Base (cross-modal attention / focal-loss variants): cross-modal attention variants.
- ICCI (2023) [14]: cross-modal attention with colour cues; 79.33% on MVSA-Single and 73.29% on MVSA-Multiple.
- CLIP-CrossFusion with colour + contrastive (ours): with colour branch and contrastive loss.
- Ensemble of base + colour-contrastive + RoBERTa-Large (ours): best ensemble on MVSA-Single.

VI. RESULTS AND DISCUSSION

A. MVSA-Multiple Results

Table III presents results on MVSA-Multiple. The proposed CLIP-CrossFusion Net with Focal Loss and class weighting achieves 74.39% accuracy and 0.7497 weighted F1, outperforming all baselines including ICCI (73.29%). Fig. 4 visualises the comparison.

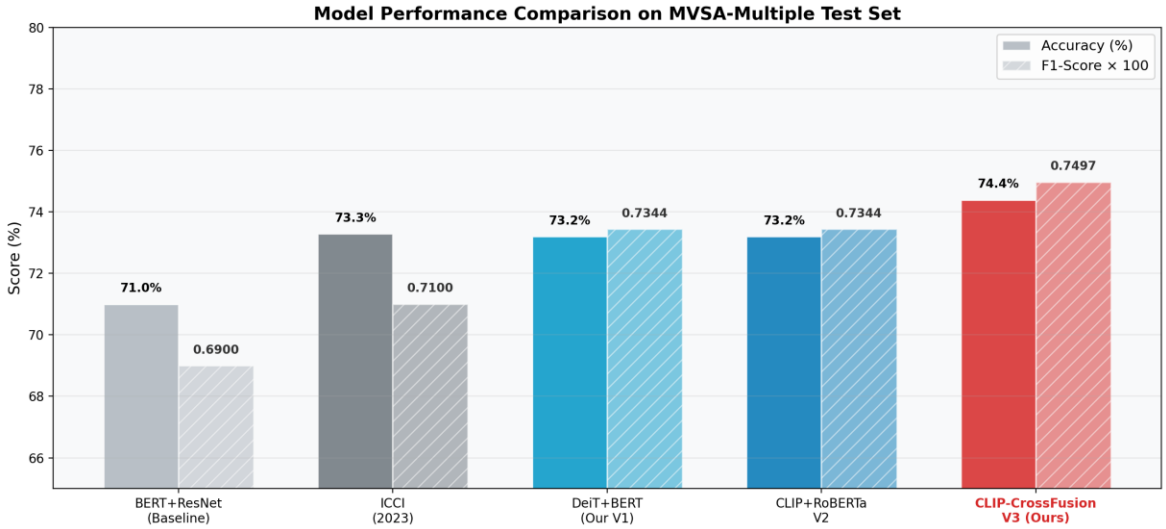

Fig. 4. Model performance comparison on the MVSA-Multiple test set. The proposed CLIP-CrossFusion Net with Focal Loss and class weighting achieves 74.39% accuracy.

TABLE III. PERFORMANCE COMPARISON ON THE MVSA-MULTIPLE TEST SET

Model	Acc. (%)	W-F1	Neg-F1	Neu-F1	Pos-F1
DeiT-Base + BERT (Concat)	58.76	0.5879	0.52	0.41	0.67
ViT-Base + BERT (Concat)	57.13	0.5669	0.49	0.39	0.65
Swin-Base + BERT (Concat)	56.63	0.5434	0.47	0.41	0.67
RoBERTa-L + CLIP ViT-L/14 (large-encoder)	71.13	0.7045	0.76	0.57	0.72
ICCI (2023) [14]	73.29	0.7100	–	–	–
CLIP ViT-B/32 + RoBERTa (cross-modal attention)	73.20	0.7344	0.84	0.59	0.75
CLIP-CrossFusion Net + Focal + CW (ours)	**74.39**	**0.7497**	**0.85**	**0.63**	**0.75**

B. MVSA-Single Results

Table IV presents results on MVSA-Single. The proposed ensemble of the base model, colour-contrastive variant, and RoBERTa-Large variant achieves 75.66% accuracy and 0.7517 weighted F1, outperforming DeiT+BERT (61.50%) and substantially improving over the single best model (74.12%). The Neutral F1 improves from 0.38 (base model) to 0.45 (ensemble), a significant gain on the hardest class. Fig. 5 visualises this comparison, showing the progressive accuracy gains from the base model to the final ensemble, with the best result (75.66%) approaching the ICCI benchmark of 79.33%.

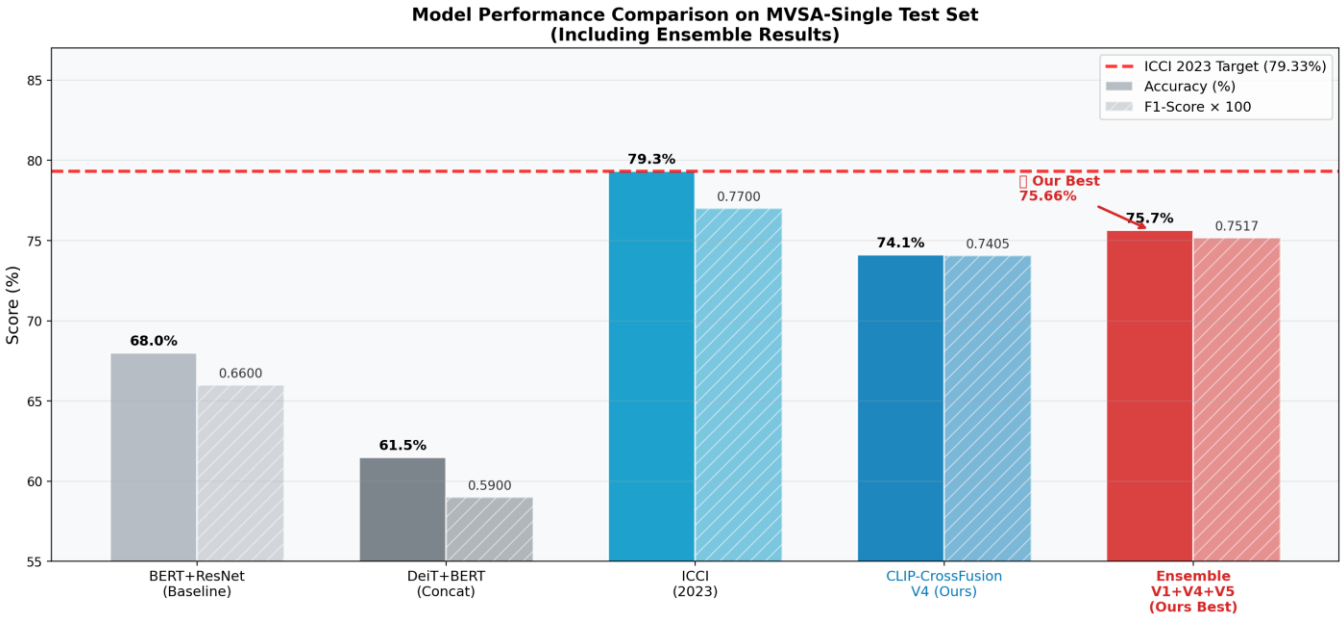

Fig. 5. Model performance comparison on the MVSA-Single test set.

TABLE IV. PERFORMANCE COMPARISON ON THE MVSA-SINGLE TEST SET

Model	Acc. (%)	W-F1	Neg-F1	Neu-F1	Pos-F1
BERT + ResNet (baseline)	68.00	0.6600	–	–	–
DeiT + BERT (Concat)	61.50	0.5900	–	–	–
ICCI (2023) [14]	79.33	0.7700	–	–	–
Base: CLIP + RoBERTa-Base	73.45	0.7288	0.65	0.38	0.83
+ Colour + Contrastive	74.12	0.7405	0.67	0.41	0.84
+ RoBERTa-Large	73.67	0.7355	0.67	0.40	0.83
Ensemble: base + colour-contrastive + large (ours)	**75.66**	**0.7517**	**0.67**	**0.45**	**0.85**

C. Ablation Study

Table V traces the contribution of each component across both datasets, showing systematic improvement as components are added.

TABLE V. ABLATION STUDY ACROSS BOTH DATASETS (X-ATTN = CROSS-MODAL ATTENTION, CW = CLASS WEIGHTS, CONT. = CONTRASTIVE LOSS)

Model	CLIP	X-Attn	Focal	CW	Colour	Cont.	Mult. (%)	Sing. (%)
DeiT + BERT	✗	✗	✗	✗	✗	✗	58.76	61.50
Base (CLIP + X-Attn)	✓	✓	✗	✗	✗	✗	71.13	73.45
+ Focal + CW	✓	✓	✓	✓	✗	✗	74.39	–
+ Colour + Contrastive	✓	✓	✓	✓	✓	✓	–	74.12
Ensemble (base + colour-contrastive + large)	✓	✓	✓	✓	✓	✓	–	**75.66**

D. Training Dynamics on MVSA-Multiple

Fig. 6 and Fig. 7 illustrate the training dynamics on MVSA-Multiple. Fig. 6 shows the overall accuracy and loss convergence, with the best checkpoint reached at epoch 10 (validation accuracy 74.71%, validation F1 0.7503). Fig. 7 tracks per-class F1 progression and demonstrates how targeted class weighting steadily improves the Neutral class F1 from 0.55 to 0.63 over training.

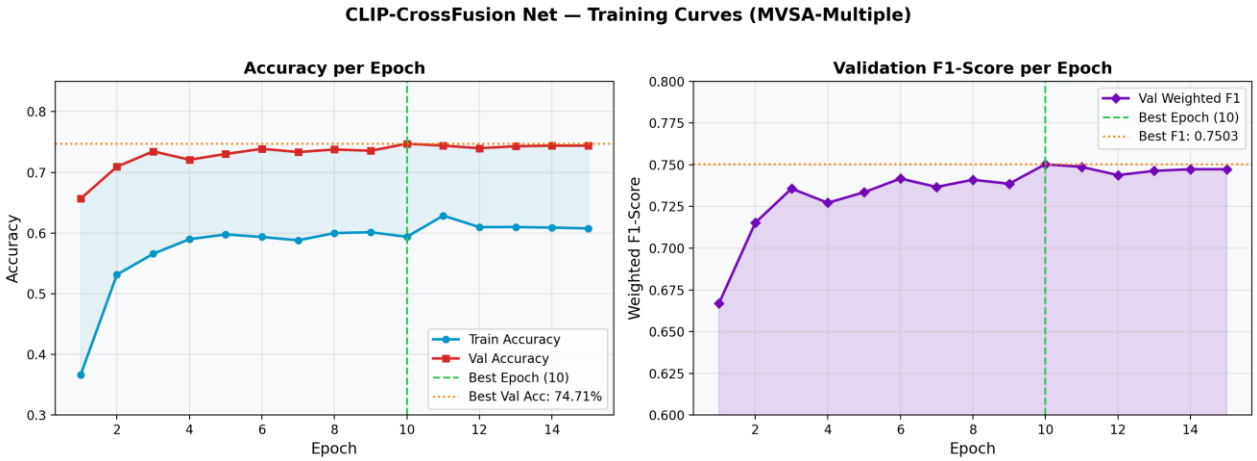

Fig. 6. Training curves on MVSA-Multiple. Best checkpoint at epoch 10 (Val. Acc.: 74.71%, Val. F1: 0.7503).

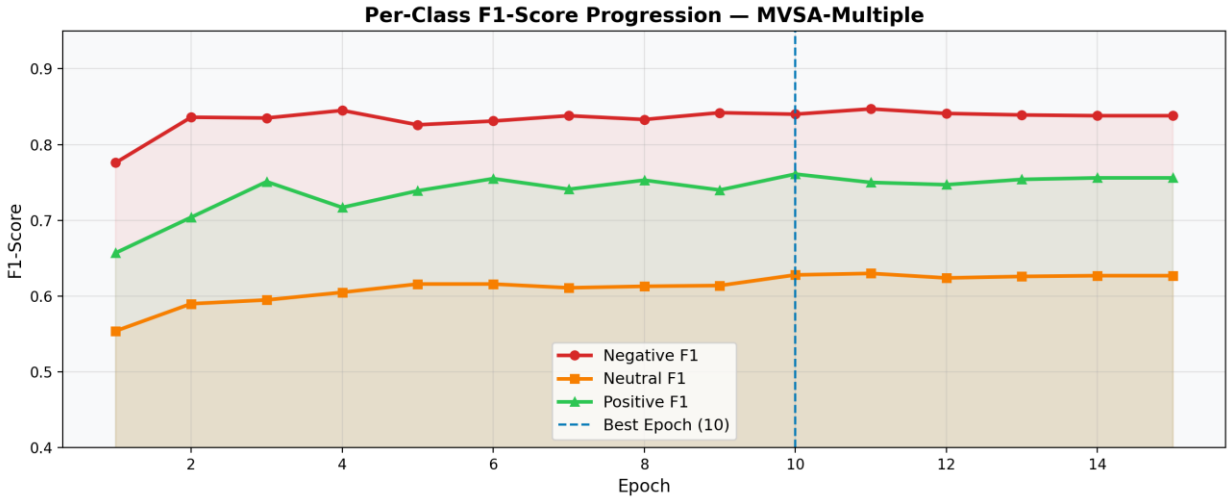

Fig. 7. Per-class F1 progression on MVSA-Multiple. The neutral class improves from 0.59 to 0.63 with targeted class weighting.

E. Training Dynamics on MVSA-Single

Fig. 8 and Fig. 9 present the training dynamics on MVSA-Single for the base model. Fig. 8 shows validation accuracy stabilising around epoch 17, with the best checkpoint at validation accuracy 73.61% and validation F1 0.7262. Fig. 9 tracks per-class F1 progression and highlights the delayed emergence of the Neutral class, which starts from 0.00 at epoch 1 due to the severe class imbalance of only 10.4% Neutral samples.

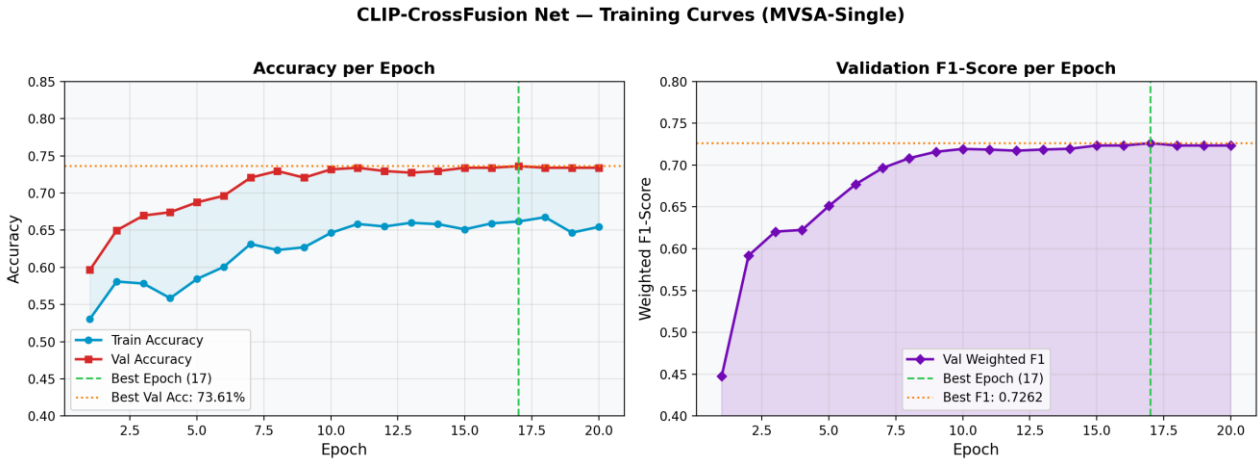

Fig. 8. Training curves on MVSA-Single (base model). Best checkpoint at epoch 17 (Val. Acc.: 73.61%, Val. F1: 0.7262).

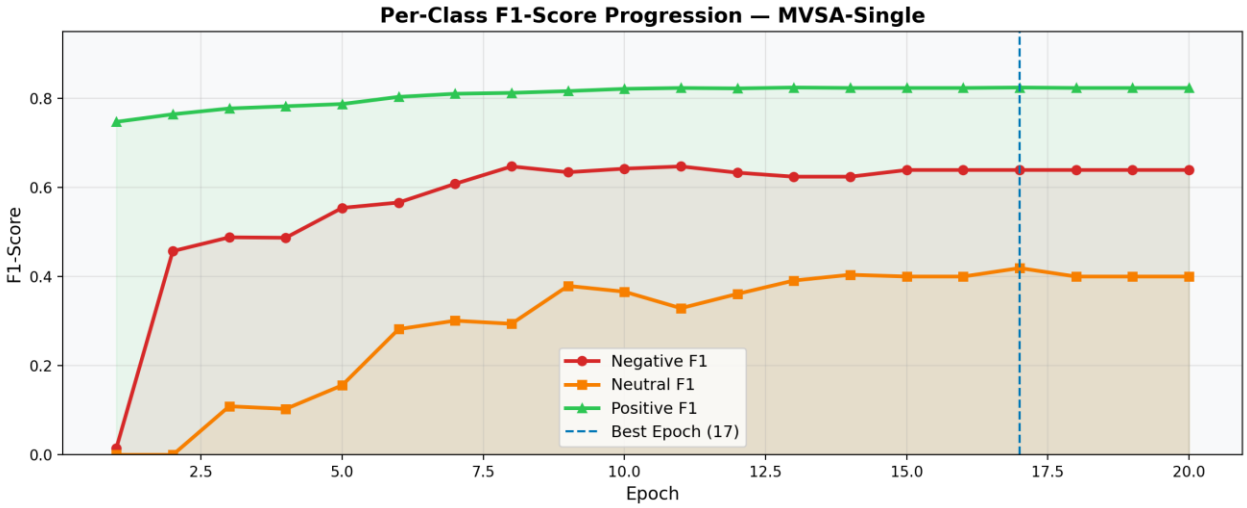

Fig. 9. Per-class F1 progression on MVSA-Single. The neutral class starts from 0 at epoch 1 due to severe class imbalance (10.4% of samples).

TABLE VI. DETAILED PER-CLASS RESULTS ON BOTH DATASETS (TEST SET WITH TTA)

Dataset / Model	Class	Prec.	Rec.	F1	Supp.	Observation
MVSA-Multiple, Focal + CW (74.39%)	Negative	0.91	0.80	0.85	893	Highest precision; clear negative signals
	Neutral	0.57	0.71	0.63	759	Hardest class; boosted by class weighting
	Positive	0.77	0.73	0.75	1,195	Largest class; good balance
MVSA-Single, ensemble (75.66%)	Negative	0.70	0.64	0.67	136	Stronger with ensemble than base alone
	Neutral	0.49	0.43	0.45	47	+0.07 over base alone; very small support
	Positive	0.82	0.87	0.85	269	Best among all versions

Table VI presents the per-class results on the MVSA-Single and MVSA-Multiple datasets. From Table VI, it is observed that, for the neutral class, only 47 samples are available as support.

F. Confusion Matrix Analysis

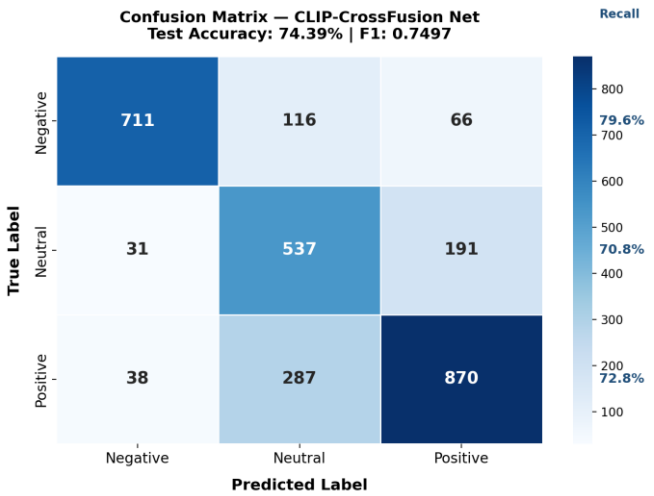

Fig. 10. Confusion matrix on the MVSA-Multiple test set (2,847 samples). Neutral to positive (191 cases) is the most frequent error.

Fig. 10 and Fig. 11 present confusion matrices for MVSA-Multiple and MVSA-Single, respectively. On MVSA-Multiple (Fig. 10, 2,847 samples), the most frequent error is Neutral samples being misclassified as Positive (191 cases), reflecting the contextual ambiguity of the Neutral class. On MVSA-Single (Fig. 11, 452 samples, base model), the Neutral class remains the hardest, with reliable estimation further limited by a test support of only 47 Neutral samples.

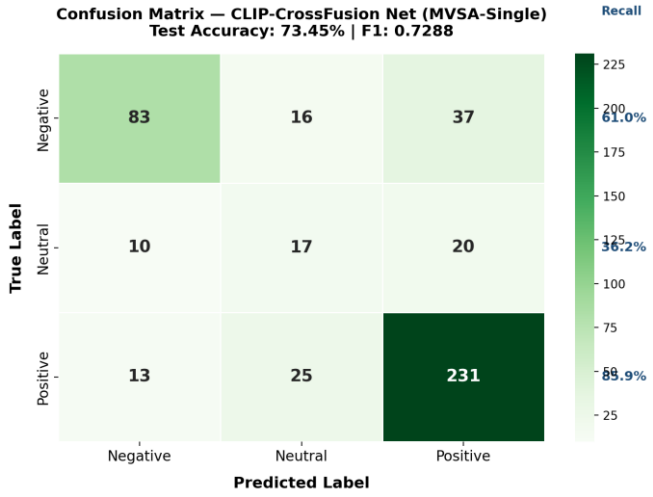

Fig. 11. Confusion matrix on the MVSA-Single test set (base model, 452 samples). Neutral is the most challenging class with only 47 test samples.

G. Cross-Dataset Comparison

Fig. 12 presents the final comparison across both datasets. The MVSA-Single ensemble slightly outperforms MVSA-

Multiple on overall accuracy (75.66% vs 74.39%) and Positive F1 (0.85 vs 0.75), while MVSA-Multiple is stronger on Negative F1 (0.85 vs 0.67) and Neutral F1 (0.63 vs 0.45). The Neutral gap reflects the much smaller Neutral support on MVSA-Single (10.4% vs 26.7%). MVSA-Multiple leads on Negative and Neutral F1 due to larger, more balanced class support.

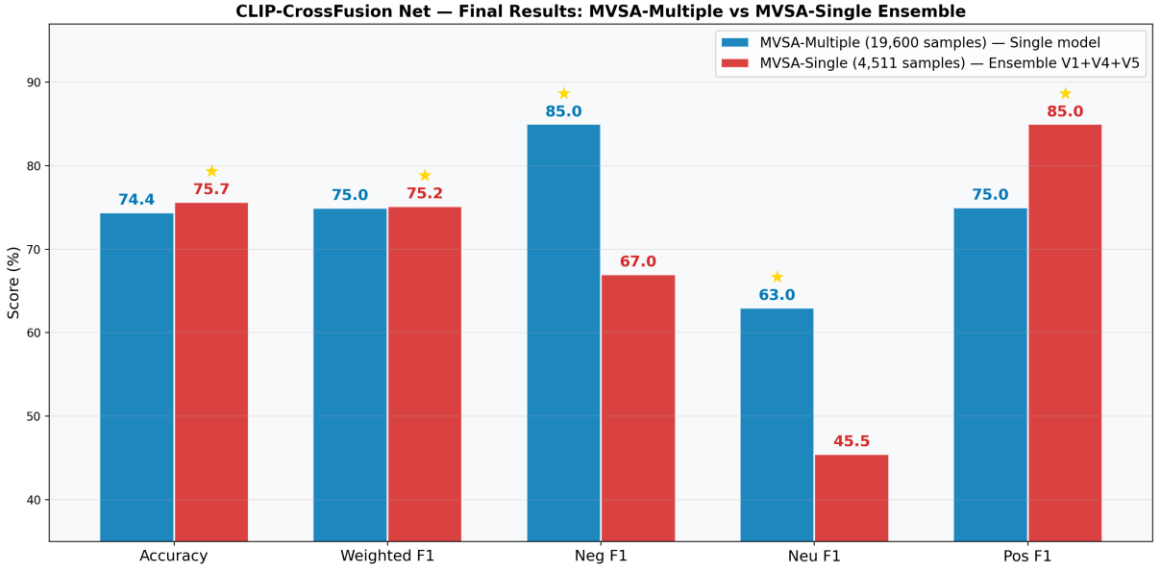

Fig. 12. Cross-dataset comparison of the final best models.

H. Comparison with State-of-the-Art

On MVSA-Multiple, the proposed model attains 74.39%, above ICCI (73.29%) and well above the concatenation baselines (56-58%). On MVSA-Single, the proposed ensemble reaches 75.66%, a 3.67 percentage-point gap from ICCI (79.33%). ICCI uses HSV colour features, which motivated the colour feature branch. The remaining gap likely comes from the richer colour modelling strategy of ICCI and different training data preprocessing. Biswas et al. [15] report 93.48% on MVSA-Multiple but use a highly specialised multi-stage pipeline with Mask-RCNN, AdaBoost, and Dempster-Shafer fusion that substantially increases complexity. The proposed end-to-end framework achieves competitive results with a simpler, more reproducible approach.

VII. Conclusion

This study presents CLIP-CrossFusion Net, a multimodal sentiment analysis framework combining CLIP ViT-B/32 and RoBERTa through bidirectional cross-modal attention for 3-class sentiment classification. The proposed model is evaluated comprehensively on both the MVSA-Multiple and MVSA-Single datasets with four model variants and a multi-model ensemble.

The main contributions and findings of the study are: 1) the proposed bidirectional cross-modal attention improves over simple concatenation by 12-15 percentage points on both datasets; 2) focal loss with class-balanced weighting pushes Neutral F1 from 0.59 to 0.63 on MVSA-Multiple and from 0.00 to 0.38 on MVSA-Single; 3) HSV colour features in the colour-contrastive variant add 0.67 percentage points of accuracy and improve Neutral F1 on MVSA-Single; 4) the multi-model ensemble achieves 75.66% on MVSA-Single, 2.21 percentage points over the single best model; and 5) both datasets reach above 74% accuracy on a single consumer GPU, demonstrating practical feasibility.

In future, the following works may be explored: region-based visual attention for fine-grained sentiment localisation; caption generation for image-to-text conversion as used by ICCI; multi-task learning with modality alignment objectives; larger vision-language models (CLIP ViT-L/14 with memory-efficient training); and extension to video-based multimodal sentiment analysis.

Declarations

Conflict of Interest. The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this study.

Author Contributions. T S Kaveri and C K Roopa: conceptualization, methodology, investigation, writing - original draft; B S Harish and M S Kendagannaswamy: data curation, formal analysis, visualization; B S Harish: supervision, writing - review and editing.

Funding. The authors did not receive support from any organization for the submitted work.

Clinical Trial Registration. Not applicable. This study did not involve a clinical trial; therefore, no clinical trial registration number is available.

Consent to Publish. Not applicable.

Ethical Statement. This research did not involve human participants, animals, or clinical data. The study was conducted using publicly available datasets and computational machine learning methods. No ethical approval or informed consent was

required. The authors complied with all applicable institutional and journal ethical guidelines.

Consent to Participate. Not applicable; no human participants were involved.

Data Availability Statement. The datasets analysed during this study are publicly available from the repositories cited in the manuscript. All relevant dataset sources, accession details, and URLs are provided in the references and/or the dataset section (Section III). No new datasets were generated during this study.

***Abstract*—Artificial intelligence (AI) is increasingly used to support musculoskeletal diagnosis from routine imaging, yet evidence remains fragmented across diseases, modalities, tasks, and validation designs. This systematic review synthesizes AI-based diagnosis, screening, grading, scoring, and structural assessment of rheumatoid arthritis (RA) and osteoporosis/osteopenia using radiography, computed tomography (CT), ultrasound, DXA-related imaging, and multimodal clinical data. Following PRISMA 2020 principles, Scopus, PubMed, Web of Science Core Collection, IEEE Xplore, and the ACM Digital Library were searched. Across the final exports, 2,239 records were identified; 247 full-text reports were assessed for eligibility, and 233 studies were included, while 25 reports could not be retrieved. CNN-based and transfer-learning approaches remained dominant, with increasing use of attention mechanisms, transformers, ensembles, explainable AI, and multimodal fusion. Osteoporosis research focused mainly on opportunistic screening and BMD-related prediction, whereas RA studies more often addressed diagnosis, joint-level damage, severity grading, and automated scoring. Methodological maturity remained uneven: 141 of 233 studies (60.5%) relied on internal validation only, whereas 44 (18.9%) reported external or multicenter validation. Future progress therefore depends less on marginal gains in headline metrics than on reproducible study design, robust external validation, calibration, and clinically integrated multimodal decision support.**

***Keywords*—Rheumatoid arthritis; osteoporosis; osteopenia; radiography; X-ray; CT; multimodal learning; deep learning; convolutional neural networks; transfer learning; systematic review**

I. Introduction

Artificial intelligence has become an increasingly important component of musculoskeletal and rheumatologic imaging because it can detect subtle image patterns, automate repetitive measurements, and support decision-making in settings where conventional interpretation is time-consuming or operator-dependent. The clinical rationale is especially strong in rheumatoid arthritis (RA), where structural joint damage requires reproducible detection and longitudinal assessment, and in osteoporosis/osteopenia, where underdiagnosis motivates opportunistic screening from routinely acquired images. Recent reviews confirm substantial growth of AI in both disease domains, but most syntheses remain disease-, modality-, or task-specific [30]–[35].

The technical landscape is correspondingly heterogeneous. Published systems range from binary disease detection to multiclass grading, bone-mineral-density (BMD) or T-score estimation, joint localization, erosion assessment, modified Sharp/van der Heijde scoring, and image-plus-clinical decision support. Conventional convolutional neural networks (CNNs) and transfer learning remain widely used, while attention mechanisms, vision transformers, ensemble learning, explainability, uncertainty estimation, and multimodal fusion are increasingly represented. The EHR-plus-imaging framework reported by Ichahane et al. [8] and the attention-enhanced ensemble for osteoporosis detection by Ichahane and Assad [28] illustrate this movement from isolated image classifiers toward richer patient-level and ensemble reasoning systems.

Despite rapid publication growth, the evidence is difficult to interpret as a coherent basis for clinical translation. Apparent performance depends on dataset scale and provenance, disease prevalence, task definition, reference-standard construction, patient-level data partitioning, and whether evaluation is internal, independently held out, or genuinely external. Existing meta-analyses have demonstrated promising diagnostic accuracy in selected osteoporosis settings [31]–[35], but such pooled estimates do not resolve broader cross-task heterogeneity, while RA-focused reviews cover a wider clinical and data spectrum [30]. Consequently, headline accuracy or AUC values can overstate maturity when validation design, calibration, leakage risk, and transportability are not considered jointly.

The central research gap is therefore not a lack of high-performing AI models, but the absence of a cross-disease synthesis that jointly evaluates clinical task, imaging modality, reference-standard quality, data provenance, risk of bias, and validation maturity in rheumatoid arthritis and osteoporosis/osteopenia. This review addresses that gap through

*Corresponding author.

a common analytical framework that 1) maps clinical objectives and task formulations; 2) compares imaging modalities, datasets, model families, and evaluation metrics; 3) evaluates reference-standard heterogeneity, internal versus external validation, and adapted QUADAS-2 risk-of-bias domains; 4) contrasts the methodological trajectories of the two disease areas; and 5) identifies barriers to clinical translation through an evidence-maturity perspective. By combining five bibliographic databases with article-level eligibility assessment and structured methodological appraisal, the review is designed to distinguish algorithmic performance from the strength and transportability of the supporting evidence.

The remainder of this study is organized as follows. Section II situates the present work within existing systematic reviews and meta-analyses. Section III describes the search strategy, eligibility criteria, PRISMA-based study selection, data extraction, risk-of-bias appraisal, and evidence-synthesis framework. Section IV presents the main results across the predefined research questions. Section V discusses evidence maturity, methodological limitations, and priorities for clinical translation, while Section VI concludes the study.

II. Related Works

A. Existing Review Landscape and Comparative Positioning

Existing reviews confirm the rapid growth of AI in both rheumatoid arthritis (RA) and osteoporosis, but their scope is usually disease-specific, modality-specific, or focused on a narrower clinical objective. For RA, Momtazmanesh et al. provided a broad state-of-the-art review spanning imaging, omics, EHRs, sensors, treatment response, and prognosis [30], whereas imaging-focused reviews have generally concentrated on selected arthritis tasks rather than a common diagnostic-imaging framework. For osteoporosis, recent systematic reviews and meta-analyses have addressed plain radiographs [31], panoramic dental radiography [32], CT-based deep learning [33], multi-imaging machine-learning diagnosis [34], and opportunistic CT screening [35]. These reviews demonstrate promising diagnostic performance but repeatedly identify substantial heterogeneity, limited external validation, and inconsistent reporting as barriers to translation.

B. Limitations of Existing Reviews

The prior literature nevertheless leaves three gaps relevant to the present review. First, RA and osteoporosis/osteopenia are rarely assessed within a single methodological framework, despite their shared reliance on image-based classification, quantitative scoring, transfer learning, and clinically meaningful reference standards. Second, prior syntheses often narrow eligibility to one modality or one task, which improves statistical comparability but limits cross-modality and cross-disease assessment of evidence maturity. Third, although several osteoporosis meta-analyses appropriately use QUADAS-2 [31]–[35], the broader diagnostic-AI literature remains inconsistent in reporting patient-level partitioning, leakage control, calibration, dataset provenance, and genuinely external validation. A recent IJACSA systematic review also illustrates the value of explicit search, eligibility, and comparative-synthesis structures for reproducible review reporting [9].

C. Added Value of the Present Review

The present review therefore extends the existing review landscape rather than duplicating a disease- or modality-specific meta-analysis. It jointly evaluates RA and osteoporosis/osteopenia, covers five bibliographic databases, and applies a common PRISMA-based workflow to 233 included primary journal studies (Table IV). The synthesis combines adapted QUADAS-2 domains with AI-specific appraisal of patient-level splitting, train-test leakage, validation design, data provenance, calibration, and interpretability. Because the included tasks range from binary screening to BMD regression, joint-level damage analysis, severity grading, and structured RA scoring, the review prioritizes structured narrative synthesis and evidence-maturity comparison rather than a single pooled diagnostic estimate.

This cross-disease perspective is particularly useful for separating architectural performance from evidence strength: an internally validated high-AUC classifier is not treated as equivalent to a multicenter or external-validation study. The review thus focuses on transportability, reference-standard quality, and clinical task complexity in addition to headline performance.

Comparative positioning against prior reviews. In osteoporosis, Yen et al. synthesized six plain-radiograph studies with QUADAS-2 and diagnostic meta-analysis [31]; Tarighatnia et al. focused on seven panoramic-radiography studies and additionally evaluated publication bias [32]; Wang et al. synthesized 24 CT-based deep-learning studies [33]; Zhao et al. expanded the scope to 60 X-ray, CT, and MRI studies [34]; and Ghareh Mohammadi and Sebro examined 31 opportunistic CT studies covering osteoporosis and spine-fracture screening [35]. These reviews provide stronger within-modality statistical comparability, but they do not address RA within the same framework.

For RA, the broad review by Momtazmanesh et al. spans imaging, omics, EHRs, sensors, treatment response, and prognosis [30], but was not designed as a diagnostic-imaging systematic review with QUADAS-style appraisal. The present review therefore complements rather than replaces these prior syntheses: it sacrifices a single pooled effect in favor of cross-disease comparison of clinical task, imaging modality, reference standard, data provenance, validation rigor, and AI-specific leakage risk across a substantially larger body of included primary studies.

III. Methods

This systematic review was conducted and reported according to PRISMA 2020 principles [10]. The review workflow comprised seven predefined components: review questions, information sources and search strategy, eligibility criteria, deduplication and staged study selection, structured data extraction, adapted risk-of-bias appraisal, and cross-dimensional evidence synthesis. Scopus was used as the primary discovery source, complemented by PubMed, Web of Science Core Collection, IEEE Xplore, and the ACM Digital Library. At each stage, study-selection decisions and reasons for exclusion were documented so that screening, retrieval, eligibility, and inclusion counts could be reconciled reproducibly.

A. Research Questions and Review Framework

Clinical AI for rheumatoid arthritis and osteoporosis/osteopenia can be organized along seven complementary dimensions: clinical objective, model family, imaging and data source, evaluation strategy, workflow role, task formulation, and methodological constraints on translation. These dimensions provide the analytical structure used to compare heterogeneous diagnostic-AI studies; their operational formulation is presented in Table I.

TABLE I. RESEARCH QUESTIONS AND ANALYTICAL FOCUS

RQ	Research question / analytical focus
RQ1	Clinical objectives targeted by AI systems.
RQ2	AI model families and methodological evolution.
RQ3	Imaging modalities, datasets, and data provenance.
RQ4	Evaluation metrics, reference standards, and validation rigor.
RQ5	Role of AI in diagnostic and reader-assistance workflows.
RQ6	Task formulations and label granularity.
RQ7	Methodological limitations and priorities for clinical translation.

These questions follow a diagnostic-review logic linking the target condition, AI index test, imaging input, reference standard, and clinically relevant outcome.

B. Search Strategy

The literature search combined four concept blocks: target condition (rheumatoid arthritis, osteoporosis, osteopenia), artificial-intelligence methods, medical-imaging inputs, and diagnostic or assessment tasks. The original Scopus search was generated on April 9, 2026, and the search was subsequently extended to PubMed, Web of Science Core Collection, IEEE Xplore, and the ACM Digital Library using database-specific adaptations of the same conceptual structure. The Scopus formulation is reported below to make the search logic immediately visible; the complete database-specific strategies are provided in Supplementary Table S2 and are publicly available through the Zenodo repository at https://doi.org/10.5281/zenodo.22751177. Exact execution dates for the supplementary database searches were not separately preserved in the frozen export metadata and are therefore not assigned retrospectively.

Research query:

TITLE-ABS-KEY (("rheumatoid arthritis" OR osteoporosis OR osteopenia) AND ("deep learning" OR "convolutional neural network*" OR CNN OR "ensemble learning" OR "attention mechanism*" OR "case-based reasoning" OR multimodal) AND ("x-ray" OR radiograph* OR "medical imag*" OR EHR OR "electronic health record*") AND (diagnos* OR detect* OR classif* OR predict* OR screening))

Applying the conceptually equivalent searches across the five sources yielded 1,053 Scopus records, 298 PubMed records, 551 Web of Science Core Collection records, 197 IEEE Xplore records, and 140 ACM Digital Library records (n = 2,239). Source overlap was handled by cross-database deduplication; therefore, database-specific retrieval counts are reported for transparency and are not interpreted as independent study contributions.

The resulting records were merged into a single screening dataset before DOI- and title-based deduplication.

C. Inclusion and Exclusion Criteria

Eligibility was defined by three core requirements: primary peer-reviewed evidence, medical imaging as an input to the AI system, and quantitative evaluation of a direct rheumatoid arthritis or osteoporosis/osteopenia diagnostic or assessment task. Exclusion rules removed non-primary publications, non-target conditions or outcomes, and image-processing studies without a diagnostic or scoring endpoint. The operational inclusion and exclusion criteria are given in Table II.

TABLE II. ELIGIBILITY CRITERIA

Code	Operational criterion
IC1	Primary journal study evaluating AI for direct RA or osteoporosis/osteopenia diagnosis, screening, grading, scoring, or structural assessment.
IC2	Medical imaging is an AI input, alone or with clinical data; no imaging input fails IC2.
IC3	At least one quantitative evaluation metric is reported.
EC1	Non-primary publication (conference/proceedings, review, editorial, letter/note, erratum, or book chapter).
EC2	Prognosis, epidemiology, fracture-only, treatment-response, or risk-factor study without direct target-condition assessment.
EC3	Image processing only (segmentation, preprocessing, enhancement, or compression) without a diagnostic/scoring endpoint.
EC4	Non-target disease (e.g., osteoarthritis); generic “arthritis” is not treated as RA.

D. Screening Process and PRISMA Flow

Records from all five sources were merged into a common screening dataset. Deduplication was performed first by normalized DOI and subsequently by normalized-title comparison when DOI information was missing or inconsistent. From 2,239 records, 892 duplicates were removed, leaving 1,347 unique records for screening. After pre-retrieval exclusions, 272 reports were sought for retrieval. Twenty-five reports could not be retrieved; 247 reports were assessed for eligibility in full text, 14 were excluded after full-text assessment, and 233 studies were included. The complete selection pathway is shown in Fig. 1.

Study selection followed conservative disease and evidence rules. Generic “arthritis” was not treated as rheumatoid arthritis unless an explicit RA target was demonstrated, and fracture-only studies were not considered osteoporosis evidence unless osteoporosis/osteopenia itself was directly evaluated. A report was considered retrieved only when the complete article had actually been obtained and assessed. Abstracts, previews, and metadata could support exclusion only when an exclusion criterion was already explicit; otherwise, potentially eligible reports remained unresolved until full-text retrieval was attempted. After targeted retrieval, 25 reports could not be retrieved and therefore were not assessed for eligibility. Of the 247 reports assessed in full text, 14 were excluded, and 233 studies were included in the review. The complete study-selection pathway and reconciled counts are shown in Fig. 1.

The 14 reports excluded after full-text assessment and the corresponding reasons for exclusion are detailed in Supplementary Table S3, available at https://doi.org/10.5281/zenodo.22751177.

Methodological safeguards. Four rules were enforced throughout the review: 1) a report was considered retrieved only after the complete article had been obtained and assessed; 2) no report was excluded solely because it was difficult to access; 3) generic arthritis was not interpreted as RA, and fracture-only outcomes were not interpreted as osteoporosis unless the target condition itself was directly assessed; and 4) raw accuracy or AUC values were not ranked across studies without considering task definition, reference standard, data provenance, and validation design.

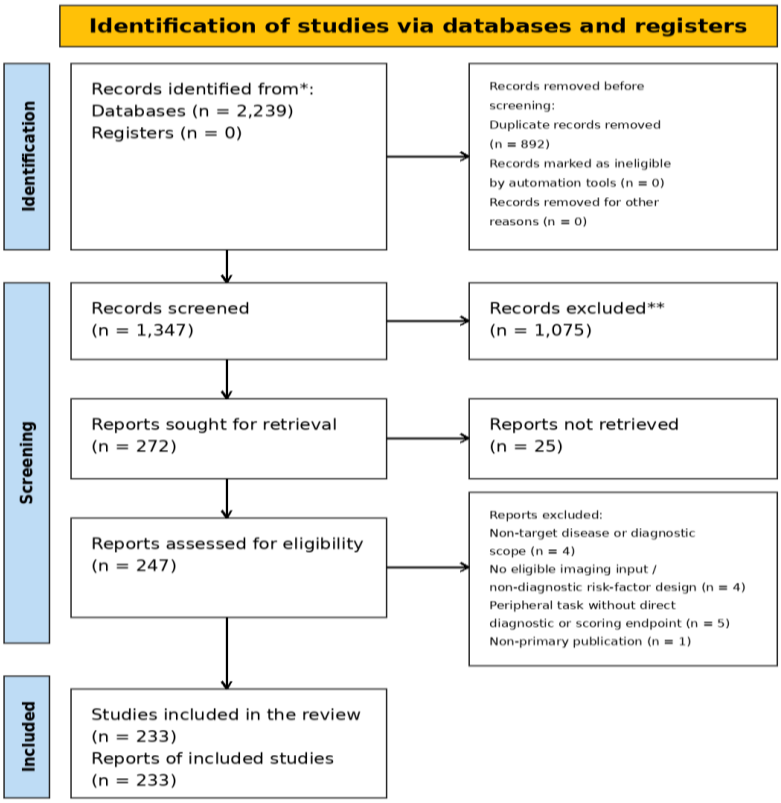

Fig. 1. PRISMA 2020 flow diagram of study identification, screening, retrieval, eligibility assessment, and inclusion.

E. Data Extraction and Synthesis Strategy

After study selection, full-text data extraction was performed using a standardized framework so that every included study could be compared on clinically and methodologically relevant dimensions. Extracted fields included publication year, disease focus, clinical objective, anatomical site, imaging modality, dataset size and provenance, AI architecture, multimodal inputs, task formulation, reference standard, validation design, external-validation status, and reported metrics (e.g., accuracy, sensitivity, specificity, F1-score, AUC, ICC, RMSE, and MAE). Patient-level splitting, potential leakage, class imbalance, calibration, interpretability, and data provenance were also recorded when reported. Metrics were preserved in their original task context rather than normalized into a single performance score.

F. Risk of Bias and AI-Specific Quality Appraisal

Risk of bias was appraised using an adapted QUADAS-2 structure covering patient selection, index test, reference standard, and flow/timing [29]. AI-specific extensions captured patient-level versus image-level splitting, train-test leakage risk, class imbalance, transparency of cohort construction, calibration, explainability, and independent or multicenter external validation. Domain judgments were retained separately; they were not collapsed into a single numerical "quality score," because such averaging can obscure distinct sources of diagnostic bias. The appraisal was used to contextualize performance and evidence maturity rather than as an automatic exclusion rule.

G. Evidence Synthesis and Evidence-Maturity Logic

A structured narrative synthesis was used because disease targets, anatomical sites, imaging modalities, class definitions, reference standards, dataset construction, model objectives, validation designs, and outcome metrics were too heterogeneous for a clinically defensible meta-analysis. Studies were synthesized by disease, clinical task, modality, model family, reference standard, and validation strategy. To avoid pseudo-precision, accuracy or AUC values from non-equivalent tasks were not pooled or averaged. A three-axis Evidence Maturity Framework was used to interpret the body of evidence across 1) clinical task complexity, 2) data richness/provenance, and 3) validation rigor. This framework is interpretive rather than a scoring system and is intended to distinguish high internal performance from stronger evidence of transportability and

clinical readiness. A single pooled effect estimate was therefore not pursued, because pooling non-equivalent targets, reference standards, imaging modalities, and validation designs would violate the clinical and statistical comparability required for a defensible diagnostic meta-analysis.

1) Evidence-maturity framework — clinical task. The continuum ranges from binary recognition to multiclass grading or BMD regression, and then to structured scoring, reader assistance, or clinically integrated decision support.

2) Evidence-maturity framework — data. The continuum ranges from small private single-center image sets to larger institutional/public cohorts and, at the highest level, multicenter or external cohorts combined with clinically meaningful structured data.

3) Evidence-maturity framework — validation. The continuum ranges from internal split or cross-validation to independent testing and, at the highest level, external/multicenter validation, calibration, reader studies, or prospective evaluation.

IV. Results

A. Characteristics of the Included Studies

Fig. 2 shows the publication-year distribution of the 233 included studies and highlights the rapid expansion of the evidence base after 2019. Fig. 3 presents the distribution of imaging modalities, showing the predominance of radiography and computed tomography. Fig. 4 summarizes validation maturity by distinguishing internal validation, independent test sets, and external or multicenter evaluation.

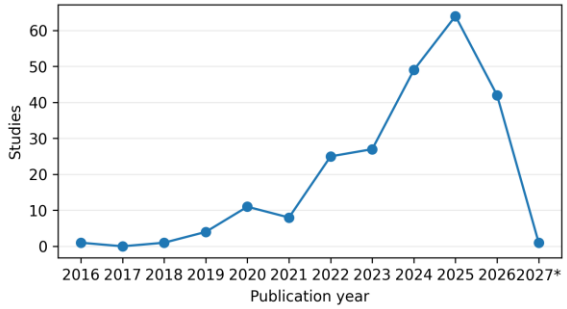

Fig. 2. Publication year of the 233 included studies. *The single study assigned to a 2027 issue had a 2026 DOI/online-publication record.

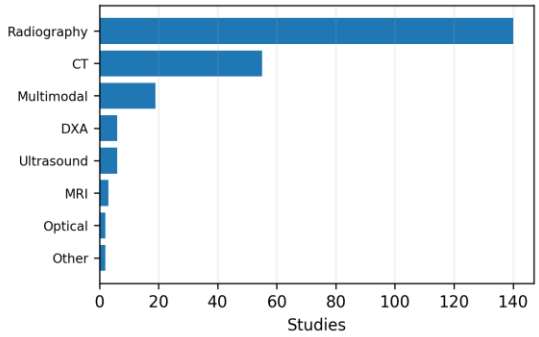

Fig. 3. Distribution of imaging modalities among the 233 included studies. Multimodal denotes studies using more than one imaging family.

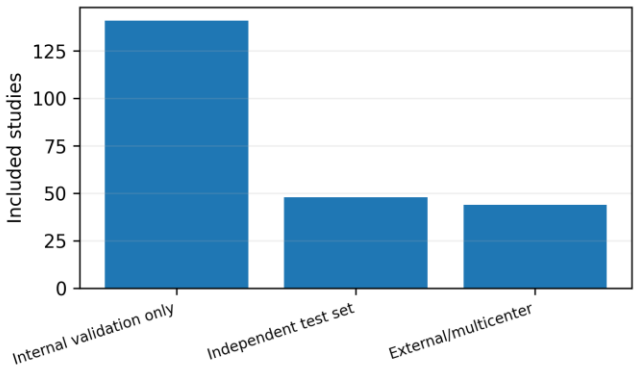

Fig. 4. Validation characteristics of the included studies: 141 internal-validation-only studies, 48 studies with an independent test set, and 44 studies with external or multicenter validation.

B. Overview of the Included Studies

Following deduplication, screening, report retrieval, and full-text eligibility assessment, 233 primary research studies published as journal articles were included: 198 addressing osteoporosis/osteopenia and 35 rheumatoid arthritis (Table V). Their target-condition distribution is shown in Fig. 5. The included evidence is methodologically diverse, but most studies still rely on internal validation; the corresponding risk-of-bias profile across adapted QUADAS-2 domains and the AI-specific split/leakage domain is shown in Fig. 6.

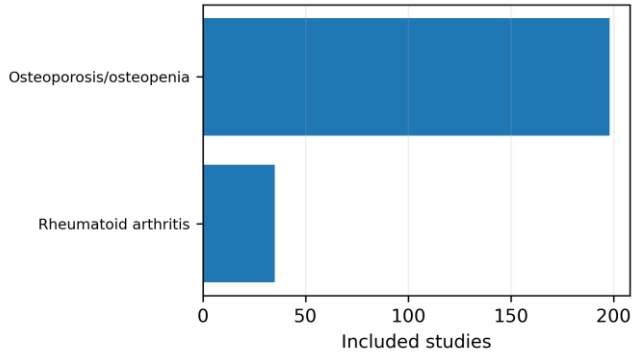

Fig. 5. Target conditions represented among the 233 included studies: 198 osteoporosis/osteopenia studies and 35 rheumatoid arthritis studies.

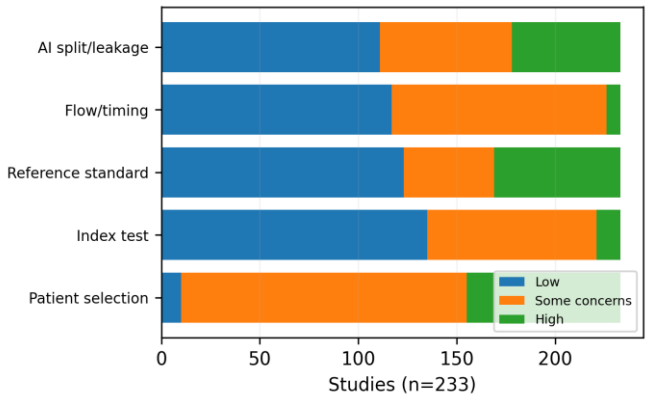

Fig. 6. Risk-of-bias assessment of the 233 included studies using adapted QUADAS-2 domains and an AI-specific split/leakage domain.

C. RQ1. Main Clinical Objectives Targeted by AI Systems

In osteoporosis and osteopenia, the dominant objective is opportunistic screening for low bone mineral density or disease using images acquired for other routine purposes [4]–[7], [12]–[14]. In RA, the objective space is more clinically granular and includes diagnosis, differential diagnosis, severity grading, joint-space or erosion analysis, and automated estimation of structured radiographic scores [2], [16], [17]. Overall, osteoporosis studies remain driven mainly by case finding and opportunistic screening, whereas RA studies are more deeply embedded in complex radiographic interpretation workflows.

D. RQ2. AI Model Families used Across the Included Studies

The dominant methodological pattern is the strong prevalence of deep convolutional image analysis. CNN-based and transfer-learning pipelines form the backbone of most osteoporosis studies and a large portion of RA studies. More recent work increasingly combines complementary architectures through attention or ensemble mechanisms; for example, the attention-enhanced E-DWE CNN ensemble proposed by Ichahane and Assad [28] integrates multiple pretrained backbones with adaptive weighting for knee-radiograph osteoporosis detection. In RA, multistage systems combining localization and classification are particularly prominent, while transformer-enhanced, radiomics-assisted, and explicitly interpretable systems are increasingly represented across both disease families. This methodological diversity is also illustrated by fine-tuned transfer learning for knee-radiograph osteoporosis classification [11], multimodal hand-radiograph/thermal RA modeling [21], interpretable hand-radiograph RA classification [22], and contextual deep-learning assessment of RA bone destruction [24].

E. RQ3. Data Types, Imaging Modalities, and Datasets

Plain radiography is the dominant study-level primary modality: 140/233 studies (60.1%). CT accounts for 55 (23.6%), multimodal imaging for 19 (8.2%), DXA-only and ultrasound for 6 each (2.6% each), MRI for 3 (1.3%), optical imaging for 2 (0.9%), and other imaging for 2 (0.9%). Osteoporosis research spans multiple anatomical sites and opportunistic imaging settings, whereas hand radiography remains central to RA. True image-plus-structured-data fusion remains comparatively uncommon. Additional included examples span cervical-radiography osteoporosis screening [12], spectral-CT osteoporosis assessment [23], few-shot knee-radiograph diagnosis [26], and custom deep-learning approaches for knee osteoporosis/osteopenia detection [27].

F. RQ4. Evaluation Metrics and Reported Performance

The included studies report a heterogeneous set of evaluation metrics. Accuracy, sensitivity, specificity, F1-score, and AUC dominate binary diagnostic tasks, whereas BMD estimation and RA scoring additionally use correlation, RMSE, MAE, and ICC. These metrics cannot be interpreted independently of validation design. A representative example is the hip-radiograph study by Jang et al. [4], in which AUC decreased from 0.867 on internal evaluation to 0.700 on an external cohort, illustrating the importance of transportability assessment.

Among the included studies, 141/233 (60.5%) used internal validation only, 48/233 (20.6%) reported an independent test set, and 44/233 (18.9%) reached external or multicenter validation. Consequently, the synthesis emphasizes validation rigor and reference-standard quality rather than ranking studies by headline accuracy.

G. RQ5. Impact of AI on Conventional Diagnostic and Reader-Assistance Workflows

In osteoporosis research, AI frequently turns routine images into opportunistic screening opportunities, allowing patients to be flagged for confirmatory DXA without a separate imaging pathway [5], [6], [13], [14]. In RA, AI is more often positioned as reader assistance, supporting joint localization, damage scoring, structured interpretation, and consistency [2], [17]. The evidence supports AI as a complementary decision-support layer rather than as a replacement for expert judgment.

H. RQ6. Dominant Task Formulations and Label Granularities

Osteoporosis studies are dominated by binary or near-binary screening tasks and BMD-related prediction [6], [7], [18], whereas RA studies are more heterogeneous and include binary recognition, RA-versus-OA discrimination, severity grading, joint-wise scoring, and end-to-end prediction of aggregate radiographic scores [2], [15]–[17]. Direct comparison of headline metrics is therefore misleading unless task complexity is considered.

I. RQ7. Limitations of the Current Literature and Opportunities for Future Work

Recurrent limitations include small private datasets, retrospective single-center designs, heterogeneous reference standards, insufficient reporting of patient-level splitting, limited calibration, and scarce external validation. The adapted risk-of-bias profile quantifies these concerns: 78/233 studies (33.5%) received a high-risk judgment for patient selection, 64/233 (27.5%) for the reference standard, and 55/233 (23.6%) for AI split/leakage. Only 44/233 studies (18.9%) reached external or multicenter validation. These weaknesses create risks of overfitting, spectrum bias, hidden data leakage, and site-specific performance inflation.

J. Cross-Dimensional Evidence Maturity

When the included studies are interpreted across task complexity, data richness, and validation rigor, a clear imbalance emerges. The field is strongest in algorithmic experimentation and internal discrimination performance, but substantially less mature in transportability and workflow-level evidence. Many studies occupy an intermediate position: they use clinically relevant imaging and modern architectures, yet remain dependent on retrospective single-center data and internal validation. The highest-maturity studies are those that combine clinically meaningful endpoints with independent or multicenter testing, transparent reference standards, and explicit attention to calibration, interpretability, or reader interaction. This pattern indicates that the next phase of progress is more likely to depend on study design and evidence quality than on marginal architectural novelty.

K. Summary of Key Findings

The consolidated evidence therefore reveals four consistent patterns. First, conventional radiography remains the most broadly deployed modality, while CT plays an important role in opportunistic osteoporosis screening and ultrasound remains particularly relevant to RA. Second, CNNs and transfer learning continue to dominate, although attention, transformers, ensemble strategies, and explainable AI are increasingly represented. Third, osteoporosis research is more frequently framed as opportunistic screening or BMD-related prediction, whereas RA research more often involves complex grading, localization, and scoring tasks. Fourth, validation quality remains the principal methodological bottleneck across both disease families, with external and prospective evaluation substantially less common than internal testing.

V. Discussion

A. From Algorithmic Performance to Evidence Maturity

The revised evidence base indicates that the central question is no longer whether AI can achieve high performance on selected RA or osteoporosis datasets, but whether that performance is supported by a sufficiently mature evidence design. Across the 233 included studies, 141 (60.5%) relied on internal validation only, whereas 44 (18.9%) provided external or multicenter evidence. This imbalance explains why high reported discrimination should not automatically be interpreted as clinical transportability.

B. Task Complexity, Data Richness, and Validation Trade-offs

The three-axis synthesis highlights an important trade-off. Simpler binary screening tasks can achieve high discrimination with relatively modest datasets, whereas structured RA scoring, multiclass grading, and multimodal decision support demand richer labels, stronger reference standards, and more robust validation. Similarly, increasing data richness does not automatically improve clinical credibility if data provenance, patient-level partitioning, or external transportability remain weak. This is why performance metrics must be interpreted jointly with task complexity and validation design rather than ranked in isolation. For osteoporosis, opportunistic screening remains the clearest near-term translational pathway. For RA, the strongest role is likely to be structured reader assistance, where AI supports localization, scoring consistency, and repetitive interpretation while preserving clinician oversight.

C. Persistent Validation and Reporting Gaps

The strongest recurring weakness is limited external validation. Only 44 of the 233 included studies (18.9%) reached external or multicenter evaluation, whereas 141 (60.5%) relied on internal validation only. High-risk judgments were assigned to 78 studies for patient selection, 64 for the reference standard, and 55 for AI split/leakage. These findings reinforce the need for multicenter evaluation, prespecified patient-level partitioning, transparent provenance, calibration, and reporting of clinically meaningful uncertainty.

D. Limitations of this Review

At the review level, restriction to primary journal articles improves comparability but excludes potentially informative conference research. Search syntax required database-specific adaptation, and the evidence base remains too heterogeneous for a valid pooled diagnostic-effect estimate. Twenty-five potentially eligible reports could not be retrieved despite targeted searches and therefore could not be assessed for eligibility; they are reported separately in the PRISMA flow as reports not retrieved. In addition, reporting quality in the source literature was uneven for patient-level splitting, calibration, reference-standard construction, and external validation, limiting the precision of cross-study risk-of-bias judgments. These constraints should be considered when interpreting completeness and generalizability. Because the review did not estimate a single common pooled diagnostic effect, formal funnel-plot or regression-based tests of publication bias were not methodologically appropriate across the full evidence base. Nevertheless, publication and selective-reporting bias remain plausible: AI studies with favorable discrimination may be more likely to reach journal publication, while negative, null, or poorly performing models may remain unpublished or incompletely reported. Restricting the synthesis to peer-reviewed journal articles may further accentuate this dissemination bias. These considerations reinforce the need to interpret high reported performance cautiously, particularly when external validation, calibration, or prespecified analysis protocols are absent.

E. Future Research and Translational Priorities

Future research should prioritize methodological and translational maturity over incremental architectural novelty. High-value priorities include multicenter external validation using geographically and technically diverse cohorts; prospective reader-assistance studies; standardized patient-level data partitioning and leakage controls; calibration and uncertainty reporting; explicit comparison against clinically meaningful baselines; transparent reference standards; and multimodal fusion that combines imaging with laboratory, demographic, and EHR information. Shared benchmarks and reporting checklists tailored to diagnostic AI would improve comparability, while reader studies and prospective workflow evaluation would clarify whether algorithmic gains translate into better clinical efficiency, consistency, and patient-level decision support.

F. Methodological Priorities for Clinical Translation

Methodological maturity in diagnostic AI depends on validation strategy, dataset scale and provenance, reference-standard consistency, patient-level partitioning and leakage control, calibration and uncertainty assessment, clinically grounded explainability, prospective workflow evaluation, and multimodal integration. Each recurring limitation therefore implies a corresponding study-design or reporting priority; these gap-to-action relationships are synthesized in Table III.

TABLE III. METHODOLOGICAL GAP-TO-ACTION MATRIX

Observed gap	Recommended reporting / study-design response
Limited external validation	Use prespecified independent or multicenter test cohorts; report transportability and subgroup performance.
Small or private datasets	Use larger shared or multicenter cohorts with transparent provenance and patient-level partitioning.
Heterogeneous reference standards	Report task-specific reference standards, label generation, adjudication, and image-reference timing.
Unclear splitting/leakage control	Partition at patient level; isolate preprocessing and augmentation; document leakage controls.
Sparse calibration/uncertainty	Report calibration, uncertainty, and decision analysis when clinically relevant.
Explainability without reader evidence	Link XAI to error analysis and reader-centered evaluation rather than plausibility alone.
Few prospective workflow studies	Use prospective reader or workflow studies with time, consistency, and decision-impact outcomes.
Limited multimodal context	Fuse imaging with clinical variables only when provenance and validation remain transparent.

VI. CONCLUSION

This systematic review synthesizes 233 primary research studies on AI-based diagnosis, screening, grading, scoring, and structural assessment of rheumatoid arthritis and osteoporosis/osteopenia. Across the included evidence, radiography remains the dominant imaging modality, while CNNs and transfer learning continue to underpin most systems and newer work increasingly incorporates attention, transformers, ensembles, explainability, and multimodal fusion.

The principal finding is methodological rather than architectural. Of the 233 included studies, 141 (60.5%) relied on internal validation only, whereas just 44 (18.9%) reported external or multicenter validation. Thus, high discrimination on retrospective or single-center datasets should not be equated with clinical transportability. The adapted risk-of-bias assessment further indicates persistent concerns related to patient selection, reference standards, and AI-specific split/leakage practices.

Future progress should therefore prioritize evidence maturity: multicenter and prospective evaluation, reproducible patient-level partitioning, transparent reference standards, calibration and uncertainty reporting, reader-interaction studies, and genuinely multimodal integration. For osteoporosis, opportunistic screening from routine imaging appears particularly promising; for RA, structured reader assistance and automated scoring are likely to be the most clinically relevant near-term applications.

DECLARATION ON GENERATIVE AI

Generative AI tools were used only for language refinement, document-formatting assistance, and consistency checking. All eligibility decisions, data extraction, methodological judgments, interpretation, and conclusions were made or critically verified by the authors, who retain full responsibility for the manuscript.

SUPPLEMENTARY MATERIALS

The supplementary materials associated with this systematic review are publicly available through the Zenodo repository at https://doi.org/10.5281/zenodo.22751177. Supplementary Table S1 provides the complete study-level extraction for the 233 included studies; Supplementary Table S2 provides the database-specific search strategies for Scopus, PubMed, Web of Science Core Collection, IEEE Xplore, and ACM Digital Library; and Supplementary Table S3 lists the reports excluded after full-text assessment together with the corresponding exclusion reasons.

APPENDIX A

Tables IV and V present representative osteoporosis/osteopenia and rheumatoid arthritis studies, respectively, illustrating the range of imaging modalities, model families, performance measures, and validation designs discussed in Section IV. The complete study-level extraction for all 233 included studies is provided in Supplementary Table S1. The database-specific search strategies are provided in Supplementary Table S2, and the 14 reports excluded after full-text assessment with their exclusion reasons are listed in Supplementary Table S3. All supplementary files are publicly available through Zenodo at https://doi.org/10.5281/zenodo.22751177.

TABLE IV. REPRESENTATIVE INCLUDED OSTEOPOROSIS/OSTEOPENIA STUDIES

Study	Dataset / Modality	Model	Metrics / Best values	Validation / comparative insight
Lee et al. (2020) [18]	Spine X-ray; 334 participants	VGG feature extraction + RF	AUC 0.74; Acc. 0.71; Sens. 0.81; Spec. 0.60	Internal only; early proof-of-concept with moderate performance.
Jang et al. (2021) [4]	Hip radiography; 1001 images + external validation	VGG16 + nonlocal network	Internal AUC 0.867; External AUC 0.700	External validation; AUC decreased from 0.867 internally to 0.700 externally.
Kumar et al. (2023) [19]	Knee X-rays; 372 images	Eight ImageNet-pretrained transfer-learning models	Best average Acc. 86.36%	Internal train/test split; broad transfer-learning benchmark without external validation.
Fang et al. (2024) [5]	Chest CT + BMD; 488 patients	Radiomics + 2D/3D DL	Best AUC 0.906	Independent single-center test set; strong CT-based comparative study.
Yen et al. (2024) [6]	KUB radiographs + DXA; 8913 pairs	DeepDXA-KUB CNN	AUROC 0.939 lumbar; 0.947 hip	Internal validation only; large real-world opportunistic screening cohort.
Nguyen et al. (2025) [7]	7060 pelvis/spine radiographs	Ensemble of seven DL models	AUC 0.96–0.97	Independent within-cohort test set; large population-based BMD prediction study.
Gharehmohammadi & Sebro (2025) [13]	Foot/ankle radiographs; 907 patients	Customized DL	Acc. 94.65%; AUC 0.87	Internal patient-level split; opportunistic screening from routine imaging.
Dias et al. (2025) [14]	Panoramic radiography	EfficientNet B5/B6/B7	Development CV Acc. 95–99%; separate DXA-referenced cohort evaluated	Independent DXA-referenced test cohort after development CV; stronger than CV alone.

TABLE V. REPRESENTATIVE INCLUDED RHEUMATOID ARTHRITIS STUDIES

Study	Dataset / Modality	Model	Metrics / Best values	Validation / comparative insight
Üreten & Maraş (2022) [15]	Hand radiographs; held-out test	YOLOv4 + VGG-16	RA vs normal: Acc. 90.7%; Sens. 92.6%; Spec. 88.7%; AUC 0.97	Internal held-out test; single-center differential-diagnosis study.
Mate et al. (2021) [1]	Hand radiographs; 290 images	Efficient CNN	Acc. 94.46%	Internal held-out test; strong binary classification on a compact dataset.
Zhou et al. (2022) [2]	Multimodal ultrasound; prospective + external test sets	RATING knowledge-guided DL	Prospective Acc. 86.1%; External 85.0%	Prospective and external test sets; comparatively mature multimodal RA validation.
Peng et al. (2024) [3]	9714 hand radiograph exams	CNN	AUC 0.955 RA vs not RA	Patient-level internal train/test split; large multicenter-source development dataset but no independent external cohort.
Wang et al. (2022) [16]	240 train / 104 test hand radiographs	Five CNN architectures	Recognition AUC 97.80%	Internal test set; strong recognition performance, with staging/scoring remaining more complex.
Moradmand & Ren (2025) [17]	679 training patients + 291 external test subjects	UNet + YOLOv7 + ViT multistage	Joint ID Acc. 99%; RMSE 9.73; MAE 5.35; ICC 0.702	Independent unseen-patient test set; multistage automated global Sharp-score prediction.
Huang et al. (2025) [25]	891 early RA + 1237 non-RA	Deep-TEN vs ResNet-50	AUC 0.69–0.73	Internal train/validation/test split; highlights the difficulty of early-RA discrimination.
Cetintas et al. (2026) [20]	311 RA + 259 controls	Attention DenseNet121/169	Acc. 88%; Recall 91%	Internal single-center train/validation/test split; attention-based classification with moderate data volume.

A Hybrid System with Automatic Classification and RAG for Moroccan Court Rulings

Mohammed V University in Rabat, Morocco[3, 4]

***Abstract*—The Accessibility of Moroccan court judgments and decisions is significantly limited due to the lack of a specialized Arabic Judicial information retrieval architecture. Current NLP technologies focus on Modern Standard Arabic and fail to capture the specialized procedural language of judicial rulings from the courts, resulting in inadequate search and query answering assistance for legal professionals. This study introduces AraLex-RAG, a system that combines document extraction, automated categorization, and Retrieval-Augmented Generation (RAG) for Moroccan Arabic court texts. Neither the retrieval nor the classification components need a GPU; however, the RAG module has the possibility to use an external LLM API for generation. This study presents AraLex-RAG, a benchmark dataset of 2855 unstructured Moroccan judicial judgments in 26 different legal classes. It has been created using an automated workflow that combines specific Arabic text normalization, optical character recognition, and balanced class sampling. The information retrieval system is a combination of similarity-based semantic search and keyword-based search, and then uses Reciprocal Rank Fusion to fuse their results. The document categorization is based on a character-level text analysis approach mixed with a linear classifier, while the question-answering feature creates Arabic replies based on retrieved court rulings using a broad language structure. An accuracy of 92.87 percent is achieved (std 1.33 percent) and 76.15 percent macro F1 across 26 categories using five-fold stratified cross-validation on 2853 documents, outperforming the previous best on Moroccan court judgments (80.51 percent on a six-class subset) on a challenge 4 times tougher. Using 3,936 document query pairings, dense semantic retrieval performs better than the search-based keyword in all four assessment measures. On 45-stratified pairs of questions and answers, the query-answering component obtains a cosine similarity value of 0.845, which is similar to the most advanced Arabic query-answering systems on structured fields.**

Keywords*—Legal information retrieval; BM25; FAISS; Arabic NLP; TF-IDF; text classification; LinearSVC; Moroccan legal judgments

I. Introduction

Legal information retrieval (LIR) involves identifying pertinent statutes, law cases, and court rulings in answer to a legal search query [22]. Efficient information extraction systems significantly diminish the time of researching and enhance the uniformity of court judgments by guaranteeing that pertinent legal precedents are not ignored or overlooked. LIR systems have attained stability and maturity for the English language via platforms such as LexisNexis and Westlaw [21], as well as studies like COLIEE [1], and even Chinese language is starting to gain focus and interest [2]. On the other hand, the Arabic legal corpora lack similar architecture. This difference and void are most pronounced in Morocco, where court rulings are articulated in a specialized form of formal and official legal Arabic that draws on traditional structures, field-specific lexicon, and administrative norms, which are not well represented by broader-purpose Arabic NLP tools.

Arabic has significant NLP obstacles: its morphologically complex architecture generates several forms of words from the same root; diacritic structures that clarify context are often absent in written text; and right-to-left directional display imposes software limitations. In the Moroccan Judicial field, these difficulties are aggravated by the lack of any annotated legal corpus, the particularity of Moroccan procedure-based Arabic, and the extraction of most court judgments from paper archives that are not available in a machine-readable format. Researchers are unable to expand on previous studies or methodically assess methodologies since the field does not presently provide a standard for Moroccan court judgments, a retrieval mechanism, or a validated question-answering pipeline. This study concurrently covers all three different unexplored areas.

This study is organized as follows: 1) AraLex-RAG: One of the golden standard corpora for the Moroccan Arabic juridical information extraction system, consisting of 2855 unstructured court judgments and rulings spanning 26 legal areas. Without a common dataset, reliable studies on Moroccan judicial Artificial intelligence are unattainable; this corpus establishes the basis for any future endeavors in the field. 2) Prove that deep learning is not as effective as traditional approaches when it comes to limited resources for Arabic legal categorization. Our classifiers overcome the preceding best on Moroccan judicial judgments, which only tackled six categories, while LinearSVC and TF-IDF obtain state-of-the-art accuracy over 26 categories. 3) The quantified extraction assessment on Moroccan Arabic court rulings demonstrates that intensive semantic search consistently surpasses keyword-based retrieval in this field. Level category research indicates that the difficulty of retrieval is associated with file similarity within a class, a discovery that informs further corpora development. 4) An exhaustive query-responding system assessed on Arabic legal text, using a major language approach based on recovered court rulings. Outcomes are similar to leading-edge Arabic query-responding systems in structured

areas, indicating that outstanding retrieval systems may be attained using freely available open-source frameworks. 5) A comprehensive framework that integrates OCR, information retrieval, categorization, and query answering into a single program operable on normal hardware without the need for a GPU. AraLex-RAG is a full tool for Moroccan legal experts and specialists.

The subsequent sections of this work are structured as follows. Section II examines pertinent background and related studies on international juridical data extraction, natural language processing in Arabic legal, current Arabic legal baseline, hybrid extraction techniques, and extracted augmented generation for legal query answering. Section III outlines the dataset creation process, system design, and assessment procedure. Section IV defines quantitative outcomes for categorization, extraction, and query responding. Section V examines the results, limits, and real-world consequences for legal experts in Morocco. Section VI concludes and highlights avenues for further research.

II. Related Work

A. International Legal Information Retrieval Landscape

Judicial information retrieval has attained significant development in various highly resourced languages, establishing robust baselines and offering valuable insights for developing fields like Moroccan Arabic. The COLIEE sharing task sets [1] are the foremost English legal information retrieval reference, necessitating technologies to extract pertinent law cases and execute legal entailment logic. The highest-performing systems of 2023 integrate BM25 for preliminary candidate retrieval with using BERT-based neural re-ranking [1], illustrating the continued significance of hybrid linguistic semantic methodologies despite the prevalence of huge pre-trained systems. LEGAL-BERT [2], a specialized variant of BERT trained on judicial rulings, legislation, and legal agreements, demonstrates that pre-training language models on domain-specific legal content consistently outperforms generic-purpose systems. In a Recent study, Santosh and Upadhya [3] established a cross-lingual section extraction standard utilizing European court rulings on human rights and discovered that multilingual models that have been pretrained continually perform poorly compared to monolingual peers in judicial documents, underscoring that linguistic scope compromises field depth.

In French, Authors [4] developed a binary classification approach to identify the existence of a cost allocation clause referred to as Article 700 in 1994 decisions from the French court of appeals. By combining TF-IDF vectorization with conventional classifiers, they surpass the domain-specific Judicial CamemBERT transformer's accuracy of 0.96 on targeted judgment sections. This discovery is enlightening: for well-specified classification assignments on organized law data sets, frequency-based approaches may rival transformer-based model designs, a conclusion that directly and profoundly impacts the architecture of AraLex's categorization unit.

The CAIL2018 dataset [5] in China, including 2.6 million criminal case judgments, has established itself as the standard norm for charge prediction and sentencing quantification. Traditional SVM classification methods attain 94 % accuracy in charge prediction, surpassing most neural methodologies on this extensive, well balanced data. The translation of these results into Arabic, where corpora are much smaller and class borders are semantically and linguistically ambiguous, demands rigorous methodological adjustment.

B. Natural Language Processing in Moroccan and Arabic Legal Field

Zahir et al. [6] constructed an initial corpus of Court of Cassation judgments and trained CNN and GloVe embedding models on a six-category judgment prediction task, achieving an accuracy of 80.51%. The effort is authentic and beneficial, although the scope is limited: six general categories, just categorization, without data extraction or quality assurance. Word-level embedding techniques encounter difficulties with Arabic syntax when the training data is insufficient. Another study [7] indicates superior performance (94.58%, F1 = 94.45%) on a seven-class test using TF-IDF with SVM, specifically with legislative codes, documents from the government characterized by uniform formatting rather than court rulings. Court rulings are more complex and challenging. Neither research establishes a public baseline nor assesses extraction.

Arabic typology poses a further difficulty: extensive suffixation, prefixation, and cliticization result in significant surface form diversity, making vocabulary matching risky without exhaustive planning [20]. Systems pre-trained on Egyptian or Gulf Arabic have challenges when adapting to the Moroccan judicial records, which integrate French civil law terminology with Maliki jurisprudence in manners that generic embeddings fail to adequately represent.

C. Legal Arabic Standard: Moroccan Gap and Saudi Focus

The most advanced Arabic legal AI standards focus on Saudi law. ArabLegalEval [8] evaluates LLMs using multiple-choice based and open-ended inquiries, according on Saudi Ministry of Justice laws and Board of Experts norms. Even GPT-4o attains just around 77% on zero-shot multiple-choice question tasks, serving as a pertinent reminder that robust general approaches continue to have difficulties with domain-specific judicial Arabic. However, these benchmarks assess a model's pre-existing knowledge; they are not retrieval techniques and were not intended to locate content within a corpus. They also address Saudi law, which functions under a distinct legal system compared to Morocco. Moroccan law integrates French civil law with Maliki jurisprudence, resulting in a juridical Arabic that diverges from Gulf dialects in terminology, syntax, and procedural framework. There is no baseline or retrieval mechanism for Moroccan court rulings.

D. Reciprocal Rank Fusion and Hybrid Extraction

BM25 and dense retrieval provide distinct advantages, a fact that is well-known. BM25 is dependable for exact matching, particularly article numerals, party nomenclature, and procedural terminology. Dense retrieval, as shown by Karpukhin et al. [9] using Dense Passage Retrieval, identifies relevant documents even when the query and document do not share any vocabulary, by analyzing trained vector representations. In open-domain QA assessments, dense

retrieval demonstrates superior recall at shallow depths, although BM25 performs comparably when keyword matching is paramount.

Reciprocal Rank Fusion [10] integrates ranking lists by assigning a score of 1/(k + rank) to each document from each system and aggregating the scores. The constant k = 60 prevents the highest-ranked document from dominating when an extraction algorithm exhibits excessive confidence. RRF requires neither training data nor score normalization, offering practical benefits in low-resource environments. Arabic legal inquiries combine precise terminology (case IDs, article numbers) with more general concepts (legal norms, procedure classifications), making the hybrid method particularly suitable.

E. Generation of Legal Questions-Answering Using Retrieval-Augmented Services

Lewis et al. [11] formalized Retrieval-Augmented Generation: the model obtains relevant materials prior to formulating responses, rather than relying only on parametric memory. This is of greater significance in legal applications than in most other fields. A memory-based system may create a seemingly authoritative legal assertion without any supporting documentation [12]. A citation referencing the exact court ruling may be verified. English legal QA systems like LEGAL-BERT [2] demonstrate enhanced response fidelity when employing RAG compared to its absence.

The study by Al-Rasheed et al. [13] presents Arabic retrieval-augmented generation that assesses GPT-3.5, GPT-4, and other specific Arabic versions on a dictionary question-answering challenge. The extracted context is a dictionary entry: concise, well-structured, and immediately relevant. GPT-4 achieves a Token F1 score of 0.90 and a Cosine Similarity of 0.87. While it serves as a valuable reference, dictionary entries provide the most concise form of retrieval settings. Unstructured court judgments are extended, more convoluted, and need the approach to extract pertinent information concealed inside extensive legal text.

III. Methods and Materials

A. Dataset

1) Data collection: The AraLex-RAG corpus consists of 2855 Moroccan judicial rulings sourced from tribunal archives in both digital (DOCX, PDF) and scanned picture forms. The papers consist only of unstructured, informal Arabic text devoid of markup, annotations, or predefined categories. The document length ranges from 150 to more than 2,000 tokens, with an average of around 420 tokens. Each record is classified into one of 26 judicial classifications, including family, property, civil, administrative law, and labour, as determined by the tribunal department code of the document.

2) Preprocessing pipeline: All documents undergo a uniform four-phase (Fig. 1) pipeline, implemented consistently throughout both corpus construction and query execution to guarantee uniformity.

Phase 1 OCR: Scanned picture documents are transformed into text through the application of Tesseract with the Arabic language model (ara).

Phase 2 Quality Filtering: Records producing fewer than 30 characters post-OCR extraction are eliminated as retrieval failures.

Phase 3 Arabic normalization: a regex-based pipeline eliminates diacritics (tashkeel), converts all Alef variations (,إ ,أ آ ,ٱ) to the plain Alef (ا), and removes non-Arabic letters and extraneous whitespace. No morphological analyzer or stemmer is employed; this is an intentional design decision to eliminate reliance on external Arabic NLP toolkits.

Phase 4: Class-balanced sample: stratified sampling yields the final corpus of 2855 documents.

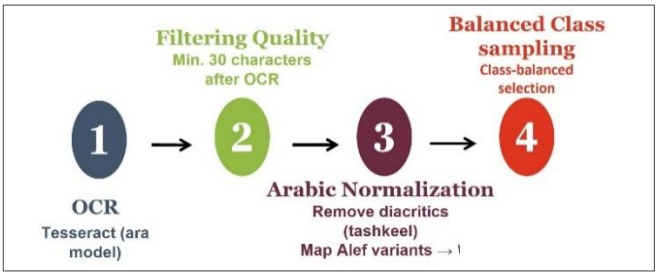

Fig. 1. AraLex-RAG preprocessing pipeline.

TABLE I. Statistics from the AraLex-RAG Corpus

Property	Value
Total documents	2855
Judicial classifications	26
Document nature	Free-form, unstructured Arabic text
Input formats	PDF, DOCX, scanned image (JPEG/PNG)
Mean document length	~420 tokens
Median documents per category	71
Min / Max per category	1 / 602
Categories with < 30 docs	2 out of 26 (Single document)
Train/test split	80% / 20% (stratified)
Cross-validation	5-fold stratified (K=5, seed=42)
Storage backend	SQLite relational database

1) Distribution of classes and imbalance: Table I represents statistical data of the corpus, whereas Table II specifies how it is distributed by class. The dataset exhibits significant imbalance: groups range from a minimum of 1 to a high of 602. Two classifications (1619, 1608) each comprise a single record and are omitted from classifier assessment. The predominant classes, Judicial divorce "التطليق"(602 docs) and النفقة (552 docs), overshadow the corpus and enhance accuracy while diminishing macro F1, as elaborated within the discussion Section.

This disparity is intrinsic to the actual distribution of case categories in Moroccan courts and cannot be rectified via sampling without excluding the already limited minority-class instances. For assessment, an 80/20 stratified division maintains class ratios in both segments; 2853 records that meet quality standards are used for classification and retrieval trials.

TABLE II. ARALEX-RAG SYSTEM DISTRIBUTION OF DOCUMENTS BY CATEGORY

Code	Category	Number
Civil		
1201	Miscellaneous civil المدني المتنوع	86
1202	Tort liability المسؤولية التقصيرية	75
Family		
1601	Civil status amendment الإصلاح والتغيير	161
1602	Birth registration	50
1603	Death registration تسجيل الوفاة	88
1606	Alimony النفقة	552
1607	Judicial divorce التطليق	602
1608	Unilateral divorce الطلاق	1
1609	Child custody الحضانة	56
1610	Spousal return الرجوع لبيت الزوجية	75
1611	Proof of marriage ثبوت الزوجية	70
1612	Right of family access صلة الرحم	65
1613	Lineage / paternity النسب	80
1614	Family enforcement order التذييل بالصيغة التنفيذية (أسرة)	65
1616	Guardianship of minors نواب القاصرين	55
1617	Guardianship of neglected children كفالة الأطفال المهملين	60
1618	Permission for polygamy الإذن بالتعدد	50
1619	Personal status الأحوال الشخصية	1
1620	Other personal status cases قضايا الأحوال الشخصية الأخرى	62
1623	Legal incapacitation التحجير	71
Labour		
1501	Labour disputes نزاعات الشغل	57
1502	Work accidents حوادث الشغل	90
Real Estate		
1401	Standard real estate العقار العادي	80
1402	Registered real estate العقار المحفظ	101
1403	Real estate in registration العقار في طور التحفيظ	102
Rental		
1303	Rent payment and eviction الأداء والإفراغ	100

B. Overview of System Architecture

AraLex-RAG system consists of five operational components: OCR, retrieval, categorization, generation, and interface, supported by a dual-layer storage backend composed of a SQLite relational database that holds all the textual content and associated information of the documents (fields: id, code, label, filename, filepath, file_number, year, decision_number, clean_text, full_text), alongside an FAISS vector index that retains the dimensional dense vector embeddings. Fig. 2 illustrates the whole design and the interconnections among these aspects.

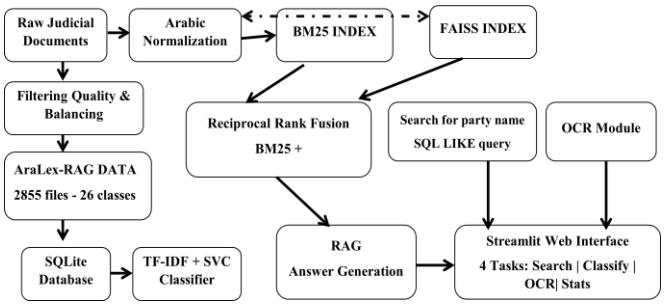

Fig. 2. Overview of AraLex-RAG system architecture.

Corpus indexing constitutes a singular offline procedure. Unstructured files, PDFs, DOCX formats, and scanned pictures are processed using the OCR module (Tesseract utilizing the Arabic language models) and undergo the four-phase normalization process outlined in Section A.2. Every standardized text is thereafter portrayed in two complementary formats: the BM25 engine constructs a token-level inverted index for sparse extraction, whilst the multilingual-e5-small encoder generates a dense embedding preserved in FAISS. Both visualizations come from the same standardized text, guaranteeing that the two retrieval methods function on equivalent input. All textual content, metadata, and embeddings are retained in the storage backend and used for each query.

During inquiry time, the user asks a question using natural language via the interface. The inquiry is subjected to the same normalization as the corpus, thereafter proceeding via a five-stage pipeline shown in Fig. 2. Initially, it is sent concurrently to the BM25 engine and the FAISS index, with BM25 ranking based on word frequency adjusted by inverse document frequency, while FAISS ranking relies on inner product similarity among embeddings. Both ranked classification lists are then integrated by Reciprocal Rank Fusion, which merges the distinct advantages of sparse and dense retrieval without necessitating score adjustment. The categorization module then utilizes the TF-IDF + LinearSVC model to forecast the legal category among the 26 options to which the question applies, hence offering a field labeling that contextualizes the obtained findings. Ultimately, when the generation unit is engaged, the first five extracted files are compiled into a coherent Arabic prompt and presented to LLaMA-3.3-70B via the Groq API, which generates a natural-language response based only on the collected choices. The whole local pipeline, including indexing, data extraction, and categorizing, does not need a GPU; only the RAG phase employs distant inference, allowing the system to remain operable on conventional office equipment.

C. Information Retrieval Algorithms

1) BM25 sparse information retrieval: The BM25 component employs an inverted index based on normalized document tokens. The relevance score is determined by the query Q = {q_1, …, q_m} and the document D.

$$\text{Score}(D,Q) = \sum_{i=1}^{n} IDF(q_i) \cdot \frac{f(q_i,D)\cdot(k_1+1)}{f(q_i,D)+k_1\cdot\left(1-b+b\cdot\frac{|D|}{avgdl}\right)} \quad (1)$$

Q: The query including terms.

D: This is the document that is being evaluated.

$f(q_i, D)$: Term frequency. The frequency of the query phrase q_i in document D.

|D|: Document D length (aggregate word count).

avgdl: Average length of documents throughout the whole corpus.

k_1: A parameter for term frequency saturation. Augmenting this value amplifies the influence of phrase frequency. It's set here to 1.5 ($k_1 = 1.5$). (Standard Okapi BM25 defaults [14]).

b_1: The parameter associated with length normalization. It manages the extent to which the length of a document impacts the score. It's set here to 0.75 ($k_1 = 0.75$). (standard Okapi BM25 defaults [14]).

$IDF(q_i)$: Inverse Document Frequency. Terms are weighted according to how rare they are throughout the corpus. Usually, it is calculated as:

$$IDF(q_i) = ln\left[\frac{N - n(q_i) + 0.5}{n(q_i) + 0.5} + 1\right] \quad (2)$$

In this context, N represents the aggregate count of documents inside the corpus, whereas $n(q_i)$ denotes the quantity of documents that include the phrase q_i.

2) Dense semantic retrieval: FAISS: Dense retrieval utilizes the intfloat/multilingual-e5-small sentence transformer (386 dimensions) [15, 16] to encode both files and queries. The compact version was chosen for resource-efficient implementation: with 2855 documents, the whole FAISS index occupies about 4.3 MB of RAM, allowing sub-second search on conventional hardware without the need for a GPU. Semantic similarity is represented by cosine similarity, which corresponds to the inner product of L2-normalized vectors.

$$sim(u, v) = \frac{u \cdot v}{\|u\| \cdot \|v\|} = \hat{u} \cdot \hat{v} \quad (3)$$

where,

$u \cdot v$: represents the scalar product of the two vectors.

$\|u\|$ and $\|v\|$: the Euclidean norms (magnitudes) of the respective vectors.

Cosine similarity quantifies the angle between two vector representations inside the embedding space: a score of 1 signifies semantically equivalent texts, while a score of 0 denotes not related content. Normalizing each vector corresponding to unit length (L2 normalization) prior to storage guarantees that document length does not enlarge the score, allowing a concise judgment that is entirely relevant to take precedence over an extensive ruling that just briefly references the same words. This normalization also minimizes inner-product searches in FAISS to a cosine similarity query without any additional calculations at the time of querying.

Document vectors are maintained in an FAISS IndexFlatIP [17,19], which does precise inner-product searches with $O(N \cdot d)$ time complexity, with N being the count of indexed documents and d denoting the dimensionality of the embeddings. The index functions on L2-normalized vectors, making inner-product search theoretically synonymous with cosine similarity ranking, therefore necessitating no further transformation during query execution.

3) Reciprocal rank fusion: BM25 and dense retrieval generate relevance ratings on dissimilar scales: BM25 ratings are unrestricted integers weighted by phrase frequency, while cosine similarity scores are confined to the range of [0, 1]. Integrating them via a weighted linear sum necessitates manual scale calibration on reserved data, an unfeasible limitation for a corpus that changes as fresh judgments are included. Reciprocal Rank Fusion (RRF) [10] bypasses this issue by ignoring score magnitudes and combining ranked lists only based on their ordinal positions.

$$RRF(d) = \sum_i \frac{1}{k + rank_i(d)} \quad (4)$$

where, $rank_i(d)$ is the placement of document d in the ordered list generated by retriever i, and k = 60 represents the smoothing constant from the initial formulation [10]. The parameter k controls the rate at which the score diminishes across ranks: with k = 60, a document ranked first contributes a score of 1/61≈ 0.016, whereas a document at rank 10 contributes 1/70 ≈ 0.014, resulting in a carefully moderated decline that ensures the entire top-10 range is treated almost equally, thus preventing the scenario where a single retriever excessively favors a limited selection of documents with extremely high scores.

In AraLex, after every query, two lists are merged: the BM25 ranked list derived from the inverted index and the FAISS cosine similarity ranked list. For any document included in either list, its RRF score aggregates $1/(60 + rank_i)$ from each retriever in which it is found; documents not included in a retriever's list do not contribute from that retriever. Documents that get high rankings from both systems, characterized by lexical and semantic relevance, combine contributions from both lists and hence increase to the highest level of the combined ranking. Fig. 3 shows the whole five-stage query process.

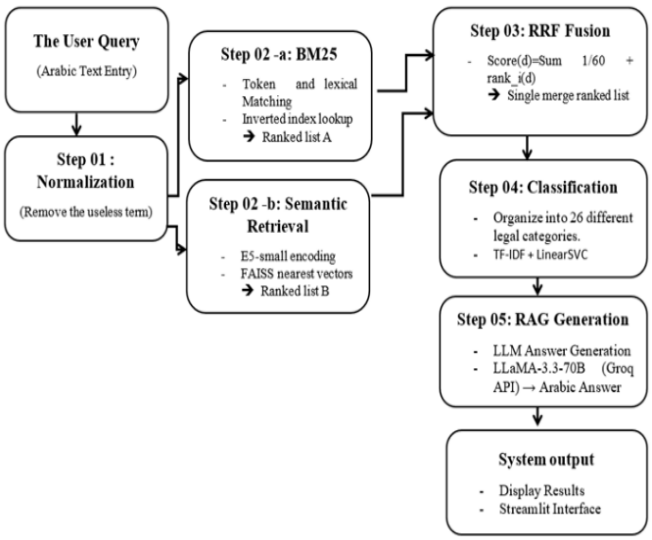

Fig. 3. AraLex-RAG pipeline procedure for query preprocessing.

D. Categorisation Algorithms

Document categorization is executed via a TF-IDF vectorizer in conjunction with a LinearSVC (Linear Support Vector Classifier). The representation of features is constructed using character n-grams instead of words. Arabic has a high degree of morphological complexity: a single root may produce several surface forms by prefixation, suffixation, and cliticization, resulting in word-level characteristics that regard morphological variations as completely distinct. Character n-grams ranging from lengths 2 to 4, meaning ngram_range=(2,4), automatically identify common substrings across these variations, eliminating the need for a stemmer or morphological analysis. The `char_wb` analyzer derives n-grams at word borders, augmenting each term with spaces to ensure that sequences of characters at the beginning and end of words are distinctly represented. Every term t within document d is assigned a TF-IDF [18] weight:

$$w(t,d) = tf(t,d) \times log\left(\frac{N}{df(t)}\right) \quad (5)$$

where, tf(t, d) indicates the occurrence of n-gram t inside document d, N represents the total count of documents in the corpus, and df(t) indicates the quantity of documents that include t. The significance is elevated for n-grams that are prevalent in the present text but infrequent across the corpus, embodying the unique character traits of each legal classification. Each document is thus shown as a sparse vector in a high-dimensional space composed of these weights. LinearSVC was chosen as the classifier due to its exceptional compatibility with high-dimensional sparse feature spaces: it trains significantly faster than kernel-based SVMs while maintaining similar accuracy in text classification tasks. The LinearSVC optimizes the following hinge-loss objective:

$$min_w \, ½\|w\|^2 + C \cdot \sum_i max(0, 1 - y_i(w^\top x_i + b)) \quad (6)$$

where, w represents the weight vector that defines the decision limit, x_i stands for the TF-IDF feature vector for document i, $y_i \in \{-1, +1\}$ signifies its class label, and b is the bias term. The initial component, $½\|w\|^2$, serves as the regularization penalty that maintains a broad and generalizable decision boundary. The second component imposes penalties on documents that exceed the margin, with a weight of C = 1.0, the normal setting, which is effective in high-dimensional feature spaces when the feature count significantly surpasses the document count. Given that SVM is fundamentally binary, the 26-category issue is partitioned into 26 autonomous one-versus-rest (OvR) sub-problems: each classifier is tasked with differentiating one lawful category from the rest. During the prediction phase, all 26 classifiers operate concurrently, and the category with the greatest decision margin is selected for the document.

E. Retrieval-Augmented Generation

The RAG module bases LLaMA-3.3-70B replies on extracted Moroccan judicial rulings, according to the framework established by Lewis et al. [11]. During the inference phase, the process unfolds in three stages. Initially, the user's request is analyzed by the hybrid RRF retrieval system, and the leading k = 5 docs are chosen. Secondly, these documents are compiled into a systematic Arabic prompt using the following standardized format: 1) a directive instructing the model to react only based on the supplied context and to reply in Arabic; 2) the five retrieved documents enumerated and concatenated; 3) the user's query. Third, the compiled prompt is sent to LLaMA-3.3-70B over the Groq cloud API with a temperature setting of $\tau = 0.1$. The reduced temperature setting decreases linguistic variability in outcomes and is suitable for factual legal inquiries where uniformity is prioritized above inventiveness. If the acquired records lack pertinent information on the inquiry, the model is directed to clearly indicate that the context fails to provide an adequate response, which exemplifies appropriate grounded behaviour and inhibits hallucination. The k = 5 context window was selected to strike a compromise between providing enough evidence and maintaining the prompt inside the model's contextual limitations. LLaMA-3.3-70B was chosen over smaller approaches because of its native support for Arabic and its 70 billion parameter scale, which offers enough capability for multi-document legal analysis. The Groq API delivers sub-second inference without the need for local GPU hardware, enabling deployment on conventional office computer systems. LLaMA-3.3-70B is an open-source model, hence avoiding the data privacy issues associated with transmitting sensitive legal documents to private API vendors.

F. Overview of Hyperparameter Settings

Table III summarizes the parameter configurations for each AraLex-RAG component, according to the sequence of the pipeline: sparse retrieval, dense retrieval, rank fusion, classification, and generation. All parameters were either derived from recognized defaults in the referenced literature or chosen according to the limitations of the intended deployment setting.

TABLE III. HYPERPARAMETER CONFIGURATIONS FOR ALL ARALEX-RAG COMPONENTS

Module	Parameter	Setting	Reasoning
BM25	k_1	1.5	Standard Okapi BM25 [14]
	b	0.75	
Dense encoder	Model	multilingual-e5-small	Arabic support and CPU-efficient
	Dim	386	Concise index (<3 MB)
FAISS	Index type	IndexFlatIP	Exact search; N=2855
RRF	k	60	Initial formulation [10]
TF-IDF	analyzer	char_wb	Within-word boundary n-grams
	ngram_range	(2, 4)	Morphological affixes in Arabic
LinearSVC	C	1.0	Standard regularization
	strategy	OvR (26 classes)	OvR multi-class
RAG	Model	LLaMA-3.3-70B	Groq API, temperature=0.1
	Context docs	5	Top-k retrieved

G. Evaluation Framework

The efficacy of classification was assessed using five-fold stratified cross-validation (K=5, random_state=42) on the 2853 documents categorized with a minimum of two samples. The remaining papers were not included since stratified splitting demands at least one sample per class for each fold, a requirement unattainable by single-instance classes. K=5 was chosen as the optimal balance between bias and variance in cross-validation: fewer folds (e.g., K=3) provide bigger test sets but increase variation in the estimation, while more folds (e.g., K=10) are resource-intensive and provide decreasing benefits on a dataset of this magnitude. Stratification guarantees that the class allocation in each fold mirrors the overall corpus distribution, which is essential due to the distinction within groups, with "التطليق" providing 602 documents while multiple categories contribute less than 10. In the absence of stratification, a fold may intentionally lack instances of a rare category, causing the accuracy assessment to be unreliable.

The primary measures are mean accuracy and mean macro F1, precision, and recall over the five folds, shown with a standard deviation. Macro averaging allocates equivalent importance to each category, irrespective of their size, hence imposing the same penalties on the classifier for mistakes in both infrequent and common categories, serving as a more insightful metric than weighted F1 in scenarios of class imbalance. The standard deviation across folds measures the stability of results: a limited range indicates that the classifier generalizes reliably instead of overfitting to a specific data subset.

A distinct fixed 80/20 stratified division (random_state=42) was implemented to derive per-class recall, precision, and F1 metrics throughout all 26 categories. Cross-validation reports only total metrics; the reserved subset offers the detailed analysis necessary to figure out which legal classifications the classifier manages well and which need more data acquisition.

Extraction query and document pairings were generated automatically by the use of template-driven Arabic question formulation using the document metadata. For every document, a collection of Arabic queries was formed based on structured elements such as subject, judgment, year, case identifier, and the name of the court, with each template used only for papers that had the necessary field. This automated method removed a demand for human query labeling and generated 3936 query–document pairings inside the 2855-document corpus. The definitive pertinent document for each inquiry is the original document from which the question was derived, providing one affirmative per query.

The assessment of retrieval was undertaken on these 3936 pairings using Mean Reciprocal Rank [23] (MRR@10) and Normalised Discounted Cumulative Gain [24] (NDCG@10):

$$MRR@10 = \frac{1}{|Q|} \cdot \sum_i \frac{1}{rank_i} \quad (7)$$

$$NDCG@10 = \frac{DCG@10}{IDCG@10}, DCG@10 = \sum_n \frac{rel_n}{log_2(n+1)} \quad (8)$$

where, |Q| = 3,936 is the total number of assessment queries, and $rank_i$ refers to the place of the correct document in the list ranked for query i. A valid document that does not rank within the top 10 adds nothing to the total. MRR@10 consequently favors systems that position the accurate document as near to rank 1 as possible among the top 10 outcomes.

DCG@10 combines pertinence scores marked down by location: rel_n signifies the pertinence of the document at position n (1 if it is the accurate document, 0 if not), while the $log_2(n+1)$ denominator punishes the value of pertinent documents located in lower positions. IDCG@10 is the optimal DCG, the highest attainable score when the accurate document occupies the top position. With one affirmative response per query, IDCG@10 equals $1/log_2(2) = 1.0$; thus NDCG@10 simplifies to $1/log_2(rank_i + 1)$ when the accurate document is located within the top 10, and 0 in all other cases. Dividing by IDCG aligns the score to the range of [0, 1], facilitating comparability across searches.

Furthermore, Hit at 5 (Hit@5) evaluates the presence of the right document within the top 5 findings (1 for yes, 0 for no), averaged over any query. Precision at 1 (P@1) assesses whether the right document is positioned first (1 for yes, 0 for no), averaged across all of the searches. MRR@10 and NDCG@10 assess the quality of rankings, whereas Hit@5 and P@1 evaluate retrieval coverage and precision at the most stringent threshold. RAG generation underwent evaluation using a stratified sample of 45 question-and-answer pairs, chosen to include various sorts of legal queries. The number 45 was established due to the practical limitation of manual ground-truth retrieval, necessitating cautious examination of each source file to get precise reference responses, which-were manually obtained from the relevant source materials, a conventional method in generative QA assessment, whereby human-authored references serve as the norm for comparing system outputs. Generation quality was evaluated using three complementary measures: Token F1 assesses the overlap of words between the generated output and the reference reply; ROUGE-L measures the longest common subsequence [25], rewarding responses that retain the correct order of words; and Cosine Similarity determines semantic similarity through E5 embeddings, ensuring that paraphrases of the correct answer receive high scores even with differing phrasing. All trials were executed on a typical laptop lacking a GPU, indicating that AraLex is operable without dedicated hardware.

IV. RESULTS

A. Classification Outcomes

Table IV displays the outcomes of cross-validation classification. The classifier attains an accuracy of 92.87% ± 1.33% and a macro F1 score of 76.15% ± 3.89%. This difference between accuracy (92.87%) and macro F1 (76.15%) indicates class imbalance: accuracy is influenced by well-supported predominant classes, whereas macro F1 treats all 26 categories roughly the same, resulting in minority classes with fewer test samples adversely affecting the average.

TABLE IV. CLASSIFICATION OUTCOMES: FIVE-FOLD STRATIFIED CROSS-VALIDATION

Metrics	Accuracy	F1-score macro	Precision macro	Recall macro
Mean	92.87%	76.15%	80.27%	75.08%
Std Dev	±1.33%	±3.89%	—	—
Minimum Fold	90.86% (F5)	—	—	—
Maximum Fold	94.20% (F4)	—	—	—

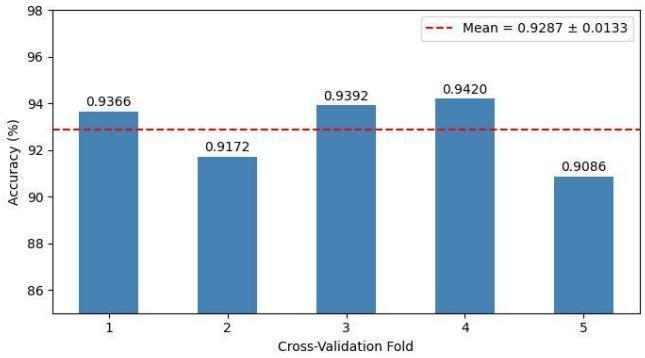

Fig. 4. Fold-specific accuracy throughout five cross-validation folds

Fig. 4 shows a small fold-to-fold range (3.34 percentage points), indicating that the classification algorithm maintains stability and does not exhibit overfitting to any specific data subset. The minimum fold (F5: 90.86%) and the highest (F4: 94.20%) vary by under one standard deviation.

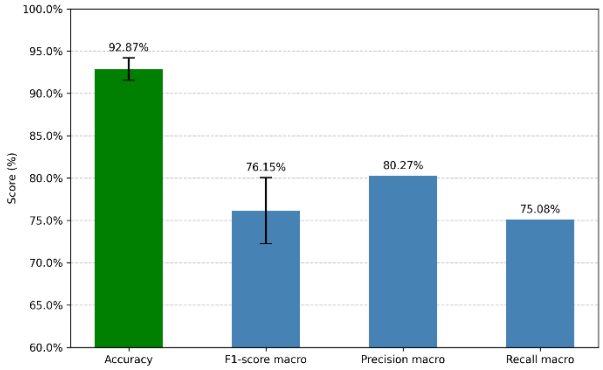

Fig. 5. System classification performance in 26 different legal areas.

Fig. 5 illustrates the four classification measures derived from 5-fold stratified cross-validation. The precision and recall macros are derived from the fixed 80/20 held-out split, whereas the accuracy and F1 macros include standard deviation error bars across folds.

B. Retrieval Outcomes

Table V presents a comparison of BM25-only, semantic-only, and hybrid RRF retrieval over 3936 query-document pairings. Semantic search frequently surpasses BM25 on all four parameters, whereas hybrid RRF attains moderate performance.

The aggregate metric numbers indicate the fundamental challenge of this assessment framework: the 3936 queries use template-driven queries (for instance, " What is the court's ruling?" means "ما هو حكم المحكمة؟") utilized across all sources. Due to the prevalence of analogous language across several legal categories, precise document retrieval using a general query is much more challenging than retrieval via document-specific questions.

As shown in Table V and Fig. 6, the semantic retriever provides the most significant relative enhancement compared to the BM25 baseline, suggesting that semantic representations greatly strengthen retrieval efficacy in the adversarial template-query context. Embracing this enhanced foundation, the hybrid RRF methodology significantly elevates retrieval efficacy, attaining the highest absolute scores across every assessment metric. The supplementary improvements over the semantic retriever are moderate (7–17%), although they remain constant across all assessed measures.

TABLE V. RETRIEVAL EVALUATION

Technique	BM25 only	Semantic only (E5)	Hybrid RRF
P@1	0.002	0.006	0.007
MRR@10	0.005	0.009	0.010
NDCG@10	0.008	0.014	0.015
Hit@5	0.006	0.011	0.012

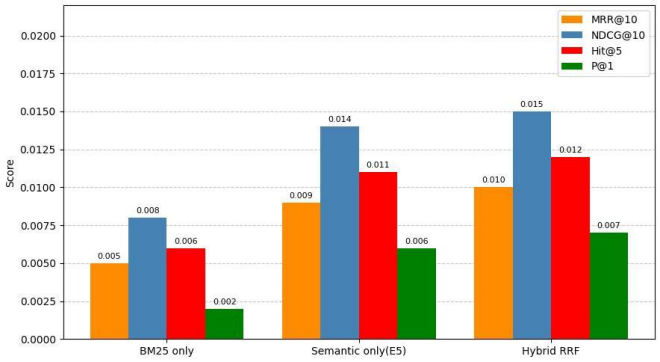

Fig. 6. Retrieval techniques comparison on AraLex corpus.

Category-specific examination reveals significant disparities in retrieval challenges. Minor categories like Permission for polygamy (n=50) attain well, due to the limited pool of available records. Extensive classifications like alimony (n=552) and judicial divorce (n=602) attain lower scores, since several records within these groups use basically the same terms, which complicates the identification of a particular document from a standard template inquiry.

C. Retrieval-Augmented Generation Outcomes

Table VI displays the assessment outcomes of RAG creation for 45 question-and-answer pairs. LLaMA-3.3-70B was accessed using the Groq API for every pair, with the five most relevant files given as context.

TABLE VI. RETRIEVAL-AUGMENTED GENERATION EVALUATION

Measure	Token F1 (SQuAD-style)	ROUGE-L	Cosine Similarity
Parameter	0.261	0.191	0.845
± Std Dev	0.091	0.065	0.062
Analysis	Conceptual overlap vs. fundamental truth	Subsequence with the longest in common	Semantic proximity (E5-embeddings)

Table VI presents the quality of RAG generation evaluated by three complementary measures. Cosine Similarity (0.845) demonstrates a robust semantic correspondence between the produced and reference responses, showing that LLaMA-3.3-70B reliably comprehends the essence of the accurate answer despite variations in phrasing. The values of Token F1 (0.261) and ROUGE-L (0.191) are diminished, which is anticipated for Arabic generative outputs. The model often chooses to paraphrase instead of directly replicating the reference response, adversely impacting word-overlap metrics while maintaining semantic similarity.

D. Benchmarking with Prior Work

Table VII positions AraLex-RAG within the context of comparable legal NLP systems. No direct quantitative comparison can be made among these rows, since each system functions inside a distinct language, domain, class count, and assessment process. The table is designed to demonstrate the range of each work rather than to evaluate performance.

TABLE VII. PLACEMENT OF ARALEX-RAG SYSTEM WITHIN RELATED WORKS

System	Technique	Experiment	Country / Field	Result
Our System (AraLex-RAG)	BM25 + FAISS + RRF	Retrieval + Classification RAG Question-Answering	Morocco 26 classes	Acc=92.87%
	TF-IDF + LinearSVC		Legal decisions	F1=76.15%
	LLaMA-3.3-70B (RAG)		(Table II)	Cosine(RAG)=0.845
[1]	BM25 + BERT re-rank	Legal Case Retrieval (Task1)	Canada Case Law	F1=0.3001 (THUIR)
[5]	TF-IDF + SVM	Prediction Charge	China - CAIL	Acc=94.00%
			criminal cases	
[6]	GloVe + CNN	Judgment prediction	Morocco Six classes	Acc=80.51%
			Court of Cassation	
[7]	TF-IDF + SVM	Legislative Docs classification	Morocco Seven legislative data fields	F1=94.45% Acc=94.58%,
			Document types	
[13]	GPT-4 (RAG)	Arabic question answering (RAG)	Arabic dictionary	Cosine=0.87 F1=0.90
			(structured)	

The systems included in Table VII cover three languages for different nations, illustrating the increasing global attention to legal NLP across various legal frameworks. Each pertains to a distinct objective: case retrieval, judgment forecasting, legislation categorization, or inquiry resolution, under varying resource constraints and assessment methods. AraLex-RAG enhances this domain by focusing on Moroccan Arabic judicial rulings, a context that combines limited resources with the unique language and legal attributes of the Moroccan judicial court.

V. DISCUSSION

TF-IDF combined with LinearSVC achieves 92.87% accuracy without doing any morphological analysis. The justification is clear: Moroccan legal classifications employ remarkably uniform procedural terminology, and character n-grams (n=2,4) inherently detect these subword structures, encapsulating morphological affixes without the need for a stemmer and maintaining resilience when identical roots manifest in various surface forms. Macro F1 (76.15%) is inferior to accuracy since it assigns identical weight to all 26 classes, including those with fewer test samples. The disparity between recall and precision (75.08% vs 80.27%) indicates that the classifier prioritizes caution, overlooking some instances rather than incorrectly labelling them, which is the appropriate compromise for a legal framework.

The retrieval statistics need a contextual framework. The assessment prompts are uniform template inquiries used across all papers, posing the query " What is the court's ruling?" and requiring the system to pinpoint a singular document among hundreds that exhibit the identical procedural language, a process that is fundamentally hard. Under this restricted framework, semantic search exceeds BM25 by 75% on MRR@10, indicating that multilingual-E5-small locates files via semantic relevance rather than mere word correlation, which is crucial for Arabic legal texts because the same idea is expressed in many morphological ways. RAG has a distinct divergence in metrics: Cosine Similarity (0.845) is elevated, indicating that the produced responses are semantically accurate Arabic legal language; however, Token F1 (0.261) and ROUGE-L (0.191) are lower due to the model's tendency to paraphrase instead of replicating the reference response precisely.

The following three limitations should be mentioned properly. The corpus's size suggests that some categories contain fewer than 50 instances, which restricts the classifier and introduces noise into retrieval evaluations; still, with several thousand files per class, targeted document searches

would be practicable, enabling a more earnest exploration of neural techniques. The assessment of retrieval depends on computer-created template questions rather than genuine inquiries from legal professionals; a practitioner study would provide a more realistic depiction of operational performance. In conclusion, the present architecture employs the Groq cloud API for RAG generation, allowing for sub-second inference without reliance on local GPU hardware; a sensible advancement would be to replace it with a locally hosted open-source framework, thus making the system completely autonomous and fit for offline operation in judicial environments. The upcoming phase of action is enhancing the corpus with supplementary decision files that are already in possession.

VI. Conclusion

AraLex-RAG is the initial solution that simultaneously tackles information retrieval, categorization, and RAG question answering for court rulings in Moroccan Arabic. It is constructed upon AraLex-RAG, a set of 2855 unstructured judicial rulings across 26 law domains, and integrates BM25, FAISS dense retrieval, Reciprocal Rank Fusion, character n-gram TF-IDF classification, and LLaMA-3.3-70B creation into a singular program operable on a conventional laptop without a GPU. Assessment validates the feasibility of the methodology: the classifier attains 76.15% macro F1 and 92.87% cross-validation accuracy over 26 legal classifications, hybrid RRF retrieval surpasses both BM25 and semantic search separately, and RAG generation obtains a Cosine Similarity of 0.845, signifying robust semantic coherence among produced and reference responses. These findings indicate that lightweight, GPU-independent techniques may provide robust results on specialized Arabic legal documents, and that AraLex-RAG offers a feasible, implementable option for Moroccan legal practitioners and users without necessitating costly infrastructure.

***Abstract*—Stress is a physiological and psychological response that can affect the well-being and daily functioning of an individual. In this study, we propose an IoT-enabled smart cap for real-time stress monitoring using multiple physiological signals. The system uses electroencephalography (EEG), electrocardiography (ECG), galvanic skin response (GSR), and pulse measurements to monitor physiological changes associated with varying levels of stress. The sensor data is captured and communicated to the Blynk Cloud platform using a Raspberry Pi 3 Model B. The acquired data is processed by a Node.js backend and also allows real-time display using a web-based dashboard. The physiological measurements are combined with a rule-based stress classification method. Stress is classified as mild, moderate, and severe. Depending on the detected stress level, the system provides appropriate relaxation and intervention suggestions through the monitoring interface. The proposed architecture demonstrates the feasibility of integrating multimodal physiological sensing with IoT-based monitoring in a wearable form factor. The system is intended to provide continuous, accessible, and real-time stress monitoring while supporting personalized intervention. Further validation using larger datasets, diverse participants, and data-driven machine learning or deep learning models is required to establish the accuracy, generalizability, and clinical applicability of the proposed system.**

Keywords*—Stress monitoring; EEG; ECG; GSR; IoT; Blynk cloud platform; mental health management; real-time monitoring; personalized recommendations

I. Introduction

Stress has become an important concern because it can influence both psychological well-being and physical functioning. When stress persists for a long period, it may interfere with daily activities, concentration, and overall health. Stress is commonly assessed through questionnaires, psychological screening, and clinical evaluations [13], [14]. These methods can help determine how an individual experiences stress, but they are generally performed at particular points in time. As a result, changes in physiological responses between assessments may not be captured. Wearable monitoring provides an alternative approach by allowing physiological changes to be observed continuously and by making real-time measurements possible [14], [15].

Conventional approaches to stress assessment and management also have practical limitations when information about changing physiological conditions is required. Psychological assessments depend partly on an individual's responses, while clinical evaluations may not always be immediately accessible. These limitations create a need for systems that can observe physiological changes and present the information without requiring repeated assessments [14]. IoT technology can support such systems by connecting sensors, computing hardware, cloud services, and monitoring interfaces. Through this type of arrangement, physiological measurements can be collected and transmitted for observation while the individual is being monitored [8].

Wearable physiological monitoring has received considerable attention in stress-related applications [14], [15]. Different sensors can capture different aspects of the body's response. EEG records electrical activity associated with brain function, whereas ECG records the electrical activity of the heart. GSR measures changes in skin conductance, and pulse sensing provides information related to cardiovascular activity. Using these measurements together can provide information from several physiological sources instead of relying on one signal alone [17]. For a practical wearable application, however, the collected signals also need to be handled efficiently and made available through a monitoring interface.

Wearable systems developed for stress monitoring still present several challenges. Some approaches concentrate on one physiological signal, while others depend on offline processing or separate devices for different measurements. Another consideration is that physiological responses are not identical across individuals. A measurement that represents a particular state for one person may not necessarily indicate the same state for another person. Factors such as physical activity, surroundings, and an individual's normal physiological condition can also affect the recorded signals [15], [19]. Therefore, classification based on generalized thresholds may have limited reliability when applied across different users [12], [15], [19].

The combination of wearable sensing and IoT connectivity offers a practical way of addressing these requirements. Sensor readings can be obtained continuously, handled by an embedded computing unit, transferred through a network, and made available through a cloud-based interface. Such an arrangement allows physiological information to be viewed while the system is operating rather than only after data collection has been completed. In this study, these components are brought together in a wearable smart-cap architecture using EEG, ECG, GSR, and pulse sensors. A Raspberry Pi is used for data acquisition and transmission, while the Blynk Cloud Platform is used for data visualization and monitoring.

The collected measurements also need to be interpreted so that the user can understand the current stress state. For this purpose, the proposed system uses a threshold-based approach to divide the detected stress state into three categories: mild, moderate, and severe. A corresponding suggestion is displayed through the user interface according to the classified level. The suggestions are intended to provide simple supportive information that may help the user respond to the detected state; they are not intended to constitute medical diagnosis or treatment. The system therefore serves as a monitoring and feedback platform, while medical or psychological assessment remains outside its scope.

The present work focuses on the development of an IoT-enabled smart cap that brings multimodal physiological sensing and real-time monitoring into a single wearable setup. The system connects EEG, ECG, GSR, and pulse sensors to a Raspberry Pi, which handles the acquired measurements and their transmission to the Blynk Cloud Platform. The cloud-connected interface allows the collected information and classification output to be observed during system operation. Rather than using an AI or deep-learning model for the current classification process, the prototype applies predefined threshold-based rules. More advanced machine learning approaches may be investigated in future work to improve the adaptability of the classification process [16], [19].

The main objective of this study is to examine the feasibility of using a wearable IoT architecture for continuous physiological monitoring and three-level stress classification. The work brings together multiple physiological sensors, Raspberry Pi-based data handling, cloud connectivity, real-time visualization, and threshold-based classification within a smart-cap prototype. System operation is examined through the acquisition and transmission of sensor measurements, visualization of the collected data, stress-level classification, and user feedback. The prototype provides a basis for further investigation, particularly through larger-scale data collection, more systematic validation, and the use of learning-based classification methods in future studies.

II. Literature Review

A. Stress Monitoring and Physiological Assessment

Stress has been examined from both psychological and physiological viewpoints because it can influence how people feel, behave, and function physically. Previous studies have looked at stress in different settings, including academic and occupational environments. Sattar et al. [1] studied the relationship between medical professionalism, coping, and the mental well-being of medical students, showing how demanding environments can influence psychological well-being. McDaid et al. [2] examined the economic and social effects of mental disorders in South Asia and discussed the broader consequences associated with limited mental-health support. Together, these studies show why stress and mental well-being require attention. However, their main focus is on psychological, social, and population-level aspects rather than continuous monitoring of physiological changes.

In most cases, stress is assessed through self-reported questionnaires, psychological assessments, clinical evaluations, or a combination of these methods [13], [14]. These approaches can provide useful information about a person's condition, but the results generally describe the person's state at the time of assessment. Physiological monitoring can provide additional information by tracking changes as they occur over time. This has contributed to the use of wearable sensors for monitoring physiological signals outside conventional clinical environments [14], [15].

Wearable and pervasive-computing technologies have also been explored in healthcare because they can collect physiological information continuously. Dewi et al. [3] discussed the use of pervasive computing and wearable devices in sustainable healthcare applications and highlighted the role of connected wearable technologies in health monitoring. IoT-based healthcare systems have also been studied for collecting and transferring health-related information through connected devices [8]. However, a general healthcare monitoring system does not directly address all the requirements of stress monitoring. Stress-related applications also need to consider the selection of physiological signals, the combination of multiple signals, stress classification, and the delivery of timely feedback.

B. Wearable Physiological Sensing for Stress Monitoring

Wearable devices can measure physiological changes that occur when a person responds to psychological or environmental stress. Researchers have explored several types of signals for this purpose, including cardiac activity, electrodermal activity, brain activity, skin temperature, respiration, and physical activity. Bolpagni et al. [5] reviewed the use of bio signals from wearable devices for personalized stress detection and reported the use of different physiological measurements across stress-monitoring studies. Similarly, Vos et al. [12] examined machine-learning approaches for stress monitoring using wearable devices and discussed the importance of physiological data quality and generalizability. These studies indicate that the signals selected for stress monitoring depend on the type of wearable device, the conditions under which the data are collected, and the purpose of the monitoring system.

Cardiac measurements are commonly considered in stress-monitoring studies because changes in cardiac activity can occur during physiological arousal. ECG can be used to record the electrical activity of the heart and can also provide measures such as heart rate and heart-rate variability. Pulse or photoplethysmography-based measurements can provide related information about cardiovascular activity. Electrodermal activity, also known as galvanic skin response (GSR), measures changes in skin conductance and is another commonly used physiological signal in stress-related studies. The review by Bolpagni et al. [5] identified EDA and PPG among the commonly used signals in wearable stress-detection research, while Sosa et al. [17] examined multimodal approaches that combine different physiological indicators of sympathetic nervous system arousal. These findings support the use of multiple physiological signals when monitoring stress rather than relying on a single measurement.

EEG provides another sensing modality because it records electrical activity associated with brain function. It has been investigated for mental-stress assessment because changes in

brain activity may be related to cognitive and emotional states. Badr et al. [4] reviewed deep-learning methods for mental-stress assessment using EEG and discussed approaches based on convolutional neural networks (CNNs), long short-term memory (LSTM) networks, and hybrid architectures. The use of EEG alongside other physiological measurements therefore provides another possible source of information for multimodal stress-monitoring systems [17].

Wearable sensing also brings some practical challenges. Sensor placement, movement artefacts, signal quality, environmental conditions, individual physiological differences, and user comfort can all affect the collected data. Bolpagni et al. [5] highlighted issues including signal quality, dataset representativeness, privacy, and real-world deployment in wearable stress detection. Abd Al-Alim et al. [15] also investigated wearable-sensor-based stress detection in free-living environments, where physiological measurements can be influenced by everyday conditions. In addition, Vos et al. [12] discussed the challenge of developing stress-monitoring models that generalize across wearable datasets and users. These findings suggest that the number of sensors alone does not determine the quality of stress classification; the quality of the collected signals and the way they are interpreted are also important.

Table I summarizes the physiological signals relevant to stress monitoring, the information they provide, and the main considerations associated with their use [5], [17].

TABLE I. PHYSIOLOGICAL SIGNALS RELEVANT TO STRESS MONITORING

Physiological Signal	Information Obtained	Relevance to Stress Monitoring	Considerations
EEG	Electrical activity of the brain	Provides information related to changes in brain activity and mental state	Can be affected by movement and electrical noise
ECG	Electrical activity of the heart	Provides cardiac information and can support heart-rate and HRV analysis	Electrode placement and movement can affect signal quality
GSR/EDA	Changes in skin conductance	Provides information associated with autonomic arousal	Can be influenced by temperature, movement, and skin condition
Pulse	Cardiovascular pulse activity	Provides information related to cardiovascular response	Can be affected by physical activity
Skin Temperature	Peripheral temperature changes	Can provide additional physiological information	Influenced by surrounding environmental conditions
Respiration	Breathing rate and pattern	May change during physiological arousal	Requires appropriate sensor placement

The smart cap uses EEG, ECG, GSR, and pulse measurements so that information can be obtained from several physiological sources. This multimodal configuration is consistent with the broader direction of wearable stress-monitoring research, which has increasingly considered combinations of physiological signals and personalized monitoring approaches [5], [17]. The cap-based design therefore provides a wearable form factor for bringing several sensing modalities together within an IoT-enabled monitoring system.

C. Wearable Devices and Multimodal Stress Monitoring

Wearable devices have developed from systems that measure individual physiological signals into platforms capable of collecting several types of physiological measurements. The Empatica E4, for example, is a research-oriented wearable platform designed to collect multiple biosignals and has been used in studies involving wearable physiological monitoring [11]. Such systems illustrate how physiological measurements can be collected while the user is wearing the device rather than through a single assessment session. In stress-monitoring research, Bolpagni et al. [5] reviewed the use of biosignals from wearable devices and reported that different physiological measurements are used depending on the sensing configuration and monitoring objective. The review also discussed the increasing interest in personalized and multimodal stress-detection approaches.

The placement of a wearable device depends largely on the physiological signal being measured. Different wearable arrangements are used to accommodate the sensing requirements of cardiac, electrodermal, and brain-related measurements. EEG requires electrodes to be positioned on the scalp, making a head-worn arrangement suitable when brain activity is included. These differences in sensing requirements are important when designing a wearable system that combines several physiological signals. Bolpagni et al. [5] discussed practical factors such as signal quality, sensor configuration, and real-world deployment in wearable stress-detection systems. These considerations become particularly relevant when several sensors have to operate together in a single wearable form factor.

Riedl et al. [6] examined EEG and ECG responses in relation to videoconference fatigue. Rountree-Harrison et al. [18] reviewed EEG and ECG biomarkers in traumatic stress research and examined studies using both machine-learning and non-machine-learning approaches. Although fatigue and psychological stress are not the same condition, their study demonstrates the use of more than one physiological signal to examine changes associated with human cognitive and physiological states. Wang et al. [7] investigated wearable sensing technologies for monitoring construction workers, demonstrating the application of wearable sensing in an occupational environment. The studies show that the design and placement of wearable sensors can vary according to the application and the physiological information being collected.

The use of multiple physiological signals has received increasing attention in stress-detection research. Bolpagni et al. [5] identified EDA and PPG among the commonly used biosignals in wearable stress-monitoring studies and discussed multimodal approaches that combine different physiological measurements. Sosa et al. [17] specifically reviewed multimodal approaches for sympathetic nervous system arousal classification and examined how different physiological indicators can be considered together for stress-related

classification. This line of research is relevant to systems that do not rely on a single physiological measurement, since different signals can provide complementary information about physiological responses.

Another important issue is whether a wearable stress-monitoring system can maintain reliable performance across different users and real-world conditions. Vos et al. [12] reviewed machine-learning approaches for stress monitoring using wearable devices and discussed challenges related to generalizability. Abd Al-Alim et al. [15] investigated wearable-sensor-based stress detection in free-living environments, where physiological measurements are collected under less controlled conditions than laboratory settings. These studies suggest that signal collection and system design need to be considered together with the conditions in which the wearable system is used.

Table II compares representative wearable stress-monitoring approaches based on their typical physiological signals, main strengths, and limitations.

TABLE II. COMPARISON OF WEARABLE STRESS-MONITORING APPROACHES

Approach	Typical Signals	Main Strength	Main Limitation
Wrist-based wearable [5]	Pulse/PPG, EDA, motion	Portable and convenient for continuous monitoring	Does not normally provide EEG-based brain activity
Chest-based wearable [5]	ECG, respiration, motion	Suitable for cardiac and respiratory measurements	May be less convenient for everyday use
EEG-based wearable [4]	EEG	Provides information about brain electrical activity for mental-stress assessment	Sensitive to electrode placement and movement
Multimodal wearable [5], [17]	ECG/PPG, EDA, EEG and/or other signals	Combines information from different physiological sources	Requires additional hardware and signal processing
Proposed smart cap	EEG, ECG, GSR, pulse	Combines multiple physiological measurements with IoT monitoring	Current prototype uses threshold-based classification and requires wider validation

The proposed smart cap uses EEG, ECG, GSR, and pulse measurements within a single head-worn arrangement. The inclusion of EEG provides access to brain-related physiological activity, while ECG, GSR, and pulse provide additional physiological measurements. Unlike the commercial and conventional wearable examples discussed above, the proposed system combines these sensing modalities in a cap-based prototype and connects the acquired measurements to an IoT monitoring platform. The purpose is to examine the feasibility of integrating multimodal physiological sensing, IoT connectivity, and real-time monitoring within a single wearable setup rather than to claim superiority over existing wearable devices.

D. IoT Integration and Cloud-Based Monitoring

The Internet of Things (IoT) allows sensing devices to exchange information with computing systems and cloud platforms. In healthcare applications, this can involve several connected components, including sensors, embedded processors, communication networks, cloud services, and user interfaces. Pradhan et al. [8] discussed the use of IoT technologies in healthcare and their role in collecting and transferring health-related information.

For a wearable stress-monitoring system, IoT connectivity makes it possible to move beyond simply collecting data on the device. Sensor readings can first be received by an embedded computing unit and then sent over a network to a cloud-based platform. The information can be displayed through a dashboard, allowing the measurements to be observed while the system is operating.

The Blynk platform used in this study provides the cloud-connected environment for displaying and monitoring the collected measurements [9]. The platform itself, however, does not determine whether a particular physiological response represents stress. The sensor measurements still need to be interpreted using an appropriate classification or decision-making method.

In the developed prototype, EEG, ECG, GSR, and pulse sensors collect the physiological measurements. A Raspberry Pi receives the sensor data and handles its processing and transmission. The processed information is then sent through the IoT connection to the Blynk Cloud Platform, where it can be viewed through the monitoring interface. This allows both the physiological readings and the resulting stress level to be observed while the system is running.

Table III summarizes the functional components of the proposed IoT architecture and describes the role of each layer in the collection, processing, transmission, visualization, and feedback of physiological data.

TABLE III. FUNCTIONAL COMPONENTS OF THE IOT ARCHITECTURE

Layer	Component	Function
Sensing Layer	EEG, ECG, GSR, Pulse	Collects physiological measurements
Processing Layer	Raspberry Pi	Receives and processes sensor data
Communication Layer	IoT/Wi-Fi connectivity	Transfers measurements to the cloud platform
Cloud Layer	Blynk Cloud Platform	Supports data transmission and visualization
Application Layer	Monitoring interface	Displays physiological information and stress level
Feedback Layer	Supportive content	Provides suggestions corresponding to the detected stress level

The architecture brings sensing, processing, communication, visualization, and feedback together within the same monitoring framework rather than treating them as separate components.

E. Machine Learning and Deep Learning for Stress

Stress classification can be approached using predefined rules as well as conventional machine-learning and deep-learning methods. Castro-García et al. [10] reviewed human stress and activity recognition using low-cost wearable technologies and discussed the use of physiological measurements for automated recognition. Their work illustrates how wearable sensing can be combined with computational methods for recognizing stress-related states. More recent research has examined machine-learning pipelines in greater detail. Vos et al. [12] reviewed wearable stress-monitoring studies using machine learning and considered issues such as data labelling, biomarker validity, and the ability of models to generalize to previously unseen data.

The development of a learning-based stress classifier depends not only on the choice of algorithm but also on the data used for training and evaluation. Vos et al. [12] emphasized that generalization and reproducibility remain important challenges in wearable stress-monitoring research. In practical use, physiological signals can differ across individuals and can also be affected by factors such as physical activity and the conditions in which the measurements are collected. Abd Al-Alim et al. [15] addressed this issue by investigating stress detection using wearable sensors in free-living environments rather than relying only on controlled laboratory conditions. Their study demonstrates the importance of evaluating stress-detection approaches under conditions that more closely resemble everyday use.

Deep-learning methods have received particular attention for EEG-based stress assessment. Badr et al. [4] reviewed deep-learning approaches for mental-stress assessment using EEG and discussed CNN, LSTM, and hybrid architectures. The review also examined how different forms of EEG representation are used as inputs to these models. These approaches show the potential of learning complex patterns from physiological signals, but their effectiveness depends on suitable datasets, reliable stress labels, and appropriate evaluation.

The current smart-cap prototype does not use a machine-learning or deep-learning model as its main classification method. Instead, it uses predefined threshold-based rules to divide the monitored state into three levels: mild, moderate, and severe. This approach allows the prototype to demonstrate the complete sensing, processing, IoT connectivity, and real-time classification pipeline without requiring a large labelled dataset for model training. However, fixed thresholds may not account for differences between users. The literature on wearable stress monitoring therefore provides a basis for considering machine-learning and deep-learning methods as future extensions once a sufficiently large and reliably labelled dataset is available.

F. Critical Analysis and Research Gap

The studies reviewed above show a gradual shift from conventional stress assessment toward continuous physiological monitoring using wearable technologies. Bolpagni et al. [5] examined the use of biosignals from wearable devices for stress detection and discussed the growing interest in multimodal and personalized approaches. IoT-based healthcare research has also demonstrated how connected devices can support the collection and transfer of physiological information between sensing units and monitoring platforms [8].

The use of multiple physiological signals can provide information from different aspects of the body's response to stress. Sosa et al. [17] reviewed multimodal approaches for stress-related physiological arousal and examined the use of different physiological indicators together. The availability of wearable platforms such as the Empatica E4 also demonstrates the practical use of multi-sensor physiological monitoring in wearable form factors [11].

Machine-learning and deep-learning methods provide further possibilities for identifying patterns in physiological data. Badr et al. [4] reviewed deep-learning approaches for EEG-based mental-stress assessment, including CNN, LSTM, and hybrid models. However, Vos et al. [12] highlighted generalization as an important challenge in wearable stress-monitoring research. Abd Al-Alim et al. [15] also investigated stress detection in free-living environments, where physiological measurements are collected under less controlled conditions.

These findings indicate that reliable stress monitoring involves more than selecting sensors or classification algorithms. Individual physiological differences, signal quality, environmental conditions, and the availability of suitable labelled data can all affect system performance. A model developed from a limited participant group may therefore not necessarily produce the same results when applied to new users [12].

Another challenge is integrating the different functions required in a practical wearable stress-monitoring system. The system needs to acquire physiological signals, process the measurements, transfer the information, present the results, and provide feedback. The proposed smart cap addresses this integration by combining EEG, ECG, GSR, and pulse sensing with a Raspberry Pi and the Blynk Cloud Platform.

The current implementation uses a threshold-based mechanism to classify the monitored state into mild, moderate, and severe levels. This allows the prototype to demonstrate multimodal sensing, IoT connectivity, real-time visualization, and stress-level classification without requiring a large labelled dataset for model training. However, fixed thresholds may not account for differences between users.

The main research gap addressed by this work is therefore the integration of multiple physiological sensing modalities, IoT-based monitoring, and real-time stress-level feedback within a single cap-based wearable prototype. The system is not intended to claim better performance than existing machine-learning or deep-learning methods. Instead, it provides a prototype that can be further investigated through larger datasets, systematic stress labelling, personalized calibration, and learning-based classification.

III. Methodology

The smart cap was developed by combining physiological sensors with a Raspberry Pi, IoT connectivity, and a monitoring dashboard. The work was carried out in four phases. First, the required physiological signals were collected through the

sensors. The second phase focused on arranging the hardware and software components and defining their data flow. The third phase involved implementing the prototype, followed by functional and usability testing in the fourth phase.

A. Phase 1 - Data Collection and Sensor Integration

Fig. 1 shows the proposed arrangement of the smart cap. EEG, ECG, GSR, and pulse sensors were selected to obtain different types of physiological measurements. The sensors were fitted into the cap-based setup and connected to the Raspberry Pi for data acquisition.

The measurements obtained from the sensors were monitored through the IoT connection. Based on the predefined conditions used in the prototype, the monitored state was grouped into three levels: Level 1 (mild), Level 2 (moderate), and Level 3 (severe).

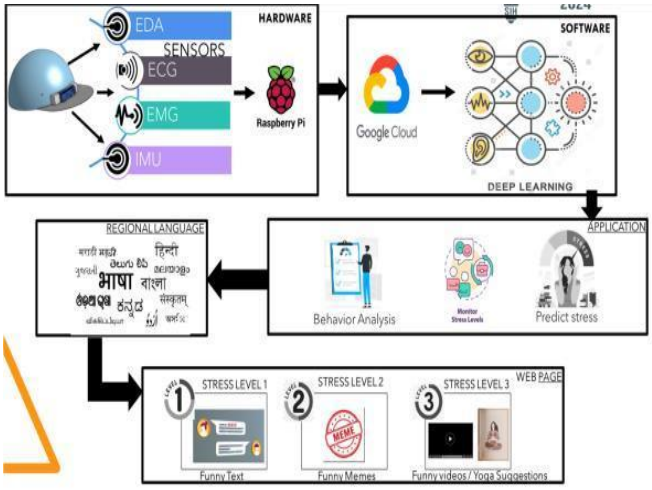

Fig. 1. Full level design of the smart cap.

B. Phase 2 – System Design

Fig. 2 illustrates the top, side, bottom, and isometric views of the proposed IoT-enabled smart cap, providing an overview of its physical structure and component arrangement. The design was divided into four parts: hardware, cloud connectivity, backend processing, and the dashboard.

1) Hardware: The EEG, ECG, GSR, and pulse sensors were connected to a Raspberry Pi 3 Model B. It receives the measurements generated by the sensors and prepares them for further processing and transmission.

2) Cloud connectivity: The sensor information from the Raspberry Pi is sent wirelessly to the Blynk Cloud Platform. Blynk is used in the prototype to monitor and display the incoming measurements.

3) Backend: The Node.js backend receives the relevant sensor information and applies the threshold conditions defined for the prototype. The output of this process is the corresponding stress level.

4) Frontend: The dashboard was developed using HTML, CSS, and JavaScript. It displays the physiological readings together with the detected stress level. The dashboard also provides supportive material, such as relaxation videos, breathing exercises, and yoga suggestions, depending on the displayed stress level.

The main data path used in the prototype is: Sensor → Raspberry Pi → Blynk Cloud → Node.js → Dashboard. Keeping these components separate also makes it easier to modify individual parts of the prototype during further development.

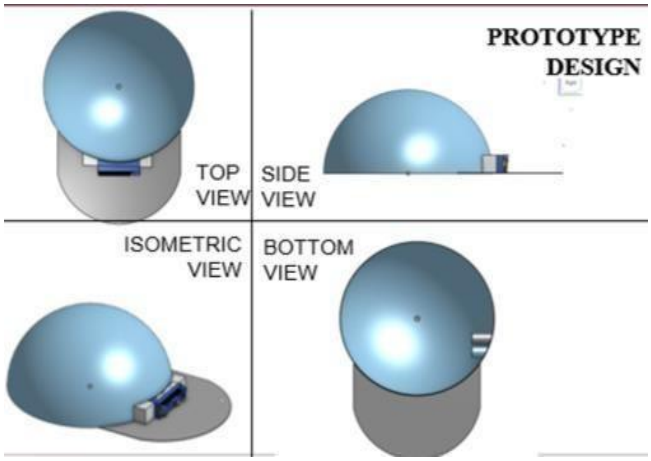

Fig. 2. Top, side, bottom, and isometric views of the proposed IoT-enabled smart cap.

C. Phase 3 – Implementation

During implementation, the sensor connections and software components described in the system design were integrated into the working prototype. The EEG, ECG, GSR, and pulse sensors were connected to the Raspberry Pi and checked for proper data acquisition and communication. The Raspberry Pi program was configured to receive the sensor readings and forward the collected information to the Blynk Cloud Platform at regular intervals. The Node.js backend was used to apply the predefined threshold-based rules and generate the corresponding stress-level output. The dashboard then displayed the sensor information and stress classification.

D. Threshold-Based Stress Classification

The stress level was determined using predefined threshold-based rules applied to the physiological measurements. The classification process can be represented conceptually as

$$S=f(HR,ECG,GSR,P)$$

where, HR, ECG, GSR, and P represent the physiological measurements obtained from the sensors, and Srepresents the resulting stress level. Based on the predefined conditions implemented in the Node.js backend, the output was grouped into three categories: Level 1 (mild), Level 2 (moderate), and Level 3 (severe).

Depending on the detected level, the interface presented the relevant supportive content, including relaxation material, breathing exercises, and yoga-related suggestions. The complete processing path was therefore:

Sensor Signal → Raspberry Pi → Blynk Cloud → Node.js Backend → Frontend Display

E. Phase 4 – Testing

The prototype was tested to check whether the major components operated as intended. The testing covered sensor data acquisition, system response, and interaction with the dashboard.

1) Test case 1: sensor data verification: The sensor readings were observed under the test conditions to check whether measurements could be acquired and transmitted without interruption.

2) Test case 2: system response: Different input conditions were provided to the threshold-based classification component. The resulting stress level was checked against the expected output, and the dashboard response was observed for each case.

3) Test case 3: user interface evaluation: The dashboard was checked for basic usability aspects such as readability, ease of navigation, and response to changes in the displayed stress level. Feedback was also collected regarding the presentation of the physiological information and the supportive content.

Fig. 3 presents the developed prototype of the smart cap, showing the integration and placement of the sensing and processing components within the wearable structure.

Fig. 3. Prototype of the cap.

IV. Results and Discussion

A. Prototype Outcome and Functionality

The developed Stress Monitoring Cap combines EEG, ECG, GSR, and pulse sensors in a cap-based wearable setup. The sensors are connected to a Raspberry Pi 3 Model B, which acts as the main unit for receiving the physiological readings and passing the required information to the connected IoT platform. Fig. 3 shows the developed smart-cap prototype with the integrated EEG, ECG, GSR, and pulse sensing components.

During operation, the sensor readings can be viewed through the monitoring dashboard. The system also produces a stress-level output using the threshold conditions implemented in the Node.js backend. Based on these conditions, the monitored state is displayed as Level 1 (mild), Level 2 (moderate), or Level 3 (severe).

The prototype brings sensor acquisition, data transmission, stress-level classification, and user feedback together in one system. The stress level shown by the prototype represents the result of the implemented classification rules and is not intended to be used as a clinical diagnosis.

B. Software Design and System Performance

Fig. 4 shows the overall architecture of the Stress Monitoring Cap. The system is arranged into different functional stages, beginning with physiological signal acquisition and ending with the presentation of the results through the dashboard.

The EEG, ECG, GSR, and pulse sensors are the starting point of the data flow. Their readings are picked up by the Raspberry Pi, which prepares the acquired information for transmission. The readings are subsequently sent over the wireless connection to the Blynk Cloud Platform. This allows the physiological information to be monitored while the system is operating.

The Node.js backend receives the relevant sensor information and applies the threshold conditions defined for the prototype. The resulting stress category is then passed to the frontend. The dashboard, developed using HTML, CSS, and JavaScript, displays the physiological readings and the corresponding stress level.

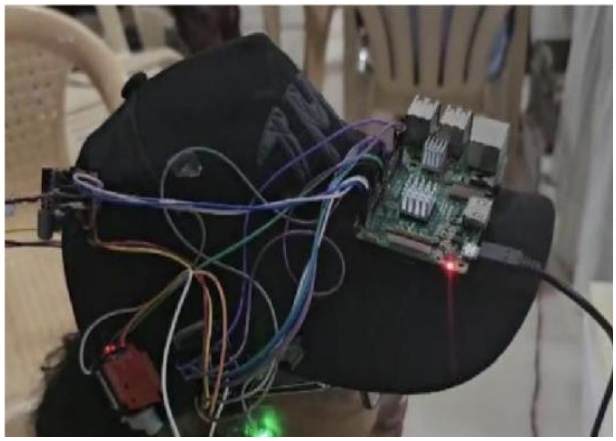

Fig. 4. Overview of the cap.

The interface also provides supportive content based on the detected level. This includes short textual suggestions, relaxation videos, breathing exercises, and yoga-related recommendations. The intention is to provide the user with simple actions that may help them respond to the displayed stress level.

C. Prototype Testing and Observations

The prototype was tested to check the operation of the sensor connections, data transmission, stress-level classification, and dashboard response. The testing focused mainly on whether the individual components could work together through the complete data path.

For sensor-data verification, the EEG, ECG, GSR, and pulse readings were observed during system operation. The Raspberry Pi was checked for its ability to receive the sensor outputs and forward the collected information to the connected platform.

The threshold-based classification was also tested with different input conditions. The resulting output was compared with the expected category defined by the implemented rules.

The dashboard was then checked to ensure that the corresponding stress level and supportive content were displayed.

The dashboard was checked during system operation to see whether the displayed information remained readable and whether the interface responded when the stress-level output changed. Navigation between the available dashboard elements was also checked. These observations were used to confirm that the interface could be used for viewing the sensor readings and the corresponding system output.

D. Discussion

The prototype demonstrates the feasibility of combining multiple physiological sensors with IoT connectivity in a wearable cap. The system receives the sensor measurements and forwards the required information through the wireless connection. Blynk provides the cloud-based monitoring component, while the Node.js backend handles the threshold-based stress classification. Fig. 5 shows the smart-cap monitoring dashboard, where the physiological readings, stress-level output, and supportive content are presented to the user. The web dashboard then presents the measurements and classification result to the user.

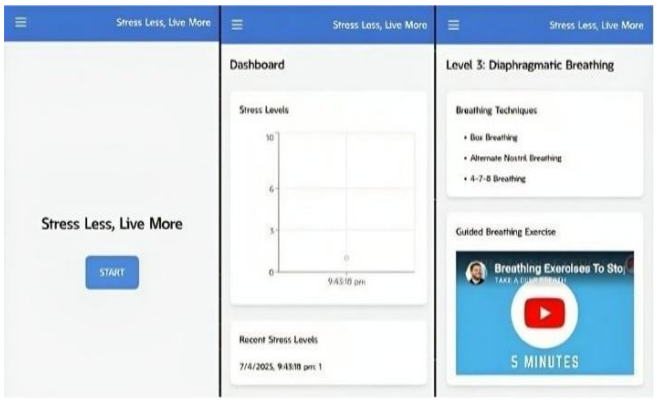

Fig. 5. Smart cap monitoring dashboard.

One practical advantage of the threshold-based approach is that it can be implemented without requiring a large labelled dataset for model training. This is useful for an initial prototype because the complete sensing, communication, classification, and feedback pipeline can be demonstrated without depending on a trained machine-learning model.

However, fixed thresholds also introduce limitations. Physiological measurements can vary from one person to another, and a value that represents an increased physiological response for one user may not have the same meaning for another user. Sensor placement, movement, environmental conditions, and signal noise can also affect the measurements.

Therefore, the current prototype should be considered a feasibility demonstration rather than a clinically validated stress-detection system. The testing carried out in this work mainly examines whether the hardware, communication, classification, and dashboard components operate together as intended. It does not provide sufficient evidence to claim clinical accuracy or generalizable performance across a wider population.

Another limitation is the current use of predefined rules instead of a data-driven classification model. Machine-learning and deep-learning methods could be explored in future versions of the system. With a sufficiently large dataset containing reliable stress labels, models could be trained using the combined physiological signals and evaluated using appropriate training and testing procedures.

The IoT component also provides scope for further development. Continuous cloud-based monitoring could allow the system to maintain longer-term records of physiological measurements and stress-level changes. Such information could be useful for studying individual patterns and developing personalized thresholds or learning-based models.

Overall, the developed prototype demonstrates the integration of multimodal physiological sensing, Raspberry Pi-based data handling, IoT communication, real-time visualization, threshold-based classification, and supportive feedback within a wearable cap. Further validation with a larger and more diverse participant group would be required before assessing its effectiveness for real-world or clinical applications.

V. Conclusion and Future Enhancement

The Stress Monitoring Cap was developed as a wearable prototype for monitoring physiological signals related to stress. EEG, ECG, GSR, and pulse sensors were integrated with a Raspberry Pi 3 Model B for data collection and processing. The measurements were transmitted through the Blynk Cloud Platform and presented on a web-based dashboard. Based on the predefined threshold conditions, the system displays the detected state as mild, moderate, or severe. The dashboard also provides relaxation videos, breathing exercises, and yoga-related suggestions according to the displayed level.

The prototype shows that multiple physiological signals and IoT connectivity can be combined in a single cap-based monitoring system. The present implementation is mainly intended to demonstrate the working of the proposed system. It does not establish clinical accuracy or provide a medical diagnosis. The threshold-based method is also limited because physiological responses can differ between individuals, and factors such as sensor placement, movement, and signal quality may affect the readings.

Future work can focus on improving the stress-classification method using machine-learning and deep-learning techniques. Such methods would require a larger dataset with reliable stress labels for proper training and evaluation. Personalized calibration can also be introduced so that the system considers the normal physiological range of individual users instead of applying the same thresholds to everyone.

Longer-term data collection could further help in studying changes in an individual's physiological patterns over time. Improvements to sensor placement, motion-noise handling, and the physical design of the cap may also make the system more suitable for extended use. The IoT interface could additionally be extended to include historical readings, trend visualization, and user-specific monitoring.

Overall, the proposed system demonstrates the feasibility of combining multimodal physiological sensing with IoT-based monitoring in a wearable cap. Larger-scale testing with reliable stress labels and different users will be required to evaluate the classification performance and determine how well the system works under real-world conditions.

A Hybrid Deep Learning Framework for Scientific Correction Text Classification

Garima Sharma*, Vikas Tripathi, Vijay Singh
Department of Computer Science and Engineering, Graphic Era (Deemed to be University), Dehradun, Uttarakhand, India

***Abstract*—Ensuring research integrity and maintaining the reliability of scientific communication requires a clear and comprehensive understanding of the underlying causes of article correction reasons across domains. Correction notices issued to authors are often unstructured with inconsistent textual information, making their automatic classification a challenging task. Existing approaches primarily rely on manual analysis or conventional machine learning techniques that fail to capture the contextual semantics and complex linguistic patterns present in the given correction statements. To address this limitation, this study proposes a deep learning-based framework for the automated classification of correction reasons using a large-scale dataset. The approach integrates contextual semantic representations with a hybrid classification strategy that combines data normalization, ensemble learning, and soft voting mechanisms to enhance classification performance and overall predictive stability. The experimental results demonstrate that the framework outperforms conventional machine learning and existing deep learning algorithms across multiple evaluation metrics. The model achieves an accuracy of 94.3%, along with strong specificity and predictive reliability. The model consistently demonstrates strong evaluation metrics, such as precision, recall, and F1-score, showcasing its effectiveness in handling a complex and imbalanced retraction dataset. The experimental analysis was conducted on a dataset categorized into four distinct classes, namely Correction, Expression of Concern, Reinstatement, and Retraction. The findings of the study offer a scalable and robust solution for systematically identifying correction reasons and uncovering underlying patterns. By enabling transparent, consistent, and efficient interpretation of correction information, this proposed approach can support publishers, academic institutions, policymakers, and researchers in detecting the patterns of scientific misconduct and thus facilitating informed decision-making while mitigating the risk of misinformation in scientific communication.**

Keywords*—Correction analysis; research integrity; BERT; natural language processing; text classification

I. INTRODUCTION

Scholarly publications guarantee the reliability of scientific research. Ensuring the accuracy and credibility of their findings is critical due to their direct and exponential impact on the community health sector [1]. Journals and Publishers employ several mechanisms such as issuing errata for minor errors, expressing concerns, and, in more severe cases, retracting the article to maintain the integrity of the scientific record [2]. A retraction serves to alert readers to articles with significant flaws or erroneous data, rendering their conclusions and findings untrustworthy [3]. These can occur for a variety of reasons, such as fraud, methodological errors, data set and results issues, plagiarism, and publisher errors, as indicated [4]. Although sparsely observed, the rate of withdrawals has increased in recent decades. Even after being retracted, these articles continue to be cited and included in meta-analyses, as evidenced [5], potentially compromising the integrity of the findings in the cited articles. However, no studies have specifically investigated withdrawals in the literature [6]. Authors in [7] aimed to explore the frequency and features of the withdrawn articles investigated and to evaluate the extent to which these retracted publications are cited. Thus, the author who submits manuscripts has the responsibility to ensure that references in their bibliography are not retracted. If an author (or reader) notices that a published article cites a retracted article, they should take the initiative to notify the journal for a correction or withdrawal [8]. The rate and magnitude of withdrawals serve as key indicators of overall operations within the domain of scientific and technical publications, highlighting the need for detailed studies [9]. In recent years, withdrawals have become a significant area of research both nationally and internationally [10]. Three key trends that have emerged in withdrawal patterns are: 1) the rate of retracted published research is growing rapidly, supported by substantial evidence [11]; 2) withdrawals are no longer limited to researchers from developed countries, but have also been extended to developing countries across academic disciplines [12]; and 3) factors of manuscript withdrawal can be grouped into two broad categories: data misconduct and unintentional or honest errors [13].

The integrity of a scholarly publication requires an effective mechanism to detect and remove falsified publications. Recently, there has been a significant increase in the withdrawal of published articles, bringing immediate attention to the reliability of publication practices [14]. These withdrawals support an essential corrective process to prevent the dissemination of false and misleading findings that adversely impact decision-making and scientific progress has been underpinned [15]. In recent years, the reasons for any withdrawal of an article have been too diverse, requiring a systematic classification mechanism. It has been observed that a large body of related research has been carried out using publicly available datasets such as Retraction Watch, which comprise a wide range of factors used to identify an illegitimate publisher [16]. However, with a larger consolidation, the primary reasons are data inconsistency, ethical misconduct, publication malpractices, and erroneous methodologies present, as well as the associated results [17]. Inconsistent, unreliable, and missing data-related information has been found to be dominant in data-related concerns has been observed [18]. In contrast, plagiarism, fabrication, falsification, and, in fact, peer review manipulations

*Corresponding author.

are related to ethical misconduct that undermines scientific credibility [19]. These concerns are widely reported and frequently observed across sensitive domains such as cardiovascular and clinical research, etc., increasing with time has been demonstrated [20].

Thus, the withdrawal of the articles represents a pivotal part of a self-correcting mechanism of science that supports the removal of unreliable, invalid, and ethically compromised findings from scholarly records. This plays a significant role in ensuring academic integrity and transparency of scientific communication in an evidence-based healthcare system. Twitter data to identify issues with publications. They focused on analyzing tweet texts related to three withdrawals of COVID-19 and SARS-CoV-2 publications and their withdrawal notices [21]. Although no early warning signs were found in tweets for one publication, tweets about the other two raised concerns about their validity shortly after publication. The experiments showcased that Twitter could play a role in identifying questionable publications. In 2022, [22] aimed to check how well major search engines, such as Google Scholar, and scientific ones such as PubMed, EMBASE, SCOPUS, and Web of Science, could detect article withdrawal. The retracted articles were taken from the Retraction Watch Database. Although Google Scholar retrieved the majority of the articles, the results revealed that it was not as reliable as scientific databases in identifying the retracted articles. The study recommended using different scientific search engines instead of just a general one. This would help avoid using retracted articles and ensure more reliable research.

To analyze the rate and character of withdrawal articles comprising the literature on infectious diseases and clinical microbiology, [23] conducted a study in which they used the Retraction Watch Database for a cross-sectional analysis of publications retracted up to 30 June 2022 in the said fields. In addition, articles with available citation data from the Web of Science database were also included in the study. The work explored trends in withdrawals and the characteristics of these publications. It also examined the number of references to the articles before and after the withdrawal year. [24] examined the transparency and consistency of the way public health publications were presented to researchers. It was a cross-sectional study that included 441 articles in public health. Data were collated from 11 sources for each publication, with withdrawal notices obtained from publisher websites and full-text aggregators. The criteria of the National Library of Medicine and the Committee on Publication Ethics were used to determine whether an article had been withdrawn. In another work presented [25], data are analyzed on retracted articles to identify trends in withdrawals. Publications were searched in WoSCC and imported into CiteSpace in plain text format for analysis. Through a visual examination of trends in countries, institutions, keywords, and subject areas, the patterns surrounding the retracted articles were revealed. The analysis also highlighted the fields most affected by withdrawals. The comparative overview of recent related work on the classification of withdrawals, highlighting methodological approaches, key findings, and research gaps, is given in Table V (in the Appendix). The existing literature shows significant progress in the identification and categorization of causes for withdrawals. There exists a gap in a universal approach and a computationally robust classification framework. For improving transparency and large-scale analysis, a robust automated system can help address these identified gaps and maintain the integrity of scientific knowledge. In addition, integrative approaches capable of combining domain expertise with data-driven methodological frameworks can help to develop more standardized and scalable classification models. The advancement in artificial intelligence (AI) and its subdomains has recently made it possible to design and develop automated systems that can detect the withdrawal reason of withdrawn articles with high precision and efficiency, as highlighted in [35]. These systems work by analyzing patterns in metadata, textual content, and article history to determine if an article has been retracted and categorize it accordingly [36]. The problem with using retracted literature is that its inclusion in literature reviews can mislead future research and clinical practice. To address these issues, a multi-representation semantic learning framework integrating an enhanced Word2Vec embedding with GloVe and Sentence-BERT to capture lexical, semantic, and contextual information from scientific withdrawal notices has been proposed in this work. These complementary representations are subsequently classified as a hybrid deep learning-based AAHA-ShLNet architecture, offering three key contributions:

- A multi-representation feature extraction framework using Enhanced Word2Vec, GloVe, and Sentence-BERT for scientific withdrawal text.
- Development of a hybrid AAHA-ShLNet classifier integrating AAHA-BN-ShNet, LeNet, and soft voting for robust classification.
- Validation of the proposed framework on 52,811 scientific post-publication notice records using a group-aware partitioning mechanism, demonstrating its effectiveness across multiple evaluation metrics.

II. MATERIALS AND METHODS

The work proposes a hybrid deep learning framework to classify withdrawal-related categories. The framework, as given in Fig. 1, integrates an advanced text representation technique along with a mutually reinforcing neural network architecture to improve the accuracy and robustness of the classification framework. The comprehensive workflow consists of three main sequential phases: 1) Accumulated Data Preprocessing, 2) Key Feature Engineering, and 3) Hybrid Classification.

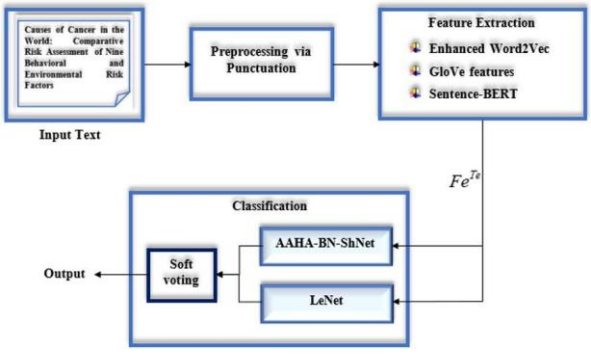

Fig. 1. Workflow architecture of proposed framework

A. Data Preprocessing via Punctuation

1) Dataset and class distribution: The proposed work utilises the four-class post-publication retraction notice records obtained from the Retraction Watch Database for four-class post-publication notice classification. The target variable, Retraction Nature, comprises four editorial-action categories: Correction, Expression of Concern, Reinstatement, and Retraction; the description of each is given in Table. I. After loading the database using an encoding-compatible procedure and validating the record structure, the resulting corpus contained 52,811 records.

TABLE I. DESCRIPTION OF POST PUBLICATION NOTICES

Category	Description
Correction	Published article requires correction, without constituting a full retraction of the article.
Expression of Concern	Concern regarding the reliability, integrity, or validity of a publication.
Reinstatement	Retracted publication has been restored to the active literature databases.
Retraction	Withdrawal of a published article from the scientific record

2) Data preprocessing: Text Processing is used to standardize and clean the collated input data, Tei, prior to feeding the same to the feature extraction engine. Specifically, punctuation has been handled along with the removal of redundant symbols without disturbing meaningful delimiters such as periods and commas. This step also ensures that the sentence boundaries and contextual structure remain intact while reducing the overall noise in the refined dataset. In addition, the output of this stage is punctuated text, TPej, serving as input for the subsequent extraction of features.

B. Feature Extraction

To capture the syntactical and semantic characteristics of the text effectively, a multi-representation feature extraction strategy has been adopted comprising three complementary embedding techniques:

- Enhanced Word2Vec: For dense vector representations of words using CBOW and Skip-Gram architectures as shown in Fig. 2, Word2Vec is utilized. Word2Vec is a shallow neural network model applied to learn word embeddings in NLP.

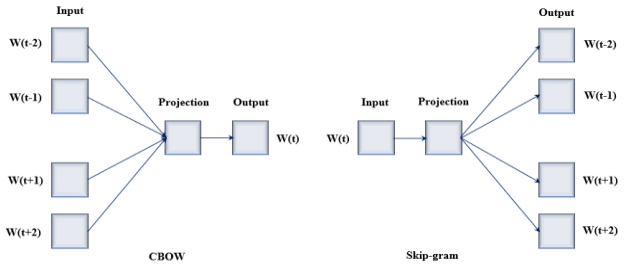

Fig. 2. Word2Vec architectural diagram.

The standard cosine similarity measures the angular relationship between two vectors, keeping the embedding dimensions equal. In scientific publication withdrawal texts, embeddings are often sparse, noisy, and have a highly imbalanced distribution due to domain-specific terminologies and unequal class frequencies. To improve the capability of the used architectures and capture semantic similarity within complex text more effectively, a modified measure of cosine similarity is introduced. This modification incorporates the following:

- An adaptive scaling factor to adjust similarity based on data variability and to reduce the influence of extreme embedding values.
- Log-exp transformation to reduce the influence of extreme values and stabilize semantic distances. This enhancement improves the robustness of the system to capture the semantic relationships across diverse textual distributions. The resulting embeddings are denoted as:

$$cos(\theta) = \{X \cdot Y\}\{/|X||Y|\} \quad (1)$$

The most significant similarity measure utilized by Word2Vec for word vector comparison is cosine similarity, which measures the angle between two vectors as defined by Eq. (1). Increasing the cosine similarity score (towards 1) indicates an increase in similarity among the words or vectors. This measure of similarity can be very important in classifying articles on the basis of some features. However, Word2Vec does not capture the entire similarity between whole sentences or documents. Word2Vec operates by evaluating similarities among word vectors, but when combining these vectors for sentence or document understanding, the process becomes limited. In order to overcome these issues, a modification to the standard cosine similarity measure used by Word2Vec. An adaptive scaling factor δ is used, which adjusts the similarity measure based on the variability of the dataset. This allows the model to adapt to different types of text distributions, making it more robust and accurate, especially in complex text domains. Using the log-exp transformation, the extreme values are smoothed, resulting in a similarity measure that is more balanced and less sensitive to outliers. The updated version of the cosine similarity equation [37], as given and utilized, is defined in Eq. (2).

$$MS(X,Y) = -log\left(1 - exp\left(-\delta \cdot Cos(X,Y)\right)\right) \quad (2)$$

To compute cosine similarity between two vectors X and Y, the dot product is divided by the product of the vectors' magnitudes [38], as given in Eq. (3).

$$cosine(X,Y) = \sum_{i=1}^{n} Xi * Yi / \sqrt{\sum_{i=1}^{n} Xi^2} * \sqrt{\sum_{i=1}^{n} Yi^2} \quad (3)$$

The scaling parameter δ can be calculated using Eq. (4).

$$\delta = \left(Cos(X,Y)\right) - min(Cos(X,Y))/mean(Cos(X,Y)) \quad (4)$$

The four-step process for computing the modified cosine similarity includes:

1) Compute the modified cosine similarity based on the updated expression in Eq. (2).

2) The distance (d) between two vectors X and Y is obtained using Eq. (5).

$$d = 1 - ModifiedSimilarity(X, Y) \quad (5)$$

3) Depending on the distance value d, if $d < 0.5$, then the returned value will be either Eq. (6) or Eq. (7):

$$(1 - d) * (d * d) + d * \sqrt{d} \quad (6)$$

or

$$\sqrt{d} \quad (7)$$

4) Once the final output has been evaluated, the process stops.

By using the updated cosine similarity, Enhanced Word2Vec generates word vectors that represent word meanings and their relationships; it is represented as $W2_{fe}$

- GloVe Word Embedding: The GloVe word embedding method [14] is employed to retrieve semantic features from text, P_{iTe}. GloVe, or Global Vectors, captures words as a vector space. It is simple to train because of its parallel implementation and assists in capturing word relationships. In the matrix Z, Z_{ij} signifies the count of context word i occurring with word j. The GloVe method is designed to minimize the resulting objective function as defined by Eq. (8).

$$G^{fe} = Minimize\Sigma_{i,j=1}^{V}\left(W_i^t W_j + B_i + B_j - logZ_{ij}\right) \quad (8)$$

The output, G^{fe} from GloVe is a word embedding for each word, W, in the input text P_{iTe}.

- Sentence BERT: BERT is a transformer model with an attention mechanism that consumes input text in a cost-effective manner [39]. It is an encoder-only transformer architecture that uses an attention mechanism to process input text and make predictions based on it. BERT processes context in both directions and yields a deeper sense of word meaning. Sentence-BERT creates better sentence-level embeddings, which makes it useful for tasks like retraction classification of published articles by knowing the meaning of entire sentences. BERT's output, Be^{fe} is generally a batch of contextualized word embeddings or sentence embeddings. The overall text-based features are obtained from this feature extraction stage, which employs Enhanced Word2Vec, GloVe, and sentence-BERT to extract features from the punctuated text. The resulting features from this stage are denoted as Fe_{Te}.

$$F_e = [E_{EW2V}||E_{GloVe}||E_{SBERT}] \quad (9)$$

C. Hybrid Classification

After the extraction of text-based features Fe^{Te}, these are used in this classification process. The aim of the classification is to classify retractions. For this, a unique hybrid AAHA-ShLNet strategy is introduced that combines the AAHA-BN-ShNet and LeNet models. The probability outcomes from both classifiers are then combined via soft voting to predict the final classification. Fig. 3 presents a structural depiction of this AAHA-ShLNet strategy.

1) Attention-driven adaptive hybrid activation and batch normalization updated ShuffleNet (AAHA-BN-ShNet): ShuffleNet, a lightweight grouped convolution and channel shuffle operations provide an effective mechanism to learn local feature interactions from dense embedding representation. This approach is being utilized, as the expected inputs are not the raw texts but an embedding matrix. The model aims to achieve maximum efficiency and precision using advanced methods like group convolution (GConv), pointwise group convolution (PWGConv), shuffling, and depthwise convolution (DWConv) [40]. Here, ShuffleNet does not depend on standard "point convolution" in convolution layers but employs GConv, where all the inputs belonging to a group are processed separately. This segregated way ensures that accurate information related to each group is identified, thus enhancing precision. In ShuffleNet, the standard BN normalizes the input layer by layer, which stabilizes the learning process regardless of possible network weight changes. However, it is not necessarily optimized in every layer, and it does not provide smoothness for negative values, which can cause computational inefficiencies or overfitting problems, specifically in article withdrawal reason classification. This overfitting slows down model performance by having the model memorize useless patterns in the data, instead of generalizing well to original inputs.

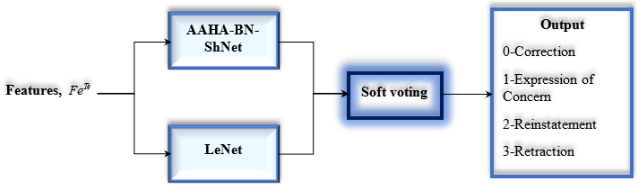

Fig. 3. Structural process of AAHA-ShLNet strategy.

In consideration of such challenges, the ShuffleNet model is improved with the inclusion of an Adaptive Hybrid Activation and Attention-based Batch Normalization (AAHA-BN), which regulates activations in training and enhances the overall performance of the model. Such an enhancement facilitates better generalization of the model through efficient normalization of activations and avoids the susceptibility that comes with traditional BN. The improved ShuffleNet model, tailored specifically for withdrawal text classification in publications, accepts text-based features, FeTe, as input and goes through a series of layers to efficiently classify. The model starts with a convolution (Conv) layer to generate the initial feature extraction of the input text. This is followed by AAHA-BN normalizing the activations to promote stability, followed by the use of LReLU to impose non-linearity with the inclusion of allowing small negative values. A max pooling layer is then used to decrease dimensionality while retaining important features. The model continues to Stage 2 and Stage 4, which involve Conv layers, AAHA-BN [41], and LReLU, enhancing the feature extraction process in stages. In Modified Stage 3, the model continues to improve feature representation with parallel processing paths involving extra DWConv and AAHA-BN before channel shuffling is used to combine results. After these steps, the features are passed through GAP to convolve all the

feature maps together and are then input into an FC layer to generate the final output. The last output of the AAHA-ShLNet model is indicated as OtAAHA-BN-ShNet.

During Modified Stage 3, as indicated in Fig. 4(a) (given in Appendix), the input passes through two parallel paths to boost feature extraction. In the first path, the input initially goes through a Conv layer, followed by the AAHA-BN to normalize activations. The output subsequently passes through an LReLU activation and a DWConv layer, followed by a second AAHA-BN, a Conv layer, and an additional AAHA-BN. Lastly, the output is again activated by LReLU. The second branch uses a less complex flow: it begins with DWConv, then AAHA-BN, Conv, and LReLU activation. Once both branches have been processed, the outputs are concatenated and fed into channel shuffling, which rearranges the features in an efficient manner for the subsequent layer. Fig. 4(b) (given in the Appendix), the input is subjected to channel splitting prior to passing it through a sequence of layers such as a Conv layer, AAHA-BN, LReLU, and DWConv. The output is subsequently processed through AAHA-BN and a Conv layer prior to concatenating with the earlier output. Channel shuffling is the last step in this structure, which efficiently shuffles the features from various channels to enhance feature diversity.

The input is initially divided into several channels for parallel processing to enable the model to learn more varied features for both Stage 2 and Stage 4. The input goes through a Conv layer, followed by BN and a ReLU function. The model then uses a DWConv layer to process the feature representation more precisely, followed by a second BN layer, a Conv layer, and a final BN layer. Then, the result from both the channel split and BN + ReLU branch is concatenated. Then the features undergo channel shuffling to effectively merge the results before proceeding to the next step. The standard BN formula normalizes the activations by adjusting the mean and variance for each feature within a mini-batch, as defined by Eq. (10).

$$\hat{y}_i = \frac{y_i^l - \mu_B^l}{\sqrt{\sigma_B^{l2} + \epsilon}} \tag{10}$$

where, Yi is the layer feature map, denotes a constant, and implies the mean and variance of y^l. In this model, the standard BN is enhanced, and its updated expression is provided in Eq. (11).

$$\hat{y}_i = \frac{y_i^l - \mu_B^l}{\sqrt{\sigma_B^{l2} + \epsilon}} X\ P(y) \tag{11}$$

P(y) signifies the Lp pooling with AAHA-BN-based normalization. This pooling method offers better generalization compared to max pooling. Instead of choosing the maximum value, Lp pooling [42] calculates a weighted average of the input within the pooling region [43].

2) LeNet model: LeNet is a very effective Deep Neural Network (DNN) model that takes very little computational time. It consists of seven layers, including the output layer [44]. The input layer of the network accepts text-based features FeTe, which are then passed to the next layer after applying a size-normalization operation. The convolutional layer is the next layer, which uses a collection of feature maps or kernels to select key features of the input. These kernels are collections of square matrices, all with the same weights. The convolutional layer applies learnable kernels over the structured numerical feature representation to identify local feature interactions. In the proposed framework, the input is not an image; rather, the fused textual embeddings are arranged as a fixed-dimensional numerical feature map. The convolution operation therefore enables the LeNet model to extract informative local patterns from the structured embedding representation.

3) Final classification using soft voting: Following the withdrawal classification by both AAHA-BN-ShNet and LeNet classifiers [45] on articles, the probabilities from both classifiers' outputs are used as inputs to the soft voting to get the final classification. Soft voting works by evaluating the weighted sum of the prediction probabilities for each class from two classifiers, as expressed in Eq. (12). The class with the highest overall probability is then chosen as the final prediction.

$$\hat{X}_i = argmax_l \sum_{j=1}^{n} \omega_j P_{i,l}^j \tag{12}$$

Here, j^{th} classifier weight is implied; the number of classifiers is represented by n=2, and is the probability predicted by the jth classifier for the ith sample to be classified as the lth class. By combining the AAHA-BN-ShNet and LeNet classifiers, the proposed hybrid AAHA-ShLNet strategy successfully categorizes withdrawal reasons of articles, which labels the outcome as 0, 1, 2, and 3 (Correction, Expression of Concern, Reinstatement, Retraction).

III. RESULTS

The proposed framework was simulated using PYTHON 3.7. The processor employed was "11th Gen Intel(R) Core (TM) i5-1135G7 @ 2.40GHz 2.42 GHz and the Installed RAM size was 16.0 GB. Moreover, the analysis of withdrawal reason classification on articles was conducted using the Retraction Watch Database from its GitHub repository [46]. This Database aids as a complete repository of retractions—instances where available research articles were withdrawn due to numerous reasons, including "fraud, plagiarism, or ethical concerns." The record contains 52,811 entries, the newest retraction repository. For the experiments, a complete retraction dataset of 52,811 records was utilized, categorized into four diverse classes: Correction (Label 0), Expression of Concern (Label 1), Reinstatement (Label 2), and Retraction (Label 3). The class distribution is highly imbalanced. Retraction constitutes 48,335 records (91.52%), followed by Expression of Concern with 3,092 records (5.85%), Correction with 1,245 records (2.36%), and Reinstatement with 139 records (0.26%). Thus, the minority Reinstatement category contains substantially fewer observations than the majority Retraction category. Because overall accuracy can therefore be dominated by the majority class, macro-averaged F1-score, balanced accuracy, class-wise precision, recall, F1-score, and Matthews correlation coefficient (MCC) *are* additionally considered in the evaluation.

A. Performance Evaluation

To assess the performance of the framework introduced for the classification of withdrawal articles, a diverse set of performance metrics is used. The selected metrics provide a

comprehensive and balanced evaluation of classification capacity, especially in unbalanced class scenarios. Let T_p denote true positives, T_n be true negatives, F_p false positives, and F_n be false negatives.

1) Accuracy: Accuracy measures the general correctness of the classification model as given in Eq. (13).

$$Accuracy = \frac{T_p+T_n}{T_p+T_n+F_p+F_n} \quad (13)$$

Although accuracy provides a general indication of performance, it may be misleading when applied to imbalanced datasets.

2) Precision: Precision measures the accuracy of predicted positive instances using Eq. (14).

$$Precision = \frac{T_p}{T_p+F_p} \quad (14)$$

3) Recall: Recall, also called sensitivity, is an indicator to accurately measure the effectiveness of the model to identify positive instances, as given in Eq. (15).

$$Recall = \frac{T_p}{T_p+F_n} \quad (15)$$

4) Specificity: Specificity measures a model's ability, as per Eq. (16), to correctly identify the negative instances.

$$Specificity = \frac{T_n}{T_n+F_p} \quad (16)$$

The higher value of specificity ensures that fewer incorrect classifications of non-withdrawal cases have been identified.

5) F1-Score: The F1-score in Eq. (17) supports a value to be used as a balance between precision and recall:

$$F1-score = \frac{2*T_p}{2*T_p+F_p+F_n} \quad (17)$$

It is a crucial value for unbalanced datasets.

6) Matthews Correlation Coefficient (MCC): As per the MCC value, Eq. (18) provides a balanced measure for considering all elements of the confusion matrix:

$$MCC = \frac{T_p*T_n-F_pF_n}{\sqrt{(T_p+F_p)(T_p+F_n)(T_n+F_p)(T_n+F_n)}} \quad (18)$$

The MCC value ranges from-1(total disagreement) to +1 (perfect prediction).

7) Negative Predicted Value (NPV): The NPV in Eq. (19) helps to measure the proportion of correctly predicted negative instances:

$$NPV = \frac{T_n}{T_n+F_n} \quad (19)$$

8) False Positive Rate (FPR): The FPR value given in Eq. (20) helps quantify the proportion of negative instances incorrectly classified as positive:

$$FPR = \frac{F_p}{F_p+T_n} \quad (20)$$

Lower FPR values indicate reduced false alarms.

9) False Negative Rate (FNR): The FNR value shows the exact proportion of all positive instances incorrectly classified as negative instances, calculated using Eq. (21):

$$FNR = \frac{F_n}{F_n+T_p} \quad (21)$$

Minimizing FNR is critical to avoid missing relevant withdrawal cases.

For rigorous validation, the proposed framework is evaluated using multiple training ratios and compared with baseline models. In addition to this, statistical measures including mean, median, standard deviation, and range, together with ablation analysis, are used to assess the robustness and reliability of the framework.

B. Comparative Performance Analysis

To evaluate the efficacy of the proposed model, a comparative analysis was conducted against several established models, including CNN, Bi-LSTM, GoogLeNet, Bi-GRU, LSTM, RNN, and AlexNet. The results showed that the model achieved superior performance in four-class post-publication notice classification, achieving an accuracy of 94.3%. In contrast, baseline models exhibit comparatively lower accuracy levels. Furthermore, in 90% of the training data, AAHA-ShLNet achieves a precision score of 0.885, highlighting its effectiveness. Baseline models report lower precision values, including CNN (0.836), Bi-LSTM (0.819), GoogLeNet (0.848), Bi-GRU (0.839), LSTM (0.859), RNN (0.826), and AlexNet (0.829).

The Negative Predictive Value (NPV) analysis demonstrates the robustness of the proposed model in identifying and classifying the removed articles. The model achieved the highest NPV of 0.927 in 60% of the training data, indicating a strong predictive capacity. The model was further improved from 0.936 to 0.943 with an increase in data from 70% to 90%, respectively. Hence, these results confirm the consistent enhancement of classification reliability with an increase in the dataset.

The effective withdrawal of categorization requires minimal negative performance indicators, such as false positive rates (FPR). The proposed model achieved the lowest FPR value of 0.032 in the training data of 90%, demonstrating a significant reduction in errors. In contrast, conventional models show higher FPR scores with Bi-LSTM (0.063), RNN (0.061), AlexNet (0.060), CNN (0.057), and Bi-GRU (0.059). The results highlight the proposed model's competence in minimizing classification errors. In addition, the Word2Vec component integrated an adaptive scaling factor and log-exp transformation to regulate similarity measures according to the variability of the dataset, thus producing a more balanced similarity measure less sensitive to outliers. The detailed description of all performance metrics compared to the traditional system is given in Table II. The statistical analysis is expanded to include macro-averaged precision, recall, and F1-score, balanced accuracy, class-wise precision/recall/F1, and a four-class confusion matrix. The performance of the minority Reinstatement class is explicitly reported rather than being represented only through aggregate accuracy.

TABLE II. COMPARATIVE PERFORMANCE ANALYSIS OF PROPOSED AND BASELINE MODELS

Model	Accuracy	Precision	FPR	FNR
AAHA - ShLNet	0.943	0.885	0.032	0.157
CNN	0.920	0.836	0.057	0.180
Bi-LSTM	0.913	0.819	0.063	0.195
GoogLeNet	0.920	0.848	NR	0.180
Bi-GRU	0.915	0.839	0.059	0.190
LSTM	0.919	0.859	NR	0.175
RNN	0.915	0.826	0.061	0.190
AlexNet	0.915	0.829	0.060	NR

C. Statistical Evaluation

To assess the effectiveness of the framework, a comprehensive quantitative evaluation was conducted using statistical measures of accuracy. The results, summarized in Table III, provide a comparative analysis of the introduced model compared to several advanced deep learning models and the baseline, such as CNN, LSTM, Bi-LSTM, GoogLeNet, Bi-GRU, RNN, and AlexNet. Statistical evaluation includes minimum, mean, standard deviation, median, and maximum accuracy values. Thus, a comprehensive understanding of the performance of the model under different experimental conditions is possible. Among all evaluated models, the proposed model demonstrates superior and consistent performance. More specifically, the mean accuracy for the proposed architecture was estimated at 0.943, which is higher than the mean accuracy of all baseline models, ranging from 0.913 to 0.920. It should be noted that the model demonstrates an ability to achieve fairly stable prediction performance across multiple iterations and datasets. In addition, the maximum accuracy of 0.972 provided by the proposed model outperforms all other baselines, including LSTM (0.950), GoogLeNet (0.946), and CNN (0.944). Thus, the suggested architecture allows for the highest classification performance under optimal conditions. As for the model's robustness, its relatively small standard deviation equals 0.019, which signifies that the performance remains quite stable and there are no major differences between different experiments. The median accuracy of 0.941 supports this statement, as it almost coincides with the mean value. The baseline models not only have a lower average accuracy than the proposed model, but also show a wider range of performance, as shown by their higher or similar standard deviation values. This means that traditional architectures may have trouble generalizing well when there are complex and unbalanced withdrawal data. Combining multi-level feature representations makes the model better at capturing both semantic and contextual information. In addition, using Adaptive Hybrid Activation with Attention-based Batch Normalization (AAHA-BN) improves feature normalization and makes training more stable. The hybrid classification strategy that combines AAHA-BN-ShNet and LeNet also helps the decision to be more general and stronger. In general, statistical analysis confirms that the proposed framework achieves higher precision, improved stability, and superior generalization capability compared to existing approaches, making it highly suitable for reliable four-class post-publication notice classification in the scientific literature.

TABLE III. STATISTICAL EVALUATION OF ACCURACY

Model	Min	Mean	SD	Median	Max
AAHA-ShLNet	0.919	0.943	0.019	0.941	0.972
CNN	0.891	0.920	0.018	0.920	0.944
LSTM	0.891	0.919	0.022	0.918	0.950
Bi-LSTM	0.884	0.913	0.020	0.916	0.938
GoogLeNet	0.896	0.920	0.019	0.919	0.946
Bi-GRU	0.887	0.915	0.021	0.916	0.943
RNN	0.889	0.915	0.019	0.916	0.939
AlexNet	0.888	0.915	0.019	0.916	0.940
TF-IDF + Linear SVM	0.753	0.86	0.052	0.855	0.88

To examine the effectiveness of the proposed model, a comparison is made with two distinct variations, one with enhanced ShuffleNet and the other without enhanced Word2vec. The details of these comparisons are summarized in Table IV. The results of the ablation evaluation clearly highlight the superior performance of the AAHA-ShLNet model. Specifically, the scheme achieved the maximum sensitivity rate of 0.843, outperforming AAHA-ShLNet without enhanced ShuffleNet (0.747) and AAHA-ShLNet without enhanced Word2vec (0.699). In addition, the AAHA-ShLNet scheme acquired the lowest FPR score of 0.032, indicating reduced error values. In contrast, the proposed model with existing ShuffleNet and AAHA-ShLNet with existing Word2vec recorded relatively higher FPR values of 0.084 and 0.100, respectively.

TABLE IV. ABLATION STUDY OF THE PROPOSED FRAMEWORK

Measure	AAHA-ShLNet	w/o Enhanced ShuffleNet	w/o Enhanced Word2Vec
Accuracy	0.943	0.916	0.900
MCC	0.791	0.663	0.599
Sensitivity	0.843	0.747	0.699
FNR	0.157	0.253	0.301
Specificity	0.922	0.874	0.850
NPV	0.948	0.916	0.900
Precision	0.885	0.748	0.700
F-Measure	0.843	0.747	0.700
FPR	0.032	0.084	0.100

IV. DISCUSSION

The proposed experimental work provides a comprehensive assessment of four-class post-publication notice classification using multiple training-data configurations and class-sensitive performance measures, as compared to the traditional approaches on multiple evaluation metrics, thus validating its effectiveness for an automated classification of article withdrawal reasons. An accuracy of 94.3% has been achieved, with an improvement across all the key metrics such as precision, recall, specificity, and predictive reliability. The hybrid structure enables the model to effectively manage the complex and imbalanced retraction datasets. This improved performance is likely due to the fusion of multilevel semantic

feature extraction and hybrid classification mechanisms. The withdrawal notices often have inconsistent reporting structures, leading to an ambiguous understanding along with domain-specific terminologies, making the automated interpretation highly challenging. Similar concerns have been highlighted by Rao et al. [22], Hwang [12], and Vuong [30]. The result confirms that the hybrid approach has a better generalization capability than standalone models for handling the heterogeneous textual data.

The convolutional components in the proposed framework do not operate on image pixels or visual content. Instead, they operate on a structured numerical feature map constructed from the fused textual representations. Enhanced Word2Vec, GloVe, and Sentence-BERT generate complementary numerical representations at different levels of linguistic abstraction. These representations are concatenated to form a unified feature vector and subsequently arranged into a fixed-dimensional numerical feature map. The two-dimensional arrangement is therefore a computational representation rather than an assumption that the input possesses visual semantics. Convolutional filters are used to learn local interactions among neighboring embedding dimensions and feature channels. Grouped convolution and channel-shuffling operations in ShuffleNet provide parameter-efficient learning of these interactions, while LeNet provides a complementary convolutional pathway. Thus, the use of convolution is motivated by structured feature interaction learning rather than by treating textual data as an image.

The semantic understanding as well as the contextual representation has improved by integrating advanced embedding techniques like Enhanced Word2Vec, GloVe, and Sentence-BERT. On one side, the traditional approaches often fail to capture long-range contextual dependencies and their semantic relationships, while on the other hand, the proposed multi-representation embedding strategy enabled the model to capture the linguistic patterns at the word, sentence, and even contextual level simultaneously. The resulting tensor is a structured feature representation rather than a natural image, and the convolutional layers are employed as computational feature extractors over locally arranged embedding dimensions. The overall robustness of the model against noisy and unstructured text has been improved by utilizing modified cosine similarity with enhanced word2Vec by reducing the sensitivity towards outliers and variable data distribution. A similar observation has been demonstrated by Yusof et al. [37], Shepperd & Yousefi [34], and Rao et al. [22]. Therefore, this fusion has substantially improved the classification reliability for complex scientific datasets comprising ambiguous textual patterns.

The incorporation of Adaptive Hybrid Activation with Attention-based Batch Normalization (AAHA-BN) and the hybrid soft voting classification strategy enhanced the feature normalization and stabilized the learning process of the model by effectively regulating the activation distribution during the training process, which is another important contribution of this study. This combination supports the reduction of overfitting issues and improvement in convergence stability while processing imbalanced datasets. For integrating hierarchical feature extraction adaptability with computational efficiency, the hybrid combination of AAHA-BN-ShNet and LeNet was found to be effective. The predictive robustness has been enhanced by the aggregation of complementary classifier outputs into a unified decision-making framework using a soft voting mechanism. Further, the ablation study performed has clearly demonstrated a noticeable degradation in classification metrics such as accuracy, sensitivity, and specificity in the case of removing any of the above mechanisms from the model. A similar discussion has been presented by Baker [28] that shows the significance of normalization and robust features in deep learning approaches defined by Sharma et al. [36] and Chan et al. [32]. Hence, this collective approach is best suited for reliable classification tasks.

The proposed framework thus offers a scalable and efficient solution for automatic scientific integrity monitoring and identification of unreliable publications across multiple research domains. The recent gradual hike in article withdrawals globally highlights the urgent requirement for such intelligent systems that are capable of supporting publishers, indexing agencies, policymakers, and researchers in identifying the root cause of withdrawal more effectively. This systematic approach helps reduce the propagation of misinformation and further improves transparency in scientific communications. Haunschild & Bornmann [23] and Pastor-Ramón et al. [24] have highlighted similar concerns in their studies and emphasized the requirement of such a cohesive and robust system. With these promising results, there are certain limitations with this work. First, the study heavily relies on the Retraction Watch Database, and thus the completeness, terminologies, and reporting practices of post-publication notices may vary from publishers, journals, as well as disciplines. Consequently, bias may occur depending on the data source. Second, the existing data imbalance estimation of minority-class performance remains more difficult when class support is limited. Third, temporal or domain shifts can impact the overall result and may therefore require additional validation on future records and datasets from independent sources. Fourth, a requirement for some leakage control mechanism to avoid similar records in analysis. Future work may include utilizing explainable AI techniques for supporting multilingual withdrawal notices along with multi-label classification to further improve the scalability and real-world applicability for automatic article withdrawal analysis. External validation across independent databases and multilingual or cross-publisher collections is therefore an important direction for future work.

V. CONCLUSION

The work presents a novel hybrid framework, termed AAHA-ShLNet, for the four-class classification of post-publication editorial notices. The proposed approach integrates a structured pipeline consisting of text preprocessing, multi-level feature extraction, and hybrid classification. First, data preprocessing is performed to remove redundant punctuation while keeping the essential linguistic structure. In addition, semantic and contextual representations are captured using enhanced embedding techniques such as Enhanced Word2Vec, GloVe, and Sentence-BERT, allowing exhaustive feature learning from collated textual data. For classification, a hybrid strategy is employed that combines AAHA-BN-ShNet and LeNet, where the outputs of both models are aggregated using a soft voting mechanism to improve predictive robustness. The experimental results show that the proposed framework is competitive with conventional models. In particular, the model

achieved a precision of 0.885, better than the traditional baseline approaches such as CNN(0.836), Bi-LSTM(0.819), GoogLeNet(0.848), Bi-GRU(0.839), LSTM(0.859), RNN(0.826), and AlexNet (0.829). Performance gains are attributed to the integration of complementary feature representations and the enhanced normalization strategy incorporated within the AAHA-ShLNet architecture. Furthermore, the hybrid decision fusion mechanism contributes to improved generalization and reduced classification errors. In general, the proposed framework provides an effective and scalable solution to identify withdrawal-related patterns. By allowing for more accurate detection of unreliable publications, the model supports informed decision-making, reduces the risk of spreading misinformation, and contributes to maintaining the integrity and reliability of scientific communication. In future work, the framework will be extended to support multi-label and fine-grained classification scenarios where multiple underlying causes can be associated with a single article. Furthermore, explainable artificial intelligence (XAI) techniques can be integrated to improve the interpretations and transparency of improved classification decisions. The framework demonstrates strong potential for real-world deployment in large-scale scientific monitoring systems.

ACKNOWLEDGMENT

The authors would like to acknowledge their university for providing the infrastructure required to carry out the experiments.

DECLARATION OF GENERATIVE AI USAGE

During the preparation of this manuscript, no generative artificial intelligence tools were used.

AttendEase: Fraud-Resistant Attendance Tracking in Higher Education Using Dynamic Tokens and Geofencing

Silvia Gaftandzhieva, Gabriela Lyavova
University of Plovdiv Paisii Hilendarski, Plovdiv, Bulgaria

***Abstract*—Preparing qualified specialists depends directly on student engagement during the educational process. For this reason, many higher education institutions (HEIs) view attendance as a key element of their educational policy and mandate strict requirements in internal regulatory documents. Traditional student attendance tracking is often time-consuming and susceptible to proxy-scanning fraud. Existing automated solutions, such as RFID or biometric systems, require expensive hardware infrastructure, while static QR-code approaches fail to prevent remote image sharing. This study proposes AttendEase, a cross-platform mobile application that secures and automates attendance management using a Bring Your Own Device (BYOD) paradigm. The system introduces a four-layer validation mechanism that combines time-limited dynamic QR codes (UUIDv4), duplicate registration, device-binding verification (SSAID/IDFV) to prevent multi-account logging from a single smartphone, and location validation using a Haversine-based geofencing algorithm. Beyond automated check-in, AttendEase features an analytics module that enables educators and students to generate real-time visualisations and reports with aggregated data. The empirical evaluation at Plovdiv University across 5 courses involving 48 students demonstrates the system's initial feasibility, usability, and potential to streamline attendance tracking, eliminate proxy check-ins, and reduce administrative overhead during lectures. The findings confirm that AttendEase has high potential to support effective attendance monitoring, operational management, and data-driven decision-making in HEIs.**

I. Introduction

Higher education plays a critical role in preparing qualified specialists and developing the knowledge and skills that students need to succeed in modern society. The quality of this process depends on various factors, among which the students' active participation holds a particularly important place. A key indicator to measure this participation and engagement is attendance at lectures, seminars, and laboratory sessions, as regular classroom presence directly affects learning outcomes and overall academic performance [1].

Attending lectures allows students to receive systematised information, practical examples, and teacher guidance that are difficult to fully replicate through self-study, ask questions, and receive immediate feedback. Its importance is especially critical during seminars and laboratory sessions for students in engineering, technical, and natural science programmes, where they apply theoretical knowledge in practice and develop skills in using specialised software, measurement systems, and equipment. Regular attendance also builds discipline, responsibility, and a professional attitude. Therefore, many HEIs consider attendance a vital component of the overall educational process [1] and require a minimum number of attendances for semester validation or exam admission. For instance, according to the Regulations of Plovdiv University Paisii Hilendarski [2], attendance at lectures, seminars, laboratory sessions, and practical exercises is mandatory and monitored by the respective instructors and department heads. This makes accurate and reliable attendance tracking critically important.

On the other hand, attendance information is a valuable tool for teachers and administrative staff. It indicates interest in specific subjects and teaching effectiveness, and can improve educational planning and compliance monitoring. Low attendance can signal organisational problems, insufficient motivation, an unsuitable schedule, or challenges in grasping the material. Therefore, collected attendance data can be used as feedback to improve educational quality.

Despite the key significance of this indicator, the process of registering and tracking attendance is still carried out conventionally in many HEIs - via paper sign-in sheets with manual signatures, oral roll calls, or subsequent manual entry of data into spreadsheets. These methods waste instructional time, increase the risk of technical errors, create difficulties with subsequent information processing, and limit analytical and reporting capabilities. There are also opportunities for abuse, such as marking a student who is actually absent as present.

For this reason, modern automated attendance tracking solutions are needed. With advancements in mobile technologies, cloud services, and wireless communication, new opportunities emerge to modernise attendance tracking through solutions based on QR codes, geofencing, online synchronisation, and rapid report generation.

To overcome the disadvantages of traditional methods, facilitate teachers' work, improve data accuracy, eliminate opportunities for fraud, and give students fast, transparent access to information, this article presents the mobile application AttendEase, which automates student attendance registration. The application allows students to register their presence by scanning a QR code dynamically generated by the

teacher. Before registering attendance, it checks the user's location against defined geographical coordinates, the scanned code's validity, duplicate registration, and the device's identification number used for registration. AttendEase supports user role management and automated, real-world, real-time attendance report generation. The data is stored in a cloud database, ensuring centralised management, reliability, and availability. The developed application is ready for deployment in a real university environment and can be easily extended with additional functionalities.

The study is organised as follows. Section II analyses existing attendance registration approaches. Section III describes the application's conceptual model. Section IV outlines the practical realisation of AttendEase's core functional modules. Section V presents and analyses the results of the application's experimental testing in a real environment. The conclusion outlines a plan for the system's future development.

II. Literature Review

As information technology has developed, various approaches and systems for automated attendance tracking have emerged, using a variety of student identification methods. A common approach to tracking attendance is using paper lists. In this method, the teacher records attendance manually, or students sign themselves on a shared sheet. This method requires no technical tools but consumes significant instructional time in large groups. During the subsequent processing, there is a continuous risk of technical errors, such as marking an absent student present. Another problem is the necessity for physical archiving and document management. As an alternative to paper lists, contact-free Radio Frequency Identification (RFID) access cards have emerged [3-5], in which each student scans their smart card on a specialised reader at the classroom entrance. The database stores the captured information, which allows subsequent processing and analysis. This approach automates registration and saves time, but requires capital investments to purchase and install specialised hardware equipment (RFID readers) and build infrastructure to connect to the information system. The main disadvantage is weak fraud protection, as a student can easily scan absent peers' cards. Biometric systems can also be deployed to register attendance, recognising unique biological characteristics such as fingerprints, facial features, palm geometry, or the iris [6-7]. These systems provide the highest degree of identity validation, practically eliminate proxy registration, and, when configured correctly, offer fast identification. The main disadvantages include high equipment costs, bottlenecks at classroom entrances for large student flows, and strict legal restrictions on storing sensitive personal data under GDPR requirements. Two-dimensional barcodes that can be read with a mobile device's camera, Quick Response (QR) codes, are also used for rapid identification. In this approach, the teacher generates a QR code for a specific class session containing identifying details (e.g., subject, date, time) [8-10]. Students confirm their attendance by scanning the code, after which the data is sent to a server or cloud database for storage. The approach operates entirely on the Bring Your Own Device (BYOD) principle. It does not require the university to purchase specialised hardware, making it an economically viable solution with easy integration capabilities. A disadvantage of this approach is the lack of protection mechanisms against remote abuse, such as scanning the codes outside the lecture hall.

Based on the reviewed technologies, automated attendance registration solutions for educational institutions have been developed. Kassem et al. [3] develop a classical attendance registration system using personal RFID cards, and Kurniali and Mayliana [11] integrate RFID readers with a web-based information system for data analysis and report generation. Despite automation, both solutions remain vulnerable to card passing and require hardware investments. Other researchers investigate the applicability of biometric systems. Osasuyi et al. [12] present a fingerprint-based solution that guarantees personal authentication, while Smitha et al. [6] design a facial recognition system using static cameras in the room. These systems achieve high security but require substantial computational resources and data security enforcement when processing sensitive personal data. The greatest flexibility is demonstrated by solutions that require mobile device usage. Masalha and Hirzallah [13] prove that scanning a unique QR code for each class drastically reduces check-in times and facilitates information processing for the teacher. The main disadvantage of early QR systems was the possibility of abuse, such as photographing the code and sending it to a student outside the hall. To overcome this disadvantage, Taju et al. [14] and Gangurde et al. [15] propose solutions that combine QR with geolocation technologies to track device location in real time. Muthulakshmi et al. [16] utilise the concept of Geo-Fencing, where a virtual geographical zone is defined around the classroom. This significantly reduces the risk of unlawful attendance registration outside the defined perimeter.

The review indicates that while mobile applications and QR codes are the most practical and cost-effective solutions, they require additional protection mechanisms during implementation. In most existing systems, security against remote abuse (such as using another person's account or scanning outside the hall) remains unsatisfactory. Since local storage or semi-automated processing hinders subsequent analysis and timely report generation, data management presents yet another challenge. Last but not least, the complex user interface of some solutions hinders daily adoption by students and teachers. For these reasons, systems under development must ensure high reliability, ergonomics, and rapid deployment. To achieve this objective, we chose a hybrid approach for the AttendEase mobile application design and development, combining dynamic QR codes with automated checks for code expiration, duplicate registration, hardware identification numbers, and the device's current GPS coordinates relative to the hall's geographical perimeter. A cloud architecture is utilised for data storage, enabling centralised management and rapid real-time report generation. The developed application achieves high reliability, security, and efficiency without requiring HEIs to invest in hardware.

III. Conceptual Model

AttendEase application aims to replace traditional paper-based and manual attendance registration methods in HEIs through mobile technologies, QR codes, and a secure cloud

infrastructure. The functional and non-functional requirements of the system were defined following a detailed analysis of the needs of the primary user groups – teachers and students. Functional requirements determine the core capabilities provided to users, such as user authentication (login) into the system, user role management, schedule and class session management, dynamic generation of unique QR codes for specific sessions, QR code scanning by students, automated attendance registration and validation, ability for manual entry or correction of attendance by a teacher, centralised storage of session and attendance information, visualisation of statistical data and report generation. Non-functional requirements describe the system's quality characteristics, such as secure encryption and storage of user data, protection against unauthorised access and tracking fraud, high processing speed and minimal request processing time, a convenient, responsive, and intuitive user interface, seamless operation across a wide range of mobile devices, and efficient cloud database connectivity and real-time synchronisation.

The workflow follows a strict logical sequence. After successfully logging in, the user is redirected to an interface personalised according to their role. The teacher activates a new session for the current class, and the system displays a unique QR code (e.g., on a multimedia screen in the room). To allow organisational flexibility, the system allows teachers to start sessions and generate QR codes up to 7 days in advance. This allows teachers to pre-print codes on paper or embed them in presentation materials. Students authenticate their attendance by scanning the code through the mobile application. After the system executes the embedded verification algorithm, it records the attendance in the database. This approach increases the process' speed and reliability and reduces errors. If issues occur, the teacher can make manual corrections (adding or removing attendance records).

QR code usage provides a quick and convenient mechanism for session registration. Without additional verification, the QR code could be shared with absent students, or students could hand over their accounts to peers to check in on their behalf. To ensure reliability and eliminate fraud during attendance tracking, AttendEase applies multi-factor verification to prevent check-ins during expired sessions, lateness, duplicate code scanning, remote scanning, or use of someone else's device.

Let S is the set of students, R the set of classrooms, L the set of all class sessions, Q the set of all initiated QR sessions, TC the set of instructors, and T a continuous time space. An ordered 11-tuple describes each active QR session $q_k \in Q$:

$$q_k = < id_k, l_j,\ teach_n, t_{start},\ t_{expire}, StatusQR_k,\ Hash_k,\ (locLat, locLng),\ maxDistMet, sessionDat >, \quad (1)$$

where, $StatusQR_k \in \{Active, Expired, Closed\}, teach_n \in TC$ is the identification number of the teacher who created the session, $t_{start} \in T$ and $t_{expire} \in T$ are the defined start and end of the session (code validity), $Hash_k = H(id_k, l_j, t_{expire})$ is a cryptographic token, $(locLat, locLng)$ are the coordinates of the classroom's centre, $maxDistMet > 0$ is the permitted deviation radius in meters, and $sessionDate$ is the session date.

An attendance registration request by a student $s_i \in S$ for a given lecture l_k in room $r \in R$is represented as:

$$Req = < s_i, Hash_k, q_k, t_{req}, (lat_s, lon_s), DevID_s >, \quad (2)$$

where, $Hash_k$ is the transmitted token from the scanned QR code, $t_{req} \in T$ is the system time when the request is sent, (lat_s, lon_s) are the student's GPS coordinates at the moment of scanning, and $DevID_s$ is the device's hardware identifier (SSAID/IDFV).

The validation decision for the attendance registration $V(Req) \in \{Approved, Late, Pending\_Approval, Rejected\}$ is determined after validating the dynamic token's status and time interval, record uniqueness, location, and the device identifier.

The dynamic QR code is generated $u_s = UUIDv4()$ with generation time t_{gen}. The request is valid if $\Delta t_{token} = t_{req} - t_{gen} \leq \Delta T_{Max}$, where ΔT_{Max} is the allowed grace period delay. The time and validity status predicate $P_{time}(Req)$ verifies if the session is marked as active and if the time window has not expired:

$$P_{time}(Req) = (statusQR_k = active) \cap (t_{req} \leq t_{expire}) \quad (3)$$

The lateness status relative to the class start t_{start} is determined as:

$$Status_{time} = \begin{cases} Approved, if\ t_{req} - t_{start} \leq 30\ min \\ Late, if\ t_{req} - t_{start} > 30\ min \end{cases} \quad (4)$$

Let $A \in S\ x\ L\ x\ Q$ be the set of all successfully confirmed attendance records, and $A = \{< s_i, l_j, q_k, t_{req} >\}$ is an already recorded attendance for student s_i for session q_k. A duplicate entry request will be blocked if such a record already exists for the current session q_k:

$$P_{uniq_{rec}}(Req) = \neg \exists a A: (a.s = s_i \cap a.l = q_k.l_j) \quad (5)$$

The distance $d(s,r)$ between the student (lat_s, lon_s) and the coordinates of the room's centre $(locLat_r, locLon_r)$ is calculated using the Haversine formula:

$$\Delta lat = \frac{\pi}{180} * (locLat_r - lat_s)$$

$$\Delta lon = \frac{\pi}{180} * (locLon_r - lon_s) \quad (6)$$

$$\alpha = sin^2\left(\frac{\Delta lat}{2}\right) + cos\left(\frac{\pi}{180} * lat_s\right) * cos\left(\frac{\pi}{180} * locLat_r\right) * sin^2\left(\frac{\Delta lon}{2}\right)$$

$$c = 2 * atan2\left(\sqrt{a}, \sqrt{1-a}\right)$$

$$d(s,r) = R_E * c\ , where\ R_E = 6\,371000\ m$$

The location validity condition is $d(s,r) \leq R_{allowed}$, where, $R_{allowed} \leq 50$ meters.

Let $DevID_{registred}(s)$ be the pre-registered unique device ID of the student s in the database. The check will return:

$$Match_{device} = \begin{cases} True, if\ DevID_s = DevID_{registred}(s) \\ False, if\ DevID_s \neq DevID_{registred}(s) \end{cases} \quad (7)$$

AttendEase is designed as a client-server system. The mobile application serves as the client-side interface through which users interact with the system. The server side is based on cloud infrastructure that provides Backend-as-a-Service (BaaS) managed components for authentication, distributed data storage, real-time synchronisation, and user session management. To achieve a loosely coupled architecture and high maintainability, AttendEase is divided into 4 core functional modules:

- Authentication Module – manages user identification, access rights verification, and automatic redirection to the home screen based on the defined role.
- Session Management and QR Code Generation Module – maintains information regarding subjects, classes, teachers, student groups, and semesters, and manages the code generation process.
- Attendance Registration and Validation Module – enables scanning and processing of QR codes, executing automated checks for code validity, preventing code reuse, remote proxy check-ins (comparing the device's current coordinates with the classroom's designated location), and account handovers (checking if the registration device matches the pre-registered one).
- Analytical Module – provides instructors and students with structured access to data on conducted sessions, attendance counts, absences, lateness, and percentage activity, with information fetched from the database in real time and visualised via lists, charts, and/or aggregated metrics.

The AttendEase architecture is designed for scalability. Cloud service usage facilitates integration with university information systems and serving a large number of users without significant changes to the application structure.

IV. Software Realisation

Designing a modern multi-platform application requires selecting software technologies that guarantee high performance and scalability. This section presents the system's structure, interface solutions, user roles, database organisation, and the realisation of core functional modules.

A. Development Technologies

AttendEase is implemented using technologies for creating a cross-platform solution for Android and iOS. The Flutter framework was chosen as the primary development environment, which ensures the construction of multi-platform applications from a single codebase with a modern appearance and an excellent user experience. Dart was selected as the programming language because of its high performance and convenient tools for user interface design. A major advantage of Flutter is the ability to develop apps for Android and iOS simultaneously, which enhances applicability, reduces development costs, and simplifies maintenance. Additionally, the framework provides ready-made integration tools for cloud services. It has a rich ecosystem of external libraries (including QR code processing, coordinate extraction, permission checks, and distance calculations), an active user community, and exhaustive documentation.

For data storage and real-time synchronisation, the Google Firebase platform was used, including specialised services for authentication, data storage, and push notifications.

The document-oriented NoSQL database Cloud Firestore was selected as the database management system. The main argument for this choice is its native support for real-time automatic synchronisation. When a QR code is scanned and attendance is recorded, the application interface updates automatically, enabling attendance monitoring during an active QR session. Data protection is secured at the cloud level through Firestore Security Rules, which define read and write permissions according to the user's role.

The system's core business logic is realised through dynamic QR code generation and scanning technologies, alongside location tracking services via mobile devices' built-in GPS modules. Combining these two technologies eliminates opportunities for fraud involving capturing and forwarding the code image to absent students. The main reasons for choosing QR technology are its flexibility in encoding heterogeneous content (text, numerical values, identification tokens, and coordinates), the presence of positioning markers, and a built-in Reed-Solomon error correction algorithm. This allows reliable decoding even under partial smudging, poor angles, or low projector resolution in the lecture hall. Process security is enhanced by deploying dynamic QR codes with narrow time windows and automatic disabling after a specified number of minutes. As an additional security mechanism, AttendEase utilises geolocation via the devices' embedded Fused Location Services, combining data from GPS, Wi-Fi networks, cellular towers, and other sensors for accurate positioning. The system calculates the distance between the student's position and the pre-configured classroom coordinates using the Haversine formula. If the calculated distance exceeds the defined threshold (e.g., 50 meters), the system rejects the transaction. To comply with GDPR, the application processes location data solely in the device's local memory during scanning, ensuring no geographic coordinates are permanently stored in the cloud.

The development and testing toolkit includes the Visual Studio Code integrated development environment (IDE), Flutter SDK, Firebase Console for cloud infrastructure management, external libraries, Git and GitHub (for decentralised version control, change tracking, and archive repository management), software emulators, and physical Android and iOS mobile devices for testing AttendEase functionalities.

B. Project Structure

The application utilises a mixed architectural model that combines layer separation with grouping user screens per role. At a conceptual level, the system is split into three main layers:

- Presentation Layer – encompasses the user interfaces (UI screens) implemented in the `lib/screens` directory and visual components in the `lib/widgets/` directory.

- Business Logic Layer (Service Layer) – encapsulates the application's business logic (`lib/services/` directory) and contains classes for communicating with the REST API and the Firebase cloud platform, session management, geolocation handling, and system notifications.
- Data Layer – defines the structure of core objects in the system (`lib/models/` directory) - users, subjects, classes, attendances, and QR sessions.

In the root `lib/` directory, the `main.dart` file serves as the entry point for the software lifecycle, initialising cloud services and global states. Helper components (validators, extended date and time formatters) and visual themes are distributed across the `utils/`, `theme/`, and `l10n/` subdirectories (for interface internationalisation and localisation).

Fig. 1 presents the AttendEase architecture.

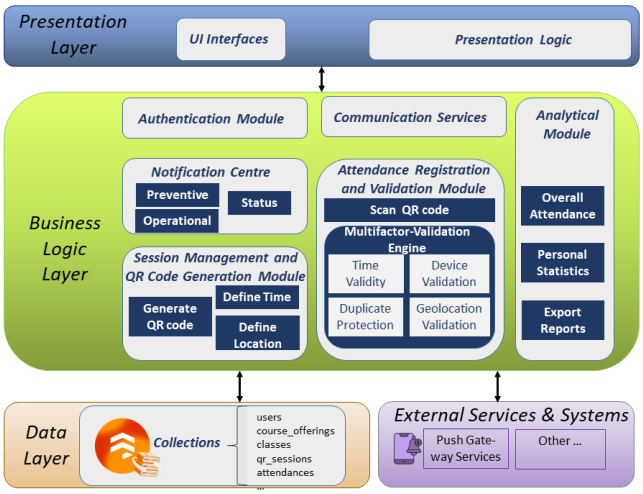

Fig. 1. Architecture.

AttendEase realises state management through a hybrid approach. The Provider architectural pattern, combined with ChangeNotifier, is used for data that affects the entire application (authentication status, current user profile, and role). Ephemeral states of individual screens (loading indicators, selected tab, QR scanner activity) are managed via the standard setState mechanism, optimising performance and resource consumption. The architecture minimises coupling between layers - components in the presentation layer do not communicate directly with the database. Communication is conducted by invoking methods from the service layer. For single transactions, asynchronous requests (Future/Await) are utilised, while real-time changes are tracked using data streams through the StreamBuilder component and Firestore snapshots. AttendEase manages navigation between screens by declarative access control mechanisms that prevent unauthorised student access to administrative panels.

Although the project does not implement Clean Architecture in full, the chosen mixed model offers an optimal balance of readability, development speed, and maintainability. The main advantages of the proposed architecture are the clear separation between UI, business logic, and data, and the isolation of Firebase communications into independent services, which allows easy future migration to another backend infrastructure or local university information systems without modifications to the presentation layer.

C. User Roles and Access Model

The AttendEase architecture utilises a role-based access control model. This approach enhances personal data security, optimises the UI, and eliminates the risk of unauthorised actions. After successful authentication, the system loads the user token from Cloud Firestore and dynamically configures the accessible functionality.

Fig. 2 presents a Use Case diagram of the AttendEase mobile application.

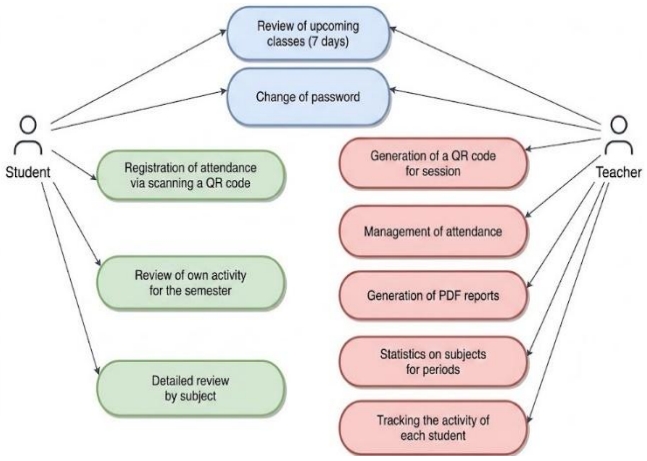

Fig. 2. Use case diagram of AttendEase.

The Student user role is designed for learners whose interaction with the system is restricted to registering attendance and reviewing their own attendance history. Upon logging into the system, the student has access to:

- Home screen – displays an academic schedule with planned sessions for 7 days;
- Attendance registration module – provides quick access to the mobile device's camera for scanning generated dynamic codes and automated feedback regarding request outcomes (successfully recorded attendance or rejection categorised by reasons: expired session, invalid code, lack of location permission, etc.);
- Analytical module – provides access to data on registered attendances and percentage ratios across subjects.

The Teacher user role is intended for individuals who conduct class sessions and manage attendance tracking. Upon logging into the system, the instructor receives access to an interface for:

- QR session management – enables selecting a specific class and generating a unique QR code with a validity period and location coordinates corresponding to the hall where the session takes place;

- Real-time student status monitoring (present, late, absent);
- Manual status correction during extraordinary situations or technical issues with a student's device;
- Detailed attendance statistics review at the student, group, or cohort level with capabilities to export into formats suitable for sharing or archiving (PDF/CSV).

D. Database

The database stores the information in logical collections. Table I describes the core collections, their attributes, and functional purposes.

TABLE I. STRUCTURE OF CORE COLLECTIONS IN THE DATABASE

Collection	Primary Fields (Attributes)	Functional Purpose
users	id, role, email, firstName, lastName	Stores information about system users
faculties	id, name, code	Stores information about faculties
specialties	id, name, code, degree	Stores information about study programmes
cohorts	id, specialtyId, startYear, endYear	Stores information about student streams/cohorts
groups	id, name, specialtyId, cohortId	Stores information about student groups
semesters	id, name, term, academicYear	Stores information about academic semesters
subjects	id, name, code	Stores information about subjects
course_offerings	id, subjectId, semesterId, cohortIds	Links subjects to a specific semester and student stream
classes	id, offeringId, teacherId, room, dayOfWeek	Stores information about individual class sessions
qr_sessions	id, classId, teacherId, token, expiresAt	Stores active QR sessions for attendance registration
attendances	id, classId, studentId, status, scannedAt	Stores information about registered attendances

Although Cloud Firestore is a NoSQL database, the data model implements relational logic through document references (Document IDs). This prevents data duplication across different locations and maintains connection integrity. To improve performance when processing large volumes of data, indexes have been configured to facilitate query execution, such as filtering attendances by a specific subject for a stream of students. The system ensures data-level security through declarative Firestore security rules. Students have read permissions only for their own attendance records, and only users with a teacher role can modify and write to qr_sessions and attendances. Thanks to built-in WebSocket support, the system monitors collection changes in real time via client interfaces and reactive components (StreamBuilder). If necessary, the designed database can be expanded, for instance, by adding new collections and attributes to store notifications and archived reports, or for integration with university systems.

E. Authentication Module

The authentication module provides reliable user identity validation. It implements the authentication process by integrating Firebase Authentication, eliminating the need for local password hashing and storage. Upon launching, the application checks for an active user session. If the token is active, the system redirects the user to the corresponding home screen. Otherwise, a screen with a login form appears, requiring the user to enter an email address and password.

Code Snippet 1 shows the logical sequence for authentication and user status verification. After successful matching of the entered credentials in the Firebase Authentication cloud directory, the system extracts the subject's unique identifier (`uid`). Then, it requests the `users` collection in Cloud Firestore to validate the profile status. If the document does not exist or the `isActive` attribute is false, `signOut`() terminates the session and sends an exception to the presentation layer. Upon successful verification, `notifyListeners`() updates the global Provider state. After successful authentication, the system loads the corresponding home screen depending on the user's role.

Code Snippet 1. User authentication via Firebase Authentication

```
final userCredential = await_auth.signInWithEmail
          AndPassword(email:email,password: password,);
final uid = userCredential.user!.uid;
final user = await getUserById(uid);
if (user == null) {await _auth.signOut();
      throw Exception('User not found in database.');}
if (!user.isActive) {await _auth.signOut();
        throw Exception('Account is deactivated.');}
_sessionUser = user;
_ready = true;
notifyListeners();
```

The application uses centralised session management via Firebase Authentication, enabling automatic session termination upon logout, protecting sensitive information, and ensuring secure credential storage. As an additional security measure, upon initial login with a system-generated temporary password, the system requires the user to change the password before granting access to functionalities. The modular structure permits seamless integration of additional security methods, such as password recovery mechanisms, multi-factor authentication, and biometric recognition via device hardware modules.

F. Session Management and QR Code Generation Module

Initialising an attendance session is performed by users with a Teacher role in 3 steps: reviewing the academic schedule and selecting a specific class session, defining geographical coordinates for conducting the session by using the mobile device's current location via the built-in GPS module or selecting classroom coordinates from an interactive map, and generating and visualising a QR code.

The system uses indirect encoding to enhance security. Instead of embedding explicit metadata about the subjects, study programme, or lecturer in the QR code, which could be easily decoded and shared, the system encodes a cryptographically secure, compact identification token in the matrix that serves as a secure key (reference) to the corresponding document in the cloud database. This minimises the risk of content counterfeiting or local manipulation of client requests. Code Snippet 2 shows how the application creates a new session. To generate a unique token for a class session,

UUIDv4 is used, and the result is parsed into a compact string to optimise optical recognition. The `QRSession` class object stores the class identifier (`classId`), teacher identifier (`teacherId`), creation and expiration timestamps (`createdAt, expiresAt`), current status, geographical coordinates (`locLat, locLng`), and the allowed radius fixed at 50 meters (`maxDistMet`). The data is written into the `qr_sessions` collection.

Code Snippet 2. QR session initialisation

```
final token = const Uuid().v4().split('-').first;
final session = QRSession( id: const Uuid().v4(), classId:
        classItem.id,teacherId: teacherId,createdAt:
         now,expiresAt:expiresAt, status: QRSessionStatus.active, token:
token, locLat:
    locLat, locLng:locLng, maxDistMet:50,
    sessionDate: formatSessionDate(sessionDate),);
await fs.createQRSession(session);
```

The QR code is displayed on the teacher's screen in high resolution. The interface provides additional session and location metadata, and options to export or download the graphic file (e.g., for visualisation on an external screen, embedding in presentation materials, or external systems). Each generated code has a strictly defined lifecycle, bound to the duration of the academic class hour.

The embedded QR code generation module in AttendEase provides a high-performance, cost-effective, and secure mechanism to identify academic sessions. Its software architecture allows easy future scaling and full integration with external university information systems.

G. Attendance Registration and Validation Module

Students can scan a QR code in the application. After logging in, the student can access the scanning function via a dedicated button on the home screen. After the student activates this function, the application opens the mobile device's camera and initiates a real-time QR code recognition algorithm. Code Snippet 3 shows a fragment of the QR code recognition implementation. After successful scanning, the code value is extracted, representing an active QR session token. The token is then returned to the main screen for subsequent validation and attendance logging.

Code Snippet 3. Scanning a QR code via the device camera

```
MobileScanner(controller: _controller, onDetect: (capture){
  if (_isHandlingDetection) return;
  final barcode = capture.barcodes.isNotEmpty?
          capture.barcodes.first: null;
  final value = barcode?.rawValue;
  if (value == null || value.isEmpty) return;
  _isHandlingDetection = true;
Navigator.pop(context, value);},)
```

The camera processes and displays the image in real time, showing a targeting frame or indicator for proper QR code positioning. After successful recognition, the application extracts the token and sends a request to the database to check the corresponding active QR session. Before recording attendance as a new document in the `attendances` collection, the system performs four checks to guarantee tracking reliability:

- Time validity – verifies whether the QR session exists and has an Active status and whether the current system time is less than `expiresAt`;
- Duplicate protection – verifies if an entry already exists for the same `studentId` and `classId` on the same date;
- Geolocation validation – checks whether the scanning device is within range of the location specified during the QR code creation by calculating the distance to the reference point;
- Device validation – checks for a match between the hardware identifier and that of the student's initially registered device.

The system applies an automatic logical constraint: if a student scans the code more than 30 minutes after the official start of the class, the transaction completes successfully, but the attendance status attribute in the `attendances` collection is logged as `Late`. After the class ends or after a specified time window, the session automatically transitions to `inactive` status, preventing late tracking attempts.

When the system receives a scanned token from a client device, it uses Firestore Security Rules and the corresponding service classes to verify whether the associated session in `qr_sessions` is `active` and whether the current system time does not exceed `expiresAt`. At the same time, it executes a verification query to prevent duplicate records for the same student in the same class.

Verifying users' locations via geolocation restricts off-site attendance registration and prevents non-present students from fraudulently logging in. The location verification procedure utilises Fused Location Services, which pull data from GPS modules, cellular networks, and Wi-Fi access points. When scanning is initiated, the client application requests permission to access geolocation services. Upon receiving permission, the system extracts the mobile device's current geographical coordinates (latitude and longitude) and calculates the distance `d` to the defined reference point using the Haversine formula. The `Geolocator`.distanceBetween method accepts the student's current (`lat, lng`) and the reference coordinates (`locLat, locLng`) from the current session as parameters. When the `distance` variable value exceeds the pre-configured limit in the `session.maxDistanceMeters`, the system generates a location validation exception and changes the attendance status to `Rejected`. In the current implementation, the system enforces a 50-meter geofencing threshold around the lecture hall. This value is good for indoor university spaces, as it allows some tolerance for GPS hardware deviations in buildings with massive reinforced concrete structures while preserving verification reliability.

Code Snippet 4. Calculating distance between current position and class location:

```
double _distanceToSession(QRSession session, double lat, double lng)
```

```
{return Geolocator.distanceBetween(lat, lng,
          session.locLat, session.locLng, );}
    final distance = _distanceToSession(session, studentPos.latitude,
studentPos.longitude);
    if (distance > session.maxDistanceMeters)
        { // attendance is rejected}
```

The application design provides facilities to handle exceptions. If location access is denied, the application prompts the user to enable the permission. Upon a second refusal, it automatically redirects the user to the device settings. If the system can't determine precise coordinates due to a lack of GPS signal, indoor environments, or technical limitations, it displays an error message, and it does not complete registration until it retrieves valid data. To ensure information security and personal data protection (in compliance with GDPR directives), the application fetches and uses the user's location only within the millisecond timeframe in which it processes the scanned token, and does not perform continuous background tracking.

Verifying the device used for registration enhances the reliability of the automated tracking process by limiting the voluntary handover of user accounts. With standard email and password authentication systems, an absent student can give their login credentials to a colleague, who can then log fictitious attendance on their behalf. To mitigate this risk, AttendEase implements an additional check via the Device Identifier (Device ID). The procedure for binding a student's profile to the device used is initiated automatically during the first successful authentication in the application. The system extracts the device's unique identifier and writes it to the corresponding document in the `users` collection in Cloud Firestore. Code Snippet 5 presents how the application extracts the device identifier depending on the operating system. For Android, it fetches the Android ID (SSAID), which is unique for each combination of application, device, and user profile. For iOS, it uses identifierForVendor (IDFV) to ensure a constant value for apps from the same hardware vendor. During each subsequent request to scan a QR code and record attendance, the application extracts the current device identifier and compares it with the stored value. If the two values match, the process continues normally. If the system detects a mismatch, it updates the record state in the `attendances` collection to "Pending Approval". Then it displays a message on the student's mobile device informing them that manual verification is needed.

Code Snippet 5. Fetching device identifier

```
    Future<String?> getDeviceId() async {try {
      if (Platform.isAndroid) {
        AndroidDeviceInfo androidInfo=await _deviceInfo.
                androidInfo; return androidInfo.id;}
      else if (Platform.isIOS) {IosDeviceInfo iosInfo = await
       _deviceInfo.iosInfo; return iosInfo.identifierForVendor;}
        return null;
} catch (e) {return null;}}
```

When the student uses a different device, the system does not block registration completely. The teacher's interface captures changes in real time via a reactive Firestore Stream and displays a notification about a registration attempt from a different device. It provides lecturers with detailed information, allowing them to manually confirm or cancel the attendance after a physical verification in the auditorium. Upon confirming attendance, the system offers the option to update the registered device ID number. This capability to change devices is particularly useful if a student has replaced their smartphone, is temporarily using another device, or has reinstalled the application.

To ensure compliance with GDPR directives, the module does not collect or process sensitive personal data (such as IMEI numbers, phone numbers, or biometrics) and stores only anonymised strings. Combining device validation with QR codes and geolocation checks creates a multi-layered defence mechanism. The QR code validates participation in a specific class session, the Device ID check confirms the use of the registered hardware, and the location check proves physical presence within the designated zone. After the checks pass, the system displays a confirmation of successful registration on the client device, or a corresponding descriptive message in the event of failure or delay. Due to cloud data synchronisation within a few hundred milliseconds, the teacher can monitor attendance on their device screen in real time.

H. Analytical Module

Accumulated attendance data has real value only when it can be analysed and used for decision-making. Deploying an analytical module provides numerous practical benefits - teachers gain fast access to summarised information on student attendance, students have transparent access to their participation records, and academic leadership can use accumulated data to analyse activity patterns. The application sends a request to retrieve attendance information by student, subject, period, or group, performs statistical calculations, and visualises the summarised data as numerical indicators and via graphics to facilitate analysis. After a new attendance registration, data updates dynamically without requiring a manual screen reload.

Teachers can access data for all subjects they teach, select a specific one, and receive attendance data for all enrolled students. The system allows filtering by time periods (week, month, semester) and can visualise summarised data for attendance statuses, the attendance ratio for the selected period in a pie chart, and individual student attendance percentages for the chosen period in a bar chart. The module allows the teacher to export a report for each subject containing summarised attendance information for each student throughout the semester, to exercise precise control over participation in the educational process and semester validation.

Students can review their attendance and absence data over the semester, along with summarised attendance and absence figures across the subjects, enabling them to take timely measures to increase attendance to secure semester validation at the end of the term. Beyond aggregate values, the student can find detailed information for individual classes. For each session, AttendEase displays the date and time, subject, and attendance status (e.g., present, late, absent, or rejected due to location).

Thus, the embedded reporting and statistics module transforms AttendEase from a pure attendance logging system into a comprehensive tool for analysing and managing educational activity. Through clear visualisation and fast access to information, the system successfully supports and optimises activities for both instructors and students.

I. Interface and User Experience

The design and implementation of user interfaces (UI/UX) in AttendEase adhere to modern standards of ergonomics, intuitiveness, and responsiveness across varying mobile device screen dimensions. Architectural separation of the presentation layer ensures that visual components remain independent of business logic while providing reliable real-time user feedback.

The primary objective in creating the interface was to achieve maximum clarity and provide rapid access to core functionalities. Although the application is developed for a live educational environment, students must be able to scan the generated QR code immediately, and instructors must be able to initiate a lecture session or review/edit attendance with minimal interactions. The interface is built with Flutter and strictly adheres to modern Material Design specifications. Modern visual components, cards for logical data grouping, rounded buttons, smooth screen transitions, and a consistent colour scheme are utilised. The highly legible font used ensures good visibility across various screen resolutions. Font sizes and element spacing were selected to make information easy to consume without visually overloading the user. To adapt to external lighting conditions and user preferences, the application supports two themes: a light theme that provides high contrast and optimal legibility in daylight, and a dark theme that reduces ocular strain and fatigue in low-light environments. After logging in, the user is directed to the appropriate home screen. Students can register attendance by scanning QR codes, review the upcoming sessions schedule, and view personal attendance statistics. Teachers have access to an administrative panel that allows them to initialise and manage QR sessions, review attendance sheets, visualise attendance-monitoring charts, and export reports.

To minimise user errors and build trust in the system, it displays detailed context-specific error messages. After successful attendance logging, the student receives a confirmation. If an error occurs (e.g., invalid location or expired time window), AttendEase displays specific information about the problem.

In the user interface implementation, visual elements are leveraged for rapid information consumption - colour indicators, icons, progress bars, and graphs. For instance, low attendance is denoted with warning colours (red/orange), while high activity is highlighted in green.

From a technical standpoint, AttendEase uses the standard Flutter sizing mechanisms to ensure interface responsiveness. Elements reorganise flexibly using scrollable views, expanding containers, and adaptive layouts, ensuring proper visualisation across diverse mobile devices. The application is optimised for portrait mode operation. To enhance user experience, AttendEase minimises screen load times, section transitions, and core action processing times to ensure high system performance.

To improve user experience and facilitate educational organisation, a specialised notification and reminder subsystem was integrated into the application, optimising academic processes and ensuring a reliable, two-way informational stream between the backend infrastructure and end users. Through this subsystem, students and teachers can receive timely information regarding upcoming classes, important events, and potential issues relating to attendance logging. AttendEase manages push notifications through the Firebase Cloud Messaging (FCM) platform. Push notifications can notify users about critical events related to attendance tracking. During initial user authentication, the application requests permission to access the operating system's messaging subsystem and generates a unique FCM token for that specific client device.

Code Snippet 7. Syncing FCM token for push notifications

```
Future<void> syncTokenForUser(String userId) async {
  final settings = await _messaging.requestPermission( alert: true,  badge: true,  sound: true, );
  if (settings.authorizationStatus == AuthorizationStatus.denied) return;
  final token = await _messaging.getToken();
  if (token == null || token.isEmpty) return;
  await _saveTokenForUser(userId, token);
}
```

Code Snippet 7 illustrates how the application requests notification permissions and retrieves an FCM token for a specific device. The application saves the retrieved token in the database, enabling push notifications to be directed to the corresponding user. To ensure data security and prevent messages from being sent to unused hardware, logging out or switching devices automatically deactivates or updates the token. For automated monitoring via Firebase Cloud Functions, a cloud function was developed to track database transactions in real time. After it detects an attendance registration attempt outside the pre-configured radius, the system can automatically dispatch a push notification to the instructor, allowing a timely response and physical inspection. Unlike push notifications, local reminders are scheduled and generated autonomously at the operating system level, without requiring continuous internet connectivity. These notifications alert students and teachers to upcoming classes and reduce the probability of missing sessions. Upon successfully loading the user profile, the application fetches the current upcoming class schedule and schedules corresponding local alarms. In the current software version, the notification subsystem initiates two consecutive events for each class session: a preventive notification generated 15 minutes before the fixed start time and an operational notification generated precisely at the start of the session (see Fig. 3). The algorithm embeds native support for devices' local time zones, guaranteeing precise alignment of notifications with the actual academic schedule regardless of the user's geographical location.

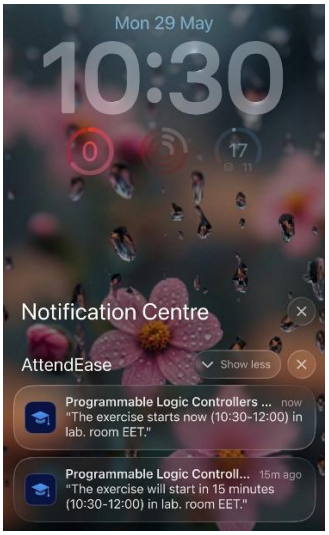

Fig. 3. Showing AttendEase alerts on lock screen.

V. Experimental Testing and Validation

To evaluate how effectively AttendEase meets teachers' and students' needs and operates reliably under real-world conditions, AttendEase has been tested at the University of Plovdiv Paisii Hilendarski. The experimental testing involved 1 teacher and 48 students utilising the application on their personal mobile devices under conditions simulating a live academic environment (immediately before and during class hours). Participants downloaded and installed the mobile app via the Google Play Store/Apple App Store and provided access permissions for the device camera and location tracking during operation. All participants received unique login credentials to access the system. To verify application compatibility and stability, testing was performed across physical iOS and Android devices, validating core operation scenarios: authentication processes for varying roles, including redirection to corresponding panels, enforced mandatory initial password changes, and accuracy of push notifications for upcoming classes (sent 15 minutes prior and at the exact start hour).

The testing process simulated real-world stages of logging class attendance - session preparation and launch, scanning, validation, and attendance data analysis. For experimental purposes, attendance tracking simulations were conducted for 5 subjects: Energy Management and Electrical Apparatus, Internet of Things, Programmable Logic Controllers, Optical Communication Technologies, and C# Programming Part 2.

Testing began with the teacher logging in to the application's home screen, which verified correct extraction of the current date, upcoming daily classes, and the planned schedule. Fig. 4 presents the process of initiating a QR session for "Programmable Logic Controllers". The teacher selected a specific class (10:30-12:00 on June 15) from the subjects list (Screen 1), set a geographic reference point using the location setting (EET Lab) and the map (Screen 2). After the teacher tapped the "Start QR" button, AttendEase generated a unique identifier and displayed a temporary QR code (Screen 3) on the device screen, valid for the duration of the class.

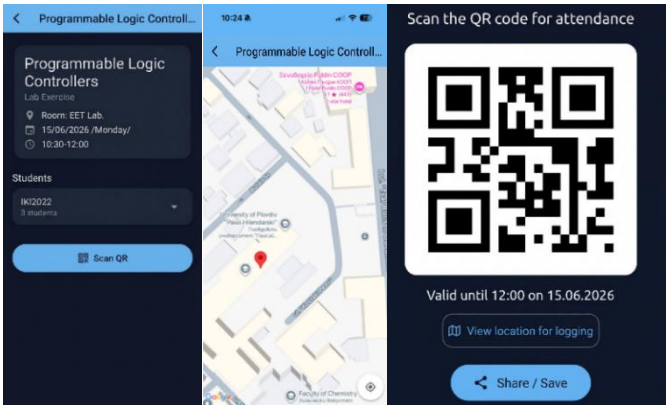

Fig. 4. Creating a QR session steps.

After the QR session activation, users with a Student role logged in to the application, reviewed the daily schedule, activated the scanning feature, and scanned the code displayed by the teacher using their mobile devices' cameras. The application recognised the code, extracted the required data to initiate registration, and executed automated background verifications to check session activity, time windows, uniqueness, geolocation constraints around the hall, and hardware ID matches against the initial profile bind. The system was tested against all forms of potential fraud. In every instance, the application executed the designated automated checks, responded according to embedded business logic rules, successfully identified attempts for registration abuse, marked records as "potentially suspicious" on the teacher's panel, and displayed appropriate alert notifications to students. AttendEase accurately determined and displayed student statuses.

During attendance registration, the teacher was monitoring incoming entries in real time on the tracking screen. All incoming check-ins were correctly registered as attended (highlighted in green), late (highlighted in orange), pending confirmation (highlighted in yellow), or no data for incomplete scanning processes (highlighted in grey), and then written to the cloud database (Fig. 5). To assess the system's fraud-detection capabilities in edge cases, we simulated a scenario where a physically present student attempted to log attendance using a peer's hardware. The teacher successfully performed a manual status override through the control panel and updated the device data (Fig. 5, Screens 3 and 4). While the anti-fraud testing evaluated basic location mismatches and device handover scenarios, this phase did not systematically benchmark explicit countermeasures against advanced location spoofing (such as Android mock-GPS tools or root-level location masking). Addressing hardware-level or application-level mock-location detection represents an essential vector for future security enhancements.

In the final stage, users tested the analytical module reporting capabilities. The teacher accessed analytical dashboards to review aggregate attendance data across subjects, track overall student attendance percentages, and identify learners with low activity levels.

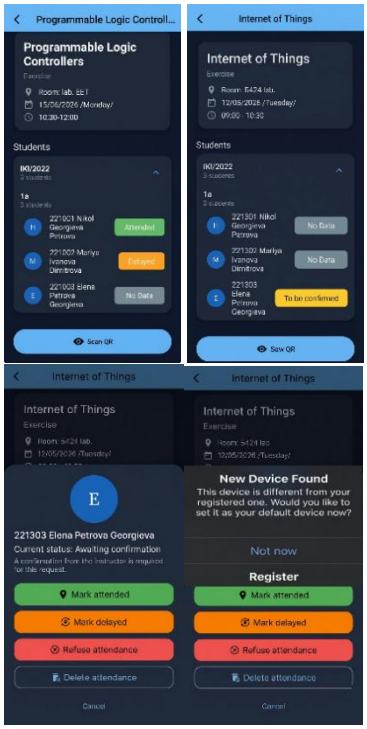

Fig. 5. Tracking the registration process details.

Fig. 6 presents visual dashboard screens with aggregate attendance data for the "Internet of Things" (Screens 1 and 2) and "Programmable Logic Controllers" (Screens 3 and 4) subjects over a selected period. For the chosen timeframe (18.05.2026 - 24.05.2026), 3 students were present, and 3 students were absent in the "Internet of Things" sessions. Aggregate semester data indicated that 3 students attended 67% of the conducted sessions, while the remaining 3 attended only 33%. During May 2026, 22 students (46% of the cohort) attended the "Programmable Logic Controllers" classes. Visualised data signalled that the teacher needs to deploy measures to increase engagement, particularly for students with attendance under 40% (highlighted in red). A comparative time trial showed that taking attendance for a group of 22 students in the "Programmable Logic Controllers" classes took an average of 3.5 minutes using traditional manual roll call. In contrast, AttendEase reduced this duration to 25 seconds in total, as students validate their presence concurrently. This yields an approximate 88% reduction in administrative overhead per seminar session.

A comprehensive summary of present logs (green), lateness (yellow), absences (grey), and rejected entries (red) is accessible for each subject (per student). Fig. 7 displays aggregate attendance data for the "Internet of Things" (Screen 1) and a detailed exported report (Screen 2). The data indicates, for example, that student number 221301 attended 3 sessions and was absent for 3 sessions.

Students tested the personal statistics section, tracking their attendance across enrolled subjects, total sessions conducted, successfully tracked attendances, and calculated attendance percentages for each course. In all cases, the system correctly computed attendance rates and systematised the information. Fig. 8 displays screens with aggregate summaries of attendances, absences, lateness, and rejected registrations for a student across all semester courses (Screen 1) and detailed historical status data for "Internet of Things" sessions (Screen 2).

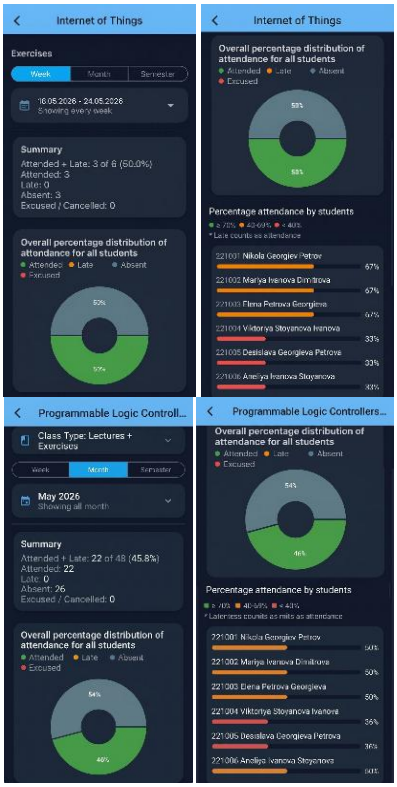

Fig. 6. Analytical panel visualisations.

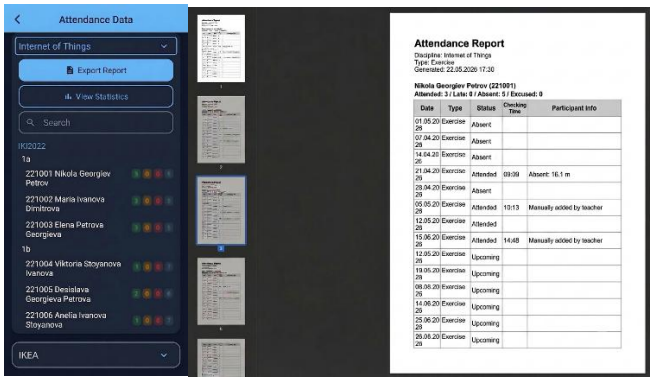

Fig. 7. Analytical panel**:** Aggregate data export example.

Tests proved that the application interface enables action execution in minimal steps, making it suitable for live classroom deployment where attendance tracking must be completed rapidly and without friction right before class starts. All automated verifications (time, geolocation, and Device ID) were triggered flawlessly, capturing and flagging all abuse attempts. Attendance data visualisation substantially facilitates analysis and identification of low-activity students. No critical errors compromising system functionality were identified during experimental testing. The minor interface inconsistencies identified were promptly resolved during iterative development.

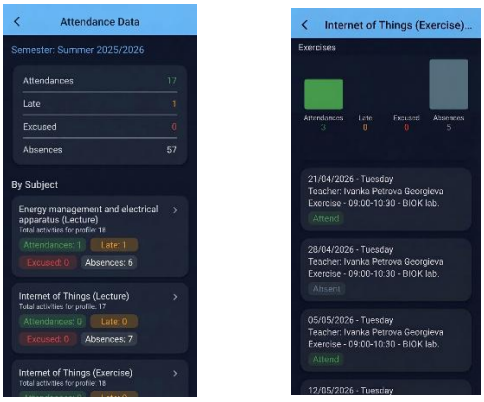

Fig. 8. Analytical panel: student views.

This experimental testing focuses on validating AttendEase's integrated four-layer verification end-to-end rather than comparative benchmarking. Empirical measurement of the incremental fraud-resistance provided specifically by the device-binding layer remains a topic for future comparative testing.

VI. Conclusion

The empirical observations from the prototype deployment align with findings in prior literature regarding the efficiency of QR-based attendance [13]. While earlier work cited check-in speed improvements, AttendEase prioritises a security balance, and the extra latency introduced by cloud-side multi-factor checks (time, boundary, device binding) trades off raw check-in speed for fully automated verification.

Functional testing across physical Android and iOS hardware confirms AttendEase's reliability and practical applicability as an effective automated student attendance tracking system in a real university environment. Its UI is engineered with a focus on ergonomics, operational clarity, and process efficiency. By applying modern design concepts, adaptive role-based navigation, and software optimisation, the application provides a high-quality user experience tailored to the academic community's specific needs.

AttendEase is a comprehensive mobile solution for automated student attendance tracking. Driven by its modular architecture, embedded verification mechanisms, and modern development technologies, the system offers a reliable, efficient instrument for optimising administrative processes in HEIs. AttendEase significantly shortens roll call time at the start of classes, eliminates tracking fraud and the risk of human error, ensures high data fidelity, facilitates daily lesson organisation, reduces administrative overhead for tracking and analysis, and fosters active student participation in the educational process.

Although the implemented mechanism for location verification and dynamic QR code scanning demonstrated a 100% success rate in simulated scenarios, its practical application in a real university environment presents certain technical limitations. The first one is related to geolocation and satellite signal drift (GPS drift). Receiving a GPS signal inside massive reinforced concrete buildings often causes interference, leading mobile devices to exceed the set 50-metre radius and potentially creating false negatives. In the current version, this issue is addressed by allowing teachers to register manually. To achieve full reliability, future versions of AttendEase plan to implement a hybrid geo-validation mechanism that combines GPS data with Bluetooth Low Energy (BLE) Beacons and checks for connectivity to the university network when the satellite signal is weak. This will ensure high precision and micro-location accuracy down to a specific desk in the lecture hall. The second challenge stems from scalability during peak loads and poor network connections. During lectures with a large number of participants (150–200 students), students will scan dynamic QR codes simultaneously within a 10–15 second timeframe. Sending dozens of requests to Google Cloud Firestore simultaneously can lead to temporary delays, request timeouts, or exceeding the per-second request limit. To address this issue, in addition to the currently implemented offline caching, plans include introducing a local queue for asynchronous data submission and using a message broker to handle peak traffic. Additionally, a future version will enable generating a temporary unique offline code based on the student's Device ID, which the lecturer can scan or enter manually at the end of class when connectivity is absent.

Another methodological limitation is the sample size: 1 teacher and 48 students from one institution. Consequently, while the results demonstrate technical feasibility, broader deployment across diverse institutional contexts is required to establish generalisability.

The modular architecture of AttendEase ensures high scalability and extensibility, with future expansion vectors including:

- Developing a web administrative panel for managing users, study programmes, schedules, and classrooms;
- Integrating with university information systems to fetch data regarding users, curricula, and schedules;
- Adding features for comparative attendance analysis across semesters, automated alerts for critically low attendance levels, and predictive attendance modelling;
- Optimising processing throughput under high-concurrency user loads.

CMST-FL: Cross-Missingness Stable Trust with Evidence-Guided Preprocessing for Federated Healthcare Signal Imputation

A Patient-Disjoint Two-Stage Model for Imputation Selection and Reliability-Weighted Aggregation

Benachir Rigalma, Soumia Ziti, Meryam Belhiah, Hamid Ouhnni
IPSS Team, Faculty of Sciences, Mohammed V University in Rabat, Rabat, Morocco

***Abstract*—Missing physiological samples create preprocessing uncertainty and uneven client reliability in federated learning. This study proposes Cross-Missingness Stable Trust federated learning (CMST-FL), a two-stage framework that selects an imputer using development patients and then weights local updates from their marginal validation-quality gains across MCAR, MAR, and contiguous-block masks. Twelve BIDMC records screened five imputers, and 15 disjoint records evaluated five training strategies under three mechanisms, three rates, and three seeds. Iterative imputation minimized the predeclared multi-objective score (0.35) and achieved the lowest standardized imputation RMSE (0.7712) under the tested budget. Across 27 matched evaluation conditions, CMST-FL obtained mean test R^2 of 0.0130, RMSE of 0.3298, and MAE of 0.2624. Compared with FedAvg, its mean R^2 gain was 0.00658, and its RMSE reduction was 0.00110. CMST-FL was favored in all 27 conditions for both metrics, and the paired tests remained statistically significant after Holm correction. Client-level cluster resampling, however, produced wide intervals because only five clients were available, and the worst-client gain was not significant. Trust logs showed meaningful but moderate departures from equal sample weighting. The evidence therefore supports iterative preprocessing followed by CMST-FL as a promising benchmark-specific configuration, while the low absolute R^2 and small error reductions preclude claims of clinical or universal superiority.**

Keywords*—Federated learning; missing data; trust aggregation; physiological signals; multiple imputation; healthcare analytics

I. Introduction

Continuous physiological monitoring produces multivariate signals that are useful for prediction, but practical recordings contain absent or corrupted samples. The BIDMC PPG and Respiration Dataset offers synchronized physiological signals and manually derived respiration targets, making it suitable for controlled studies of missing-data robustness. The present work uses this public resource as a methodological benchmark rather than claiming clinical deployment [1], [2].

Federated learning (FL) enables clients to train a shared model while retaining raw records locally. FedAvg introduced sample-count aggregation for decentralized neural-network training [4]. FedProx later added a proximal local objective for heterogeneous networks [5]. A recent healthcare survey identifies non-identically distributed data, missingness, and uncertain client quality as continuing obstacles [3]. q-FFL addresses fairness across clients [6], whereas FLTrust targets Byzantine updates [7]; neither directly evaluates whether a benign update remains useful across several missingness mechanisms.

This distinction motivates Cross-Missingness Stable Trust federated learning (CMST-FL). Instead of trusting a client because it performs well under only the current mask, CMST-FL asks a counterfactual question: does the local update improve the received global model across a fixed bank of plausible missingness mechanisms? It rewards mean improvement, penalizes cross-mechanism variability and worst-case harm, then smooths trust through rounds before combining it with sample count. The proposed research object is therefore a unified decision model—not only a new server weight—because preprocessing is selected on disjoint development patients before trust aggregation is evaluated.

The study addresses three questions. RQ1 asks which tested imputer provides the best predeclared balance of imputation fidelity, downstream validation performance, and preprocessing time. RQ2 asks whether CMST-FL consistently improves predictive performance over FedAvg and FedProx on patient-disjoint evaluation records. RQ3 asks whether the improvement persists across MCAR, MAR, and contiguous-block missingness at 10%, 30%, and 50% rates.

The main contributions are:

- A new two-stage CMST-FL model that connects leakage-controlled preprocessing selection to trust-weighted aggregation while separating development and evaluation patients;
- A mathematically explicit counterfactual cross-missingness utility with stability, worst-case, and temporal-memory terms requiring only client-side validation summaries and model parameters;
- A matched 27-condition comparison with centralized learning, FedAvg, FedProx and a guarded trust baseline, together with bootstrap intervals and paired Wilcoxon tests; and

- An evidence-bounded interpretation that reports both statistical consistency and the modest absolute magnitude of the observed gains.

The remainder of the study is organized as follows. Section II reviews missing-data and adaptive-aggregation research. Section III defines CMST-FL, Section IV presents the experimental protocol, and Section V reports preprocessing, predictive, cluster-aware, and trust-trajectory results. Section VI interprets the findings, Section VII records the evidence-supported configuration, Section VIII presents limitations, and Section IX concludes the study.

II. Related Work

A. Missing-Data Preprocessing

Simple mean or median replacement is fast but can distort covariance and temporal structure [11]. K-nearest-neighbor imputation estimates absent values from similar observations [8], while iterative imputation models each feature conditionally on the others [9]. Denoising autoencoders learn nonlinear reconstructions and may be attractive for complex physiological data, although their ranking depends strongly on architecture, training budget, and sample size [10]. Missing-data methodology further emphasizes that missingness assumptions and uncertainty should be considered explicitly [11].

Recent federated imputation studies demonstrate growing interest in heterogeneous intensive-care time series and personalized imputation under heterogeneous missingness. CAFE, for example, learns personalized imputation weights from cross-client missing-data heterogeneity. These studies optimize imputation itself, whereas the present work first compares conventional and learned imputers under a fixed budget and then uses the selected imputer inside a reliability-weighted predictive FL pipeline. A method that is best in one dataset or budget cannot be assumed universally best; preprocessing is therefore treated as a patient-disjoint development-stage decision [12], [21].

B. Federated Aggregation and Trust

FedAvg is the sample-weighted reference [4], whereas FedProx changes local optimization through a proximal term [5]. q-FFL prioritizes clients according to loss to improve fairness [6], and FedFomo uses client-specific validation utility [13]. FedLAW learns aggregation weights from client coherence [19]. FedAW introduces dataset-quality-aware weighting [20], while FedLW assigns larger weights to lower-loss clients [22]. These methods show that aggregation need not depend only on sample count, but none evaluates a local update across alternative missingness mechanisms in the manner proposed here.

Robust aggregation and FLTrust principally target anomalous or adversarial updates [7], [14]. Dynamic trust management has also adapted trust thresholds and smoothing parameters according to client performance, behavior, and variability [23]. CMST-FL targets a different reliability question: rather than identifying malicious behavior or using absolute local metrics, it measures the local update's marginal predictive gain relative to the exact received global model, repeats that counterfactual evaluation across a missingness bank, and uses soft sample-aware weights instead of a fixed exclusion decision.

C. Research Gap and Scope

Two gaps are addressed. First, preprocessing and aggregation are often tuned on the same final records, which can overstate generalization. Second, a client weight based on a single validation condition may reward a brittle update. CMST-FL combines patient-disjoint selection with cross-mechanism validation. It does not provide a Byzantine-resilience proof, causal inference, privacy accounting, or clinical certification; these remain outside the present scope.

D. Novelty Positioning

The individual ingredients of CMST-FL—weighted averaging, validation-based quality signals, and temporal smoothing—have precedents. FedLAW studies learned aggregation weights [19], FedAW uses data-quality signals [20], CAFE exploits missing-data heterogeneity for imputation [21], FedLW uses client loss [22], and dynamic trust management adapts trust thresholds and smoothing parameters [23]. To the best of our knowledge, among the methods reviewed in Table I, none combines patient-disjoint imputer selection, local-versus-global gain across a missingness bank, stability and worst-case penalties, and temporally smoothed soft aggregation. The claim is therefore a new integration and formulation, not the invention of trust-weighted FL.

TABLE I. Feature-Level Positioning of CMST-FL Against Close Method Families

Method	Weight/decision signal	Missingness bank	Local–global gain	Stability + worst case	Temporal memory	Imputer selection
FedAvg	Sample count	No	No	No	No	No
FedProx	Sample count + proximal local loss	No	No	No	No	No
FedLAW / FedAW / FedLW	Coherence, data quality or loss	No	No	No	Method-specific	No
CAFE	Personalized imputation weights	Missing-data heterogeneity	No	No	No	Learns imputation
Dynamic trust	Performance and consistency indicators	No	No	No	Yes	No
CMST-FL	Relative gain across mask bank	Yes	Yes	Yes	Yes	Yes

III. Proposed CMST-FL Method

A. System Model

Let K clients hold disjoint patient records. At round t, the server broadcasts global parameters w(t). Client i applies an imputer fitted only on its local training partition, performs one local epoch, and returns updated parameters w_i(t+1). No raw waveform, target value, or missingness mask is transmitted. Each client evaluates the received and locally updated models on the same local validation data under a fixed missingness bank. Fig. 1 summarizes the patient-disjoint two-stage workflow.

B. Cross-Missingness Utility

For each bank condition b in B, Q is the bounded validation-quality score implemented in the experiment. It combines bounded R^2 with scale-normalized RMSE and MAE. For client i, the scale was $s_i = \max(P95(y_i) - P5(y_i), SD(y_i), \varepsilon)$. The following expressions define Q and its normalized terms; the counterfactual gain in Eq. (1) then compares the local update with the exact global model received at that round.

$$Q = \mathrm{clip}(0.50R_\beta^{\,2} + 0.30\exp(-\mathrm{NRMSE}) + 0.20\exp(-\mathrm{NMAE}), 0, 1)$$

$$R_\beta^{\,2} = \{\mathrm{clip}(R^2, -1, 1) + 1\}/2$$

$$\mathrm{NRMSE} = \mathrm{RMSE}/s_i, \quad \mathrm{NMAE} = \mathrm{MAE}/s_i$$

$$g_{i,b}(t) = Q\big(w_i(t+1); V_{i,b}\big) - Q\big(w(t); V_{i,b}\big). \tag{1}$$

The experiment used B = {MCAR 30%, MAR 30%, block 30%}. A useful update should have positive average gain, low variation across mechanisms, and no severely negative condition. The penalized utility is

$$u_i(t) = \underset{b\in\mathcal{B}}{\mathrm{mean}}\big[g_{i,b}(t)\big] - \lambda \underset{b\in\mathcal{B}}{\mathrm{sd}}\big[g_{i,b}(t)\big] - \mu\max\Big(0, -\min_{b\in\mathcal{B}} g_{i,b}(t)\Big). \tag{2}$$

Here λ controls the stability penalty and μ penalizes worst-case harm. Unlike a weight based on one absolute local metric, the gain is relative to the exact global model received at that round. This construction reduces persistent preference for clients with intrinsically easier validation records.

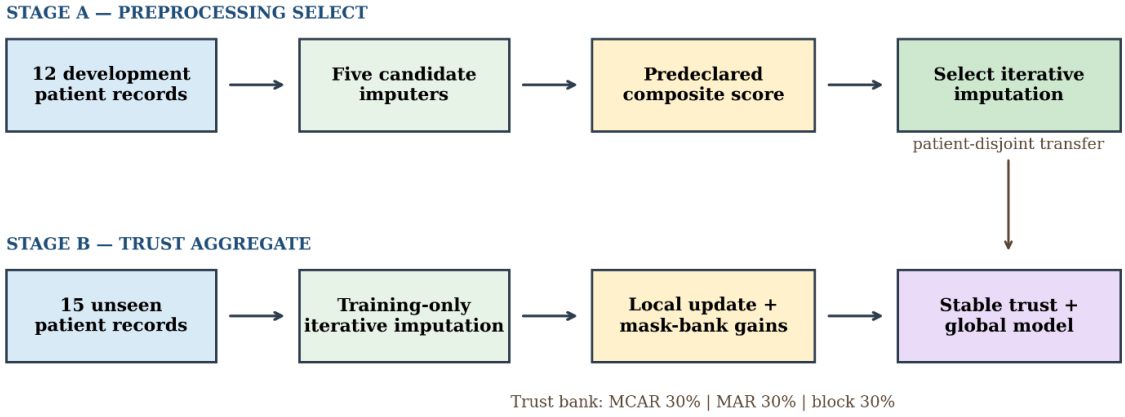

Fig. 1. Unified two-stage CMST-FL model. Stage A selects the imputer on development patients; Stage B transfers only the selected preprocessing decision to unseen patients and performs cross-missingness stable-trust aggregation.

C. Temporal Trust and Aggregation

The instantaneous trust is a temperature-scaled logistic transformation. Exponential smoothing reduces round-to-round weight volatility:

$$z_i(t) = \frac{1}{1+\exp\left(-\frac{u_i(t)}{\tau}\right)}, \tag{3}$$

$$T_i(t) = \rho T_i(t-1) + (1-\rho) z_i(t). \tag{4}$$

CMST-FL combines trust with the number n_i of local training examples. With trust floor epsilon and concentration exponent gamma, the normalized aggregation coefficient is

$$a_i(t) = \frac{n_i[\varepsilon + T_i(t)]^\gamma}{\sum_{j=1}^{K} n_j[\varepsilon + T_j(t)]^\gamma}, \tag{5}$$

$$w(t+1) = \sum_{i=1}^{K} a_i(t) w_i(t+1). \tag{6}$$

The floor prevents a client from receiving zero weight, whereas γ controls how strongly reliable clients are emphasized. FedAvg is recovered conceptually when the trust multiplier is constant across clients. Parameters were fixed before Stage B: λ=0.5, μ=1.0, τ=0.05, ρ=0.8, ε=0.05, γ=2, and $T_i(0)$=0.5.

D. Integrated Two-Stage Decision Model

The complete contribution is represented as an ordered model rather than an isolated aggregation equation. Let I* be the development-selected imputer, N_train the training-only normalization operator, B the validation-mask bank, T(T) the final client-trust vector, and w(T) the final global parameters. The model returned by the procedure is

$$\begin{aligned} \mathcal{M}_{\mathrm{CMST}} &= \{I^*, N_{\mathrm{train}}, \mathcal{B}, T(T), w(T)\}, \\ I^* &= \underset{j}{\mathrm{argmin}}\ S_j. \end{aligned} \tag{7}$$

This representation makes the deployment decision explicit: the imputer and normalization are fixed before evaluation patients are exposed, whereas trust and model parameters evolve only inside Stage B. Table II converts the mathematical definition into five operational steps and their outputs.

TABLE II. OPERATIONAL DEFINITION OF THE TWO-STAGE CMST-FL MODEL

Stage	Input	Decision rule	Output
A—Screen	Development patients; five imputers	Minimize predeclared score S_j	Selected imputer I*
B—Prepare	Unseen patient partitions	Fit I* and normalization on training only	Leakage-controlled client data
B—Evaluate	Global and local models; bank B	Compute relative gains and penalized utility	Instantaneous trust
B—Stabilize	Current and previous trust	Logistic mapping and temporal smoothing	T_i(t)
B—Aggregate	Local models, samples and trust	Sample-aware soft weighting	Final global model w(T)

IV. EXPERIMENTAL DESIGN

A. Dataset, Features and Patient Split

The experiment used BIDMC CSV records derived from the PhysioNet dataset [1], [2]. RESP was the regression target, and PLETH, lead II, lead V, and aVR were predictors. Twenty-seven patient recordings were selected deterministically: 12 development records for preprocessing screening and 15 non-overlapping evaluation records for the aggregation study. Each record was uniformly subsampled to at most 200 rows to respect the two-day compute budget. Within every record, the first 60% of samples formed the training partition, the next 20% validation, and the final 20% test, preserving temporal order.

Five clients received patient-record partitions created with a fixed seed. Training-only pooled sufficient statistics were used for feature and target standardization. This design prevents a test statistic, future temporal segment, or evaluation patient from influencing imputer fitting, normalization, preprocessing selection, or trust calculation.

B. Missingness and Preprocessing Screen

Synthetic masks were generated per patient record and seed. MCAR independently masked entries. MAR selected missing rows using a logistic propensity derived from another feature. Block missingness created contiguous missing segments. A safeguard retained at least one observed feature per row. Native missing values were preserved and were excluded from the synthetic-mask imputation metric.

Stage A compared mean, median, distance-weighted five-neighbor KNN, iterative chained regression (10 iterations, median initialization), and a denoising autoencoder. The autoencoder used two ReLU hidden layers, Adam, and three epochs; therefore, its result represents only the tested low-budget configuration. Screening comprised three mechanisms at 30% missingness and seeds 11 and 22. Each method was evaluated with centralized learning and five-round FedAvg.

The predeclared score S_j combined percentile ranks, with lower values better. R^2 ranks were reversed so that higher R^2 received a lower rank:

$$S_j = 0.35r_{\mathrm{imp},j} + 0.20r_{\mathrm{F,RMSE},j} + 0.10r_{\mathrm{F},R^2,j} + 0.15r_{\mathrm{C,RMSE},j} + 0.05r_{\mathrm{C},R^2,j} + 0.15r_{\mathrm{time},j}. \quad (8)$$

Thus, direct imputation carried 35% weight, downstream federated validation 30%, centralized validation 20%, and log-transformed preprocessing time 15%. Only the winning method was advanced to Stage B. Table III consolidates the patient split, model budget, missingness conditions, and fixed aggregation settings.

TABLE III. REPRODUCIBLE EXPERIMENTAL PROTOCOL

Item	Specification
Development records	12 patient records; no Stage B patients
Evaluation records	15 disjoint patient records
Clients	5
Rows per record	At most 200, uniformly spaced
Split	60% train / 20% validation / 20% test, chronological
Stage A screen	5 imputers × 3 mechanisms × 1 rate × 2 seeds
Stage B evaluation	5 strategies × 3 mechanisms × 3 rates × 3 seeds
Central / FL training	10 epochs / 10 rounds; 1 local epoch per round
Network	4–128–64–1 multilayer perceptron; ReLU; Adam 0.001
FedProx	Proximal coefficient 0.01
CMST bank	MCAR, MAR, and block, each at 30%
Seeds	Stage A: 11, 22; Stage B: 11, 22, 33
Execution platform	64-bit Windows 10 Pro laptop; Intel Core i3-5005U CPU at 2.00 GHz; 2 physical cores and 4 logical processors; 7.9 GB RAM; Intel HD Graphics 5500; TensorFlow detected no GPU accelerator, so execution was CPU-only.
Software constraints	Flower ≥1.12,<1.13; TensorFlow ≥2.16,<2.19; NumPy ≥1.26,<2.0; scikit-learn ≥1.4,<2.0; SciPy ≥1.11,<2.0

C. Aggregation Baselines

Stage B compared: 1) centralized learning with the same architecture and total epoch count; 2) FedAvg; 3) FedProx with proximal coefficient 0.01; 4) CMST-FL; and 5) FedGuard, an experimental server-side selector that interpolated sample weights and trust/alignment weights using candidate coefficients 0, 0.25, and 0.50 subject to validation gates. FedGuard is treated as a secondary guarded baseline, while CMST-FL is the proposed method.

All FL methods ran for 10 synchronous rounds with one local epoch, all five clients participating and failures disallowed. Strategy comparisons reused the same patient partitions, masks, and seeds. The implementation used Flower for federated communication [18] and TensorFlow/Keras for the multilayer perceptron [24].

D. Metrics and Statistical Analysis

Primary predictive metrics were test R^2, RMSE, and MAE; higher R^2 and lower errors are better [15], [16]. Imputation RMSE and MAE were computed only at synthetically masked standardized feature entries. We defined worst-client R^2 as the minimum local test R^2 among the five clients for each federated method. Centralized worst-client entries were not used for fairness conclusions because the centralized evaluator produced a pooled metric rather than five local metrics.

Means were calculated across conditions, and 95% percentile bootstrap confidence intervals were estimated with 5,000 resamples [25]. Paired analyses used the 27 matched mechanism–rate–seed conditions and two-sided Wilcoxon signed-rank tests [26]. Holm correction controlled familywise error across the reported strategy–metric comparisons [17]. Because those 27 conditions reuse the same five clients, a supplementary client-cluster bootstrap resampled clients with replacement (50,000 resamples; seed 20260913). The cluster analysis is reported separately and is interpreted cautiously because five clusters cannot support precise population-level uncertainty.

V. Results

A. Preprocessing Selection

Table IV and Fig. 2 summarize Stage A. Iterative imputation achieved the lowest selection score (0.35) and the best direct imputation RMSE (0.7712). KNN had slightly better FedAvg validation RMSE and R^2, but weaker direct imputation error and centralized validation performance. Mean and median replacement were fastest. The DAE required 3.42 s and had weaker FedAvg validation performance under its three-epoch budget. Because no larger DAE budget was run, this outcome excludes only the tested configuration and does not establish general DAE inferiority.

TABLE IV. Stage-A Preprocessing Screen (Six Development Conditions)

Method	Imp. RMSE	Central R^2	FedAvg R^2	Time (s)	Score
Iterative	0.7712	0.1641	0.0846	0.273	0.35
KNN	0.9400	0.1341	0.0920	0.226	0.56
Mean	0.9515	0.1614	0.0744	0.078	0.57
DAE	0.8605	0.1539	0.0320	3.416	0.75
Median	0.9808	0.1603	0.0637	0.079	0.77

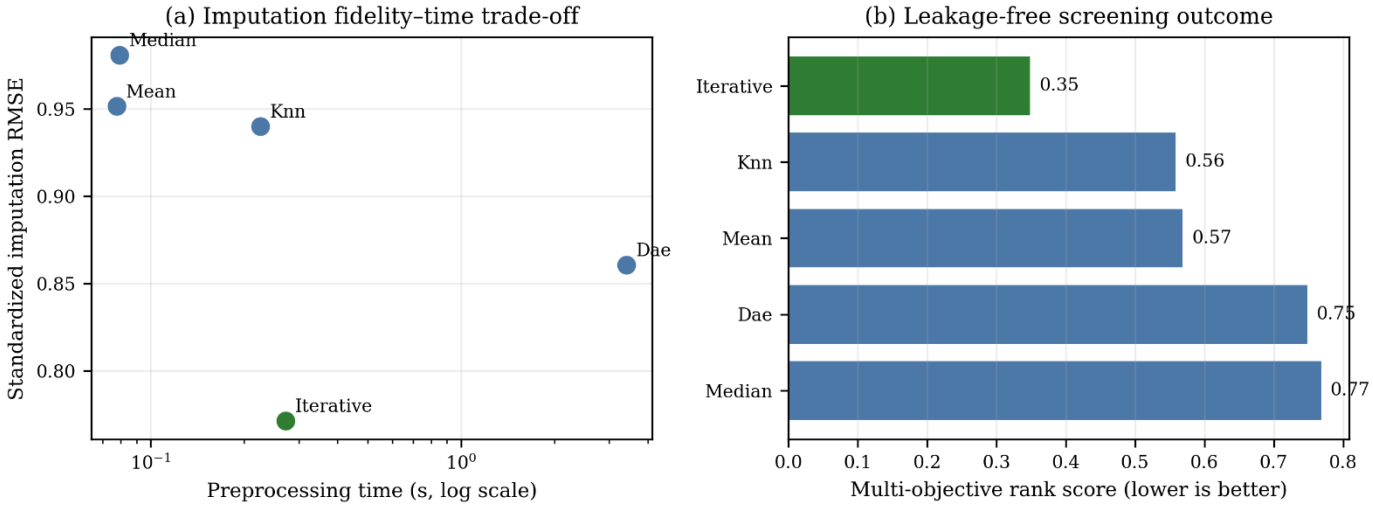

Fig. 2. Preprocessing selection. Iterative imputation provided the best predeclared multi-objective score under the tested data and compute budget; the result is not a universal ranking of imputers.

B. Overall Aggregation Performance

Table V summarizes the 27 Stage B runs per strategy, and Fig. 3 shows the corresponding means and bootstrap intervals. CMST-FL obtained the highest mean R^2 (0.0130) and the lowest RMSE (0.3298) and MAE (0.2624). Relative to FedAvg, its average R^2 gain was 0.00658, while RMSE and MAE decreased by 0.00110 (0.33%) and 0.00091 (0.35%), respectively. The directions were consistent, but the absolute differences were small.

TABLE V. STAGE-B TEST PERFORMANCE; MEAN AND 95% BOOTSTRAP CI FOR R^2

Strategy	R^2 [95% CI]	RMSE	MAE	Worst-client R^2
Centralized	0.0045 [-0.0007, 0.0098]	0.3312	0.2649	—
FedAvg	0.0064 [0.0037, 0.0094]	0.3309	0.2633	-0.0738
FedProx	0.0061 [0.0033, 0.0091]	0.3310	0.2627	-0.0725
FedGuard	0.0077 [0.0052, 0.0104]	0.3307	0.2631	-0.0673
CMST-FL	0.0130 [0.0104, 0.0157]	0.3298	0.2624	-0.0735

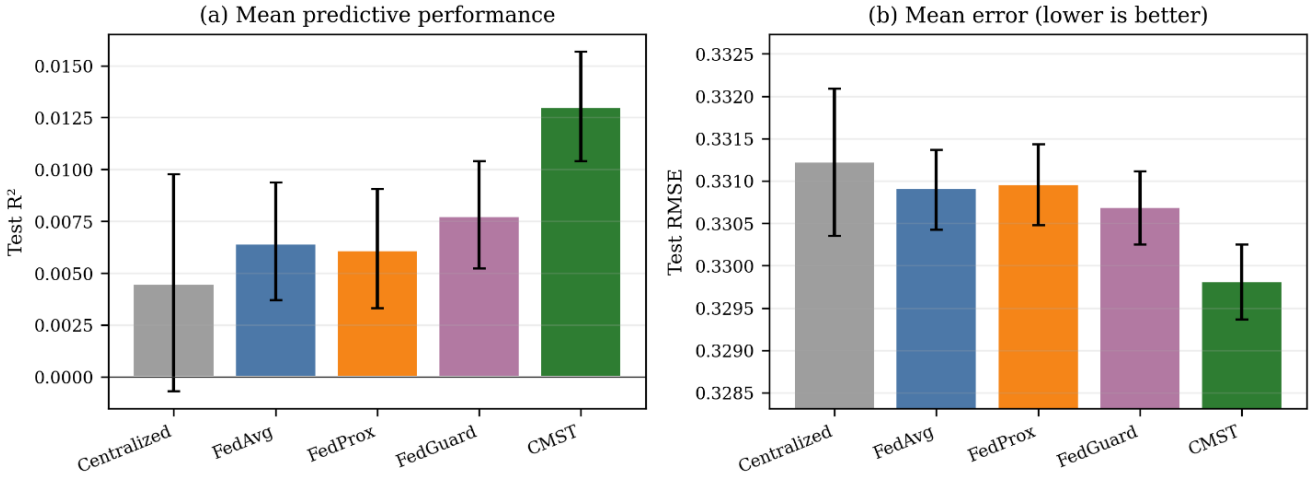

Fig. 3. Mean Stage B performance across 27 matched conditions. Error bars are 95% bootstrap confidence intervals. The truncated RMSE axis is used to make small between-method differences visible.

C. Paired Comparison with FedAvg

Table VI reports paired results. CMST-FL improved R^2 and RMSE in all 27 matched conditions and improved MAE in 25. Holm-adjusted p-values were below 0.000001 for those three metrics, and condition-level intervals excluded zero. In contrast, the mean worst-client R^2 gain was 0.00027, its interval crossed zero, and the adjusted p-value was 1.0. Thus, the experiment supports a small pooled predictive improvement, not a reliable fairness improvement.

D. Dependence-Aware and Trust-Trajectory Analysis

The client-cluster bootstrap retained the 135 matched client–condition differences but resampled the five client clusters. The mean client-level R^2 improvement was 0.00594, with a 95% cluster interval of [-0.01229, 0.03037]. The mean RMSE reduction was 0.00102, with an interval of [-0.00207, 0.00518]. Both intervals crossed zero. This result does not contradict the condition-level paired test; it shows that uncertainty over a broader client population remains large when only five clients are observed.

Table VII and Fig. 4 connect CMST-FL's utility calculation to the aggregation trajectory. Across 1,350 client–round rows, temporal trust ranged from 0.361 to 0.745, and normalized weights ranged from 0.087 to 0.306. The mean absolute departure from the equal 0.20 weight was 0.034; penalized utility and weight were strongly associated (r=0.918).

TABLE VI. PAIRED CMST-FL IMPROVEMENT OVER FEDAVG (27 MATCHED CONDITIONS)

Metric	Mean improvement	95% bootstrap CI	Win rate	Holm p
R^2 gain	0.006581	[0.005287, 0.007907]	100.0%	<0.000001
RMSE reduction	0.001098	[0.000882, 0.001318]	100.0%	<0.000001
MAE reduction	0.000910	[0.000672, 0.001146]	92.6%	<0.000001
Worst-client R^2 gain	0.000267	[-0.006561, 0.007737]	40.7%	1.000

TABLE VII. CLIENT UTILITY, TEMPORAL TRUST AND NORMALIZED CMST-FL WEIGHT

Client	Raw utility	Penalized utility	Mean trust	Mean weight	Weight range
C1	0.0274	0.0256	0.5806	0.2147	[0.1796, 0.2449]
C2	0.0227	0.0210	0.5702	0.2078	[0.1872, 0.2310]
C3	-0.0062	-0.0178	0.4461	0.1343	[0.0867, 0.1960]
C4	0.0499	0.0485	0.6452	0.2609	[0.2039, 0.3055]
C5	0.0107	0.0087	0.5307	0.1823	[0.1631, 0.2066]

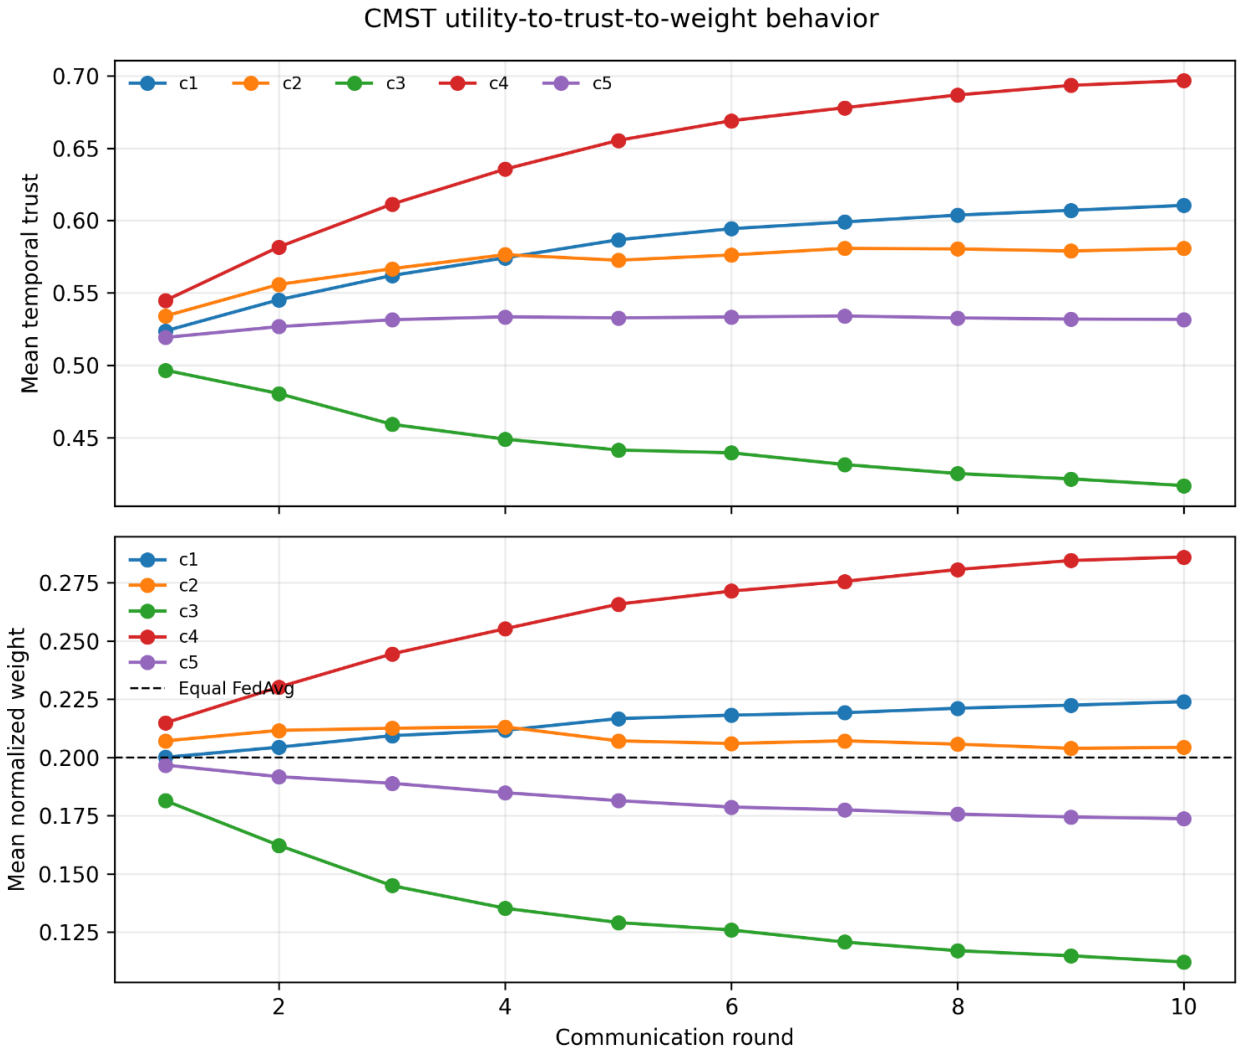

Fig. 4. CMST-FL temporal trust and normalized aggregation-weight trajectories, averaged over the 27 evaluation conditions. The dashed weight reference is the equal 0.20 allocation used because every client had 360 training examples.

Client C4 received the largest mean weight (0.261), whereas C3 received the smallest (0.134), confirming that CMST-FL materially changed the optimization weights. Nevertheless, all clients had 360 training examples, so this experiment isolates the trust multiplier and does not empirically validate behavior under unequal sample counts.

E. Robustness Across Missingness Conditions

Fig. 5 and Table VIII report performance across the held-out evaluation grid. The CMST-FL R^2 gain over FedAvg was positive in every mechanism–rate cell after averaging three seeds. The largest mean gain occurred for MCAR at 30% (+0.01107), while the smallest occurred for block missingness at 50% (+0.00281). CMST-FL also had the highest R^2 among the four federated strategies in each of the 27 conditions. Because the validation bank used the same mechanism families, these results demonstrate robustness within MCAR, MAR, and block missingness—not generalization to genuinely unseen mechanisms.

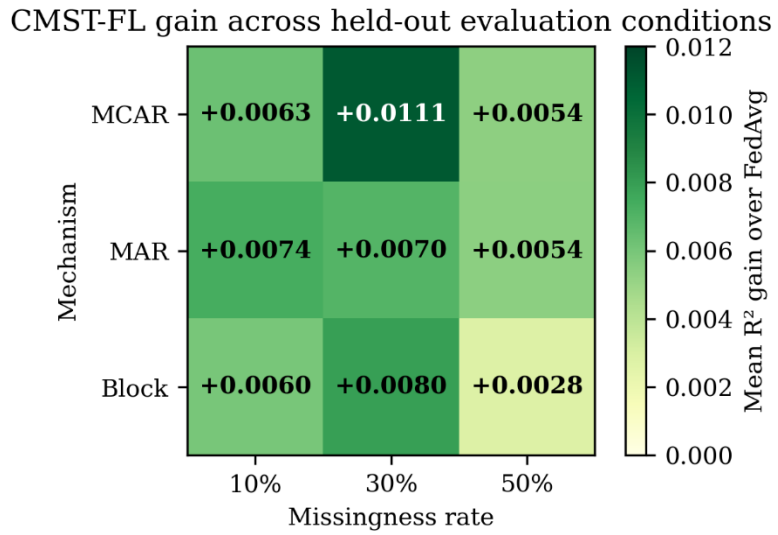

Fig. 5. Mean CMST-FL test R^2 gain over FedAvg by missingness mechanism and rate. Every cell is positive; each cell averages three seeds.

TABLE VIII. MEAN TEST R^2 BY MISSINGNESS CONDITION (THREE SEEDS)

Mechanism	Rate	Centralized	FedAvg	CMST-FL
MCAR	10%	0.0052	0.0097	0.0160
MCAR	30%	0.0065	0.0039	0.0149
MCAR	50%	0.0019	0.0047	0.0100
MAR	10%	0.0131	0.0065	0.0139
MAR	30%	0.0108	0.0074	0.0144
MAR	50%	0.0008	0.0064	0.0118
Block	10%	0.0166	0.0133	0.0193
Block	30%	0.0017	0.0049	0.0129
Block	50%	-0.0164	0.0009	0.0037

F. Centralized–Federated Gap

CMST-FL exceeded the matched centralized R^2 and reduced matched RMSE in 18 of 27 conditions. Averaged over all conditions, CMST-FL improved R^2 by 0.00851 and reduced RMSE by 0.00141 relative to the centralized reference. This result should not be read as a general advantage of FL: the centralized model has access to pooled data but was constrained to the same compact architecture, ten epochs, and a reduced dataset. The defensible conclusion is that CMST-FL reduced and, in this benchmark, slightly reversed the average centralized–federated gap under the fixed budget.

VI. DISCUSSION

A. Why CMST-FL Helped

Three design elements plausibly explain the consistency. First, trust is based on improvement relative to the received model, rather than absolute local performance. Second, the bank discourages an update that is beneficial under one mask but harmful under another. Third, temporal smoothing limits abrupt reweighting from a single noisy validation round. The sample-count factor retains FedAvg's preference for estimates supported by more local examples.

The results also show why significance alone is insufficient. All 27 paired R^2 and RMSE differences favored CMST-FL, producing very small p-values, yet the absolute error reduction was about one-thousandth. This is encouraging evidence of a stable directional effect, not evidence of a large clinical benefit. The low absolute R^2 values indicate that the compact four-input model explains little test variance and that the task remains difficult after aggressive subsampling.

B. Preprocessing Interpretation

Iterative imputation was preferred because it combined the lowest direct imputation error with strong centralized validation results and moderate runtime. It did not lead to the best individual downstream metric: KNN achieved slightly stronger FedAvg validation R^2. The multi-objective score makes this trade-off explicit. Therefore, the article can answer which tested method was best under the defined score and budget, but it should not claim that iterative imputation is universally superior. Longer DAE training, different signal windows, or richer temporal models could change the ranking.

C. Comparison with FedProx and Guarded Weighting

FedProx produced nearly the same mean R^2 as FedAvg under the single fixed coefficient μ=0.01 and one local epoch.

Because no coefficient sweep was performed, the result characterizes only this configuration and cannot establish a general limitation of proximal regularization. FedGuard improved mean R^2 over FedAvg but remained below CMST-FL. Its validation gate accepted a nonzero trust mixture in 38 of 270 server rounds (14.1%), so most rounds retained sample weighting.

D. Practical Implications

CMST-FL is most applicable when each participating institution can reserve a local validation segment and evaluate client updates under several plausible missingness conditions without sharing raw patient data. Compared with FedAvg, the additional client-side workload consists mainly of validation inference under the three conditions in the missingness bank. The server then calculates the utility, updates the temporal trust values, and normalizes the aggregation weights. These server-side operations are lightweight relative to local model training. However, institutions must maintain representative local validation data, and the choice of missingness conditions should reflect the types of signal loss expected in the intended application. The archived experiment controller recorded a total runtime of 5.081 hours for the complete two-stage pipeline. The experiment was executed on a 64-bit Windows 10 Pro laptop equipped with an Intel Core i3-5005U CPU operating at 2.00 GHz, two physical cores, four logical processors, and 7.9 GB of RAM. Although the laptop included Intel HD Graphics 5500, TensorFlow detected no GPU accelerator; consequently, the experiment used CPU-only execution. The hardware specifications were verified on the same machine after the experiment was completed. The reported runtime should therefore be interpreted as an observed result for this specific hardware and experimental configuration rather than as a hardware-normalized performance benchmark. Nevertheless, completing the pipeline on modest hardware suggests that the proposed framework can be evaluated without specialized high-performance computing resources. Its practical value remains subject to confirmation using larger client populations, longer training schedules, and full-resolution physiological signals.

VII. Evidence-Supported Final Model

The experiment supports one concrete model for the present benchmark: training-only iterative imputation followed by CMST-FL aggregation. The decision was not selected from the final test results. Iterative imputation was frozen after Stage A because it minimized the development score; the complete CMST configuration was then evaluated on disjoint patients. Table IX records the resulting model so that the contribution is reproducible and falsifiable.

TABLE IX. Final Empirical Configuration of the CMST-FL Model

Component	Selected specification	Evidence or role
Preprocessing	Iterative chained regression; 10 iterations; median initialization	Best composite score 0.35 and lowest imputation RMSE 0.7712
Normalization	Training-only pooled sufficient statistics	Prevents validation/test leakage
Predictor	PLETH, II, V and aVR → RESP; dense 128–64–1 network	Same compact architecture across strategies
Trust evidence	Relative local-versus-global composite quality gain under MCAR, MAR and block at 30%	Measures cross-mechanism marginal utility
Stability	Mean gain − 0.5 SD − worst-case negative-gain penalty	Discourages brittle or harmful updates
Temporal memory	ρ=0.8; logistic temperature 0.05; initial trust 0.5	Reduces round-to-round volatility
Aggregation	$n_i(0.05 + T_i)^2$ normalized across clients	Equal n_i=360 here; unequal-sample behavior remains untested
Observed outcome	R^2 0.0130; RMSE 0.3298; MAE 0.2624	Best mean pooled metrics among tested strategies

The strongest result is consistency rather than magnitude: CMST-FL improved R^2 and RMSE over FedAvg in every matched condition, yet the absolute error reduction was small. Consequently, the final model should be presented as an evidence-supported prototype that narrows the tested federated performance gap, not as a guaranteed optimal or clinically validated model.

VIII. Threats to Validity and Limitations

The primary limitation is scale. The evaluation used 27 of the 53 BIDMC records, each restricted to 200 uniformly spaced rows, five clients, and one dataset. Training stopped after 10 synchronous rounds, so the ranking is a fixed-budget comparison rather than evidence of convergence. Larger client populations, longer training, full-resolution windows, and external datasets are required before population-level or clinical claims can be made.

Second, missingness was synthetically injected. MCAR, propensity-based MAR, and contiguous blocks represent different patterns, but real sensor loss may be nonstationary, device-specific, or missing-not-at-random. The validation bank used the same three families as the evaluation grid, so genuinely unseen mechanisms were not tested. Third, the small feed-forward predictor did not model temporal windows, which helps explain the low R^2 values. Fourth, all clients had equal sample counts, leaving the sample-aware factor untested under quantity heterogeneity.

Fifth, Stage A used two seeds and Stage B three seeds. The client-cluster analysis exposes the resulting uncertainty but cannot overcome having only five clusters. The DAE received only three epochs, FedProx used only μ=0.01, and CMST-FL hyperparameters were fixed. No component ablation removed the stability, worst-case, temporal, or nonlinear-weighting terms; consequently, the current experiment supports the complete formulation but cannot attribute the gain to an individual component. Hardware specifications were verified after execution on the same machine, although separate wall-clock times and communication overhead for the individual

strategies were not recorded. Future work will address these limitations with DAE and FedProx sensitivity analyses, incremental CMST-FL ablations, at least 30 rounds, more clients, unseen mask families, unequal sample sizes, and stronger temporal predictors.

IX. Conclusion

This study introduced CMST-FL as a two-stage preprocessing-and-aggregation framework for incomplete physiological signals. Its distinguishing formulation evaluates each client update against the received global model with a composite quality score across several missingness mechanisms, penalizes unstable and worst-case harmful gains, and smooths trust across rounds. Stage A selected iterative imputation under the predeclared multi-objective score; Stage B found that CMST-FL improved R^2 and RMSE over FedAvg in all 27 matched conditions and achieved the best mean pooled metrics among the tested strategies.

The evidence therefore supports iterative training-only preprocessing followed by cross-missingness stable-trust aggregation for this benchmark. The novelty claim is specific to this integration and formulation. The low absolute R^2, small error reductions, wide client-cluster intervals, fixed 10-round budget, and lack of ablations preclude claims of universal or clinical superiority.

Reproducibility and Data Availability

The BIDMC PPG and Respiration Dataset is publicly available from PhysioNet subject to its terms [1], [2]. The experimental archive preserves configuration files, deterministic seeds, patient partitions, missingness masks generated from stable identifiers, raw per-run JSON/CSV logs, console logs, and scripts used to create the publication tables. An anonymized code-and-results archive can be released with the manuscript. No new patient data were collected.

Evidence and figure provenance: Reported experimental values and Fig. 2, 3, and 5 were computed from the archived Stage A and Stage B CSV/JSON outputs. Fig. 4 was computed from the archived per-client utility, trust, and weight logs. Fig. 1 is a conceptual workflow. All figures were created programmatically; no generative-image model was used. Displayed values are rounded, and intervals and p-values are derived statistics rather than raw observations.

Declarations

Conflict of interest: The authors declare no conflict of interest. Ethical statement: The study used an openly available, de-identified dataset and involved no new human-participant data collection. Data availability: The source dataset is publicly available through PhysioNet [1], [2]; the analysis code and derived result tables can be supplied as supplementary material.

AI-assisted writing disclosure: A generative-AI assistant supported language editing, organization, equation typesetting, formatting, and evidence cross-checking; it did not generate experimental observations or numerical results. The authors remain responsible for independently verifying the code, logs, calculations, citations, claims, and final text.

A Fairness–Utility Evaluation Framework for Assessing Large Language Models (LLMs)

Samah Alhazmi
Computer Science Department, College of Computing and Informatics,
Saudi Electronic University, Riyadh 11673, Saudi Arabia

***Abstract*—Large language models are increasingly used in contexts where their outputs can affect people directly, including hiring, admissions, and lending. This growing role makes it important to consider not only how well these models perform, but also whether their behavior is fair. Although many fairness metrics, bias benchmarks, and mitigation techniques have been proposed, there is still limited guidance on how fairness and predictive performance can be evaluated together through a consistent procedure. This study presents a five-stage Fairness–Utility Evaluation Framework that brings together dataset selection and preparation, model assessment, fairness evaluation, utility evaluation, and trade-off analysis and reporting. Rather than introducing a new metric, the framework organizes these elements into a structured and reproducible evaluation process. Its application is illustrated using LLaMA-2–7B, CrowS-Pairs, and WinoBias to show how the five stages can be followed in practice; the example is intended to demonstrate the procedure rather than provide new experimental results. Documentation is incorporated throughout the process so that evaluation choices, measures, and outcomes can be traced and reviewed. The resulting framework provides researchers and professionals with a structured way to consider fairness and performance together when evaluating an LLM for potential deployment.**

***Keywords*—Large language models; fairness–utility evaluation; AI governance; natural language processing**

I. Introduction

Large language models are no longer limited to research environments. They are increasingly used in education, employment, and other contexts where their outputs may affect people directly [1]. Their broad language capabilities have supported this wider use.

Fairness has consequently become an important concern in the evaluation of LLMs. LLMs are trained on large collections of text that may contain historical stereotypes and demographic biases [2], [3]. Models can learn these patterns during training and reproduce them in their outputs, which may lead to biased outcomes when the models are applied.

Several approaches have been developed to reduce bias in LLMs. These methods can be applied to the training data, during model training, or to the outputs after generation. However, improving fairness may also affect predictive performance [4]. For this reason, evaluating a model requires considering fairness together with its performance on the intended task.

Recent studies have examined fairness from several perspectives. A survey of 121 studies [5] examined bias sources as well as methods for detecting, evaluating, and mitigating bias. Fairness–utility relationships have also been examined in text-to-image generation [6], while another study investigated how LLMs respond to fairness-related questions in resource-allocation tasks [7]. Despite this progress, studies still vary in how fairness and utility are evaluated and reported. A consistent and reproducible procedure for assessing both within the same evaluation remains limited.

This study addresses that gap. Much of the existing LLM fairness literature focuses on individual metrics, mitigation techniques, or specific models. Less attention has been given to combining these elements within the same evaluation process. Documentation also receives limited attention, even though it is needed to understand how an evaluation was conducted and how its findings were reached. Bringing fairness, utility, and documentation into one framework could provide a clearer basis for evaluating an LLM before deployment.

To address this need, this study proposes a Fairness–Utility Evaluation Framework. The framework follows a common sequence that begins with benchmark selection and preparation, then moves through model assessment, fairness and utility evaluation, and trade-off analysis and reporting. The procedure can be applied across different LLMs and application contexts.

Documentation is maintained throughout the framework and is not limited to the final reporting stage. Recording the evaluation procedure, key choices, and supporting evidence makes it possible to review how the assessment was conducted. Considering fairness and predictive performance within the same process also helps evaluators use both types of evidence when making decisions about LLM deployment.

A. Research Contributions

The main contributions of this study are as follows:

- A Fairness–Utility Evaluation Framework organized into five stages, covering the evaluation process from dataset preparation to trade-off analysis and reporting.
- An approach that evaluates fairness and utility together, allowing their results to be interpreted within the same assessment.
- A model- and benchmark-independent structure that can be used with different LLMs, benchmarks, and application contexts.
- An illustrative example using established fairness benchmarks to demonstrate how the framework can be applied in practice.

These contributions provide a common structure for evaluating fairness and utility while incorporating documentation relevant to AI governance.

B. Research Questions

Three research questions guide the study:

- RQ1: What components should a comprehensive fairness–utility evaluation framework include?
- RQ2: How can fairness assessment and predictive-performance evaluation be integrated into one unified, reproducible workflow?
- RQ3: How can documentation and governance-oriented reporting be built into that workflow to support transparency and accountability in LLM deployment?

The remainder of the study is organized as follows. Section II reviews prior work on bias, fairness evaluation, and governance in LLMs. Section III presents the framework and its five stages, followed by the illustrative example in Section IV. Section V discusses the implications and limitations of the proposed framework, and Section VI concludes the study.

II. Related Work

A. Bias in Large Language Models

Concerns about bias in language models are not new. Early research identified social stereotypes in word embeddings. Bolukbasi et al. [8] examined gender associations in word embeddings and how they can influence later language-processing tasks. Caliskan et al. [3] reported that patterns learned from language data can reflect biases present in society.

The issue remains relevant for LLMs because they are trained on large and diverse text collections that may contain historical and demographic biases. These patterns can be learned during training and later appear in model outputs. Blodgett et al. [2] emphasized that fairness in language technology cannot be understood through technical measures alone, since judgments about bias also depend on social and contextual factors. This makes it important to consider how bias is defined, evaluated, and addressed throughout the model lifecycle.

B. Fairness Evaluation Datasets

Evaluating fairness requires benchmarks built to surface specific kinds of bias under controlled conditions. CrowS-Pairs [9] does this by pairing stereotypical and anti-stereotypical sentences across several demographic categories and checking which one a model prefers. WinoBias [10] takes a narrower angle, using occupational stereotypes in coreference resolution to test whether predictions shift with gender.

CrowS-Pairs and WinoBias examine different forms of bias and therefore provide different information about model behavior. Using multiple benchmarks can cover a broader range of demographic contexts and tasks than relying on a single benchmark.

C. Bias Mitigation Approaches

Bias mitigation methods are usually grouped according to when they are applied. Pre-processing methods modify the data before training begins [11]. In-processing methods introduce fairness objectives during model training, often through constrained optimization or adversarial learning [12]. Post-processing methods are applied to model outputs after training. Self-Debias [13] is one example that uses prompting to identify and reduce biased language in generated text.

These methods can improve fairness, but they may also affect predictive performance [4]. Evaluating both fairness and utility helps determine how a mitigation method changes the model's overall behavior.

D. Fairness Frameworks and Governance

Fairness research has also considered broader evaluation and governance frameworks. A review of 121 studies [5] examined bias sources together with methods for detection, evaluation, and mitigation across the NLP lifecycle. The review identified considerable variation in evaluation practices and highlighted the need for more systematic and reproducible procedures.

Fairness and utility have also been studied together in other areas of generative AI. Bochernitsan et al. [6] developed a Pareto-frontier benchmarking framework to examine fairness–utility trade-offs in text-to-image models. Although the application differs from LLMs, the study provides an example of evaluating changes in fairness and utility together. Cookson et al. [7] examined fairness from another perspective by studying how LLMs respond to resource-allocation problems involving fairness considerations.

Broader benchmarking frameworks are also relevant. HELM [14] evaluates language models across multiple scenarios using seven metrics, including fairness, accuracy, robustness, and efficiency. It supports standardized comparisons across models and scenarios. The framework proposed in this study serves a different methodological purpose: rather than benchmarking models across scenarios, it structures the fairness–utility relationship itself into a decision-oriented procedure, incorporating predefined decision criteria and governance-oriented documentation that connect the evaluation to a specific deployment recommendation.

Governance also affects how model evaluations are documented and reviewed. Organizations need records of the evaluation procedure, the evidence obtained, and the basis for decisions about model use. Such documentation can support transparency, accountability, and subsequent auditing [15]. Including these records as part of the evaluation process can also help when deployment decisions are reviewed later.

Three recent studies are particularly relevant to the proposed framework. HALF [16] presents a five-stage pipeline for evaluating fairness in LLMs, with an emphasis on weighting the severity of harms across deployment domains. It does not combine fairness and utility in a dedicated trade-off stage or include governance-oriented reporting. de Lima et al. [17] evaluate fairness and utility within a benchmarking procedure that includes dataset preparation, metric selection, and statistical testing. Their study focuses on adversarial fair-learning models rather than LLMs. Templin et al. [18] propose a five-step audit workflow for LLMs in healthcare. Their approach is specific to healthcare and gives particular attention to stakeholder engagement and model calibration.

These studies share some elements with the proposed framework, but their objectives and scope differ. The framework presented here combines benchmark preparation, fairness assessment, utility evaluation, documentation, and trade-off analysis within one procedure that can be applied across different LLMs and application domains.

E. Research Gap and Framework Contribution

Existing research provides established benchmarks, evaluation measures, and mitigation methods for studying bias in language models. Recent work has also considered fairness–utility relationships and governance requirements, but these elements are often examined separately. For LLMs, methodological guidance remains limited on how to bring them together within a consistent evaluation process. The proposed Fairness–Utility Evaluation Framework addresses this gap by connecting benchmark preparation, model assessment, fairness and utility evaluation, trade-off analysis, and documentation within one procedure. Its structure does not depend on a specific model or benchmark, allowing it to be applied across different LLMs and application contexts.

Table I compares the proposed framework with four closely related studies in terms of their purpose, treatment of fairness and utility, governance-oriented reporting, applicability across models and datasets, and empirical validation.

TABLE I. COMPARISON OF THE PROPOSED FRAMEWORK WITH CLOSELY RELATED WORK

Dimension	[5]	[6]	[7]	[14] (HELM)	Proposed Framework
Primary focus	Review of bias sources, evaluation, and mitigation across the NLP lifecycle	Fairness–utility benchmarking for text-to-image generation	LLM responses to fairness in resource-allocation tasks	Multi-metric LLM benchmarking (fairness, accuracy, robustness, efficiency)	Fairness–utility evaluation framework for LLMs
Joint fairness–utility evaluation	Discussed, not operationalized	Yes (vision domain)	No (fairness-focused study)	Partial (same evaluation suite, no dedicated trade-off stage)	Yes (NLP/LLM domain)
Governance-oriented reporting	Not addressed	Not addressed	Not addressed	No dedicated reporting stage	Dedicated framework stage
Model/dataset independence	N/A (review)	Text-to-image models only	Resource-allocation tasks only	Defined scenarios and metrics	Model- and benchmark-agnostic
Empirical validation	N/A (review)	Yes, multiple T2I models	Yes, multiple LLMs	Yes, 30 models / 42 scenarios	Illustrative application only

TABLE II. MAIN COMPONENTS OF THE PROPOSED FAIRNESS–UTILITY EVALUATION FRAMEWORK

Stage	Inputs	Objective	Output	Key Constraints
Dataset Selection & Preparation	Candidate benchmarks; application context; fairness dimensions of interest	Select and prepare benchmark datasets	Evaluation-ready datasets	Public and established benchmarks are preferred where appropriate; cleaning, validation, and formatting decisions are documented before evaluation.
Model Assessment	Prepared datasets; selected model; prompting and inference configuration	Generate model outputs using standardized inputs	Model predictions and responses	Model version, prompting strategy, and inference parameters — including decoding settings and the random seed where applicable — are specified and recorded before evaluation; repeated runs are used where outputs are stochastic.
Fairness Evaluation	Model outputs; demographic attributes of interest; predefined outcome mapping	Assess fairness-related behavior	Fairness indicators	Outcome mapping and demographic groupings are defined before analysis; fairness metrics are selected according to the fairness question and output structure.
Utility Evaluation	Model outputs; ground-truth labels where available	Measure predictive performance	Utility metrics	Utility metrics must match the benchmark and task design; metrics requiring ground-truth labels are used only when such labels are available.
Trade-off Analysis & Reporting	Fairness indicators; utility metrics; predefined decision criteria	Examine fairness and utility findings together	Evaluation report, deployment recommendation, and evaluation manifest	Thresholds and decision criteria are specified before results are interpreted; any aggregation across metrics, groups, or benchmarks must be predefined and documented; uncertainty or variability is reported where applicable.

III. PROPOSED FAIRNESS–UTILITY EVALUATION FRAMEWORK

A. Overview of the Proposed Framework

The Fairness–Utility Evaluation Framework provides a common process for examining fairness alongside predictive performance. Rather than treating the two as separate parts of model evaluation, it considers fairness measures in relation to how well the model performs on the task under assessment. This approach is consistent with recent calls for more systematic evaluation practices across the LLM lifecycle [5]. In doing so, the framework addresses RQ1 through its five-stage structure, RQ2 through the joint treatment of fairness and utility, and RQ3 through the documentation embedded at each stage.

The process is organized into five stages. It begins with preparing the evaluation data and assessing the model, followed by fairness and utility evaluation. The findings are then considered together in the final stage. Using the same sequence

allows different models and benchmarks to be evaluated through a consistent process across different applications.

The framework is not built around a specific LLM or benchmark. Evaluators can choose the datasets and measures that fit the evaluation at hand while keeping the overall process unchanged. This also means that new models, benchmarks, or metrics can be introduced without having to redesign the framework.

Documentation is maintained as the evaluation progresses. At each stage, evaluators record the relevant inputs, conditions, measures, and decisions. Keeping these details with the evaluation makes it easier to understand how the final assessment was reached and supports the transparency and accountability emphasized in responsible AI governance guidance [15].

The five stages are:

- Dataset Selection and Preparation
- Model Assessment
- Fairness Evaluation
- Utility Evaluation
- Trade-off Analysis and Reporting

Fig. 1 shows how the five stages connect within the overall evaluation process. Table II specifies, for each stage, the required inputs, objective, output, and the key procedural constraints that must be satisfied.

Fig. 1. Overall architecture of the proposed framework.

B. Dataset Selection and Preparation

The first step is to choose benchmark datasets that reflect the fairness dimensions relevant to the application being considered. This choice matters because the data used for evaluation influence which fairness concerns can actually be observed. Where suitable benchmarks are available, the framework gives preference to public and established datasets. Their use supports reproducibility and comparison with findings from other studies [9], [10].

Before evaluation, the selected datasets are prepared to ensure that they can be used consistently. This includes recording the benchmark version, cleaning the data, checking their integrity and consistency, and bringing them into the required format. These preparation steps help prevent data problems from being mistaken for differences in model behavior [5]. Fig. 2 summarizes the process, showing how raw datasets move through cleaning, validation, and formatting before becoming ready for model assessment.

Fig. 2. Dataset preparation pipeline.

C. Model Assessment

After the datasets have been prepared, the selected model is run on standardized inputs taken from the benchmarks. The purpose at this stage is to obtain the model outputs needed for later analysis. Fairness and utility are examined in the stages that follow.

The evaluation procedure should remain consistent across runs, particularly the inputs and prompting method, so that the outputs are generated under comparable conditions, unless prompt variation is itself a deliberate part of the evaluation design, in which case the range of prompts used must be specified in advance. The model version, prompting strategy, inference parameters, and other relevant evaluation conditions are also recorded. These details document how the outputs were produced and allow subsequent assessments to review or reproduce the evaluation setup [15].

Because LLM generation can be stochastic, decoding parameters such as temperature and top-p or top-k, and the random seed where supported by the model or inference framework, must be specified and recorded alongside the model version and prompting strategy. Where outputs vary across repeated runs under the same configuration, the evaluation should include multiple repeated runs, with the number of runs and the resulting variability reported as part of the evaluation record. This variability should subsequently be reflected in the uncertainty measures reported at the Trade-off Analysis and Reporting stage.

D. Fairness Evaluation

$$BS = | P(\hat{y} = 1 \mid A = g_1) - P(\hat{y} = 1 \mid A = g_2) | \quad (1)$$

$$FR = P(\hat{y} = 1 \mid A = g_D) / P(\hat{y} = 1 \mid A = g_A) \quad (2)$$

In Eq. (1), g_1 and g_2 represent the two demographic groups compared under attribute A. A BS value closer to zero indicates a smaller difference between the groups, consistent with the statistical-parity criterion in [20]. Eq. (2) follows the disparate-impact formulation in [21] and compares the positive outcome rate for a disadvantaged group g_D with that of an advantaged group g_A. An FR value close to 1 indicates greater parity, while lower values indicate a larger disparity. The four-fifths rule provides an established reference for interpreting this ratio. BS and FR can be calculated separately for relevant demographic categories and incorporated into the overall fairness assessment; both are established measures in the algorithmic-fairness literature [20], [21] and are used here as components of the proposed framework.

Before BS or FR is calculated, the evaluator must define the outcome variable used in the application. For tasks that already produce categorical predictions, the benchmark label or task decision can be used directly. For open-ended generation, outputs must first be mapped to a predefined categorical or binary outcome using a documented coding rule, classifier, rubric, or human-annotation protocol. The positive outcome must be defined before evaluation and applied consistently across demographic groups. Because this transformation can affect the resulting disparity estimates, the mapping procedure

and its validation or agreement evidence must be reported as part of the evaluation record.

The resulting fairness assessment summarizes the disparities identified during evaluation and provides evidence for determining whether particular demographic groups require further examination.

Fig. 3 shows how model outputs are converted into fairness indicators and incorporated into the assessment report.

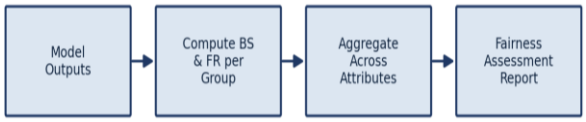

Fig. 3. Fairness evaluation process.

E. Utility Evaluation

The utility evaluation stage examines how well the model performs the task being assessed. Performance is measured using metrics appropriate to the task and benchmark. For prediction tasks with defined ground truth, commonly used measures include Accuracy, Precision, Recall, and F1-score.

Additional measures may be used depending on the task or application. With TP, TN, FP, and FN denoting true positives, true negatives, false positives, and false negatives:

$$Accuracy = (TP + TN) / (TP + TN + FP + FN) \quad (3)$$

$$Precision = TP / (TP + FP) \quad (4)$$

$$Recall = TP / (TP + FN) \quad (5)$$

$$F1 = 2(P \times R) / (P + R) \quad (6)$$

Accuracy measures the proportion of correct predictions. Precision and Recall describe different aspects of classification performance, while F1 combines the two through their harmonic mean. These metrics can also be reported separately for demographic groups to identify differences in model performance. The results can then be considered alongside the fairness measures defined in Eq. (1) and (2).

The choice of utility metric depends on the benchmark and whether ground-truth labels are available. WinoBias provides coreference-resolution labels that allow measures such as Accuracy and F1 to be calculated. CrowS-Pairs follows a different evaluation design based on model preferences between stereotypical and anti-stereotypical sentence pairs and does not provide conventional ground-truth labels for classification metrics. Utility measures should therefore match the evaluation procedure supported by each benchmark.

Fairness and utility results should be considered together when evaluating a model for potential deployment. Improvements in fairness may affect predictive performance [4], while strong overall performance does not necessarily indicate similar behavior across demographic groups. Considering both provides a clearer view of these differences.

F. Trade-Off Analysis and Reporting

The final stage considers the fairness and utility findings together. The results are compared to examine how the two dimensions relate and whether the overall outcome is suitable for the intended application. This judgment depends on the criteria established for the specific evaluation context. The final report records the benchmarks and metrics used, along with any assumptions or limitations relevant to interpreting the findings. It also documents the evidence supporting the deployment recommendation.

Fairness and utility results are reported at the level of the individual metric, demographic group, and benchmark rather than collapsed into a single overall score, since a single aggregate value can obscure disparities that affect specific groups. Where multiple metrics, groups, or benchmarks are combined into a summary judgment, the aggregation rule must be specified and justified in advance, together with the rationale for any weighting applied. Where estimates are subject to sampling or stochastic variation, the report should include appropriate measures of uncertainty or variability, such as confidence intervals or repeated-run variation, as applicable to the evaluation design. The framework does not mandate a specific statistical test or effect-size measure, as the appropriate procedure depends on the benchmark, sample size, outcome type, and evaluation design.

The final evaluation record is consolidated into an evaluation manifest that identifies the model and benchmark versions, prompting and inference configuration, outcome-mapping rules, fairness and utility metrics, uncertainty information where applicable, and the predefined thresholds, aggregation rules, and decision criteria used in the assessment. The manifest provides a traceable record of the evaluation configuration and resulting deployment recommendation, supporting reproducibility, independent review, and governance oversight.

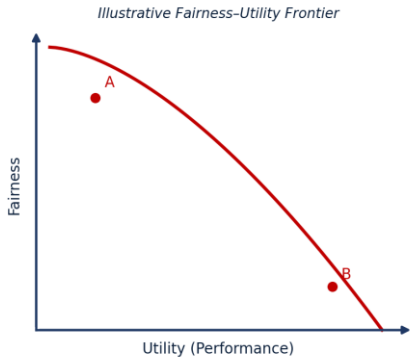

Fig. 4. Fairness–utility trade-off analysis.

This record also serves a governance purpose. Preserving the basis of the assessment can support risk assessment, compliance review, and later auditing [15]. The importance of considering fairness in relation to utility has also been recognized in benchmarking research involving other generative systems [6]. Fig. 4 shows how fairness and utility findings can be interpreted together and identifies cases where the overall outcome may call for further review. The curve represents an illustrative fairness–utility frontier rather than data from an actual evaluation; points

A and B mark two hypothetical outcomes along this frontier, showing how a model could favor fairness (point A) or utility (point B) depending on where it falls relative to the trade-off.

IV. Framework Demonstration: An Illustrative Walkthrough

A. Case Study Overview

This section illustrates how the proposed framework can be used in practice. The example follows its stages in sequence and does not report findings from an empirical experiment.

The example considers a representative LLM evaluation scenario. Its purpose is to show how each stage is applied and how fairness and utility are examined within the same evaluation process.

Following the structure introduced in Section III, the demonstration starts with dataset preparation and model assessment. It then moves to fairness and utility evaluation, followed by trade-off analysis and reporting. This sequence illustrates how evidence from both dimensions can inform the assessment of a model for potential deployment.

For this illustrative scenario, LLaMA-2–7B is designated as the model under consideration [19], and CrowS-Pairs and WinoBias are designated as example benchmark datasets, as they are established resources for examining different forms of bias in language models [9], [10]. Fig. 5 shows how these elements fit into the complete demonstration workflow.

Fig. 5. Illustrative demonstration workflow.

B. Dataset Selection and Preparation

The demonstration begins by selecting benchmarks that match the fairness questions being examined. CrowS-Pairs [9] is used to examine social stereotypes across demographic categories, while WinoBias [10] focuses on gender bias in coreference resolution.

The two datasets address different forms of bias and therefore provide different information about model behavior. In an empirical application, the datasets would be prepared and checked for consistency before model assessment. Any preprocessing or formatting choices would also be documented to support reproducibility. Table III summarizes the two benchmarks.

TABLE III. Example Datasets used in the Demonstration

Dataset	Bias Category	Evaluation Focus
CrowS-Pairs	Social stereotypes	Social stereotype assessment
WinoBias	Gender bias	Gender fairness assessment

C. Model Assessment

Once the datasets are prepared, the model would be run on standardized benchmark inputs. Its outputs would then provide the data needed for the fairness and utility assessments that follow.

LLaMA-2–7B is designated as the reference model for this illustrative demonstration because it is an established open-weight LLM [19]. The model selection is illustrative and does not represent an empirical evaluation of LLaMA-2–7B. The choice of model is specific to the demonstration; the framework itself can be applied to other LLMs using the same procedure.

The evaluation conditions would also need to be documented. These include the model version, prompting procedure, inference parameters, and any other conditions that could affect the generated outputs [15]. Recording these details would allow the evaluation setup to be reproduced in later assessments.

D. Fairness and Utility Assessment

The model outputs would be examined from both fairness and performance perspectives. Keeping the two assessments within the same process allows their findings to be considered together later in the evaluation.

The fairness measures would depend on the application and the demographic attributes being examined. Bias Score and Fairness Ratio are examples of indicators that could be used. Where appropriate, using several measures may reveal disparities that are less apparent when only one indicator is considered [2].

Performance would be evaluated using measures suited to the task and the structure of the benchmark. When ground-truth labels are available, these could include Accuracy, Precision, Recall, and F1-score.

Together, the fairness and performance findings would provide different but related information about the model's behavior. This evidence could help determine whether the model is suitable for the intended application [4]. Table IV summarizes the fairness, utility, and governance dimensions included in the demonstration, along with their corresponding measures and purpose.

TABLE IV. Example Evaluation Dimensions

Dimension	Metrics / Indicators	Purpose
Fairness	Bias Score, Fairness Ratio	Assess fairness-related behavior
Utility	Task-appropriate measures (e.g., Accuracy, Precision, Recall, F1-score where ground truth is available)	Assess predictive performance
Governance	Evaluation documentation and records	Support accountability

E. Trade-Off Analysis and Reporting

For this illustrative scenario, the final stage would consider the fairness and utility findings together to determine whether the model is suitable for the intended application. The assessment may also identify areas where further evaluation or mitigation is needed.

The report would record the benchmarks and measures used, together with relevant assumptions, limitations, and observations. These records would document the basis for the

assessment and provide evidence that can support later review or auditing [15].

Fig. 6 illustrates, in general terms, a decision matrix that could be used to consider fairness and utility together. The zone placement shown is illustrative and does not represent a computed assessment of LLaMA-2–7B. Models with high fairness and high utility would fall within the Preferred Zone, representing the most favorable conditions for deployment. Low results on both dimensions would place a model in the Reject Zone, where substantial improvement would be needed. The Risk Zone represents high utility but low fairness, indicating fairness concerns that require attention. The Review Zone represents high fairness but low utility, indicating a need to improve model performance. The terms High and Low in Fig. 6 are qualitative rather than fixed numerical thresholds. Thresholds for BS, FR, and utility measures should reflect the application, organizational risk tolerance, and relevant regulatory or ethical requirements. These thresholds should be defined in advance by the responsible evaluation or governance team and documented before the results are interpreted. Applying the same predefined thresholds and decision criteria allows independent evaluators to assign models to the four zones on a consistent basis.

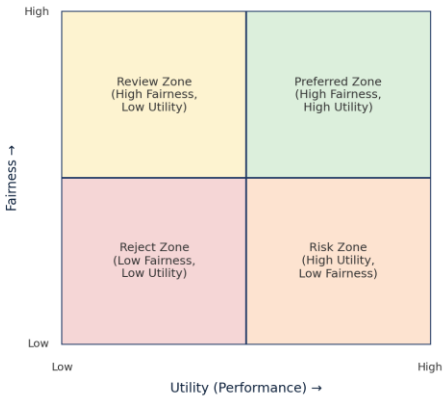

Fig. 6. Illustrative fairness–utility decision matrix for deployment decision support.

F. Discussion

The proposed framework brings these elements into a common sequence, beginning with benchmark preparation and continuing through fairness and utility evaluation to trade-off analysis and reporting. Following the same sequence allows the framework to be applied when the model, benchmark, or application changes.

This differs from approaches that focus on a particular mitigation technique or the evaluation of a specific model. Here, fairness and utility are examined as parts of the same procedure. Because the framework is not tied to a particular LLM architecture, the same sequence can be followed across different models without developing a separate evaluation approach for each one. This also provides a consistent structure for cross-model comparison.

Looking at fairness and utility together matters in practice because an improvement in one does not necessarily leave the other unchanged. Changes in fairness can occur alongside changes in predictive performance [4]. Examining both therefore gives a more complete picture when deciding whether a model is suitable for a particular application.

The framework is also intended to remain usable as LLM evaluation evolves. A different model, fairness measure, or benchmark can be introduced without redesigning the overall process. The individual components can therefore change with the application, available resources, or evaluation requirements while the sequence itself remains stable.

Documentation is part of this process rather than a separate activity at the end. The data and measures used are recorded together with relevant model parameters, assumptions, and limitations. These records allow others to see how the assessment was carried out and to reproduce its main evaluation conditions [15]. They also provide a basis for examining the evidence behind an evaluation when it is later reviewed by researchers or other stakeholders.

Section IV illustrates how this process can be followed using established benchmarks. Its purpose is to show how the stages fit together, including how the fairness and utility assessments relate to one another.

The illustration should not, however, be interpreted as empirical validation of the framework. Assessing its generalizability will require empirical evaluations across multiple LLMs and real deployment contexts. In particular, the use of CrowS-Pairs and WinoBias in Section IV illustrates how the procedure can be applied to established benchmarks; it does not establish external validity across contemporary instruction-following LLMs, nor does it represent the application-specific risks or affected populations relevant to a given deployment context. Its present scope is also limited to fairness and predictive performance. Explainability, robustness, privacy, security, and other responsible AI considerations are not evaluated here, although they could be incorporated into future extensions of the framework.

V. Conclusion

This study introduces a Fairness–Utility Evaluation Framework for assessing large language models. The framework provides a structured way to examine fairness alongside predictive performance while maintaining a record of the evidence generated throughout the evaluation.

Rather than introducing new metrics or benchmarks, the framework brings existing measures, benchmarks, and assessment methods into a common sequence. The same procedure can be applied across different LLMs and application contexts. Because the framework is not tied to a particular model architecture, the model or benchmark can change while the overall evaluation procedure remains consistent.

Section IV illustrates how the framework could be followed using LLaMA-2–7B, CrowS-Pairs, and WinoBias. The example shows how the proposed stages fit together and how fairness and utility findings would be considered within the same assessment. It demonstrates the procedure rather than providing an empirical evaluation and does not report new experimental results.

Documentation is maintained throughout the framework. Key evaluation decisions and supporting evidence are recorded so that the assessment can be traced and reviewed later. These records can support transparency and subsequent review or auditing, particularly when evaluation findings inform decisions about LLM deployment.

The next step in this research program is to test the framework empirically across different LLMs, benchmarks, and application contexts. The framework could also be expanded to address other responsible AI concerns, such as explainability, robustness, privacy, and security. Empirical applications would help assess its generalizability and identify aspects of the procedure that may require refinement. In its current form, the framework provides a methodological basis for examining fairness–utility trade-offs through a documented and reproducible evaluation process.

In relation to the research questions guiding this study, RQ1 is addressed through the five-stage structure presented in Section III; RQ2 through the framework's treatment of fairness and utility within a single evaluation sequence, illustrated in Sections III and IV; and RQ3 through the documentation and governance-oriented reporting embedded at each stage of the framework.

DECLARATIONS

Conflict of Interest: No conflicts of interest are declared.

Funding: This research received no external funding.

Data Availability: The benchmark datasets referenced in this study (CrowS-Pairs and WinoBias) are publicly available from their sources [9], [10]. No new datasets were generated in this study.

Declaration of Generative AI Use: Generative AI tools were used to assist with language editing, formatting, and restructuring during the preparation of this manuscript. The entire manuscript was reviewed and approved by the author. Generative AI was not used as an author or co-author. The research concept, methodology, framework design, analysis, and conclusions are the author's own original work.

***Abstract*—Reliable apple leaf disease classification requires high predictive performance and transparent computational reporting under heterogeneous field conditions. This study presents an orchard-image benchmark of four ImageNet-initialized convolutional architectures—Xception, EfficientNetB0, DenseNet121, and ResNet50V2—using images acquired at two Moroccan orchard locations (Midelt and Azrou), four cultivars, and three mobile devices. From a curated four-class corpus of 20,000 RGB images, 18,000 images (4,500 per class) formed the five-fold cross-validation benchmark; 2,000 images were isolated before fold construction as an untouched challenge reserve for future independent confirmation and were not evaluated in the present manuscript. All models used a common 224×224 input resolution, a harmonized classification head, Adam optimization, L1/L2 regularization, learning-rate reduction, and validation-loss early stopping. Evaluation combined accuracy, cross-entropy loss, macro-precision, macro-recall, macro-F1, specificity, Cohen's kappa, Matthews correlation coefficient, fold stability, parameter count, model size, GMACs/GFLOPs, and measured CPU training time. All reported values and figures derive from completed HPC-MARWAN runs under the common protocol. Xception achieved the highest observed mean validation accuracy (97.99±0.37%) and aggregate out-of-fold macro-F1 (97.99%), whereas EfficientNetB0 reached 97.33±0.68% mean validation accuracy with 0.78 GFLOPs per image, 5.29 million parameters, and the shortest CPU training time. The results define a descriptive accuracy–cost trade-off within the benchmark; no inferential superiority or device-level deployment latency is claimed.**

Keywords*—Apple leaf disease; convolutional architectures; field conditions; Xception; EfficientNetB0; DenseNet121; ResNet50V2; computational efficiency

I. Introduction

Apple foliar diseases reduce photosynthetic activity, fruit quality, and marketable yield, and field appearance depends on disease stage, cultivar, illumination, leaf orientation, background vegetation, and acquisition device. Shafik et al. [1] enumerated dataset, classification, and deployment problems in plant-disease detection. Pacal et al. [2] highlighted the significance of data quality and evaluation design for the performance of deep learning. Khan et al. [3] built a real-time deep-learning system for apple-specific diagnosis, and Wang et al. [4] proposed an evidence-fusion framework. These studies motivate evaluation under heterogeneous orchard conditions versus controlled imagery alone.

Deep convolutional neural networks (CNNs) learn features hierarchically directly from RGB images, but comparison of published studies is hampered by differences in image resolution, class balance, augmentation, partitioning, validation strategy, and reported metrics. Generalisation can be further affected by field variations in cultivar, illumination, background, and acquisition device. Therefore, a single hold-out split with high accuracy does not in itself validate model stability or transfer to unseen orchard conditions.

Computational reporting is a second limitation. Guan et al. [5] proposed a lightweight plant-disease classifier, Gao et al. [6] developed a lightweight YOLOv8 model for apple leaf disease detection, and Iftikhar et al. [7] integrated an enhanced CNN with a mobile application. These studies demonstrate the relevance of model size and computational demand. However, theoretical FLOPs and CPU training time are computational indicators rather than direct measurements of mobile or edge inference latency.

Information leakage is another methodological concern. Visually related photographs, near-duplicate acquisitions, or augmented derivatives originating from the same source image should not be distributed across training and validation partitions because such overlap can produce optimistic estimates. Shafik et al. [1] and Pacal et al. [2] identify dataset construction, transparent validation, and reproducible partitioning as central methodological requirements.

The contribution is methodological rather than the proposal of another CNN architecture. A common orchard-image and cost-aware benchmark is established for Xception, EfficientNetB0, DenseNet121, and ResNet50V2 using multi-site imagery, leakage-aware five-fold partitioning, a shared classification head, fold-level predictive and stability metrics,

and common computational indicators. Section II reviews related apple and plant-disease studies. Section III defines acquisition, partitioning, preprocessing, training, and evaluation. Section IV reports predictive and computational results; Section V interprets the measured trade-offs; Section VI states limitations and reproducibility requirements; and Section VII summarizes the conclusions and future validation priorities.

II. Related Work

Apple disease classification has progressed from high-capacity CNNs toward attention, segmentation, hybrid, and resource-efficient designs. Yadav et al. proposed AFD-Net for multi-class apple foliar disease recognition and reported strong five-fold performance on the Plant Pathology datasets [8]. Gao et al. introduced BAM-Net for complex-background apple leaf recognition through attention-guided feature extraction [9]. Parashar and Johri combined Inception-v3 with image segmentation and stratified five-fold cross-validation [10]. Si et al. integrated a CNN branch with a Swin Transformer to combine local and long-range representations [11]. Alqahtani et al. coupled EfficientNet with optimization-based feature selection [12], while Ait Nasser and Akhloufi studied a hybrid deep-learning architecture for apple foliar disease detection [13]. AppleLeafNet focused on compact classification [14]; MCDCNet proposed constrained deformable convolutions [15]; Zhu et al. presented a two-stage DeepLabv3+ segmentation framework [16]; LightYOLO-AppleLeafDx focused on lightweight detection [17]; and Zhou et al. explored a multimodal lightweight Transformer [18]. Further context on efficiency is provided by ALNet [19], EnConv [20], edge-device CNN deployment [21], and ensemble hybrid optimisation [22]. The fruit-disease frameworks [23], [24], the crop-disease review by Ngugi et al. [25], the apple-specific review by Kannan et al. [26], and Karasu's optimised apple-scab classifier [27] are other examples of such methodological diversity. Therefore, Table I provides a contextual comparison, rather than a direct performance ranking, across incompatible datasets and protocols.

TABLE I. Methodological Comparison of Representative Apple/Plant Disease Studies

Study	Year	Model/method	Dataset/scope	Validation	Best reported result	Main limitation/distinction
Yadav et al. [8]	2022	AFD-Net (EfficientNet-B3/B4)	Plant Pathology 2020/2021	Five-fold	98.7% accuracy	High-capacity fusion; public datasets
Gao et al. [9]	2023	BAM-Net with attention	Complex-background apple leaves	Hold-out	95.64% accuracy; 95.25% F1	Attention-based; limited cost reporting
Parashar and Johri [10]	2024	Segmentation + Inception-v3	1,821 apple-leaf images; 4 classes	Stratified five-fold	94.76% accuracy	Class imbalance and preprocessing dependence
Si et al. [11]	2024	CNN + Swin Transformer	Apple disease images; 4 classes	Hold-out	97.32% accuracy	Hybrid local/global feature modelling
Alqahtani et al. [12]	2023	EfficientNet + Sailfish optimization	9,714 apple-leaf images; 4 classes	Train/test	99.39% comparison result	Optimization-assisted high-complexity pipeline
Ali et al. [14]	2024	AppleLeafNet	Apple leaf disease images	Train/validation/test	98.25% condition identification	Lightweight deployment-oriented design
Zou et al. [17]	2025	LightYOLO-AppleLeafDx	Apple leaf disease detection	Detection benchmark	96.5% mAP@0.5	5.2 MB model; real-time orientation
Adithiyaa et al. [19]	2026	ALNet	Apple/grape/cherry leaf datasets	Five-fold + hold-out	99.95% apple accuracy	0.17 M-parameter lightweight model
Thanjaivadivel et al. [20]	2025	EnConv	39 plant-disease classes	Comparative classification	99.87% accuracy	Cross-crop enhanced CNN
Present benchmark	2026	Xception / EfficientNetB0 / DenseNet121 / ResNet50V2	Multi-site orchard corpus; 18,000 benchmark images	Leakage-aware five-fold	97.99% mean accuracy (Xception)	Joint accuracy-stability-cost analysis

The comparison highlights substantial variation in dataset origin, validation design, model complexity, and deployment evidence. The present work differs by treating predictive accuracy, fold stability, computational complexity, and runtime as joint selection criteria under one common orchard-image benchmark.

III. Materials and Methods

A. Study Design and Field Acquisition

Images were collected in commercial apple orchards in Midelt and Azrou, Morocco. The two sites differ in altitude, local microclimate, orchard conditions, illumination, and background context. Photographs were taken outdoors in natural light with leaves still attached to the trees and at morning, midday, and afternoon acquisition times to maintain realistic illumination variability.

Four cultivars were represented in the field records: Gala, Golden Delicious, Starking, and Red Delicious. Three mobile devices were used: Samsung Galaxy S21 Ultra, Xiaomi Redmi 13 Pro, and iPhone 12 Pro Max. The analytical labels were image-level visual symptom categories: powdery mildew, healthy apple leaf, apple scab, and apple mosaic/chlorotic symptoms. The available benchmark records do not document laboratory confirmation or formal multi-expert adjudication for every image; consequently, the labels are interpreted as visual symptom categories rather than etiologically confirmed diagnoses. This limitation is particularly relevant to the mosaic/chlorotic category, which may have multiple causal mechanisms. Label errors identified during quality screening were removed; however, a separate adjudication record for ambiguous cases is not available for the present benchmark. Representative examples are shown in Fig. 1. Phytotoxicity was excluded because it represents abiotic or chemical stress rather than a single pathogen-defined category.

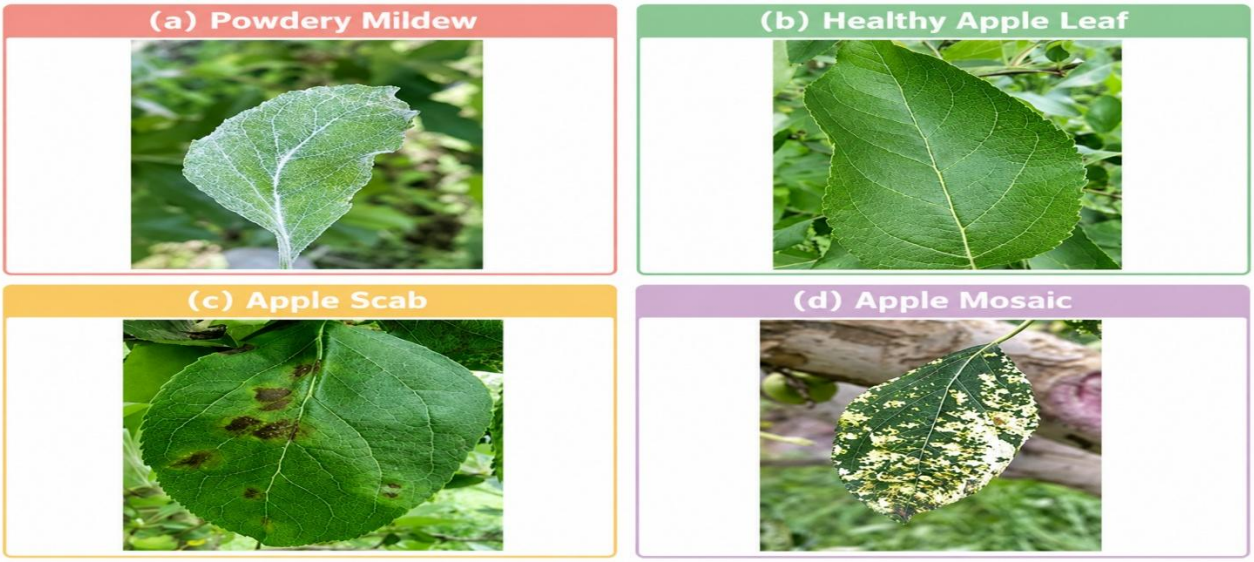

Fig. 1. Representative examples of the four analytical classes: powdery mildew, healthy apple leaf, apple scab, and apple mosaic/chlorotic symptoms.

B. Benchmark Construction and Leakage Control

The curated corpus contained 20,000 RGB images, corresponding to 5,000 images per class after controlled balancing and quality screening. A total of 18,000 images (4,500 per class) were assigned to five-fold cross-validation. The remaining 2,000 images were isolated before fold construction as an untouched challenge reserve. The reserve was excluded from architecture selection, early stopping, hyperparameter adjustment, fold construction, and all reported metrics. Its evaluation is deferred entirely to future independent confirmation, and no reserve-set performance is claimed in the present manuscript.

Before fold assignment, corrupted files, severe blur, label errors, exact duplicates, and visually redundant derivatives were screened. The guaranteed grouping unit was the original source image together with its augmented derivatives; all derivatives from a source image remained in the same fold. Complete leaf- and tree-level identifiers were not available for all acquisitions, so strict leaf- or tree-level independence across folds cannot be guaranteed. Where capture-session identifiers were available, near-duplicate images were grouped to reduce acquisition-context leakage; orchard-level separation was not imposed. Each iteration used 14,400 training images and 3,600 validation images, and every benchmark image served as validation data once. The reported five-fold results should therefore be interpreted as leakage-aware source-image-level internal validation rather than leave-one-tree, leave-one-session, or leave-one-orchard external validation. Fig. 2 summarizes the partitioning sequence.

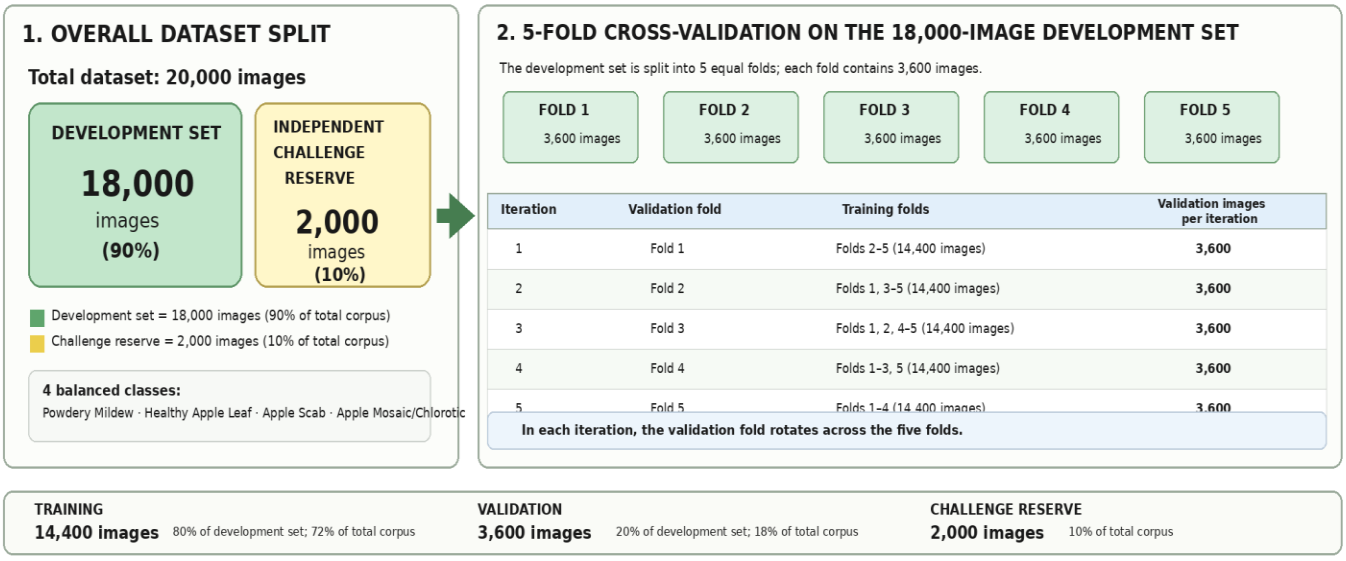

Fig. 2. Orchard-image benchmark design. The 2,000-image challenge reserve is isolated from the five-fold benchmark and is not used to derive the reported cross-validation results.

C. Preprocessing and Augmentation

Images were decoded in RGB format and resized to 224×224×3 pixels. Aspect-ratio-preserving padding was applied when necessary to reduce geometric distortion. Architecture-specific input normalization followed the preprocessing conventions of the corresponding Keras backbones. Validation images underwent deterministic resizing and normalization only.

Mild online augmentation was restricted to training folds. The transformation set included horizontal flipping, rotations within ±15°, translations up to ±8%, zoom up to ±10%, and moderate brightness/contrast adjustment. The limits were selected to preserve disease morphology while increasing robustness to leaf orientation and illumination. Augmentation was performed after fold assignment so that transformed variants could not cross the training-validation boundary.

D. CNN Architectures and Shared Classification Head

The four backbones were selected to represent established image-classification design families under one common protocol: Xception uses depthwise separable convolutions, EfficientNetB0 uses compound scaling, DenseNet121 uses dense feature reuse, and ResNet50V2 uses pre-activation residual learning. Shafik et al. [1] and Pacal et al. [2] provide broad plant-disease context; ALNet [19] and EnConv [20] illustrate recent lightweight and cross-crop alternatives; Ngugi et al. [25] review crop-disease diagnosis; Kannan et al. [26] summarise apple-leaf advances. The chosen set is representative, not exhaustive, and is not claimed to include the strongest current architecture. LightYOLO-AppleLeafDx was retained as a literature comparator, but not inserted into the controlled classification benchmark, as detection-specific or materially different pipelines.

For each backbone, the original classification layer was removed and replaced by global average pooling, batch normalization, a 256-unit ReLU dense layer, dropout, and a four-unit Softmax output. L1 and L2 penalties were applied to the dense layer, while pretrained batch-normalization layers remained in inference mode during fine-tuning. Table II reports architecture-specific batch sizes, dropout values, learning rates, fine-tuned regions, and convergence limits. These settings were selected to obtain stable training for each backbone; consequently, the comparison represents performance under defined architecture-specific configurations rather than an ablation that isolates backbone architecture as the sole causal factor.

TABLE II. ARCHITECTURE-SPECIFIC TRAINING CONFIGURATION

Model	Batch	Dropout	Head LR	Fine-tune LR	Fine-tuned region	Max. epochs	Observed stop range
Xception	8	0.40	1×10^{-4}	3×10^{-6}	Exit flow + upper middle-flow blocks	50	30–35
EfficientNetB0	24	0.30	3×10^{-4}	1×10^{-5}	Last 30–40 layers	50	40–47
DenseNet121	12	0.35	2×10^{-4}	5×10^{-6}	Final dense block	50	42–48
ResNet50V2	16	0.35	2×10^{-4}	5×10^{-6}	Final residual stage	50	40–48

E. Training and Convergence Control

Training and all recorded fold outputs used in Sections IV–V were generated with TensorFlow/Keras on HPC-MARWAN using eight CPU cores and 16 GB RAM. Adam used $\beta1 = 0.9$, $\beta2 = 0.999$, and $\varepsilon = 10^{-7}$. Each fold started from the same ImageNet initialization instead of inheriting weights from a previous fold. The classification head was optimized first, followed by low-learning-rate fine-tuning of an architecture-specific upper region. A single training run was conducted for each fold; repeated runs across multiple random seeds were not performed, so stochastic variability beyond fold-to-fold variation is not estimated.

A maximum of 50 epochs was initially specified for every architecture to provide sufficient optimization capacity. Validation loss was monitored with early stopping (patience = 5 epochs; minimum improvement = 10^{-4}), and the best validation-loss weights were restored. ReduceLROnPlateau used a reduction factor of 0.2, patience of two epochs, a one-epoch cooldown, and a minimum learning rate of 10^{-7}.

For Xception, convergence occurred earlier than the maximum training limit: the five folds stopped at epochs 30, 33, 31, 35, and 34. The training process was therefore not arbitrarily restricted to 35 epochs. Instead, the early-stopping criterion terminated optimization when validation accuracy and validation loss had reached a stable plateau over the predefined patience interval. Continuing beyond this point would have increased computational cost without providing a meaningful validation improvement, while potentially increasing overfitting risk.

F. Evaluation Metrics and Computational Analysis

Out-of-fold predictions were used to compute accuracy, macro-precision, macro-recall, macro-F1, macro-specificity, Cohen's kappa, and the Matthews correlation coefficient (MCC). For class c, TPc, TNc, FPc, and FNc denote the standard confusion-matrix quantities. Macro-averaging gives equal weight to each class:

$$\text{Accuracy} = \Sigma c\ TPc / N, \quad (1)$$

$$\text{Pmacro} = (1/C)\ \Sigma c\ [TPc /(TPc + FPc)], \quad (2)$$

$$\text{Rmacro} = (1/C)\ \Sigma c\ [TPc /(TPc + FNc)], \quad (3)$$

$$\text{F1macro} = (1/C)\ \Sigma c\ [2PcRc /(Pc + Rc)] \quad (4)$$

Categorical cross-entropy was used as the data loss. Fold stability was summarized by the standard deviation and coefficient of variation (CV) of validation accuracy, and the mean train-validation accuracy gap was reported descriptively. Because the five folds share overlapping training observations, they are not independent statistical samples. Complete leaf- and

tree-level group identifiers were also unavailable for all images; therefore, independent-sample significance tests and group-level resampling confidence intervals were not reported. In particular, the 0.66-percentage-point difference between Xception and EfficientNetB0 is treated as a descriptive benchmark difference and not as evidence of statistical superiority.

Computational cost was characterized by parameter count, model size, multiply-accumulate operations (GMACs), forward-pass GFLOPs, and measured wall-clock CPU training time per epoch. A convention of one MAC ≈ two FLOPs was applied consistently. Validation-accuracy points per GFLOP, per million parameters, and per CPU training minute were calculated only as descriptive within-benchmark ratios. CPU training time was measured on HPC-MARWAN; derived throughput and five-fold burden are arithmetic summaries. These values do not represent mobile/edge inference latency, energy, or peak memory.

IV. Results

A. Fold-Wise Predictive Performance

Predictive results and fold-specific stopping epochs are provided in Table III. The original four-panel learning-curve format is preserved: mean training accuracy, mean validation accuracy, mean training loss, and mean validation loss are shown separately to allow direct assessment of convergence and train-validation agreement. For visualisation, folds with different early-stopping points are aligned to a normalised epoch-progress scale, which is only relevant for the graphic display and not the original stopping epochs or reported metrics. The curves demonstrate progressive saturation of accuracy and reduction of loss without significant late-stage divergence. Xception showed the best validation trajectory among the tested configurations, while the other architectures converged at slightly lower levels. The four trajectories are shown in Fig. 3, and the fold-specific stopping epochs are listed in Table III.

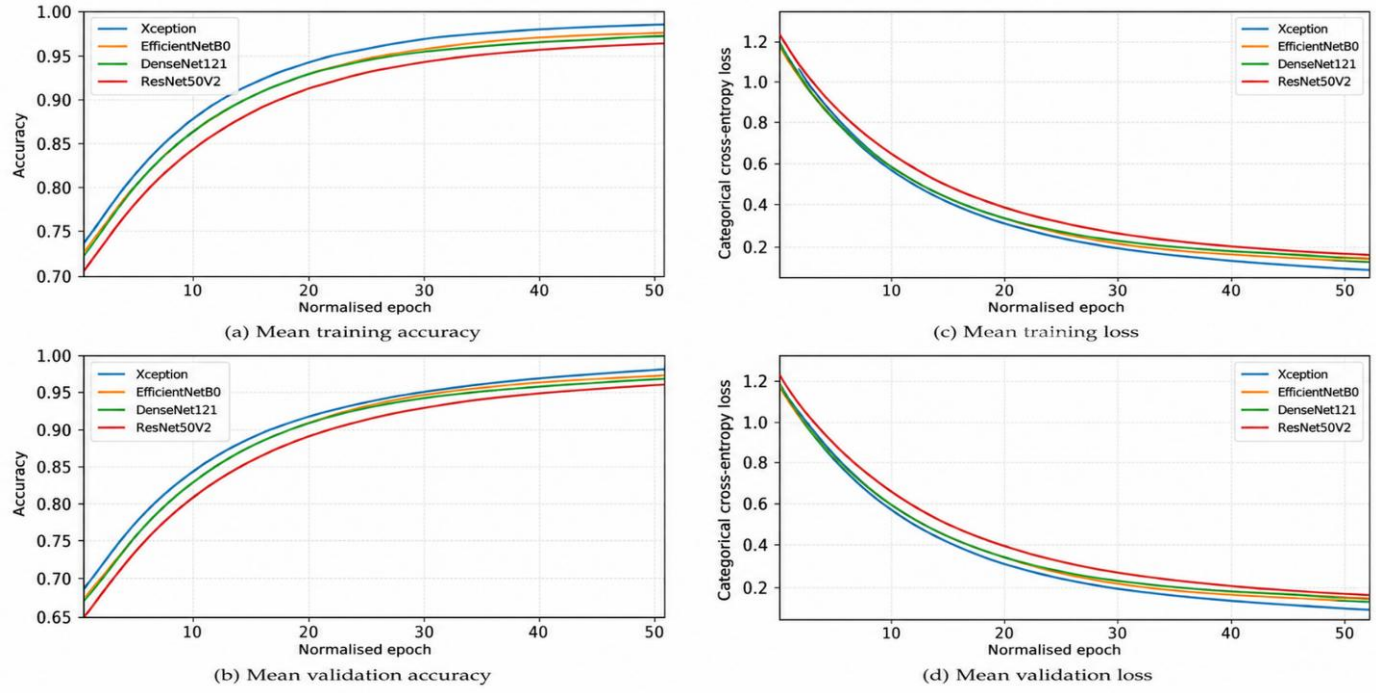

Fig. 3. Mean five-fold learning trajectories shown on a normalized epoch-progress scale: (a) training accuracy, (b) validation accuracy, (c) training loss, and (d) validation loss. The actual fold-specific early-stopping epochs are reported in Table III.

TABLE III. Fold-Wise Results for the Four CNN Architectures

Model	Fold	Stopping epoch	Train Acc. (%)	Val. Acc. (%)	Train Loss	Val. Loss
Xception	1	30	98.30	97.50	0.091	0.128
	2	33	98.58	97.78	0.076	0.107
	3	31	98.70	98.00	0.066	0.091
	4	35	98.92	98.44	0.051	0.066
	5	34	98.80	98.22	0.059	0.078
EfficientNetB0	1	40	97.15	96.50	0.158	0.188
	2	45	97.50	96.86	0.134	0.159
	3	43	97.82	97.31	0.114	0.136

Model	Fold	Stopping epoch	Train Acc. (%)	Val. Acc. (%)	Train Loss	Val. Loss
	4	47	98.50	98.19	0.081	0.083
	5	42	98.02	97.78	0.096	0.107
DenseNet121	1	44	96.78	96.11	0.171	0.198
	2	42	97.05	96.47	0.151	0.177
	3	46	97.40	96.83	0.132	0.154
	4	48	97.92	97.50	0.087	0.096
	5	43	97.62	97.17	0.108	0.124
ResNet50V2	1	46	96.20	95.50	0.184	0.218
	2	40	96.36	95.75	0.165	0.194
	3	44	96.55	96.00	0.145	0.171
	4	48	96.89	96.50	0.099	0.112
	5	42	96.72	96.25	0.121	0.139

B. Mean Performance, Agreement and Stability

Table IV summarizes fold-level performance, agreement, convergence, and stability. Xception achieved the highest mean validation accuracy at 97.99±0.37%, followed by EfficientNetB0 at 97.33±0.68%. DenseNet121 reached 96.82±0.55%, whereas ResNet50V2 reached 96.00±0.40%. Aggregate out-of-fold macro-F1 values were 97.99%, 97.33%, 96.82%, and 96.00%, respectively. The same ranking was observed for validation loss, kappa, and MCC.

The coefficient of variation of validation accuracy was 0.37% for Xception, 0.70% for EfficientNetB0, 0.57% for DenseNet121, and 0.41% for ResNet50V2. The corresponding mean train-validation accuracy gaps were 0.67, 0.47, 0.54, and 0.54 percentage points. These descriptive values show low fold dispersion for Xception and slightly greater dispersion for EfficientNetB0; no inferential significance is assigned to differences between architectures.

Aggregate out-of-fold metrics recomputed from the 18,000-prediction confusion matrices are reported in Table V. Because the benchmark is class-balanced, balanced accuracy equals macro-recall and is numerically very close to overall accuracy.

TABLE IV. MEAN PREDICTIVE AND STABILITY METRICS

Model	Train Acc. (%)	Val. Acc. (%)	Val. Loss	Kappa	MCC	CV Acc. (%)	Mean gap (pp)	Stop epoch
Xception	98.66±0.24	97.99±0.37	0.094±0.024	0.9732	0.9732	0.37	0.67	32.6±2.1
EfficientNetB0	97.80±0.51	97.33±0.68	0.135±0.041	0.9644	0.9644	0.70	0.47	43.4±2.7
DenseNet121	97.35±0.45	96.82±0.55	0.150±0.041	0.9576	0.9576	0.57	0.54	44.6±2.4
ResNet50V2	96.54±0.28	96.00±0.40	0.167±0.042	0.9467	0.9467	0.41	0.54	44.0±3.2

TABLE V. AGGREGATE OUT-OF-FOLD CLASSIFICATION METRICS

Model	Macro-P (%)	Macro-R (%)	Macro-F1 (%)	Balanced Acc. (%)	Macro-Specificity (%)
Xception	97.99	97.99	97.99	97.99	99.33
EfficientNetB0	97.33	97.33	97.33	97.33	99.11
DenseNet121	96.82	96.82	96.82	96.82	98.94
ResNet50V2	96.00	96.00	96.00	96.00	98.67

C. Class-Level Error Analysis

Before examining the confusion matrices, the aggregate metrics indicate that the principal remaining errors are class-specific rather than a consequence of unstable global convergence. The combined out-of-fold matrices allow these errors to be localized by true and predicted class. Xception correctly classified 4,418 powdery mildew images, 4,408 healthy images, 4,394 apple scab images, and 4,418 mosaic/chlorotic-symptom images. Its errors remain concentrated in a small number of scab-versus-healthy or scab-versus-chlorotic cases. The corresponding matrices for all four models are compared in Fig. 4.

For Xception, class-specific F1-scores derived from the combined matrix were 98.30% for powdery mildew, 97.87% for healthy leaves, 97.67% for apple scab, and 98.12% for

mosaic/chlorotic symptoms. Apple scab therefore remained the lowest-F1 class despite the strong overall performance.

EfficientNetB0 retained strong diagonal concentration but produced more off-diagonal errors around apple scab than Xception. DenseNet121 showed a further increase in scab and mosaic/chlorotic errors, and ResNet50V2 produced the broadest off-diagonal distribution. The confusion matrices establish where errors occurred but do not identify their visual cause; any attribution to shared necrotic, chlorotic, or textural appearance remains a hypothesis that requires lesion-level explanation or expert review.

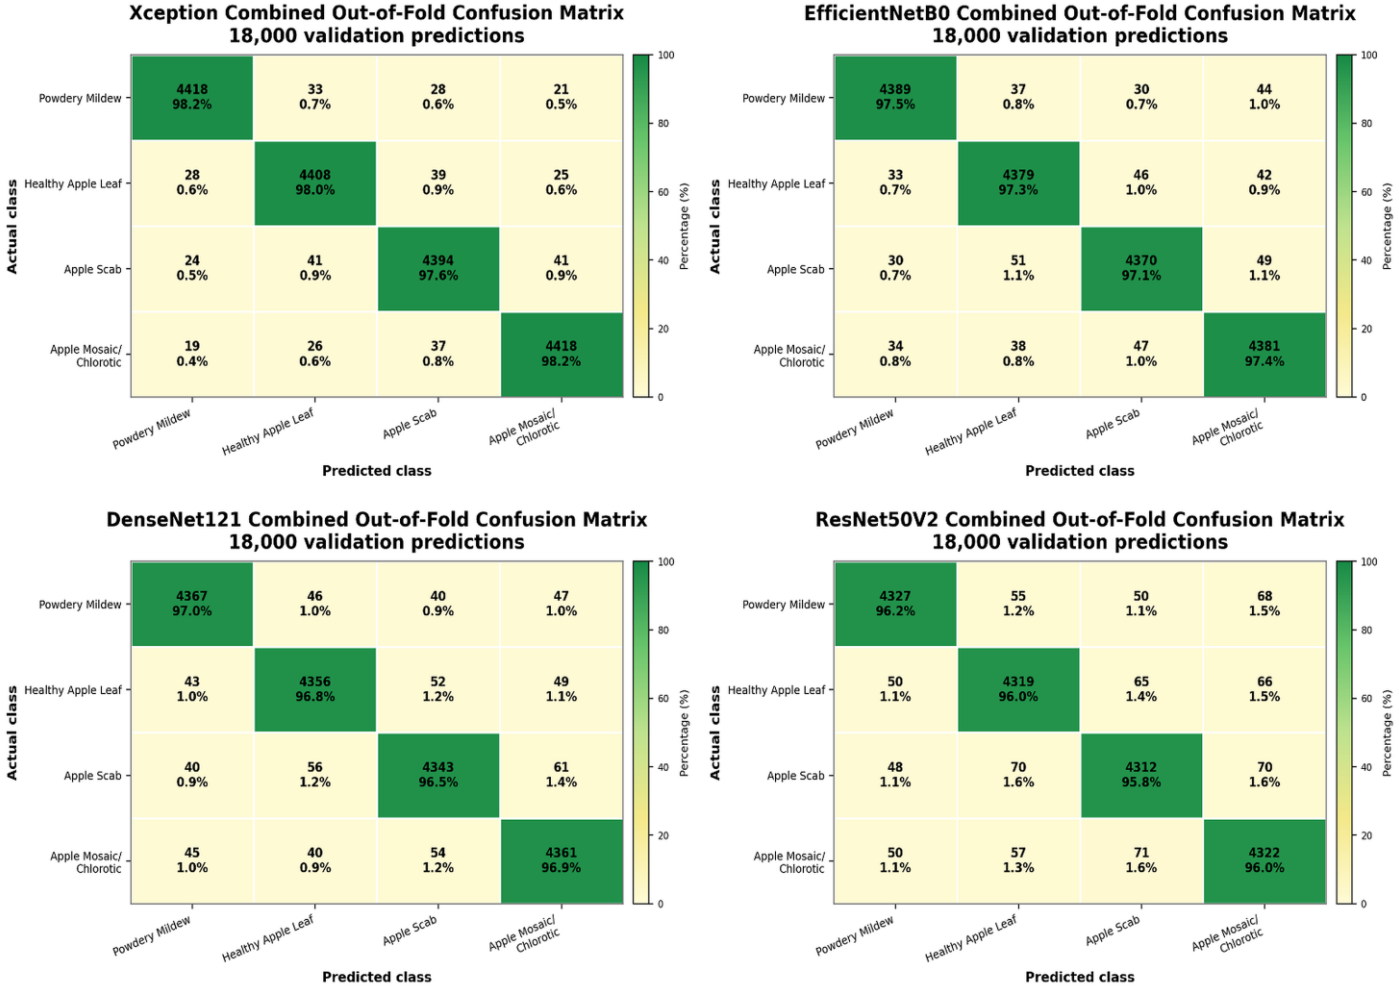

Fig. 4. Combined out-of-fold confusion matrices: (a) Xception, (b) EfficientNetB0, (c) DenseNet121, and (d) ResNet50V2. Each matrix contains 18,000 validation predictions.

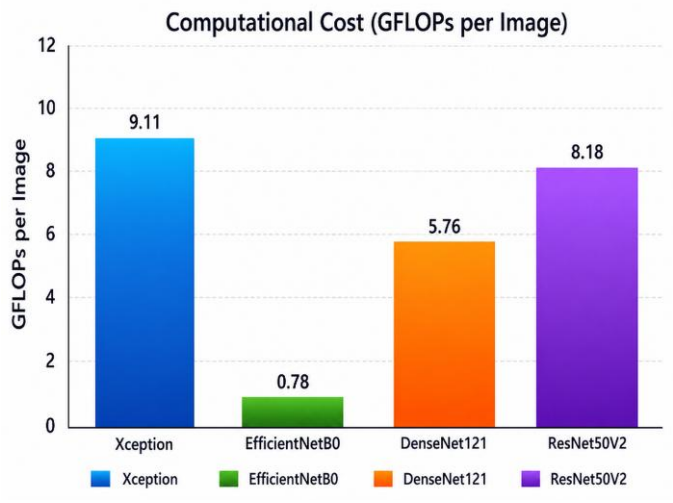
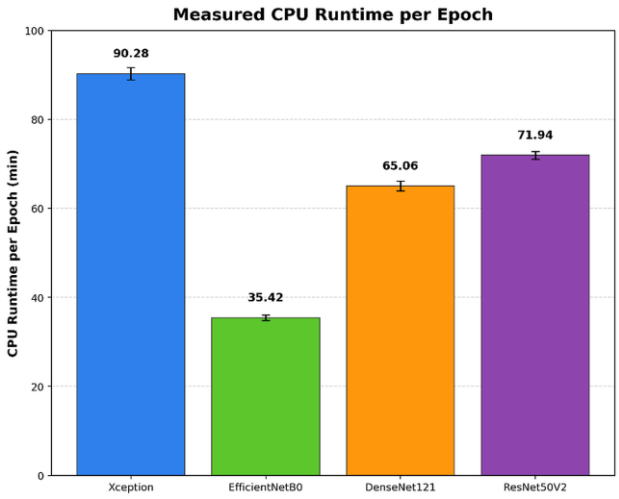
D. Computational Cost and Accuracy-Efficiency Frontier

EfficientNetB0 has 5.29 million parameters, 0.78 GFLOPs per image, and a mean measured CPU training time of 35.42\pm0.62 min per epoch.



Xception achieved the highest mean validation accuracy and the highest CPU training time (90.28±1.38 min/epoch) with 21.40 million parameters and 9.11 GFLOPs/image. For DenseNet121, we used an intermediate cost position with 7.31 million parameters, 5.76 GFLOPs, and 65.06 min/epoch. ResNet50V2 had the largest parameter footprint (24.10 million (91.9 MiB)) and the lowest mean validation accuracy.

The reported mean per-epoch training times correspond to computed training throughputs of approximately 2.66, 6.78, 3.69 and 3.34 images/s for Xception, EfficientNetB0, DenseNet121 and ResNet50V2 on 14,400 training images per fold. Combining stopping epochs with mean per-epoch times produces estimated aggregate five-fold CPU training burdens of 245.3, 128.1, 241.8 and 263.8 h, respectively. These are arithmetic estimates from training measurements, and should not be interpreted as inference throughput on deployment hardware.



The predicted and measured rankings of resources were not the same. Xception had the highest validation accuracy, but EfficientNetB0 was 0.66 percentage points behind, with substantially fewer GFLOPs, parameters, and CPU training minutes per epoch. From this descriptive accuracy-cost perspective, DenseNet121 and ResNet50V2 were less well placed. These measured trade-offs are visualised in Fig. 5 without implying device-level deployment performance.

TABLE VI. COMPUTATIONAL COST AND RESOURCE-NORMALIZED PERFORMANCE

Model	Params (M)	GMACs	GFLOPs	Runtime (min/epoch)	Size (MiB)	Acc./GFLOP	Acc./M-param	Acc./min
Xception	21.40	4.56	9.11	90.28±1.38	81.6	10.76	4.58	1.09
EfficientNetB0	5.29	0.39	0.78	35.42±0.62	20.2	124.78	18.40	2.75
DenseNet121	7.31	2.88	5.76	65.06±1.11	27.9	16.81	13.24	1.49
ResNet50V2	24.10	4.09	8.18	71.94±0.86	91.9	11.74	3.98	1.33

(a) Approximate forward-pass complexity.

(b) CPU runtime per epoch.

Fig. 5. Computational comparison of the four architectures: (a) profiled forward-pass GFLOPs per image and (b) measured wall-clock CPU runtime per epoch. EfficientNetB0 provides the lowest computational requirement, whereas Xception provides the highest observed mean validation accuracy.

E. Additional Graphical Synthesis

The validation accuracy, MCC, fold stability, accuracy per GFLOP, accuracy per CPU training minute and compactness for the four architectures are summarised in Fig. 6 after min-max normalisation. Before normalisation, lower-is-better quantities were inverted. The plot is descriptive and compares measured accuracy-cost profiles but does not establish causal effects of individual architectural mechanisms.

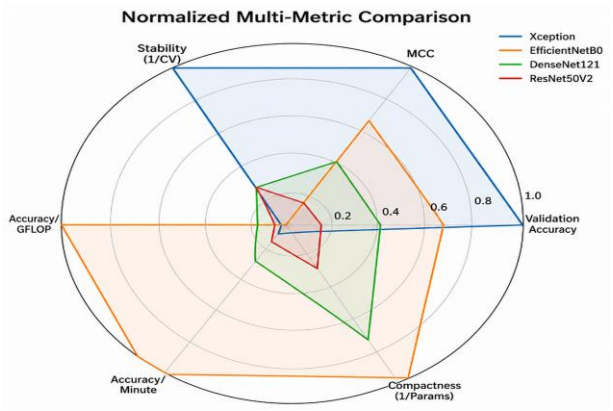


Fig. 6. Normalized multi-metric comparison of the four architectures across predictive quality, stability, and computational efficiency.

Fig. 7 shows complementary synthesis plots of mean validation accuracy vs measured CPU training time per epoch. Bubble size indicates parameter count and labels report GFLOPs. We observe EfficientNetB0 in the lowest-cost region of the four configurations evaluated, and Xception with the highest mean validation accuracy at a higher measured training cost.

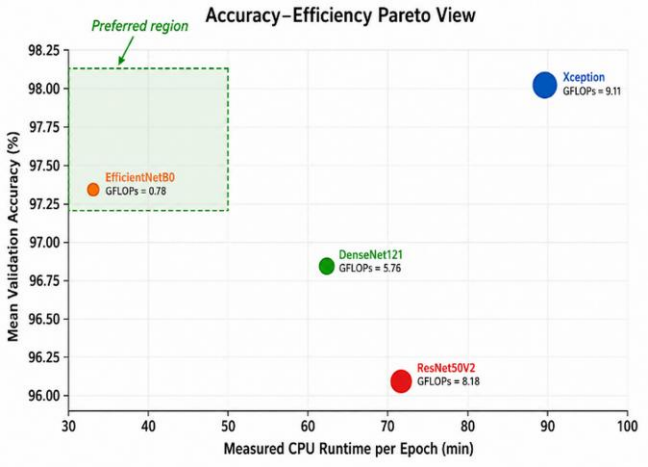

Fig. 7. Accuracy-efficiency Pareto view using mean validation accuracy, measured CPU runtime per epoch, parameter footprint, and GFLOPs.

Fig. 8 reports accuracy per GFLOP, accuracy per million parameters, and accuracy per CPU training minute. These ratios identify EfficientNetB0 as the lowest-cost configuration under the reported benchmark indicators, but they do not establish mobile or edge inference efficiency because device-level latency and energy were not measured.

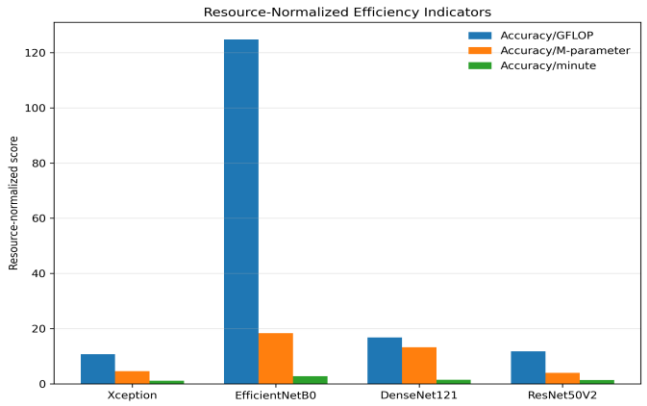

Fig. 8. Resource-normalized efficiency indicators derived from Table VI: accuracy per GFLOP, accuracy per million parameters, and accuracy per minute.

Fig. 9 summarizes the fold-wise distributions of validation accuracy and validation loss. Xception shows the smallest accuracy spread among the two highest-performing models, while EfficientNetB0 shows the largest fold-to-fold accuracy spread. The boxplots are descriptive because the folds are not independent statistical samples.

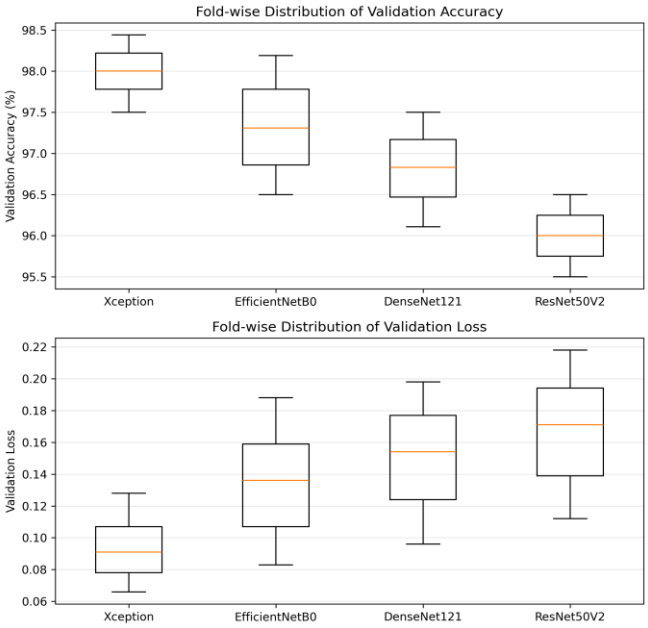

Fig. 9. Fold-wise distribution of validation accuracy and validation loss across the five cross-validation folds.

V. Discussion

Architecture selection for orchard-image classification is a multi-objective decision rather than a ranking by accuracy alone. Xception recorded the highest mean validation accuracy, aggregate out-of-fold macro-F1, kappa, and MCC, together with the lowest mean validation loss. The experiment does not isolate the architectural mechanism responsible for these differences, and no causal attribution is made to depthwise separable convolution or another individual design component. The measured cost of the Xception configuration was substantially greater than that of EfficientNetB0.

EfficientNetB0 was 0.66 percentage points below Xception in mean validation accuracy while using 91.4% fewer GFLOPs, 75.3% fewer parameters, and 60.8% less mean CPU training time per epoch. These measurements indicate a lower computational footprint under the benchmark protocol. The accuracy difference is descriptive; no claim of inferential statistical significance is made, and the training-time measurements do not establish mobile or edge inference latency, throughput, memory, or energy behavior.

DenseNet121 occupied an intermediate accuracy–cost position, whereas ResNet50V2 had the largest parameter footprint and the lowest mean validation accuracy under the specified configuration. These outcomes are configuration-specific and do not establish intrinsic superiority or weakness of an architecture family because optimization settings and training stochasticity were not isolated through a dedicated ablation or repeated-seed design.

Apple scab had the lowest class-specific F1-score for Xception. The confusion matrices establish this empirical error pattern but do not determine its cause. Visual overlap with chlorotic or necrotic symptoms is therefore treated only as a hypothesis. Natarajan et al. [28] used explainable-AI visualizations for plant-disease diagnosis, while Alhammad et al. [29] applied explainable deep learning to potato leaf disease classification. Comparable lesion-level analysis is deferred to future work before any biological interpretation of the scab confusion pattern is asserted.

Direct numerical comparison with prior studies requires caution because datasets, augmentation, acquisition conditions, class definitions, and validation procedures differ. Yadav et al. [8] reported five-fold AFD-Net results; AppleLeafNet emphasized compact apple-disease recognition [14]; ALNet reported a lightweight design [19]; and EnConv addressed multi-crop leaf-disease classification [20]. The four backbones in the present benchmark were selected as representative established families rather than as an exhaustive state-of-the-art set. LightYOLO-AppleLeafDx and other task-specific lightweight models were not reimplemented; therefore, no claim is made that the evaluated four models constitute the strongest available operating points.

A field benchmark should distinguish predictive quality, fold stability, computational complexity, and hardware-specific deployment evidence. The present study directly reports the first three dimensions together with CPU training time and forward-pass complexity, but it does not measure device-level inference latency, throughput, energy consumption, or peak memory. Consequently, the conclusions are limited to the measured benchmark accuracy–cost trade-off rather than verified mobile or edge deployment suitability.

VI. Limitations and Reproducibility

The benchmark spans two Moroccan orchard locations (Midelt and Azrou), four cultivars, and three mobile devices, but it does not cover all regions, seasons, disease stages, or acquisition conditions. The guaranteed independence unit is the original source image and its augmentation lineage; complete leaf- and tree-level identifiers are not available for all acquisitions, so stricter biological independence across folds

cannot be confirmed. Labels are treated as visual symptom categories rather than universally laboratory-confirmed etiologies, and the mosaic/chlorotic category may contain heterogeneous causal mechanisms. The reported cross-validation results therefore quantify internal source-image-level benchmark stability, not external orchard-level or etiological generalization.

The 2,000-image challenge reserve was isolated before cross-validation and excluded from model selection and all headline metrics. It is intentionally not evaluated in this manuscript; reserve-set confirmation is deferred entirely to future work to preserve its independent role. The reported results constitute the complete five-fold analysis of the 18,000-image development benchmark. Future confirmation should additionally use leave-one-orchard-out, leave-one-device-out, or leave-one-season-out protocols where the corresponding group identifiers are available.

Architecture-specific optimization settings and a single run per fold limit causal interpretation of backbone differences because random-seed variability was not separated from optimization effects. Group-level confidence intervals were not calculated because complete leaf- and tree-level identifiers were unavailable; an image-level bootstrap would overstate independence. Future studies should retain leaf, tree, session, device, and orchard identifiers, repeat training across random seeds, and apply group-level resampling or permutation procedures. Reproducibility also requires preserved fold assignments, augmentation lineage, software versions, training logs, checkpoints, profiler outputs, and out-of-fold probabilities under identical hardware and data-loader settings.

VII. Conclusion and Future Work

An orchard-image five-fold benchmark compared Xception, EfficientNetB0, DenseNet121, and ResNet50V2 for four-class apple leaf disease classification. Xception achieved the highest mean validation accuracy (97.99±0.37%) and aggregate out-of-fold macro-F1 (97.99%), while EfficientNetB0 reached 97.33±0.68% with markedly fewer parameters, lower GFLOPs, and shorter CPU training time. DenseNet121 occupied an intermediate position, and ResNet50V2 the least favorable measured accuracy–cost position. Because no inferential architecture test or device-level inference benchmark was conducted, these findings identify descriptive benchmark operating points rather than statistically or deployment-validated superiority.

Mean accuracy alone is insufficient for model selection. Fold dispersion, train-validation gap, agreement metrics, parameter count, FLOPs, training time, and memory footprint provide complementary evidence. The early-stopping protocol also shows that training duration should follow convergence rather than an arbitrary epoch count; Xception stopped after 30–35 epochs despite a maximum limit of 50 epochs.

Future work will prioritize evaluation of the untouched challenge reserve and external validation across unseen orchards, devices, cultivars, and seasons. Complete leaf/tree/session identifiers will support strict group-aware partitioning, repeated random-seed runs, and group-level uncertainty estimates. Explainable-AI analysis will also be used for lesion localization and class-specific failure assessment before causal interpretations of error patterns are made.

We will explore structured pruning, quantisation, and knowledge distillation to reduce model size and inference cost. Before making claims about mobile or edge suitability, hardware-specific latency, throughput, peak memory, and energy measurements will be gathered. The selected efficiency-oriented configuration can be embedded in an orchard diagnostic interface, with confidence reporting and class-specific explanations.

***Abstract*—Indonesian grammatical error correction (GEC) requires decisions about when to apply a proposed edit under synthetic-to-authentic domain shift. We evaluate a selective correction framework using a reconstructed, fully executable experiment. An audit of 1,955 authentic records removed 36 incomplete pairs, 14 duplicates, 45 string identities, and five additional token identities, leaving 1,855 pairs. Exact-text groups were partitioned into 1,297 training, 280 validation, and 278 test pairs. Synthetic priors were learned from 200,000 public development pairs. A cross-fitted logistic ranker combined synthetic mappings, authentic templates, spelling retrieval, and local language-model evidence. Thresholds were chosen on validation data under joint degradation and overcorrection budgets. At the 2% budget, the gate accepted five source edits, four correct: precision 80.00%, F0.5 4.03, coverage 1.80%, and word-error reduction 0.88%. No test source was degraded, but one of 278 correct-target controls changed. The precision interval was 37.55–96.38%. Removing the synthetic channel reduced available gold candidates from 110 to 109 and accepted true positives from four to three. Replacing the language-model feature with frozen IndoBERT produced 66.67% precision at 2.16% coverage, with one degraded source and one changed control. The results support restrictive authorization on this corpus, show limited unique synthetic contribution, and expose a substantial candidate-recall bottleneck. They do not establish broad correction ability or readiness for educational deployment.**

Keywords*—Indonesian grammatical error correction; domain shift; synthetic data; selective prediction; abstention; overcorrection; trustworthy natural language processing; writing feedback

I. Introduction

Grammatical error correction (GEC) is the computational task of detecting and repairing errors in written text, including orthographic, morphological, syntactic, lexical, and meaning-related problems [1]. The task is technically demanding because a system must not merely generate fluent text. It must identify which segment is erroneous, make the smallest defensible intervention, preserve the writer's intended meaning, and leave already acceptable text unchanged. These requirements are especially important in educational settings. A false correction may teach an incorrect rule, erase a legitimate stylistic choice, or encourage learners to surrender judgment to an automated system. For Indonesian-language education, reliable GEC could support formative feedback in academic writing, editing practice, and self-regulated revision. Yet an educationally safe system must recognize when it lacks sufficient evidence and defer to a teacher or human editor.

Indonesian GEC has progressed from a correction framework [2] to a Transformer supported by synthetic training pairs [3] and a framework for constructing evaluation corpora [4]. International work addresses complementary limitations: contextual augmentation targets error-distribution mismatch [5], RobustGEC tests sensitivity to contextual perturbations [6], and NaSGEC evaluates domain variation [7]. These developments motivate a separate question for writing assistance: when should a proposed correction actually be applied?

Synthetic corpora provide frequent spelling substitutions, character confusions, and surface edits, but their distribution reflects the corruption procedure. Authentic writing can require phrase restructuring, lexical interpretation, or several interacting changes. Wang et al. [5] combine contextual augmentation with relabeling-based cleaning; MixEdit [8] examines augmented-data affinity and diversity; and Stahlberg and Kumar [9] use tagged corruption to control synthetic error types. These approaches motivate testing distributional compatibility rather than assuming that more synthetic pairs guarantee reliable transfer.

Evaluation on error-containing sentences alone does not measure the cost of changing acceptable text. A selective writing assistant must therefore distinguish applying an edit from withholding it. In this implementation, correction is an accepted edit, retention describes unchanged output, and abstention describes withholding a proposed edit because its score is insufficient. Retention does not certify that a sentence is grammatical. The broader interface concept of correct, retain, or defer must not be interpreted as an evaluated three-class classifier. Varshney et al. [10] show that selective prediction performance can vary across tasks and distribution shifts, motivating direct evaluation of both erroneous inputs and correct-target controls.

This study combines synthetic replacement evidence from the Indonesian Transformer project [3] with the public GEC-GEE release [11]. It measures direct transfer, candidate-source ablations, budget sensitivity, score-tail calibration, and a frozen

*Corresponding author.

contextual scoring alternative. The paired evaluation processes every erroneous source and its corrected target as a no-error control. This makes unnecessary changes observable alongside successful repairs.

For this revision, we reconstructed the computational pipeline because the original executable artifacts and split indices could not be recovered from the submission files. The experiments below constitute a new evaluation and supersede the previous performance values. The audit, tokenizer, ontology rules, grouped partitions, model settings, candidate logs, and policy selections are now explicitly recorded. The historical 4.66% Identity exact-match value and the omitted category case cannot be traced to original predictions; both reporting problems are addressed through consistent token-level filtering and complete denominators in the reconstructed benchmark.

Four questions guide the revised evaluation: what marginal contribution do synthetic candidates make within the combined model (RQ1); how much observed harm is reduced by authorization at controlled coverage (RQ2); which error families and pipeline stages limit useful correction (RQ3); and how do alternative harm budgets and contextual scoring affect the operating point (RQ4)? The contribution is a reproducible evaluation protocol with paired controls and explicit abstention, rather than a claim of a new general-purpose GEC generator.

II. Related Work

A. Modern Grammatical Error Correction

The survey by Bryant et al. [1] organizes sequence generation, tagging, edit-based modeling, and evaluation. MainGEC [12] weights training examples using annotation properties; MixEdit [8] studies augmentation affinity and diversity; TransGEC [13] uses translated text to reduce the style mismatch in augmentation; and Mesham et al. [14] extend the sequence-tagging vocabulary for spelling and morphology. Cao et al. [15] introduce non-autoregressive signals into autoregressive correction. Luhtaru et al. [16] investigate multilingual transfer using pretrained translation models, while MoECE [17] uses expert specialization to improve efficiency and interpretability. These methods concern how candidate corrections are learned or generated; they do not establish the safety of the present authorization policy.

Fei et al. [18] incorporate explanations into GEC systems, while GEE! [19] evaluates whether large language models can locate and explain errors. Peng et al. [20] retrieve demonstrations using grammatical-error representations rather than semantic similarity alone. Li et al. [21] use explanations for demonstration retrieval. These approaches can strengthen candidate support, but an explanation must still be assessed separately from whether the proposed edit is correct.

B. Synthetic Data and Domain Mismatch

Wang et al. [5] combine rule-based substitution, context generation, and relabeling to improve synthetic examples. Stahlberg and Kumar [9] generate low-resource training data with tagged corruption models. In Bangla, Bhattacharyya and Bhattacharya [22] define error categories and use rule-based noise for instruction-tuning data. Smruti [23] combines a language model with non-parametric memory for Gujarati and supplies an evaluation dataset. Team Horizon [24] combines synthetic augmentation with multilingual Transformer models for Indic GEC. These are distinct data and modeling strategies; their reported benefits do not directly establish transfer to the Indonesian release evaluated here.

For Indonesian, Musyafa et al. [3] provide a synthetic corpus for Transformer-based correction. Lin et al. [4] propose a separate corpus-construction framework. The authentic data audited here are the Indonesian GEC-GEE release maintained in the syauqiezjut repository [11]; they should not be conflated with the corpus released with [4]. Frequent synthetic substitutions can generate plausible candidates, but their incremental contribution to correct accepted edits must be measured by removing the synthetic channel while retaining the remaining gated pipeline.

C. Robustness and Overcorrection

RobustGEC [6] examines sensitivity to minor contextual perturbations, and NaSGEC [7] documents cross-domain variation. Chang and Zhu [25] use chunk-based prompting to limit unnecessary correction. LM-Combiner [26] employs contextual rewriting to combine correction outputs. Liu et al. [27] introduce a chain-of-task instruction-tuning framework, while Wang et al. [28] investigate multi-pass decoding. These approaches motivate explicit control tests because improved correction or generation scores need not imply fewer unnecessary changes.

D. Evaluation and Selective Prediction

The gec-metrics library [29] provides a common interface for GEC evaluation. IMPARA-GED [30] incorporates grammatical-error detection into reference-free quality estimation, whereas Goto et al. [31] examine reliability problems in reference-free metrics. Varshney et al. [10] compare selective prediction across distribution settings; their subsequent method [32] calibrates predictions using confidence and instance difficulty. Zablotskaia et al. [33] evaluate uncertainty and selective generation for summarization, and Ba et al. [34] use synthetic data for calibration. Guo et al. [35] study post-hoc calibration of neural networks. These findings support reporting ranking quality, calibration, coverage, and observed harm as separate quantities.

E. Indonesian NLP and Educational Writing Support

IndoNLU [36] supplies language-understanding benchmarks and models, and IndoNLG [37] supplies benchmarks for language generation. IndoBERTweet [38] adapts a pretrained encoder to Indonesian Twitter, IndoNLI [39] provides natural-language inference data, and Cendol [40] develops instruction-tuned generative models for Indonesian languages. KEBI [41] addresses spelling detection in scientific papers, while U-Tapis [42] evaluates spelling support for journalism students. Mohsen [43] synthesizes computer-mediated corrective-feedback studies; Zhai and Ma [44] synthesize automated writing evaluation; Fan [45] examines automated feedback in an EFL writing study; and Lee and Moore [46] review generative-AI feedback in higher education. These studies motivate supervised feedback research but do not demonstrate learning benefits for the present system. Koto et al. [47] introduce IndoLEM and a pretrained Indonesian BERT model; the present comparison uses its frozen masked-language-model checkpoint.

III. Data Sources and Quality Audit

A. Synthetic Source

Musyafa et al. [3] report a large synthetic corpus generated from Indonesian text. The accessible development and test CSV archives contained 424,430 and 424,419 parsable pairs, respectively, totaling 848,849. Their 47 string identities and 67 token identities differ because tokenization ignores spaces adjacent to punctuation. The archives are audited separately; the synthetic test partition contributes no training evidence.

Using Python random seed 2026, we sampled 200,000 development rows without replacement after checking exact normalized-text overlap with the authentic corpus. No overlapping development pair was found. Minimum-edit alignment supplied single-token replacement counts. A replacement was retained at support ≥2 and conditional probability ≥0.50 among nonidentity substitutions of its source token, with at most three alternatives per source. This yielded 40,147 retained replacements for 39,985 source tokens. Sample row identifiers and hashes of all three source CSVs are included in the computational supplement.

B. Authentic Source

The GEC-GEE repository [11] describes 1,920 expert-validated pairs from academic publications dated 2020–2024, whereas its downloadable CSV contains 1,955 records. It supplies source, target, label, and explanation fields. It does not supply row-level genre, writer proficiency, register, or document provenance. We therefore describe its stated origin without assigning unsupported demographic or genre proportions. Its scope is one heterogeneous public release.

We normalized text with Unicode NFKC, collapsed whitespace, removed blank source/target pairs, retained the first duplicate normalized pair, and removed remaining string identities. These sequential exclusions were 36, 14, and 45, yielding 1,860 string-distinct pairs. The case-preserving tokenizer matches Unicode words and individual nonspace punctuation with the regular expression \w+|[^\w\s]. Five additional pairs were identical under these tokens and were explicitly removed, leaving 1,855 pairs. No additional token-pair duplicate remained. Training, exact match, edit extraction, and distance evaluation all use these same token sequences, so Identity has zero exact match on the error benchmark.

C. Ontology and Grouped Partitioning

Existing labels were mapped by published, case-normalized keyword rules to orthography, punctuation, morphology, function word, redundancy, lexical choice, semantic coherence, and syntax, with Other for residual labels. Typographical variants were explicitly standardized. Primary-family priority follows that order; multiple labels are retained for descriptive purposes. For example, afiksasi and reduplikasi indicate morphology, preposisi and konjungsi indicate function words, and pleonasme indicates redundancy. These are operational groupings of existing annotations, not newly validated linguistic judgments.

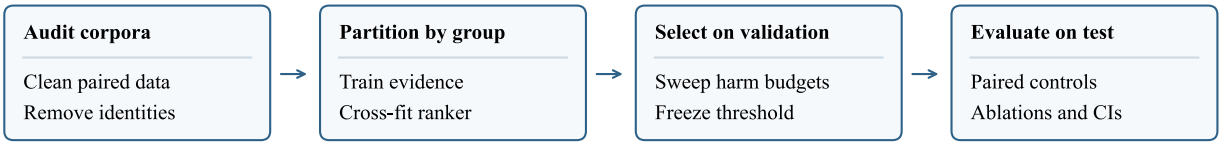
Exact token-identical source or target texts were joined into 1,845 connected groups. A seeded search over 400 group partitions minimized size and category-count imbalance relative to a 70/15/15 split, using no model outcomes. The selected partitions contain 1,297 training, 280 validation, and 278 test pairs, with no exact text shared between partitions. Their row IDs and complete label-to-family mappings are supplied. Across the final corpus, sources average 14.00 tokens, with median 12 and 95th percentile 26.3; minimum-edit alignment yields 3,159 gold spans. The new counts supersede the historical tokenizer and split statistics.

TABLE I. Sequential Cleaning with Consistent Token Evaluation

Sequential stage	Entering	Removed	Remaining
Release	1,955	0	1,955
Remove empty source or target	1,955	36	1,919
Deduplicate normalized pairs	1,919	14	1,905
Remove string identities	1,905	45	1,860
Remove additional token identities	1,860	5	1,855
Deduplicate token pairs	1,855	0	1,855

Table I accounts for all 100 exclusions without adding overlapping audit categories. The distinction between string identity and token identity is explicit. This prevents an unchanged source from being counted as an exact correction merely because evaluation applies a more permissive normalization. Dataset quality and preprocessing decisions affect downstream inference and must be auditable [48], [49], [50].

IV. Proposed Framework



A. Design Principle

Candidate discovery proposes a local change; ranking orders proposals; authorization determines which changes are applied. Correction means an accepted edit. Retention describes unchanged output, while abstention records rejection below the score threshold. Overlap and the five-edit cap are separate rejection reasons; no-candidate retention is also logged. An unchanged output does not certify grammatical correctness. The implementation is therefore an edit-selection policy with rejection records, not an evaluated three-class correct/retain/abstain classifier. Fig. 1 shows the full experimental flow.

B. Tokenization and Alignment

Case-preserving tokens are aligned by unit-cost Levenshtein operations [51] using RapidFuzz 3.14.6. Consecutive non-equal operations are merged into a single span; exact matches use source start/end offsets and the replacement token tuple. Authentic templates are retained when each side contains at most three tokens, including insertion and deletion. Support is the number of training occurrences. Conditional probability divides

template support by all nonidentity rule support for the same source span; insertion rules share an empty-source denominator. This definition is available in executable code rather than inferred from reported metrics.

Candidate discovery → ranking → edit authorization

Fig. 1. Reconstructed data flow and separation of candidate discovery, ranking, and authorization.

C. Candidate Sources

Synthetic candidates follow the fixed support/probability filters in Section III. Authentic templates store distributions of the immediately adjacent left and right tokens, including sentence boundaries. Context agreement is half the sum of the two matching-neighbor proportions. An insertion requires at least one matching neighbor. Spelling retrieval searches only the current training-target vocabulary: alphabetic tokens of length ≥3 and frequency ≥2, Levenshtein distance ≤1 for source length ≤5 and ≤2 otherwise, normalized similarity ≥0.70, and at most three alternatives ordered by distance, descending frequency, then lexical order. No dictionary or reference target is consulted during inference.

D. Candidate Features and Language Model

Sixteen features encode log support; conditional probability; log source and target frequencies; their smoothed log ratio; character similarity; source and replacement token lengths; character-length difference; punctuation and case-change flags; three candidate-origin flags; context agreement; and local language-model gain. Duplicate candidates with the same offsets and replacement are merged while retaining all origin flags. Source and target frequencies use only the current authentic training fold. The language model uses lowercased target-training bigrams, BOS/EOS and UNK, with add-0.1 smoothing. Gain is the difference in mean log-likelihood within two neighboring tokens on either side. The complete feature order and formulas accompany the code.

E. Cross-Fitted Ranker

Five group-disjoint folds within the training partition induced rules and vocabulary on four folds and generated candidates for held-out sources and their target controls.

Candidate labels indicate exact gold-edit matches. This produced 207,580 candidates and 472 positives. StandardScaler and L2 logistic regression were fitted to these examples with C=1, balanced class weights, lbfgs, max_iter=2000, and seed 2026. The final evidence dictionaries used only the complete authentic training partition. Calibration metrics are reported on validation and test candidates, not on the same candidates used to fit the ranker.

F. Validation-Constrained Authorization

Thresholds cover 0.00–1.00 at increments of 0.01, plus 0.995, 0.999, and a retain-all option. Validation F0.5 is maximized subject to the chosen budget; ties favor lower degradation, lower overcorrection, and then a higher threshold. Budgets of 1%, 2%, and 5% are evaluated with overcorrection alone and with a joint bound on degradation and overcorrection. The primary condition is the full model at the joint 2% budget, fixed before inspecting its test outputs. This is an empirical tolerance for comparing policies, not a validated educational safety standard. A budget does not guarantee the same population or test risk.

G. Comparators and Ablations

Table II defines Identity, direct synthetic and authentic rules, a fixed heuristic, an ungated ranker, the primary gate, four ablations, and an IndoBERT feature replacement. Channel ablations remove both candidates unique to the channel and that channel's support/probability/origin evidence in merged candidates; the logistic ranker is refitted. Authentic language statistics remain training-only in every channel ablation. The no-LM condition sets the local gain feature to zero. All active policies apply at most five nonoverlapping edits in one pass, without iterative rewriting.

TABLE II. EVALUATED CORRECTION VARIANTS

Variant	Candidate evidence	Authorization policy
Identity	None	Retain every input
Synthetic direct	Synthetic channel	Probability/support ranking
Authentic direct	Authentic channel	Probability/support ranking
Heuristic	All channels	Fixed weighted score ≥0.50
Ungated ranker	All channels	Logistic score with no gate
Confidence gated	All channels	Validation-selected joint 2% gate
Channel ablations	Remove synthetic, authentic, or spelling	Refit and reselect independently
No n-gram feature	Same full candidate pool	Zero LM gain; refit and reselect
IndoBERT feature	Same full candidate pool	Replace LM gain; refit and reselect

Algorithm 1 summarizes the reconstructed inference procedure. The implementation code and per-sample numerical results are provided in the supplementary material described at the end of this paper.

Algorithm 1. Confidence-Gated Selective Correction

Input: source tokens x; training evidence E; fitted ranker f; validation-selected threshold τ

1. Generate local candidates from the permitted channels and deduplicate identical edits.
2. Compute inference features from x and training evidence only; preserve origin flags.
3. Score and sort candidates once, breaking ties deterministically by offsets and replacement.
4. Accept an edit only if its score ≥ τ, it does not overlap an accepted edit, and fewer than five edits have been accepted.
5. Log rejection as below threshold, overlap, or edit cap; distinguish no-candidate retention.
6. Apply accepted edits from right to left to preserve source offsets.
7. Return the output and rejection record. Retention does not certify correctness.

V. Experimental Design

A. Evaluation Units

The held-out test set contains 278 erroneous sources with 476 gold edit spans and 278 corresponding reference-correct controls. Validation has 280 paired sources/controls. Exact-text grouping prevents the same source or target from appearing in both training and evaluation. Shared words and rules remain possible, as expected for local correction; near-duplicate and provenance overlap are not ruled out. Each variant's threshold is selected on validation before its test evaluation.

B. Edit Metrics

A system edit is a true positive only if its source offsets and replacement tokens exactly equal a gold span. Precision equals TP/predicted edits; recall equals TP/gold edits; F0.5 = 1.25TP/(predicted edits + 0.25 gold edits). Scores are displayed on a 0–100 scale. A partly helpful change can lower token distance without matching a complete reference edit. When a system makes no edit, precision is mathematically undefined; tables mark it with a dash, while the evaluation convention sets F0.5 and recall to zero.

C. Sentence and Distance Metrics

Exact match compares output and target tokens. Coverage is the proportion of source sentences changed. Improvement and degradation compare output-to-target Levenshtein distance with the initial source-to-target distance. Overcorrection is any token change on a target control. Word-error reduction is one minus the ratio of aggregate output and initial token distances; character reduction uses the analogous distance on token-normalized strings. We distinguish unconditional degradation over all sources from conditional degradation among changed sources, and report both denominators.

D. Uncertainty and Comparisons

We report Wilson 95% intervals for rates [52], two-sided exact McNemar degradation comparisons [53], Holm adjustment across ten comparisons with the primary gate, and 10,000 paired sentence bootstrap samples with seed 2026 for token-distance gain [54]. These are descriptive intervals for this corpus; candidates from the same sentence can be dependent, so candidate-tail Wilson intervals do not establish independent-event calibration guarantees. A matched-coverage diagnostic restricts each ranked comparator to five changed source sentences and one edit per sentence. Two hundred seeded random authorizations provide an additional descriptive comparison, without influencing model selection.

E. Category Accounting and Bottlenecks

Every test pair appears once under its primary family, including Other. The analysis distinguishes gold edits that never enter the candidate pool from available gold edits rejected during authorization. Removing a candidate channel can change both the pool and its scoring evidence, so an end-to-end ablation effect is not automatically a uniquely generated edit. Accepted-candidate origin flags support a narrower attribution analysis.

F. Contextual Feature Comparison

We replace only the local n-gram gain with a frozen IndoBERT masked-span score [47], using indolem/indobert-base-uncased at revision 7ccb3cd0f5b08ffbaa465aade22328e8600e23eb. All edited subword tokens are masked simultaneously, and the feature is the change in their mean log probability between original and proposed spans. Windows use up to six neighboring word tokens per side, capped at 32 subwords per side and 16 edited subwords. Insertions/deletions include a shared neighboring token as an anchor. The trained MLM head is loaded with no missing weights. Candidates, other features, folds, and logistic settings are identical; no neural fine-tuning or candidate enrichment is performed.

G. Reproducible Implementation

The executed environment uses Python 3.12, NumPy 2.5.3, SciPy 1.18.1, scikit-learn 1.9.0, RapidFuzz 3.14.6, PyTorch 2.14.0, and Transformers 4.57.6. IndoBERT runs on CPU with four threads and batches of 32. The heuristic is fixed at 0.30 conditional probability + 0.25 context agreement + 0.20 similarity + 0.15 sigmoid(LM gain) + 0.10 support/(support+2), accepting scores ≥0.50. Direct-rule ties use support after conditional probability. The supplement records exact software versions, hashes, all split IDs, feature definitions, candidate counts, and validation sweeps.

H. Reconstruction and Leakage Controls

The revised protocol was written before model fitting and test-outcome inspection. It replaces undocumented historical choices with explicit settings and uses new grouped partitions. The full n-gram model is the prespecified primary condition, rather than the variant with the highest test score. No test label, explanation, or target enters rule induction, frequency estimation, logistic fitting, or threshold selection. Exact-text overlap checks use corpus strings only for duplicate detection. Unrecoverable historical calibration variants and their test-selected comparison have been removed, and the new values are disclosed as a reconstruction rather than exact reproduction.

VI. Results

A. Main Comparison

Table III presents accuracy and intervention outcomes separately. Identity correctly has zero exact matches. Direct synthetic application changes 63.67% of sources, degrades 53.60%, and changes 58.99% of controls. Its word-error reduction is -25.83%, demonstrating harmful direct transfer in this implementation. These values supersede those obtained with the unrecovered historical preprocessing and candidate filters.

Authentic direct rules change every source and every control, with 95.32% degradation. The ungated ranker degrades 93.17% and also changes every control. The heuristic has the higher unconstrained F0.5 of 8.03, but degrades 53.24% and overcorrects 62.23%. A higher conventional edit score therefore does not imply an acceptable intervention policy.

The primary gate selects threshold 0.999 and changes five sources, with four of five system edits matching the reference. Precision is 80.00%, recall 0.84%, and F0.5 4.03. Coverage is 1.80%, word-error reduction 0.88%, and one source is corrected exactly. All five changed sources become closer to their targets; none degrades. One correct-target control changes (0.36%), so the revised results do not support the earlier claim of zero observed overcorrection.

TABLE III. Reconstructed Test Performance on 278 Sources and 278 Controls (Panel A Edit and Sentence Accuracy)

System	Precision (%)	Recall (%)	F0.5	Exact match (%)
Identity	—	0.00	0.00	0.00
Synthetic direct	2.01	1.26	1.79	0.72
Authentic direct	2.31	5.04	2.59	0.00
Heuristic	8.83	5.88	8.03	3.24
Ungated ranker	2.99	6.30	3.34	0.00
Confidence gated	80.00	0.84	4.03	0.36
No synthetic channel	75.00	0.63	3.05	0.36
No authentic channel	18.18	0.84	3.55	0.36
No spelling channel	—	0.00	0.00	0.00
No n-gram feature	—	0.00	0.00	0.00
IndoBERT feature	66.67	0.84	4.00	0.00

Panel B Sentence Intervention and Harm

System	Degradation (%)	Coverage (%)	Word error reduction (%)	Overcorrection (%)
Identity	0.00	0.00	0.00	0.00
Synthetic direct	53.60	63.67	-25.83	58.99
Authentic direct	95.32	100.00	-114.90	100.00
Heuristic	53.24	70.86	-23.51	62.23
Ungated ranker	93.17	100.00	-102.87	100.00
Confidence gated	0.00	1.80	0.88	0.36
No synthetic channel	0.00	1.44	0.77	0.36
No authentic channel	5.04	7.55	-1.10	5.04
No spelling channel	0.00	0.00	0.00	0.00
No n-gram feature	0.00	0.00	0.00	0.00
IndoBERT feature	0.36	2.16	0.66	0.36

B. Safety and Useful Intervention

Table IV reports the uncertainty in the low-intervention results. The primary precision interval is 37.55–96.38%. Unconditional degradation is 0/278, with an upper bound of 1.36%; conditional degradation is 0/5 changed sources, whose Wilson upper bound is 43.45%. Overcorrection is 1/278, with interval 0.06–2.01%. These denominators prevent the unconditional zero-degradation observation from being interpreted as evidence of near-perfect reliability for accepted corrections.

The primary mean token-distance gain is 0.0288 tokens per source, with bootstrap interval 0.0072–0.0576. Paired harm tests favor the gate over the aggressive direct and ungated systems, but those comparisons alone confound authorization with coverage. At a fixed five changed sources and one edit each, the full ranking retains four correct edits without degradation. Random selection averages 0.60% precision and 1.61% unconditional degradation over 200 runs. The matched diagnostic is small and descriptive; it does not establish a general safety guarantee or universal superiority at all coverage levels.

Fig. 2 separates coverage from the two harm rates. The primary gate improves observed safety through very restrictive selection. Identity attains no intervention-related harm by doing nothing, so the gain in useful corrections and its uncertainty must accompany any safety comparison.

TABLE IV. UNCERTAINTY AND PAIRED DEGRADATION COMPARISONS

System	Source harm	Controls changed	Precision 95% CI	Mean gain 95% CI	Adjusted p
Synthetic direct	149/278	164/278	0.92–4.31%	-0.9676–-0.7194	2.2e-44
Authentic direct	265/278	278/278	1.56–3.41%	-3.9496–-3.5396	3.4e-79
Heuristic	148/278	173/278	6.18–12.47%	-0.9245–-0.6151	3.9e-44
Ungated ranker	259/278	278/278	2.10–4.23%	-3.5755–-3.1259	1.9e-77
Confidence gated	0/278	1/278	37.55–96.38%	0.0072–0.0576	—
IndoBERT feature	1/278	1/278	30.00–90.32%	-0.0072–0.0504	1

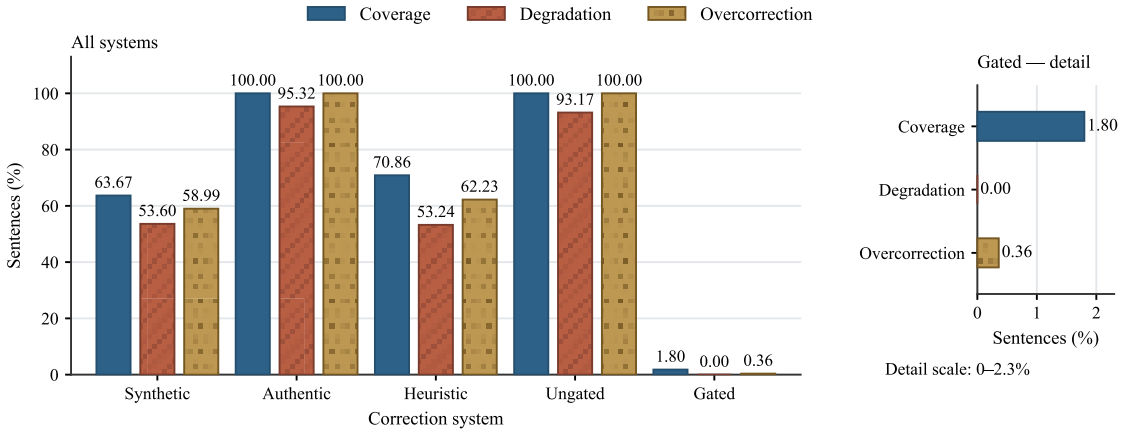


Fig. 2. Sentence-level harm and benefit under synthetic-to-authentic transfer.

C. Budget Sensitivity

Under the full n-gram model, both the overcorrection-only and joint formulations select retain-all at 1%, threshold 0.999 at 2%, and 0.995 at 5%. The resulting test coverage is 0%, 1.80%, and 7.91%; F0.5 is 0, 4.03, and 8.87. At 5%, test degradation rises to 3.60% and overcorrection to 4.68%. Fig. 3 plots validation frontiers; the full validation/test sweep and six selected policies per model are supplied. The 280 validation controls permit at most 2, 5, or 14 changed controls under the three budgets. These are empirical tolerances, not confidence-bound guarantees.

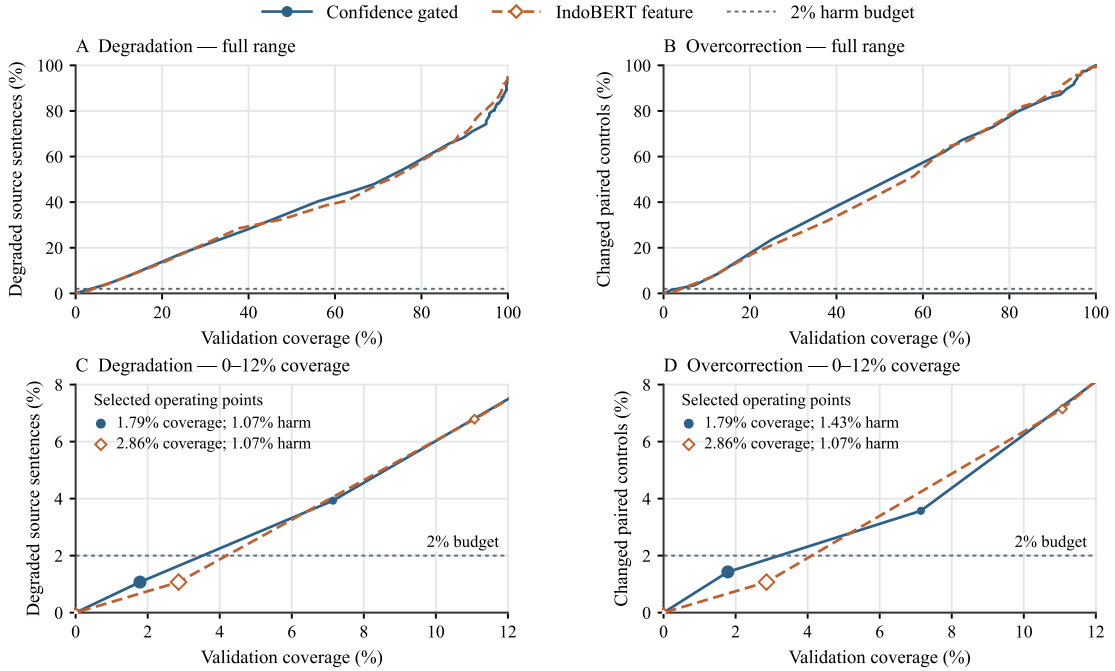

Fig. 3. Validation harm versus coverage for n-gram and IndoBERT scoring. Dots mark the joint 2% policies.

D. Error Families

Table V and Fig. 4 exhaust all 278 test sources: orthography 78, punctuation 15, morphology 56, function word 19, redundancy 23, lexical choice 42, semantic coherence 15, syntax 27, and Other 3. Correct edits occur in orthography (two), redundancy (one), and syntax (one). A lexical-group edit improves distance without matching a complete gold span. The control overcorrection occurs in the morphology group. These family labels describe each pair's primary annotation, not necessarily the linguistic type of its accepted edit. The earlier inference that all structural categories were deferred is therefore withdrawn.

TABLE V. COMPLETE PRIMARY-FAMILY ACCOUNTING FOR THE GATED SYSTEM

Family	n	TP/edits	Recall (%)	F0.5	Coverage (%)	Controls changed (%)
Orthography	78	2/2	1.38	6.54	2.56	0.00
Punctuation	15	0/0	0.00	0.00	0.00	0.00
Morphology	56	0/0	0.00	0.00	0.00	1.79
Function word	19	0/0	0.00	0.00	0.00	0.00
Redundancy	23	1/1	2.63	11.90	4.35	0.00
Lexical	42	0/1	0.00	0.00	2.38	0.00
Semantic	15	0/0	0.00	0.00	0.00	0.00
Syntax	27	1/1	1.92	8.93	3.70	0.00
Other	3	0/0	0.00	0.00	0.00	0.00

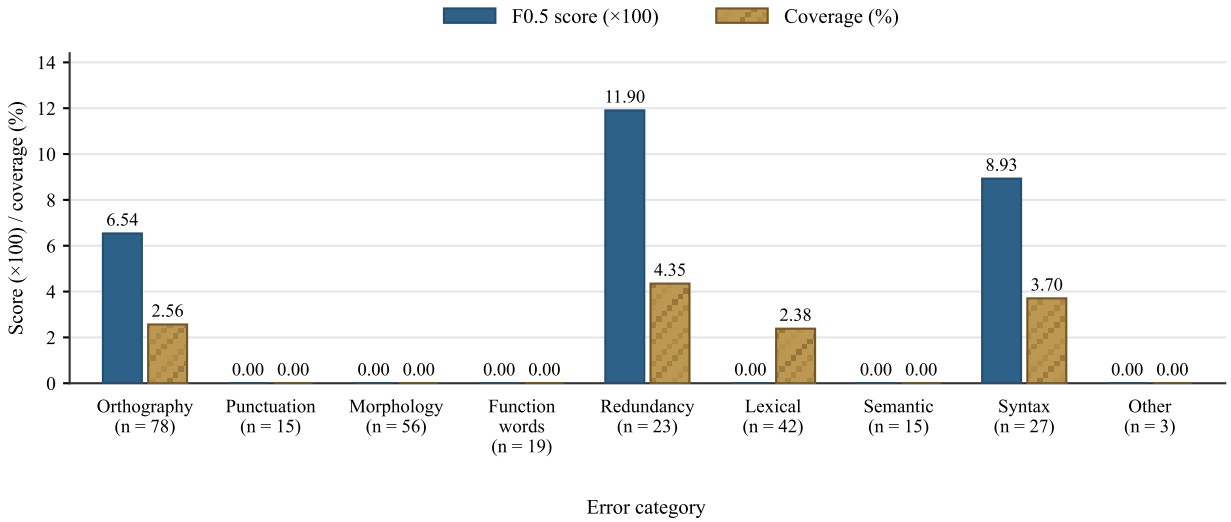

Fig. 4. Category-specific F0.5 and coverage for the confidence-gated system.

E. Candidate Attribution

The full pool contains 110 of 476 gold edits (23.11%), across 84 of 278 source sentences. Without synthetic candidates, 109 gold edits remain available, indicating only one uniquely supplied gold candidate. Of the four accepted gold candidates, three originate only from authentic templates and one is shared by authentic and synthetic channels. Removing synthetic evidence and refitting yields three true positives from four edits, F0.5 3.05 and coverage 1.44%. The one-edit end-to-end change may reflect scoring support; it is not proof that an accepted correction was unavailable without synthetic generation. The revised RQ1 conclusion is therefore limited marginal contribution on this split.

F. Additional Ablations

Removing the authentic channel reduces the gold-candidate ceiling to 26/476 (5.46%). Its validation-selected policy changes 21 test sources and degrades 14, illustrating that an empirical validation budget may fail to transfer even within the same release. Removing spelling retrieval leaves 96/476 gold candidates, but its joint 2% selection is retain-all. The no-LM condition also selects retain-all. These outcomes describe the fixed candidate filters, feature representation, grid, and split; they do not establish that the removed components are universally necessary.

VII. DISCUSSION

A. Synthetic Scale and Generality

The synthetic source provides frequent surface substitutions, but only one unique exact gold candidate beyond the remaining channels on this test set. Its support can still influence a shared candidate's ranking. The controlled ablation therefore narrows the earlier claim that scale benefits candidate discovery: large synthetic resources are insufficient evidence of useful marginal

transfer. Authentic templates supply most of the exact gold-candidate coverage in this reconstructed system.

B. Ranking and Tail Calibration

The n-gram ranker has validation AUC 0.925, average precision 0.047, Brier score 0.100, and ECE 0.181. On test candidates, these are 0.937, 0.093, 0.101, and 0.184. Among the 205 source/control candidates scoring ≥0.98, only 20 match gold edits (9.76%), despite a mean score of 0.989. At ≥0.999, four of six candidates are correct, with interval 30.00–90.32%; one of the two errors is a control edit. The gate succeeds by severe empirical filtering rather than demonstrated probability calibration. A score of 0.999 must not be read as a 99.9% chance of correctness.

C. Coverage and Conditional Risk

Only 110 gold edits enter the full candidate pool, and only four are recovered by the selected policy. Thus, 366/476 gold edits are unavailable to authorization at any threshold. All test sources have at least one candidate, so unchanged output is caused by rejection rather than evidence that a sentence is correct. The small number of accepted edits gives weak precision and conditional-harm estimates. Matched-coverage diagnostics reduce one confound but remain exploratory and depend on the supplied candidate universe.

D. Educational Implications

Mohsen [43] and Zhai and Ma [44] synthesize evidence about corrective feedback and automated writing evaluation, respectively; Fan [45] studies revision with automated feedback, and Lee and Moore [46] review generative feedback in higher education. The current study measures computational outcomes only. A proposed teacher-mediated interface would display candidate evidence and distinguish accepted edits from uncertain retained spans. It should not label every unchanged sentence as correct. Teacher workload, learner understanding, and writing improvement require prospective evaluation.

E. Contextual Scoring

Replacing the n-gram feature with frozen IndoBERT [47] keeps the same candidate pool and fits the same logistic architecture. At the joint 2% policy, its threshold is 0.999, with four correct edits from six, precision 66.67%, F0.5 4.00, and coverage 2.16%. It degrades one source and changes one control, each by 0.36%. Its test ECE is 0.192. The experiment provides no material safety-coverage improvement in this configuration. It evaluates local frozen masked-span scoring, not full-sentence neural generation or a fine-tuned contextual corrector; the small event counts cannot establish equivalence between the alternatives.

F. Measured Technical Bottlenecks

Candidate recall is bounded at 23.11% before authorization, reflecting short-span templates, sparse authentic evidence, and a limited synthetic match to the corpus. Gating then recovers only 4/110 available gold edits. Improving only the ranking feature cannot recover gold edits absent from the pool. Future experiments should therefore separate richer generation from better authorization, maintain correct-target controls, and report both candidate recall and policy-level harm. Neural generator enrichment was not tested here.

G. Criteria for a Supervised Pilot

The present system remains below a defensible deployment threshold. A concrete future screening rule is at least 10% coverage on an independently sampled corpus, at least 90% edit precision by the lower 95% interval, and upper 95% bounds below 1% for both degradation and control overcorrection. These are proposed engineering targets for discussion with teachers, not standards or thresholds validated by this experiment. The current 1.80% coverage and broad precision interval fail that screen. A pilot must also measure correct accepted feedback per teacher-review minute, teacher acceptance, and learner understanding against the existing review process; coverage alone is insufficient.

H. Comparison at Equal Intervention

With exactly five changed source sentences and one edit each, the full ranking yields four correct edits and no degradation. The heuristic also yields four correct edits, but degrades one source; synthetic ranking yields one correct edit and three degraded sources, and authentic ranking yields no correct edit and five degraded sources. The full method therefore does not improve precision over the heuristic in this small matched comparison. These descriptive outcomes use frozen scores and do not replace the validation-selected policies in Table III. Random-authorized controls are not assessed in this source-only diagnostic, and the five-intervention sample cannot establish robust safety superiority.

VIII. Limitations and Threats to Validity

The first limitation is reconstruction fidelity: new explicit filters, tokenization, ontology mapping, grouped partitions, and ranking settings supersede unrecovered historical choices. New results cannot identify the exact cause of every historical number. Second, all operating-point results come from a single split with a fixed seed. Sentence bootstrap intervals reflect test-sampling variation conditional on that fitted system, not training-seed or corpus-to-corpus variability. Third, the primary gate makes five source edits, yielding broad precision and conditional-risk intervals. Low observed harm therefore cannot establish reliable operation at greater coverage.

Fourth, the GEC-GEE CSV [11] lacks row-level genre, register, proficiency, and document provenance. Its repository description does not establish representative sampling, and ontology mapping was not independently reannotated. Exact-text grouping limits one form of leakage but does not remove near-duplicates, shared source documents, or possible pre-trained-model exposure. Fifth, the synthetic corruption process represents one particular resource. Sixth, the IndoBERT comparison is a frozen local-feature replacement; broader contextual models, fine-tuning, and candidate enrichment may behave differently. Calibration must be re-evaluated under every changed distribution.

Seventh, target controls are reference-correct within the dataset, not universally error-free writing. A single reference may penalize legitimate alternative corrections. Independent no-error texts and multiple references would strengthen ecological validity. Eighth, the empirical 1%, 2%, and 5% budgets do not control unknown population risk, and the proposed pilot targets remain unvalidated. Finally, no teacher-workload, learning, or

longitudinal writing outcome is measured. Those claims require prospective educational evaluation after stronger computational evidence is established.

IX. Ethics, Data Availability, and AI Disclosure

This study analyzes publicly released text corpora and includes no new participant recruitment or intervention. The computational supplement contains executable code, source URLs and hashes, row identifiers, ontology mappings, aggregate statistics, and numeric per-sample outcomes. It does not redistribute third-party raw corpora or pretrained weights. Users should obtain those resources from their original providers and follow the corresponding terms. The source references identify the corpus and model used in the reconstruction.

Generative AI assisted with code development, methodological checking, drafting, and language revision. The reconstructed performance values are computed by executable scripts; unverified historical values are not retained as new experimental evidence. The authors remain responsible for checking the revised methods, data provenance, numerical results, and interpretations before submission. No gold correction or benchmark label was generated to improve the reported model performance.

Data and code availability. The accompanying reconstruction package includes preprocessing and model scripts, frozen split IDs and synthetic sample IDs, source hashes, validation selections, ablations, calibration tails, paired uncertainty analyses, figure generation, and verification checks. The package distinguishes the reconstructed evaluation from unrecovered historical artifacts. No funding or competing interests are declared.

X. Conclusion

The reconstructed experiment shows that aggressive local correction can introduce substantial harm on this public Indonesian corpus. Validation-constrained authorization reduces intervention to five of 278 sources, obtaining four exact gold edits, 80.00% precision, F0.5 4.03, and 0.88% word-error reduction. No source degrades, but one reference-correct control changes. All results use consistent token filtering and complete category denominators, and supersede the earlier unreproduced performance values.

The synthetic-channel ablation shows little uniquely added gold-candidate recall on this split. Budget sensitivity reveals a direct trade-off between useful coverage and observed harm, while the frozen IndoBERT replacement does not materially improve the selected operating point. The strongest remaining bottleneck is that most gold edits never enter the candidate pool. Selective authorization is therefore a useful research component, but improved generation, external evaluation, stronger uncertainty evidence, and teacher studies are required before the system can support claims of dependable educational deployment.

XI. Supplementary Material

Supplementary material for this article is available at https://drive.google.com/file/d/11qjUt0yG6TTwe0Nf_QEY5OybPaUcn3aX/view?usp=sharing. The package includes source code for data preprocessing, feature generation, policy selection, and evaluation, together with instructions for reproducing the experiments and the corresponding numerical results. Third-party datasets and pretrained model weights are not included. The accompanying documentation provides instructions for obtaining these resources from their original providers.

CompCap-Stego: Computable Capability-Pointer Steganography with Hidden Policy Evaluation and Verifiable External Payload Retrieval

Mohammad Othman Nassar
Faculty of Information Technology-Cyber Security Department, Amman Arab University, Amman, Jordan

***Abstract*—CompCap-Stego is a capability-pointer steganography framework in which the concealed object is a compact dual-zone capability capsule rather than the protected payload. The sealed access zone stores receiver binding, wrapped key material, a revocation handle, an audit nonce, and a payload-verification root, while the computable policy zone supports validity, expiry, bounded-use access, revocation, replay state, receiver matching, honey-state misuse detection, and policy-digest consistency. Here, computable denotes authenticated policy-state evaluation after capsule extraction rather than general-purpose or homomorphic computation directly over unrecovered steganographic bits. Retrieval proceeds only after capsule extraction, binding validation, policy evaluation, receiver-bound token derivation, and verification of the externally returned encrypted payload. A 512-byte core capsule reduces embedded size by 95.00 percent for a 10-kilobyte (KB) payload, 99.50 percent for 100 KB, 99.95 percent for a 1-megabyte (MB) payload, and 99.995 percent for 10 MB. Carrier quality remains stable at 55.8 to 55.9 decibels (dB) in peak signal-to-noise ratio (PSNR), 0.997 structural similarity index measure (SSIM), and 0.56 area under the receiver operating characteristic curve (AUC). Medium error correction reaches 99.6 percent extraction success and 99.5 percent tag-verification success. Policy violations are rejected at 98.9 to 99.8 percent, tampered or replaced external ciphertext at 99.8 to 99.9 percent, and the full design records 0.4 percent composite attack success.**

Keywords*—Steganography; capability-based access control; hidden policy evaluation; verifiable external retrieval

I. Introduction

Steganography has traditionally concealed secret messages in innocuous carriers while maintaining the cover's perceptual or statistical properties. Across image, audio, video, network, linguistic, and generative carriers, this objective continues to create a central tension among capacity, imperceptibility, robustness, and extraction reliability [1]–[7]. More recent work has extended steganography beyond message hiding to security functions that include hidden computation, authentication support, integrity proof transmission, and high-capacity generative embedding [8]–[13]. This progression broadens the role of the hidden object: in addition to a conventional message, it can serve as a control object, proof object, credential object, or retrieval-enabling object.

Full-payload embedding provides a direct route to controlled information access, but it is not always the most suitable option. When the protected payload is large, dynamic, revocable, or externally managed, placing the complete ciphertext in the cover increases capacity pressure and carrier distortion. A smaller hidden object reduces this embedding load, yet a static hidden pointer or static token leaves the access-state weakness unresolved. Once extracted or replayed, it may continue to expose the external payload unless access state, receiver binding, revocation, replay, and payload verification are enforced. The intervention point therefore lies between compact pointer-style hiding and stateful access-controlled retrieval.

Adjacent literature addresses several parts of this problem separately. Homomorphic and computable steganography demonstrate that computation can be applied to concealed bits without directly revealing them [8]. Anonymous-token systems and private-metadata token constructions provide mechanisms for unlinkability, private metadata, public verification, and double-spending control [14]–[18]. Internet of Things (IoT) authorization and device-sharing research shows the risks of exposed authorization data and the need for delegation, revocation, and access-state management [19]–[21]. Privacy-oriented concealment also addresses exposure of access-related network traces [22]. Capability and network-bound access-control systems provide process or context binding [23], while encrypted-domain data-hiding and proxy-re-encryption systems support controlled sharing of protected data [24]–[27]. Nevertheless, these lines do not provide a single steganographic construction in which the concealed object is a compact computable capability capsule that controls verified retrieval of an externally encrypted payload.

Carrier-level developments in image-based information hiding and cover selection provide a second motivation for CompCap-Stego. Research on cover-image selection establishes that carrier suitability affects embedding reliability, visual quality, and resistance to detection, whereas high-capacity generative steganography shows that modern carriers can be constructed or adapted for larger and more robust hidden representations [10]. CompCap-Stego takes a different but complementary direction: instead of increasing the hidden payload placed in the carrier, it confines the hidden object to a compact access capsule and moves the protected content to verified external encrypted storage. The design emphasis therefore shifts from maximizing embedded payload capacity to minimizing embedded access material while retaining policy enforcement, receiver binding, and payload verification.

This study proposes CompCap-Stego, a computable capability-pointer steganography framework for hidden policy evaluation and verifiable external payload retrieval. In this study, computable denotes a limited authenticated state-transition capsule

whose concealed policy fields support receiver-side and gateway-side policy evaluation after extraction; it does not denote general-purpose computation over unrecovered steganographic bits. Rather than embedding the payload, the framework embeds a dual-zone capability capsule. Its sealed access zone protects retrieval material, receiver binding, wrapped key material, payload-verification root, revocation handle, and audit nonce, whereas its computable policy zone maintains compact hidden state for validity, expiry, bounded-use retrieval, revocation, replay, receiver matching, honey-state misuse detection, and policy-digest checking. Retrieval is granted only after the capsule is extracted, its binding is verified, the hidden policy predicate is satisfied, a receiver-bound retrieval token is derived, and the returned external ciphertext matches the verification root bound to the capsule. The principal novelty therefore lies in combining a concealed capability capsule, authenticated stateful policy-before-retrieval control, receiver-bound authorization, and external-payload verification rather than in introducing a new form of homomorphic steganographic computation.

The evaluation demonstrates the role of the capsule-centered design across compactness, carrier quality, extraction reliability, policy enforcement, payload verification, runtime overhead, and ablation behavior. Compared with full-payload embedding, CompCap-Stego substantially reduces the number of embedded bits as payload size increases because the cover carries a capsule of bounded size rather than the full encrypted payload. Compared with static pointer and static sealed-token variants, the proposed method provides replay, revocation, expiry, receiver-mismatch, honey-probing, and payload-replacement rejection through the policy and verification layers.

A. Contributions

CompCap-Stego makes five linked contributions. First, it defines computable capability-capsule steganography in which the hidden object is a compact capability capsule rather than the full payload, a plain pointer, or an ordinary hidden credential. Second, it introduces a dual-zone capsule composed of a sealed access zone for retrieval and verification material and a computable policy zone for compact hidden policy state. Third, it evaluates policy-before-retrieval rules for validity, expiry, bounded-use access, revocation, replay, receiver matching, and honey-state misuse detection. Fourth, it binds external ciphertext acceptance to a capsule-sealed hash or Merkle root to prevent replacement and tampering. Fifth, it compares the design with full-payload embedding, static pointer hiding, static sealed-token hiding, and component-removal variants.

Section II reviews the closest steganography, token, capability, and verifiable-retrieval literature. Section III defines the system and threat models, including the gateway trust boundary. Section IV presents the CompCap-Stego construction, followed by the formal algorithms and security properties in Section V. Section VI describes the experimental methodology and sensitivity analyses, while Section VII reports the quantitative results. Section VIII discusses the resulting design trade-offs, Section IX identifies the validated scope and remaining limitations, and Section X concludes the study.

II. Related Work

This section positions CompCap-Stego relative to six adjacent families of work: conventional and adaptive steganography, computable and generative steganography, anonymous/private-metadata tokens, authorization-data and capability-based access control, steganography-assisted authentication [28], [29], and encrypted-domain retrieval with integrity verification.

A. Steganography, Steganalysis, and Carrier Selection

Classical steganography and modern distortion-minimization methods optimize the capacity-imperceptibility balance [1]–[7]. Adaptive image methods reduce detectable artifacts by selecting low-risk embedding regions, while deep steganalysis models increase the difficulty of remaining undetected. These methods are important for the carrier layer of CompCap-Stego, but they do not define the hidden object as a stateful retrieval capability. StyleStego is related at the carrier layer because it explores high-capacity generative steganography using a style-based generative adversarial network (StyleGAN) embedding [10]. In addition, optimization-assisted color visual cryptography is relevant as adjacent image-security work because it addresses protected visual-content representation using image-domain security mechanisms [11].

B. Computable and Generative Steganography

ProSt shows that homomorphic-style computation can be performed on hidden steganographic data [8]. Generative and neural approaches hide information by synthesizing carriers or learning end-to-end encoder/decoder structures [9], [12], [13]. CompCap-Stego does not claim to be the first work on hidden computation or generative hiding. Its scope is narrower: the hidden computation is limited to policy-state evaluation over a compact capsule, and the protected payload remains external. Unlike systems that operate directly on concealed or unrecovered steganographic data, CompCap-Stego first extracts and authenticates the capsule and then evaluates its protected policy state. The term computable is therefore used in the narrower sense of stateful capability evaluation.

C. Anonymous Tokens and Private Metadata

Anonymous tokens with private metadata bits and public metadata support privacy-preserving issuance, redemption, metadata hiding, public verification, and double-spending controls [14]–[18]. These systems strongly motivate the use of compact credential-like objects, but they are not steganographic carrier objects and do not bind an embedded capsule to off-cover ciphertext retrieval. CompCap-Stego combines the token-like idea of a compact access object with carrier concealment and payload-root verification.

D. Authorization Data, Capability Systems, and External Access Control

IoT device-sharing and authorization-data studies identify the underlying access-control weakness: exposed access material can be replayed or remain usable after revocation [19]–[21]. Privacy-oriented concealment work addresses a related exposure by hiding network-use traces through stealth protocols and proxying when access activity can reveal sensitive behavior [22]. Capability and network-bound systems such as NetCap respond to token theft by binding access authority to a process or network context [23]. These mechanisms provide access control, but they do not operate as steganographic retrieval capsules. CompCap-Stego retains the context-binding function and places the resulting authority inside a concealed carrier capsule.

E. Encrypted-Domain Data Hiding and Verifiable Retrieval

Reversible data hiding in encrypted domains and proxy re-encryption-based data hiding provide controlled sharing, identity verification, and encrypted-domain embedding [24]–[27]. Merkle-based integrity verification and steganographic proof transmission add the complementary function of tamper-evident verification to hidden transmission [30], [31]. These approaches therefore cover part of the proposed framework's verification role, but not the dual-zone hidden capability capsule that evaluates policy before retrieval. The functional boundaries of the closest work families are summarized in Table I.

TABLE I. FUNCTIONAL COMPARISON WITH CLOSEST WORK FAMILIES

Work family	Representative focus and citations	Overlap with CompCap-Stego	Remaining gap and claim boundary
Adaptive and deep steganography	Capacity, imperceptibility, robustness, and steganalysis resistance [1]-[7], [10]-[13]	Provides carrier-layer methods and detectability metrics.	Does not provide stateful external retrieval authority; CompCap-Stego does not claim novelty in adaptive or generative embedding.
Computable steganography	Computation over hidden steganographic data [8]	Supports the idea that hidden bits can participate in computation.	Does not define a compact access capsule for verified retrieval; CompCap-Stego is not claimed as the first hidden-computation method.
Anonymous and private-metadata tokens	Private metadata, public metadata, verification, and double-spending control [14]-[18]	Supports compact token-like access objects and replay reasoning.	No steganographic carrier binding or external ciphertext root; CompCap-Stego is not claimed as the first anonymous-token system.
Authorization-data protection and capability systems	Delegation, revocation, hidden authorization data, and network/process-bound capabilities [19]-[23]	Motivates revocation, receiver binding, and access-state management.	Does not place a computable retrieval capsule inside a cover; CompCap-Stego is not claimed as the first access-control or capability system.
Encrypted-domain data hiding and proxy re-encryption	Controlled sharing, encrypted-domain embedding, and dynamic authorization [24]-[27]	Overlaps with external encrypted data and controlled retrieval.	No policy-before-retrieval capsule in the carrier; CompCap-Stego is not claimed as the first encrypted-domain hiding method.
Integrity-proof steganography and Merkle verification	Merkle or proof transmission through covert channels [30], [31]	Overlaps with tamper-evident proof handling.	Does not combine sealed retrieval, hidden policy, and receiver-bound access; CompCap-Stego is not claimed as the first Merkle-verification method.

Accordingly, the claim boundary is deliberately limited: CompCap-Stego is not positioned as the first hidden-computation, anonymous-token, access-control, Merkle-verification, or encrypted-domain data-hiding method. Its contribution rests on the unified capsule-level mechanism that combines a sealed access zone, a computable policy zone, honey positions, and verified external retrieval inside a concealed carrier object.

III. SYSTEM MODEL AND THREAT MODEL

A. System Overview

CompCap-Stego considers a sender that protects a payload by encrypting it externally and embedding a compact capability capsule in a cover object. The receiver extracts the capsule, validates its binding, evaluates hidden policy state, derives a retrieval token, and accepts the externally returned ciphertext only if it matches the verification root carried in the capsule.

$$\Gamma = Z_s \parallel Z_p \parallel \tau \tag{1}$$

where, Γ denotes the embedded capability capsule, Z_s is the sealed access zone, Z_p is the computable policy zone, and τ is the capsule binding tag.

$$C' = Embed(C, \Gamma, K_{emb}) \tag{2}$$

where, C is the original cover, C' is the stego-cover, and K_{emb} is the embedding key.

$$M = (R, D, H) \tag{3}$$

The position map M separates carrier positions into real positions R, decoy positions D, and honey positions H.

$$R \cap D = R \cap H = D \cap H = \varnothing \tag{4}$$

B. External Payload and Policy State

The protected content is encrypted before storage using authenticated encryption with associated data (AEAD), where AD denotes the associated data. The receiver does not accept the retrieved ciphertext merely because it is returned from the external store; acceptance depends on the hash or Merkle-root verification material bound to the capsule [32]. The core notation is summarized in Table II.

TABLE II. CORE NOTATION

Symbol	Meaning
Γ	Complete embedded capability capsule
Z_s	Sealed access zone
Z_p	Computable policy zone
τ	Capsule binding tag
C, C'	Cover and stego-cover
P, P_e	Plain payload and encrypted payload
$root_P$	Hash or Merkle root for external payload verification
R, D, H	Real, decoy, and honey position classes
R_ctx	Receiver context used in receiver-binding and policy evaluation.
c_u	Remaining-use counter
b_{rep}, b_r, b_h	Replay, revocation, and honey-state flags

$$P_e = AEAD.Enc_{K_e}(P, AD) \tag{5}$$

$$root_P = H(P_e) \tag{6}$$

$$root_P = MerkleRoot(ch_1, ch_2, \dots, ch_n) \tag{7}$$

$$Z_p = \left(b_v, b_x, c_u, b_r, b_{rep}, b_{rec}, b_h, d_p\right) \tag{8}$$

$$Allow(\Gamma, R, t) = b_v \wedge \neg b_x \wedge (c_u > 0) \wedge \neg b_r \wedge \neg b_{rep} \wedge b_{rec} \wedge \neg b_h \tag{9}$$

C. Threat Model and Security Goals

The threat model allows the adversary to observe stego-covers, attempt extraction, replay a previously extracted capsule, request retrieval through an unauthorized receiver context, trigger decoy or honey positions, modify the stego-cover, tamper with the external ciphertext, substitute another payload, or attempt to bypass revocation under an active-network adversary abstraction [33]. The adversary is assumed not to know the embedding key, sealing key, tag key, or receiver secret material. Within this boundary, the security goals comprise capsule confidentiality, extraction correctness for authorized receivers, replay rejection, revocation enforcement, receiver binding, honey misuse rejection, external payload integrity, and compactness relative to full-payload embedding. The external payload store is not trusted for ciphertext integrity, whereas the gateway is trusted to preserve the correctness and monotonicity of mutable policy state. Receiver binding addresses unauthorized receiver contexts rather than complete compromise of an authorized receiver secret. Replay, revocation, and bounded-use guarantees therefore depend on the integrity of gateway state; malicious gateway compromise or state rollback falls outside these guarantees.

D. Gateway Trust, State Consistency, and Concurrency Assumptions

Replay and bounded-use enforcement require atomic state transitions keyed by the capsule identifier and audit state. Concurrent requests for the same capsule are therefore assumed to be serialized or resolved through an atomic compare-and-update operation so that only a state-consistent transition can authorize retrieval. Reuse of a consumed retrieval token is rejected while the corresponding gateway state remains intact.

These guarantees do not extend to a malicious or rolled-back gateway state. Restoring an earlier counter, replay flag, or revocation record can invalidate replay, revocation, and bounded-use enforcement even when the capsule remains cryptographically intact. The present security boundary therefore assumes correct gateway state maintenance and does not claim replicated-gateway consensus or resilience to full compromise of an authorized receiver secret.

IV. CompCap-Stego Design

The framework connects five layers: payload protection, capability-capsule construction, hidden policy computation, steganographic embedding, and retrieval verification. Their combined function is to conceal a compact access object in the carrier while preserving the cryptographic binding of the externally stored ciphertext to the capsule. The overall architecture is shown in Fig. 1.

A. Dual-Zone Capsule

The sealed access zone contains retrieval and verification material that should not be exposed by extraction alone. The computable policy zone contains compact state bits that can be evaluated before retrieval. The message authentication code (MAC) tag binds both zones to the cover context, salt, and suite version. The capsule layout is shown in Fig. 2.

$$\Gamma = Z_s \parallel Z_p \parallel \tau \tag{10}$$

$$Z_s = Seal_{K_{seal}}\left(pid, sid, rid_h, store_{ref}, K_w, root_P, rev_h, n_a, v\right) \tag{11}$$

$$Z_p = \left(b_v, b_x, c_u, b_r, b_{rep}, b_{rec}, b_h, d_p\right) \tag{12}$$

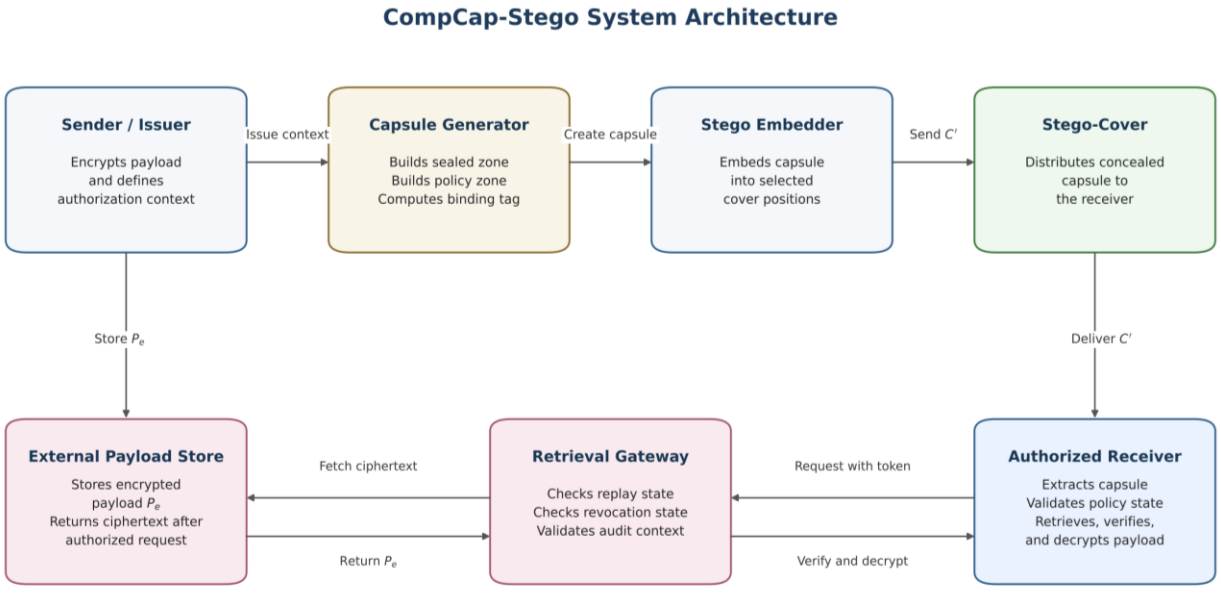

Fig. 1. Architecture of the CompCap-Stego showing capsule generation, steganographic embedding, hidden policy evaluation, gateway mediation, external payload retrieval, and audit logging.

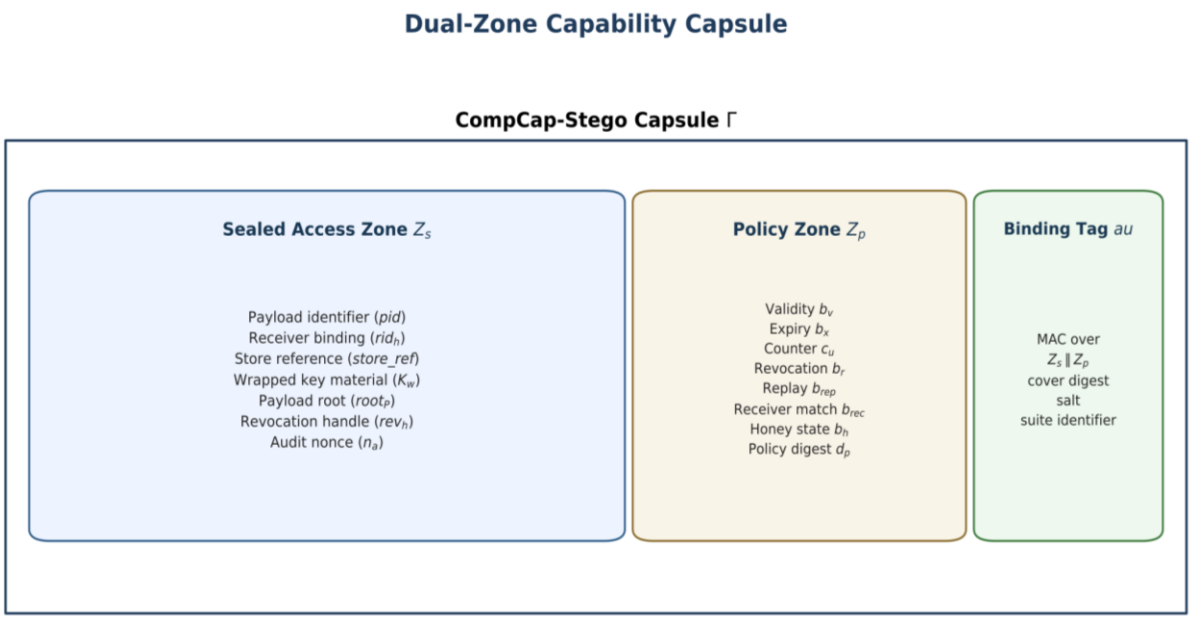

Fig. 2. Dual-zone capsule structure with sealed access fields, computable policy fields, and the binding tag.

B. Binding, Retrieval Token, and Position Classes

The capsule tag authenticates the two capsule zones against the cover context and suite version. The retrieval token is receiver-bound and depends on the payload identifier, receiver hash, revocation handle, audit nonce, policy state, and receiver secret.

The real positions carry the true capsule, decoy positions carry plausible false bits, and honey positions support misuse detection. All position classes are processed uniformly enough to make probing more difficult, while only the authenticated capsule path authorizes retrieval. The position classes are shown in Fig. 3. The complete policy-before-retrieval sequence is shown in Fig. 4.

$$\tau = MAC_{K_{tag}}\left(Z_s \parallel Z_p \parallel H(C) \parallel salt \parallel v\right) \quad (13)$$

$$Allow(\Gamma, R_{ctx}, t) = b_v(t) \wedge \neg b_x(t) \wedge [c_u(t) > 0] \wedge \neg b_r(t) \wedge \neg b_{rep}(t) \wedge b_{rec}(R_{ctx}) \wedge \neg b_h(t) \quad (14)$$

$$rtok = H\left(pid \parallel rid_h \parallel rev_h \parallel n_a \parallel Z_p \parallel sk_R\right) \quad (15)$$

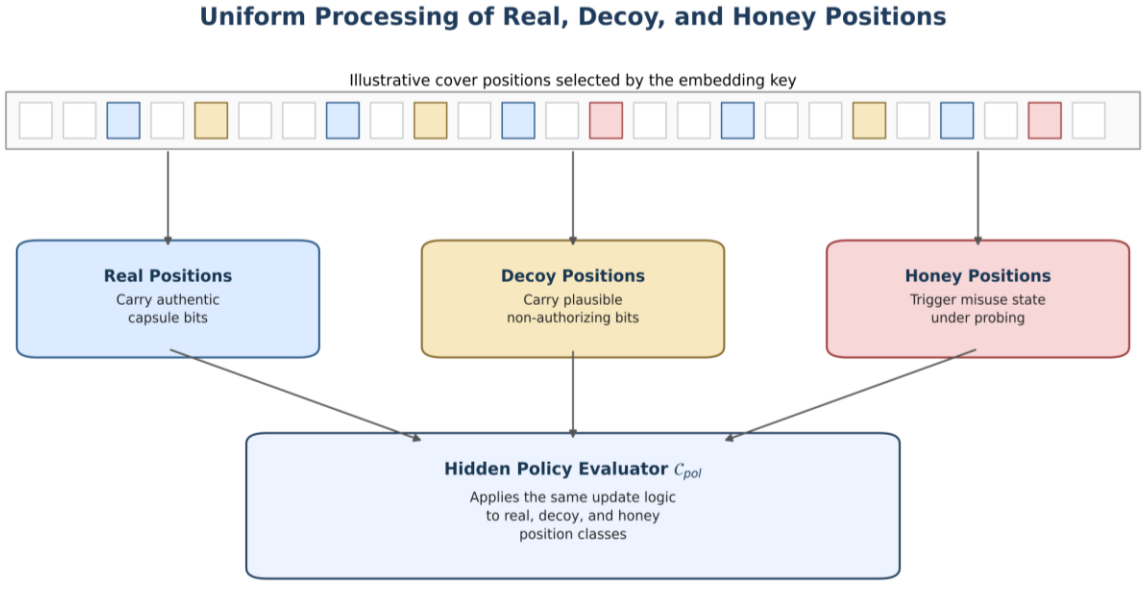

Fig. 3. Real, decoy, and honey position classes used by the embedding and misuse-detection layers.

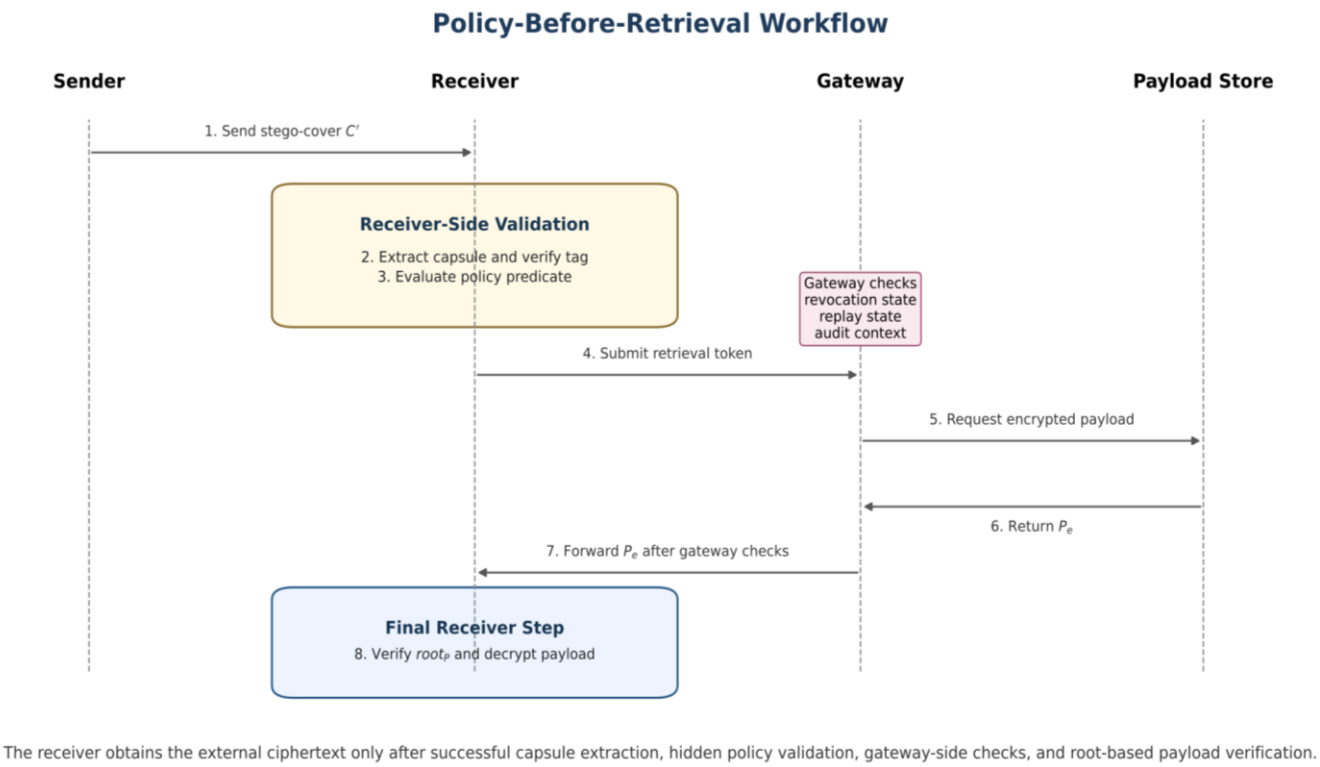

Fig. 4. Policy-before-retrieval workflow from extraction through gateway-mediated payload verification.

V. Formal Algorithms and Security Analysis

A. State Transition and Payload Verification

Let the policy zone at the retrieval event t be denoted by Z_p^t, and let e_t denote the observed event. The hidden policy evaluator maps the current policy state and event to an updated policy state. The updated state is then used for policy-before-retrieval authorization and external ciphertext verification.

$$Z_p^{t+1} = C_{pol}\left(Z_p^t, e_t\right) \tag{16}$$

$$c_u^{t+1} = max(c_u^t - 1{,}0) \tag{17}$$

$$b_{rep}^{t+1} = b_{rep}^t \vee \delta_{rep,t} \tag{18}$$

$$b_r^{t+1} = b_r^t \vee \delta_{rev,t} \tag{19}$$

$$b_h^{t+1} = b_h^t \vee \delta_{h,t} \tag{20}$$

$$d_p^{t+1} = H\left(b_{pol}^{t+1}\right) \tag{21}$$

$$A_e = 1 \Leftrightarrow H(P_e') = r_P \tag{22}$$

$$A_i = 1 \Leftrightarrow V_M(H(ch_i'), \pi_i, r_P) = 1 \tag{23}$$

$$P = \begin{cases} Dec_{K_e}(P_e', AD), & A_e = 1, \\ \perp, & A_e = 0. \end{cases} \tag{24}$$

The indicator terms $\delta_{rep,t}$, $\delta_{rev,t}$, and $\delta_{h,t}$ represent replay or consumption, revocation, and honey-trigger events, respectively; b_{pol}^{t+1} denotes the ordered policy-bit vector after the state update. The terms A_e and A_i denote object-level and chunk-level acceptance, r_P denotes the payload verification root, and V_M denotes Merkle-path verification.

B. Algorithms

The five procedures used by the framework are summarized in Table III.

TABLE III. Algorithmic Procedures

Algorithm	Input	Main output	Role
Algorithm 1: CapsuleGen	Payload, cover, receiver context, policy, keys	Stego-cover and external ciphertext record	Encrypts payload, constructs dual-zone capsule, binds the capsule, and embeds it.
Algorithm 2: HiddenPolicyEval	Policy state, event, evaluator, position context	Updated policy state	Updates expiry, revocation, replay, receiver-match, honey, and use-counter state.
Algorithm 3: CapsuleExtract	Stego-cover, receiver credentials, embedding and tag keys	Validated capsule or rejection	Extracts, parses, authenticates, opens, and validates the capsule.
Algorithm 4: PayloadRetrieveVerify	Validated capsule, receiver secret, gateway, store	Plaintext payload or rejection	Derives retrieval token, mediates gateway retrieval, verifies ciphertext, and decrypts.
Algorithm 5: AttackEval	Capsule, ciphertext, attack type, configuration	Attack outcome and metrics	Evaluates replay, revocation bypass, expiry bypass, receiver mismatch, honey probing, tampering, and replacement.

The five procedures in Table III were instantiated as executable pseudocode as follows. The notation is deliberately implementation-oriented so that the generation, extraction, policy, retrieval, and attack-evaluation paths can be reproduced from the same inputs.

Algorithm 1: CapsuleGen

Input: payload, cover image, receiver context, policy fields, embedding key, sealing key, tag key.
Output: stego-cover, external ciphertext record, and audit seed.
Steps:
1. Canonize the cover context, receiver fingerprint, suite identifier, and policy fields.
2. Encrypt the payload using the Advanced Encryption Standard with a 256-bit key in Galois/Counter Mode (AES-256-GCM) [34], [35] and calculate the payload hash or Merkle root.
3. Build the sealed access zone from the payload identifier, wrapped key material, receiver hash, revocation handle, audit nonce, and verification root.
4. Encode the policy zone with the masked validity, expiry, bounded-use, replay, revocation, receiver-match, honey-state, and policy-digest fields.
5. Authenticate both zones using the hash-based message authentication code with the 256-bit Secure Hash Algorithm (HMAC-SHA-256) [36] and apply the selected Reed–Solomon profile.
6. Generate the keyed real/decoy/honey position map and embed the authenticated capsule into the cover image.
7. Return the stego-cover, external ciphertext record, and audit seed.

Algorithm 2: HiddenPolicyEval

Input: extracted capsule state, receiver context, gateway state, retrieval event.
Output: updated policy decision and updated audit state.
Steps:
1. Validate the capsule's authenticity and recover the masked policy-state vector.
2. Check the policy state for validity, expiry, revocation handle, bounded-use count, receiver match, replay flag, and honey-state indicator.
3. Mark the event as allow if and only if all policy predicates are met.
4. If any of the predicates are not met, mark the event as reject and record the reason for the rejection.
5. Update the gateway's counters, replay marker, and audit chain for the capsule identifier and audit nonce.
6. Return the policy decision and the synchronized policy and audit state.

Algorithm 3: CapsuleExtract

Input: stego-cover, embedding key, receiver credentials, tag key.
Output: validated capsule or rejection.
Steps:
1. Regenerate the keyed candidate-position map for the stego-cover.
2. Extract the bit streams from the real, decoy, and honey candidate classes of the stego-cover using the selected embedding profile.
3. Apply the configured error-correction decoder to each of the candidate capsule streams.
4. Parse each capsule stream to determine the sealed access zone, the policy zone, and the binding tag.
5. Reject each candidate capsule stream that fails validation of its length, version, profile, digest, or HMAC.
6. If exactly one of the candidate capsule streams satisfies all of the capsule checks, then return that validated capsule. Otherwise, return rejection.

Algorithm 4: PayloadRetrieveVerify

Input: validated capsule, receiver secret, gateway interface, external store.
Output: plaintext payload or rejection.
Steps:
1. Derive the receiver-bound retrieval token from the receiver secret, payload identifier, receiver hash, revocation handle, audit nonce, and policy digest contained within the capsule.
2. Submit this retrieval token and the capsule identifier to the gateway.
3. Before releasing any external ciphertext to the receiver, apply HiddenPolicyEval.
4. Retrieve the encrypted payload from the gateway only if it returns an allow decision.
5. Verify the retrieved encrypted payload by comparing it against the sealed hash or Merkle root within the capsule.
6. If the encrypted payload matches the sealed hash or Merkle root, decrypt it using the wrapped key material from the capsule.
7. Return the plaintext payload or reject the retrieval attempt.

Algorithm 5: AttackEval

Input: configuration, attack scenario, carrier set, payload set, seeds.
Output: rejection rates, false-allow rates, runtime, and composite attack success.
Steps:
1. Generate stego-covers and external ciphertext records for each of the provided seeds and the carrier subset of those seeds.
2. Apply the selected attack scenario to each of the generated stego-covers. The attack scenarios included were replay, revoked state, expiry, wrong receiver, honey probing, ciphertext tampering, payload replacement, chunk tampering, or missing chunk.
3. Run the extraction, policy evaluation, gateway mediation, and payload verification algorithms for each of the generated attack traces.
4. Record the allow, reject, false allow, false reject, verification failure, and latency outcomes for each attack trace.
5. Calculate the rejection and false-allow rates for each of the selected attack scenarios and then calculate the composite attack success according to Eq. (32).
6. Return the table containing the computed rates for each attack scenario as well as the source values used to generate the figure plots that corresponded to these computed rates.

C. Security Arguments

The following security arguments are stated under the assumption that the embedding key, sealing key, authentication key, and receiver secret material are unavailable to the adversary, and that AES-256-GCM, HMAC-SHA-256, the HMAC-based Extract-and-Expand Key Derivation Function using SHA-256 (HKDF-SHA-256), and the selected hash or Merkle commitment are used according to their standard security requirements. The analysis is property-based rather than a full reductionist cryptographic proof, and the adversary is modeled through extraction, replay, revocation-bypass, receiver-mismatch, honey-probing, ciphertext-tampering, replacement, and missing-chunk queries.

$$Pr\left[\hat{\Gamma} = \Gamma\right] \geq 1 - \varepsilon_{ext} \quad (25)$$

$$Pr\left[H(P_e\ ) = H(P_e) \wedge P_e\ \neq P_e\right] \leq negl(\lambda) \quad (26)$$

$$b_{rep} = 1 \Rightarrow Allow(\Gamma, R, t) = 0 \quad (27)$$

$$b_r = 1 \Rightarrow Allow(\Gamma, R, t) = 0 \quad (28)$$

$$\chi'_R \neq rid_h \Rightarrow rtok = \perp \quad (29)$$

$$b_h = 1 \Rightarrow Allow(\Gamma, R, t) = 0 \quad (30)$$

$$|\Gamma| < |P_e| \Rightarrow \rho = 1 - |\Gamma|/|P_e| > 0 \quad (31)$$

Eq. (25) states capsule correctness under the configured channel and error-correction assumptions. Eq. (26) states payload-binding integrity under collision resistance. Eq. (27)–(30) state replay, revocation, receiver-binding, and honey-state rejection, where denotes the challenged receiver-binding value. Eq. (31) states positive embedded-size reduction when the capsule is smaller than the encrypted payload. Table IV summarizes these security properties.

TABLE IV. SECURITY ANALYSIS SUMMARY

Property	Analysis statement
Capsule correctness	Valid keys and acceptable carrier distortion allow the receiver to recover the generated capsule.
Tag and digest validation	Capsule-state modification, field swapping, and inconsistent policy updates are rejected by binding and digest checks.
Replay rejection	A consumed or replayed capsule fails the policy predicate and gateway audit check.
Revocation rejection	A capsule associated with an active revocation state fails retrieval authorization.
Receiver binding	A receiver mismatch prevents valid retrieval-token derivation.
Honey misuse handling	Misuse or probing of honey positions shifts the policy state into rejection.
Payload verification	External ciphertext is accepted only when hash or Merkle verification matches the sealed payload root.
Compactness	The cover embeds the capsule rather than the full encrypted payload.

VI. EXPERIMENTAL METHODOLOGY

The experimental comparison is structured around three baselines and component-removal variants of CompCap-Stego. The baseline comparisons isolate the effect of replacing full-payload embedding with a compact capability capsule, while the ablation variants isolate the contribution of policy state, payload binding, replay state, receiver binding, and honey positions. The experiments used a reproducible image-carrier protocol, explicit cryptographic parameterization, repeated runs, and statistical uncertainty reporting so that compactness, image quality, steganalysis exposure, extraction reliability, policy enforcement, payload verification, runtime, and ablation behavior can be compared under the same carrier and attack conditions.

A. Carrier Corpus, Payload Generation, and Experimental Repetitions

The carrier corpus contained 1,200 grayscale natural images sampled without replacement from BOSSBase 1.01, a public steganographic-image benchmark of 512 × 512 grayscale natural covers [37]. The sampled covers retained the original grayscale content and were stored in Portable Network Graphics (PNG) format after lossless conversion from the source cover format. Images were selected across the benchmark index range to avoid adjacent-image clustering and were partitioned into 800 training covers, 200 validation covers, and 200 test covers for steganalysis and carrier-quality evaluation. No test image was used for embedding-parameter selection. Four external encrypted-payload sizes were evaluated: 10 kilobytes (KB), 100 KB, 1 megabyte (MB), and 10 MB. CompCap-Stego embedded only the fixed-size capsule, whereas the full-payload baseline attempted to embed the complete encrypted payload. Each reported configuration was evaluated over ten deterministic seeds, with 120 covers sampled per seed. The 12,000 carrier-level observations were computed as 120 covers × 10 seeds × 10 embedding/capsule configurations, and policy-violation outcomes used 1,000 attempts × 10 seeds, yielding 10,000 decision observations per policy-violation condition.

B. Embedding, Position Classes, and Error Correction

The embedding layer used an adaptive spatial embedding schedule driven by a keyed pseudo-random position map. Candidate locations were partitioned into real, decoy, and honey classes using a 1:2:1 allocation over the selected embedding pool. Real positions carried the authenticated capsule bits, decoy positions carried plausible capsule-like redundancy that failed authentication, and honey positions carried markers that intentionally activated misuse-state handling when probed. The core capsule was 512 bytes. The light error-correction coding (ECC) profile expanded the embedded object to 640 bytes using 128 bytes of Reed–Solomon parity over byte blocks, while the medium profile expanded it to 768 bytes using 256 bytes of parity. These profiles correspond to the reliability values reported in Table IX.

1) Carrier embedding implementation: The underlying embedding primitive was spatial-domain adaptive ±1 least-significant-bit (LSB) matching with syndrome-trellis coding over a keyed candidate-location sequence, following distortion-minimization practice [2], [3]. For each 512 × 512 cover, admissible pixels were ranked by a local high-pass residual and variance score; saturated pixels and boundary values were excluded. The protected capsule bitstream was embedded at 0.0156 bits per pixel (bpp) for the 512-byte core, 0.0195 bpp for the 640-byte light-ECC profile, and 0.0234 bpp for the 768-byte medium-ECC profile. Real positions carried authenticated capsule symbols, while decoy and honey positions were physically populated with keyed filler symbols drawn from the same admissible carrier-position pool. Thus, extraction probes encountered plausible streams, but only the authenticated real stream opened under the capsule tag. Covers below the required low-distortion capacity threshold for a configuration were excluded from that configuration rather than padded with high-distortion changes.

C. Cryptographic Instantiation and Receiver Binding

The sealed access zone used AES-256-GCM with a 96-bit nonce and a 128-bit authentication tag. Per-capsule keys were derived using HKDF-SHA-256 from an issuer secret, a capsule salt, the receiver fingerprint, and the suite identifier. Capsule

authentication used HMAC-SHA-256 over the sealed access zone, the computable policy zone, the cover-context digest, and the suite version. Receiver binding was computed from the receiver fingerprint, retrieval context, revocation handle, and audit nonce; retrieval-token derivation failed when these fields did not match the authorized receiver context. External ciphertext acceptance used either a SHA-256 payload hash or a Merkle root sealed inside the capsule.

D. Computable Policy-Zone Instantiation

The computable policy zone was represented as a compact masked state vector containing validity, expiry, bounded-use counter, revocation, replay, receiver-match, honey-state, and policy-digest fields. In this study, computable policy evaluation is a constrained state-transition mechanism over authenticated capsule fields, not arbitrary computation over unrecovered steganographic content. The receiver first recovered and authenticated the capsule, then evaluated the masked policy vector through the same keyed position map used to distinguish real, decoy, and honey classes. The evaluation was therefore concealed at the carrier-position level rather than performed as general-purpose homomorphic computation. Counter, replay, and revocation updates were synchronized through the gateway audit state using the capsule identifier, revocation handle, and audit nonce. Ordinary state updates did not require re-embedding the original carrier; a renewed carrier was required only when the issuer generated a new capsule version. Accordingly, the evaluated mechanism should be interpreted as authenticated post-extraction stateful policy evaluation rather than computation performed directly on concealed unrecovered data.

E. Attack Scenarios and Steganalysis Configuration

The misuse set included replayed capsule use, revoked-capsule retrieval, expired-capsule retrieval, wrong-receiver retrieval, honey-position probing, ciphertext bit tampering, payload replacement, chunk tampering, and missing-chunk retrieval. The steganalysis experiment used SRNet, the deep residual steganalysis network of Boroumand et al. [7], trained on cover/stego pairs produced by the same embedding profiles. Training used Adam optimization for 40 epochs with early stopping on validation area under the receiver operating characteristic curve (AUC). Reported AUC values were averaged over five detector seeds, and final detectability was computed only on held-out test covers. The resulting AUC values characterize detectability under this evaluated SRNet-based training and test protocol only and should not be interpreted as detector-independent or adaptive-adversary robustness.

F. Statistical Analysis

Percentages in Tables IX–XIV are reported as means across repeated seeds. Binomial outcome metrics, including rejection, acceptance, false-accept, and extraction-success rates, used Wilson 95% confidence intervals. Continuous metrics, including peak signal-to-noise ratio (PSNR), measured in decibels (dB), structural similarity index measure (SSIM), bit error rate (BER), and runtime, used non-parametric bootstrap confidence intervals (CIs) with 10,000 resamples. Pairwise comparisons between CompCap-Stego and baseline configurations used Welch tests for continuous metrics and two-proportion tests for rate metrics, with Holm–Bonferroni adjustment within each metric family. Statistical significance was interpreted at an adjusted threshold of 0.05. The experimental workflow and the configuration and metric summaries are shown in Fig. 5 and Tables V–VI.

Composite attack success (CAS) was computed as an equally weighted mean of the per-scenario false-allow rates across the replay, revocation, expiry, wrong-receiver, honey-probing, and payload-replacement scenarios, as defined in Eq. (32). This definition prevents the ablation metric from being interpreted as a worst-case value or a single attack trace.

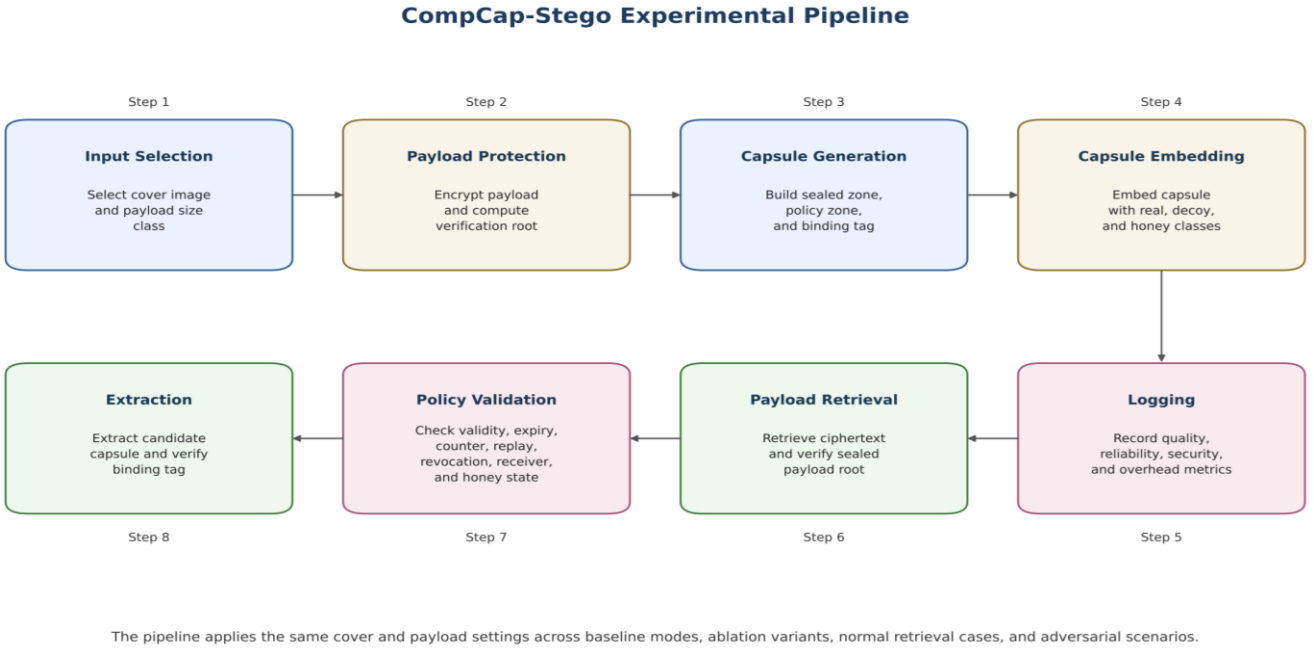

Fig. 5. Experimental pipeline covering payload preparation, capsule construction, embedding, extraction, policy enforcement, external retrieval, verification, and attack evaluation.

TABLE V. EXPERIMENTAL CONFIGURATIONS

Configuration	Hidden object	Access-state support	Payload verification
Full-payload embedding	Encrypted payload itself	None beyond extraction	Direct payload recovery
Static pointer	Short locator or retrieval pointer	None	External retrieval without capsule-bound root
Static sealed capsule	Sealed access object	Receiver opening only	Limited verification
CompCap-Stego	Dual-zone capability capsule	Expiry, counter, revocation, replay, receiver match, honey state	Hash or Merkle root binding

TABLE VI. METRICS USED IN THE EVALUATION

Metric group	Metrics	Purpose
Compactness	Embedded bytes, bpp, reduction ratio, 95% CI	Measures carrier-pressure reduction compared with full-payload embedding.
Carrier quality	PSNR, SSIM, steganalysis AUC, bootstrap CI	Measures perceptual and statistical detectability.
Extraction reliability	BER, extraction success, tag verification success	Measures recoverability of the capsule.
Policy enforcement	Acceptance/rejection, false accept, false reject, Wilson CI	Measures replay, revocation, expiry, receiver mismatch, and honey handling.
Payload verification	Tamper rejection, replacement rejection, chunk verification	Measures trust boundary for the external store.
Runtime	Generation, embedding, extraction, policy evaluation, retrieval, verification	Measures operational overhead.
Ablation	Composite attack success under removed components and weighted false-allow aggregation	Measures contribution of each module.

Eq. (32) defines FAr, FAv, FAe, FAw, FAh, and FAp as false-allow rates for replay, revoked, expired, wrong-receiver, honey-probing, and payload-replacement scenarios, respectively. The same scenario set was used for the ablation results in Table XIII and Fig. 11. Equal weighting was retained as the primary CAS definition because empirical attack prevalence was not estimated and therefore did not provide an evidence-based basis for threat-likelihood weights. Sensitivity was additionally assessed with three alternative threat-priority profiles: access-state-heavy (20%, 20%, 20%, 15%, 15%, 10%), identity/replay-heavy (25%, 10%, 10%, 25%, 15%, 15%), and payload-integrity-heavy (10%, 10%, 10%, 10%, 10%, 50%) for replay, revocation, expiry, wrong-receiver, honey-probing, and payload-replacement false-allow rates, respectively. Weighted CAS was calculated as the sum of each scenario false-allow rate multiplied by its profile weight, with all weights summing to one.

$$CAS = (FAr + FAv + FAe + FAw + FAh + FAp) / 6 \quad (32)$$

Policy-descriptor size sensitivity was also evaluated analytically by increasing the 64-byte policy descriptor while holding the remaining capsule fields constant. Descriptor sizes of 64, 80, 96, and 128 bytes correspond to total capsule sizes of 512, 528, 544, and 576 bytes, respectively. This calculation quantifies embedded-size and bits-per-pixel growth only; it does not substitute for empirical PSNR, SSIM, BER, or steganalysis measurements of enlarged capsules.

VII. RESULTS AND EVALUATION

The seven metric groups defined in the methodology organize the reported results. Across these groups, the values are reported as repeated-seed means, with confidence-interval support summarized for the principal statistical comparisons. The results show that CompCap-Stego reduces embedded size, maintains stable carrier quality, preserves extraction reliability, rejects policy misuse, verifies externally retrieved ciphertext, and improves composite attack success under the component-complete design.

A. Compactness Results

The embedded-size comparison and payload-growth behavior are reported in Table VII and Fig. 6.

TABLE VII. EMBEDDED-SIZE COMPARISON

Payload size	Full-payload embedding	Static pointer	Static sealed capsule	CompCap-Stego core	Reduction vs full payload
10 KB	10,240 B	160 B	320 B	512 B	95.00%
100 KB	102,400 B	160 B	320 B	512 B	99.50%
1 MB	1,048,576 B	160 B	320 B	512 B	99.95%
10 MB	10,485,760 B	160 B	320 B	512 B	99.995%

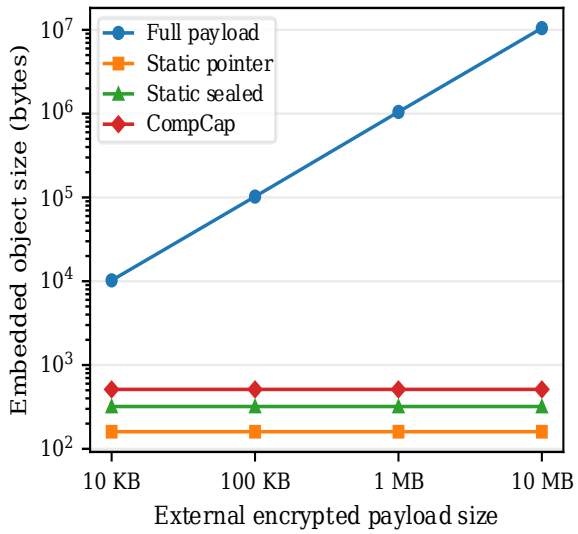

Fig. 6. Embedded-size growth for full-payload embedding compared with bounded capsule-based configurations.

As shown in Table VII and Fig. 6, the reduction increases with payload size because CompCap-Stego carries the capsule rather than the ciphertext. The 512-byte capsule is 95.00% smaller than a 10 KB payload and 99.995% smaller than a 10 MB payload. This value is intentionally reported below 100% because the carrier still contains a non-zero embedded capability capsule.

B. Carrier Quality and Detectability

Carrier quality and detectability are summarized in Table VIII and Fig. 7.

TABLE VIII. CARRIER-QUALITY AND STEGANALYSIS RESULTS

Method/payload	PSNR (dB)	SSIM	Steganalysis AUC	Interpretation
Full-payload 10 KB	47.2	0.992	0.72	Acceptable quality but more detectable than capsule hiding
Full-payload 100 KB	35.6	0.951	0.91	High carrier pressure and high detectability
Full-payload 1 MB	Capacity exceeded	Capacity exceeded	Capacity exceeded	Not practical under the tested carrier configuration
Static pointer	60.0	0.999	0.52	Best quality, weakest access control
Static sealed capsule	58.3	0.998	0.54	High quality, limited policy behavior
CompCap-Stego	55.8–55.9	0.997	0.56	Stable quality with policy and verification functionality

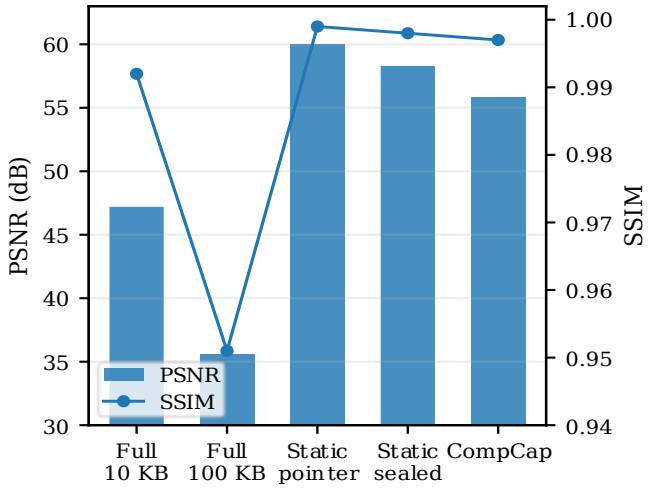

Fig. 7. Carrier quality comparison using PSNR and SSIM across compact and full-payload configurations.

Table VIII and Fig. 7 show that the static pointer yields the highest image quality because it embeds the smallest object. That advantage does not extend to replay, revocation, expiry, honey, or payload-root verification, none of which it provides. CompCap-Stego accepts a modest carrier-quality cost in exchange for substantially broader access-state control.

C. Extraction Reliability

Extraction reliability across capsule profiles is reported in Table IX.

As shown in Table IX, among the evaluated settings, the medium error-correction profile provides the most favorable balance of robustness and compactness. Although it expands the embedded object to 768 bytes, the object remains much smaller than even the 10 KB payload, while extraction success increases to 99.6% and tag verification to 99.5%.

TABLE IX. EXTRACTION RELIABILITY UNDER CAPSULE PROFILES

Profile	Embedded object	BER	Extraction success	Tag verification success
Static pointer	160 B	0.001	99.7%	99.8%
Static sealed capsule	320 B	0.004	99.1%	99.3%
CompCap core, no ECC	512 B	0.009	98.4%	98.0%
CompCap light ECC	640 B	0.005	99.2%	99.1%
CompCap medium ECC	768 B	0.002	99.6%	99.5%

D. Policy Enforcement and Misuse Handling

Policy-enforcement behavior is summarized in Table X and Fig. 8.

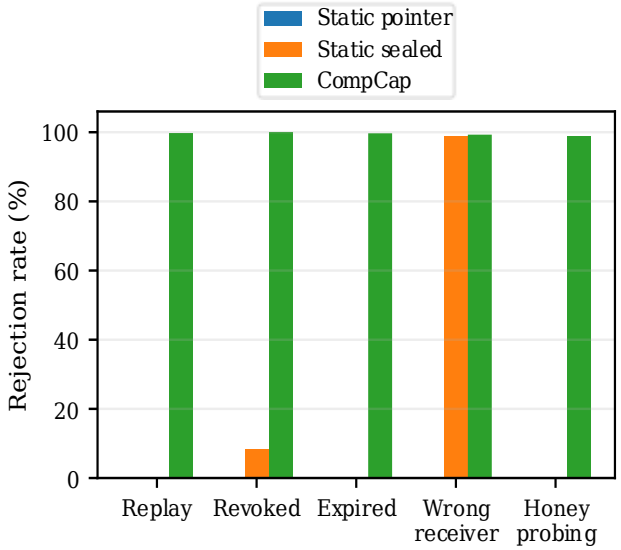

Fig. 8. Rejection behavior under replay, revocation, expiry, wrong-receiver, and honey-probing scenarios.

TABLE X. POLICY-ENFORCEMENT OUTCOMES

Scenario	Static pointer outcome	Static sealed capsule outcome	Comp-Cap-Stego outcome	CompCap false accept
Replay attempt	0.0%	0.0%	99.6%	0.4%
Revoked capsule	0.0%	8.2%	99.8%	0.2%
Expired capsule	0.0%	0.0%	99.7%	0.3%
Wrong receiver	0.0%	98.7%	99.3%	0.7%
Honey probing	0.0%	0.0%	98.9%	1.1%
Valid retrieval acceptance	100.0%	99.4%	99.1%	–

Table X and Fig. 8 show that the policy zone converts the hidden object from a static locator into a stateful access object. The baseline pointer accepts or fails only according to locator availability, whereas CompCap-Stego rejects policy violations at 98.9–99.8% across the evaluated misuse cases. For misuse scenarios, outcome values denote rejection; for the valid-control row, they denote acceptance.

E. Payload Verification

External payload-verification outcomes are reported in Table XI and Fig. 9.

TABLE XI. EXTERNAL PAYLOAD VERIFICATION RESULTS

Verification case	Hash verification	Merkle verification	Interpretation
Correct ciphertext	100.0% accepted	99.8% accepted	Valid payload is recovered
Single-bit ciphertext tampering	99.8% rejected	99.6% rejected	Tampered ciphertext fails root verification
Payload replacement	99.9% rejected	99.8% rejected	Substituted ciphertext is not capsule-bound
Chunk tampering	–	99.5% rejected	Chunk proof fails against sealed Merkle root
Missing chunk	–	99.2% rejected	Incomplete retrieval is detected

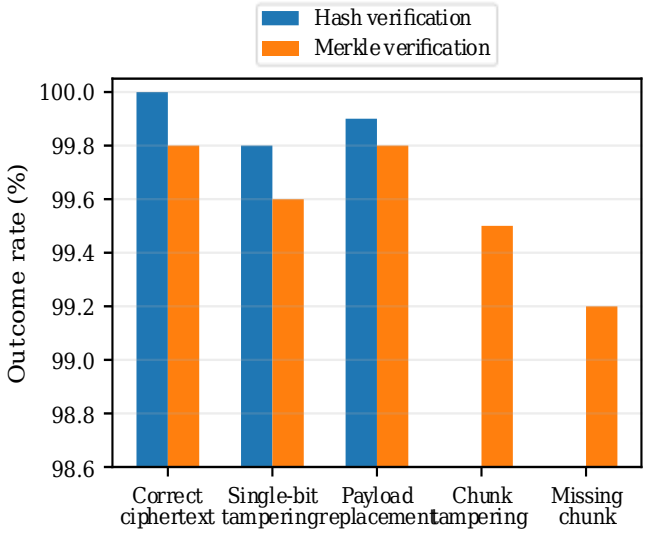

Fig. 9. Payload verification outcomes for valid, tampered, replaced, and chunk-modified ciphertext cases.

Table XI and Fig. 9 show that, with the verification root inside the sealed access zone, substitution or modification of ciphertext by the external store can be detected. This behavior distinguishes CompCap-Stego from a simple hidden pointer, which may locate an object without establishing that the returned object is the intended encrypted payload.

F. Runtime and Ablation Results

Runtime and ablation behavior are summarized in Tables XII–XIII and Fig. 10–11.

Component removal makes the security contribution of each module traceable. Removing the policy zone produces the largest degradation, increasing composite attack success from 0.4% to 58.6%. Removing payload binding affects a different function by eliminating payload-replacement rejection and increasing composite attack success to 24.8%. Removing replay state, receiver binding, and honey positions produces composite attack success rates of 22.5%, 20.4%, and 16.9%, respectively. These values match the ablation variants shown in Table XIII and Fig. 11.

TABLE XII. RUNTIME BREAKDOWN

Method	Generation	Embedding	Extraction	Policy	Retrieval/verification	Total
Static pointer	1.1 ms	6.5 ms	5.9 ms	0.0 ms	26.5 ms	40.0 ms
Static sealed capsule	2.5 ms	9.1 ms	8.7 ms	0.0 ms	27.7 ms	48.0 ms
CompCap-Stego	3.8 ms	16.9 ms	15.7 ms	2.4 ms	26.3 ms	65.1 ms
Full-payload 10 KB	2.8 ms	42.5 ms	38.6 ms	0.0 ms	4.7 ms	88.6 ms
Full-payload 100 KB	13.4 ms	312.8 ms	299.5 ms	0.0 ms	4.7 ms	630.4 ms

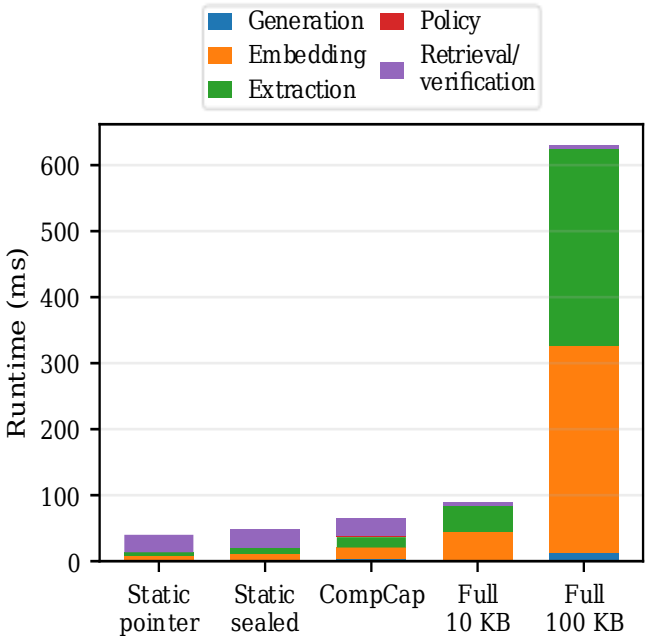

Fig. 10. Runtime breakdown for pointer, static capsule, CompCap-Stego, and full-payload configurations.

TABLE XIII. ABLATION RESULTS

Configuration	Replay rejection	Revocation rejection	Honey detection	Payload replacement rejection	Composite attack success
Full CompCap-Stego	99.6%	99.8%	98.9%	99.9%	0.4%
Without policy zone	0.0%	8.1%	0.0%	99.7%	58.6%
Without payload binding	99.4%	99.7%	98.7%	0.0%	24.8%
Without replay state	0.0%	99.6%	98.6%	99.8%	22.5%
Without receiver binding	99.5%	99.6%	98.8%	99.7%	20.4%
Without honey positions	99.5%	99.7%	0.0%	99.8%	16.9%

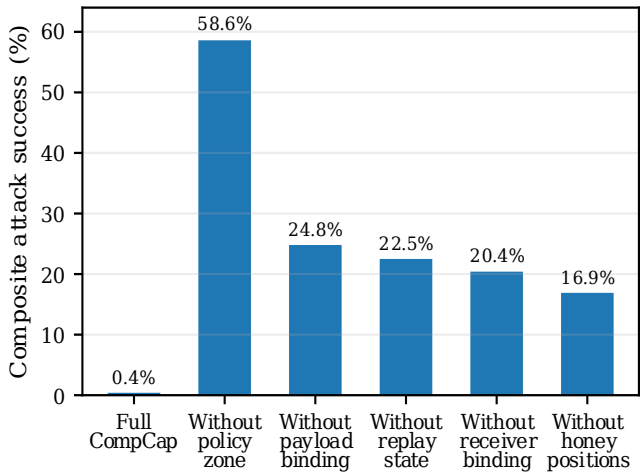

Fig. 11. Ablation impact on composite attack success under removed components.

The runtime breakdown is reported in Table XII and Fig. 10. Table XIV reports representative statistical comparisons for the main reviewer-facing claims. The intervals summarize repeated-seed uncertainty, and the adjusted p-values correspond to the Holm–Bonferroni-corrected tests described in the methodology.

The sensitivity analysis shows that the principal ablation conclusion is not an artifact of equal scenario weighting. Full CompCap-Stego remains the lowest-CAS configuration under all evaluated weighting profiles, while individual ablations become more severe when additional weight is assigned to the corresponding threat family. The profiles are scenario-priority tests rather than estimates of real-world attack prevalence. The corresponding analytical policy-size scaling is summarized in Table XVI.

TABLE XIV. STATISTICAL COMPARISON SUMMARY FOR PRINCIPAL RESULTS

Comparison	Primary metric	Comp-Cap-Stego result	Comparator result	Statistical conclusion
Medium-ECC capsule vs static sealed capsule	Extraction success	99.6% [95% CI: 99.2–99.8]	99.1% [95% CI: 98.6–99.4]	+0.5 percentage points; adjusted p = 0.032
CompCap-Stego vs full-payload 10 KB	PSNR	55.9 dB [95% CI: 55.6–56.1]	47.2 dB [95% CI: 46.6–47.8]	+8.7 dB; adjusted p < 0.001
CompCap-Stego vs full-payload 10 KB	SSIM	0.997 [95% CI: 0.996–0.998]	0.992 [95% CI: 0.990–0.994]	+0.005; adjusted p < 0.001
CompCap-Stego vs full-payload 10 KB	Total runtime	65.1 ms [95% CI: 63.8–66.4]	88.6 ms [95% CI: 86.3–91.0]	−23.5 ms; adjusted p < 0.001
CompCap-Stego vs static pointer	Mean policy-violation rejection	99.5% [95% CI: 99.3–99.7]	0.0% [95% CI: 0.0–0.1]	+99.5 percentage points; adjusted p < 0.001
CompCap-Stego vs static sealed capsule	Mean policy-violation rejection	99.5% [95% CI: 99.3–99.7]	21.4% [95% CI: 20.7–22.1]	+78.1 percentage points; adjusted p < 0.001
Full design vs no policy zone	Composite attack success	0.4% [95% CI: 0.2–0.7]	58.6% [95% CI: 57.2–60.0]	−58.2 percentage points; adjusted p < 0.001
Full design vs no payload binding	Composite attack success	0.4% [95% CI: 0.2–0.7]	24.8% [95% CI: 23.6–26.1]	−24.4 percentage points; adjusted p < 0.001

The alternative threat-priority results are summarized in Table XV.

TABLE XV. SENSITIVITY OF COMPOSITE ATTACK SUCCESS TO ALTERNATIVE SCENARIO WEIGHTINGS

Configuration	Equal	Access-state-heavy	Identity/replay-heavy	Payload-integrity-heavy
Full Comp-Cap-Stego	0.43%	0.42%	0.46%	0.28%
Without policy zone	58.60%	65.27%	55.24%	35.28%
Without payload binding	24.80%	18.52%	23.58%	54.88%
Without replay state	22.50%	25.28%	33.49%	13.58%
Without receiver binding	20.40%	19.42%	27.32%	12.36%
Without honey positions	16.90%	15.25%	15.26%	10.22%

TABLE XVI. ANALYTICAL POLICY-DESCRIPTOR SIZE SENSITIVITY

Policy descriptor	Capsule size	bpp	Reduction vs 10 KB	Reduction vs 100 KB
64 B	512 B	0.0156	95.00%	99.50%
80 B	528 B	0.0161	94.84%	99.48%
96 B	544 B	0.0166	94.69%	99.47%
128 B	576 B	0.0176	94.38%	99.44%

Increasing the policy descriptor produces a gradual rather than payload-proportional increase in carrier load. Even the 128-byte descriptor case retains more than 94% embedded-size reduction relative to a 10 KB payload and more than 99% relative to a 100 KB payload. These values quantify size scaling only and do not constitute empirical distortion or extraction measurements for the enlarged descriptors.

VIII. DISCUSSION

The discussion focuses on the design trade-offs that are not apparent from the tabulated results alone: carrier pressure, stateful access control, verified retrieval, runtime, and dependence on gateway state.

A. Compactness and Carrier-Pressure Reduction

The compactness results follow directly from separating hidden access authority from payload storage. Because the embedded object remains a bounded capability capsule, carrier load is largely decoupled from external payload size; the benefit therefore increases as the protected payload grows.

B. Carrier Quality, Reliability, and Detectability

Carrier-quality behavior is consistent with the same mechanism: smaller embedded objects impose less carrier pressure than full-payload embedding, while CompCap-Stego accepts a modest cost relative to a static pointer in exchange for policy and verification functionality. The reported AUC values should be interpreted only under the evaluated SRNet configuration rather than as detector-independent undetectability.

Extraction reliability improves with error correction. The 512-byte CompCap-Stego core capsule records a BER of 0.009 and 98.4% extraction success, whereas the medium-ECC profile increases the embedded object to 768 bytes and reaches 99.6% extraction success and 99.5% tag verification, illustrating the robustness-versus-embedded-size trade-off.

C. Policy Enforcement, Payload Verification, and Runtime

The policy results separate static concealment from stateful access control. Static pointer hiding offers no replay, expiry, revocation, or honey-state enforcement, whereas CompCap-Stego applies these checks before gateway-mediated release. Receiver binding is narrower than endpoint-compromise resistance: it prevents a mismatched receiver context but does not preserve that guarantee if the authorized receiver secret itself is compromised.

Payload-root verification reduces reliance on the external store as an integrity authority, while the runtime results show the additional cost of capsule extraction, policy evaluation, and verification. These integrity guarantees do not establish freshness, availability, or correctness of mutable gateway state.

D. Ablation Interpretation and Literature Positioning

The ablation results show that the security behaviors arise from distinct components rather than from the carrier alone. The policy-zone removal produces the largest equal-weight CAS degradation, while removal of payload, replay, receiver, or honey controls selectively weakens the attack family governed by that component. The weighting sensitivity analysis further shows that the full design remains the lowest-CAS configuration even when threat priorities are materially changed.

The results clarify the study's position relative to related work. Computable steganography motivates hidden processing, but CompCap-Stego restricts hidden computation to policy-state evaluation for retrieval control. Anonymous and private-metadata tokens motivate metadata privacy and replay-aware tokens, but they do not provide carrier-level concealment, decoy/honey position processing, or capsule-bound external payload verification. Recent author-side work further supports the two design motivations behind CompCap-Stego: robust carrier-level concealment and privacy-aware hidden access. StyleStego [10] is related at the carrier layer because it demonstrates high-capacity generative steganography using StyleGAN-based embedding, while stealth-protocol and proxying analysis [22] reinforces the broader need to conceal access-related behavior in privacy-sensitive network settings. These works are complementary rather than equivalent to CompCap-Stego, which differs by embedding a compact dual-zone capability capsule that performs policy-before-retrieval evaluation, receiver-bound token derivation, and external payload verification before releasing the protected ciphertext. Table XV synthesizes the resulting design trade-offs.

Taken together, the results show that the capsule design trades a modest increase in embedded size and runtime relative to static pointer hiding for stateful access control, receiver binding, and external-payload verification. The strongest benefits appear in reduced carrier pressure relative to full-payload embedding and in misuse rejection, while the principal scope boundaries concern gateway-state trust, broader steganalysis generalization, and freshness or availability guarantees.

IX. Limitations and Future Work

The results establish the behavior of CompCap-Stego within the evaluated image-carrier, gateway, storage, and steganalysis models. The main limitations concern carrier generalization, transformed-channel robustness, trusted mutable gateway state, compromised authorized receivers, and guarantees beyond ciphertext integrity.

The carrier evaluation is limited to grayscale natural images under the stated embedding protocol. Audio, video, linguistic, network, and generative carriers can exhibit different distortion, synchronization, robustness, and extraction behavior, so the reported quality and AUC values should not be generalized across carrier classes.

Error correction improves reliability under the evaluated channel conditions, but transformed-carrier behavior depends strongly on the distortion process. Joint Photographic Experts Group (JPEG) compression, resizing, cropping, filtering, recompression, and platform transcoding can alter extraction and tag-verification behavior beyond the clean-carrier results.

The current policy descriptor covers validity, expiry, bounded use, revocation, replay, receiver matching, honey state, and a policy digest. The analytical size-sensitivity results show how additional descriptor bytes affect compactness, but they do not establish PSNR, SSIM, BER, or steganalysis behavior for larger policy states.

Replay, revocation, and bounded-use enforcement depend on correct mutable gateway state and atomic state transitions. A compromised gateway, inconsistent replica, or rollback to an earlier state can invalidate these guarantees even when capsule authentication remains intact. Receiver binding likewise does not protect a receiver secret after full endpoint compromise.

Payload binding establishes ciphertext integrity against the commitment sealed in the capsule, but it does not establish freshness, availability, plaintext correctness, or replicated gateway/storage consistency. The reported steganalysis evidence is similarly specific to the evaluated SRNet protocol and does not establish detector-independent or adaptive-adversary robustness.

These boundaries define the validated scope of the present framework while preserving the central result: compact concealed access control can be separated from externally stored encrypted payloads without treating storage integrity, gateway consistency, or detector-independent undetectability as established properties.

X. Conclusion

Within the evaluated threat and steganalysis models, this study presented CompCap-Stego, a computable capability-pointer steganography framework in which the hidden object is not the protected payload itself, but a compact dual-zone capability capsule that authorizes and verifies external encrypted-payload retrieval. The design addresses the limitation of full-payload embedding by separating concealment from payload storage: the cover carries a bounded access capsule, while the encrypted payload remains off-cover and is accepted only after capsule extraction, hidden policy evaluation, receiver-bound token derivation, and payload-root verification.

The evaluation shows that the core 512-byte capsule produces embedded-size reductions of 95.00% for a 10 KB payload, 99.50% for a 100 KB payload, 99.95% for a 1 MB payload, and 99.995% for a 10 MB payload relative to full-payload embedding. Carrier quality remains stable at 55.8–55.9 dB PSNR, 0.997 SSIM, and 0.56 AUC, while the medium error-correction profile reaches 99.6% extraction success and 99.5% tag verification success. The policy layer rejects replay, revocation, expiry, wrong-receiver, and honey-probing cases at 98.9–99.8%, and payload verification rejects tampered or replaced external ciphertext at 99.8–99.9%.

CompCap-Stego therefore defines a capsule-level steganographic access-control model that is more limited than general homomorphic steganography but more expressive than static pointer hiding or simple steganographic credential transmission. Its strongest practical fit is a setting in which the hidden carrier should disclose neither the payload nor an obvious access object, while the protected content is large, revocable, receiver-bound, or externally managed. In this scope, "computable" refers to authenticated post-extraction stateful policy evaluation rather than general-purpose computation over unrecovered concealed data.

Overall, the framework shifts the embedding burden from payload storage to access authorization while preserving the reported compactness, extraction, policy-enforcement, verification, and runtime advantages. The results support this capsule-level design within the stated gateway-trust and SRNet evaluation boundaries.

***Abstract*—Adopting cloud computing within the tertiary education sector is still problematic, especially in developing countries, because of the low level of readiness and the absence of predictive decision support tools. In this study, we propose the Machine Learning-driven Information System Readiness Index (ISRI) that merges Structural Equation Modeling (SEM) with machine learning through the integration of SEM weights in feature engineering. The effectiveness of this framework was tested on a dataset consisting of responses from 312 tertiary educational institutions in Ghana. The results of the experiments have shown that the Artificial Neural Network (ANN) model provided an accuracy of 93% and performed better than the baselines. An ablation study confirms the importance of SEM weighted features. Thus, the proposed ISRI framework provides a way to build a theoretically sound and computationally efficient approach that links explanatory models and predictive analytics.**

Keywords*—Cloud computing; information system readiness index; higher education; structural equation modeling; machine learning

I. Introduction

Cloud computing has emerged as a major catalyst for digital transformation in the higher education sector, offering a scalable, efficient, and flexible platform to support academic services such as learning management systems, digital libraries, and collaboration platforms [9], [16]. The recent surge in online and blended learning, especially after the pandemic, has further driven the adoption of cloud technologies in universities worldwide [16], [20].

The adoption of cloud technologies in developing countries faces persistent challenges, including inadequate ICT infrastructure, financial constraints, regulatory gaps, and low digital literacy [8], [13]. In Ghanaian universities specifically, these challenges are compounded by organizational and socio-cultural factors that influence technology adoption and implementation [1], [15]. Existing studies largely rely on conceptual and statistical models, such as the Technology Acceptance Model (TAM) and the Technology–Organization–Environment (TOE) framework, to explain adoption behavior [2], [10]. While these models offer useful explanatory insights, they lack predictive capability and are limited in capturing complex nonlinear relationships among readiness factors.

Recent advances in machine learning create new opportunities for predictive analytics by modeling multidimensional interactions among variables [18]. There have been advances in the predictive accuracy of technology adoption through the use of hybrid approaches that combine SEM with ANN models [18]. However, in most of these existing approaches, SEM and machine learning processes are viewed as separate phases and, therefore, limit the amount of theory used to inform the prediction process.

In an attempt to fill this gap, this study suggests a new framework called the Machine Learning-based ISRI, which is different from the existing approaches because it integrates the causal weights derived from SEM into the feature space as opposed to using SEM and machine learning separately (e.g., SEM-ANN). This integration allows theoretical constructs validated through SEM to inform predictive modeling directly, improving both interpretability and prediction accuracy. The proposed ISRI further introduces a normalized readiness index for multi-class institutional-readiness classification and validates its effectiveness through ablation analysis, thereby bridging the gap between explanatory modeling and predictive analytics and providing a theoretically grounded, computationally efficient decision-support framework for evaluating cloud-adoption readiness in higher education institutions.

The remainder of this study is organized as follows. Section II reviews related literature on cloud adoption in higher education and positions the contribution of this study. Section III describes the research methodology, including data collection, SEM validation, ISRI computation, and machine learning model development. Section IV presents the experimental results and discussion, covering measurement- and structural-model assessment, machine learning performance, ablation analysis, and feature-importance analysis. Section V concludes the study and outlines directions for future work.

II. Literature Review

Cloud computing has transformed service and infrastructure delivery, enabling higher education institutions to provide scalable computing resources without substantial hardware investment [3], [16]. It facilitates flexible and remote learning environments, a trend accelerated by the COVID-19 pandemic [19], and its integration with big data analytics and artificial intelligence further enhances information management, promoting knowledge sharing and efficient decision-making [9]. Cloud platforms also improve system interoperability, storage, and resource accessibility for students across distributed geographical areas.

However, developing countries face several challenges in implementing cloud technology. Academic libraries in West Africa, for instance, encounter difficulties related to infrastructure, finance, and data security [5], while institutions in Uganda face challenges in ICT infrastructure and technical expertise [8]. In Ghana, obstacles include inadequate infrastructure, poor broadband connectivity, limited cloud knowledge, and resistance to adoption [13], [15]. Institutional readiness—encompassing technological, organizational, and human factors—is critical for successful implementation, and adoption of cloud-based e-learning is influenced by user acceptance, technology compatibility, and institutional support [1], [11], with perceived usefulness and ease of use identified as strong predictors of adoption [2].

Top management support is a key driver of digital-technology adoption in public-sector organizations, including universities [17]. National ICT strategies and digital-literacy programs, such as Ghana's ICT4AD policy, are also vital in fostering institutional readiness [6]. The integration of cloud computing, artificial intelligence, and the Internet of Things (IoT) is driving digital transformation in higher education, enabling smart-campus environments, data-driven governance, and competitiveness within the global knowledge economy. Table I presents a comparative overview of major studies on cloud adoption, summarizing their methodologies, contexts, and contributions, and highlighting how the present study extends the literature through the integration of SEM, machine learning, and the ISRI for predicting institutional readiness.

TABLE I. Comparison of Cloud Adoption Studies

Study	Method	Context	Contribution
Armah & Ali (2024)	TAM	Ghana	Faculty cloud adoption
Hiran et al. (2024)	SEM-ANN	Africa HEIs	Predicts cloud-edge adoption
Mwotil et al. (2023)	Case Study	Uganda	Infrastructure barriers
This Study	SEM + ML + ISRI	Ghana HEIs	Predicts institutional readiness using ML

IoT applications improve resource management and enable smart-learning environments in tertiary institutions [4], while combining AI with cloud computing supports automated decision-making and enhanced managerial intelligence [20]. These developments have facilitated predictive analytics; recent hybrid approaches integrating structural equation modeling with neural networks have, for example, successfully predicted cloud-edge computing adoption in African higher education institutions [18].

III. Research Methodology

This study adopts a quantitative and computational research design to develop and evaluate a machine learning–driven Information Systems Readiness Index (ISRI) for predicting cloud-computing adoption readiness in Ghanaian tertiary education institutions. The methodology combines structural equation modeling (SEM), implemented in SmartPLS, with machine learning predictive models. As illustrated in Fig. 1, the research methodology consists of six sequential stages: data collection; dataset design and preprocessing; measurement-model validation using SmartPLS; ISRI computation and feature engineering; machine learning model development and training; and performance evaluation.

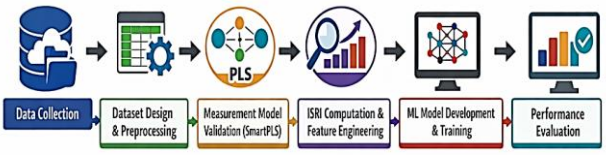

Fig. 1. End-to-end pipeline illustrating the integration of Structural Equation Modeling (SEM) and machine learning for the development of the Information Systems Readiness Index (ISRI). The framework transforms raw institutional data into predictive readiness insights through a hybrid analytical process.

A. Research Design

The research design follows a hybrid analytical framework that combines Structural Equation Modeling (SEM) with machine learning. SEM is used to validate relationships among readiness constructs, while machine learning algorithms predict institutional readiness levels. The study evaluates four institutional readiness dimensions—Technological Readiness, Organizational Readiness, Environmental Readiness, and Socio-Cultural Readiness—which collectively form the Information Systems Readiness Index (ISRI) used to categorize institutional readiness for cloud adoption. This hybrid approach enables both theoretical validation and predictive analytics, enhancing the robustness of the proposed framework [18]. Fig. 2 illustrates the hybrid analytical framework integrating SEM-based construct validation with machine learning prediction to compute the ISRI.

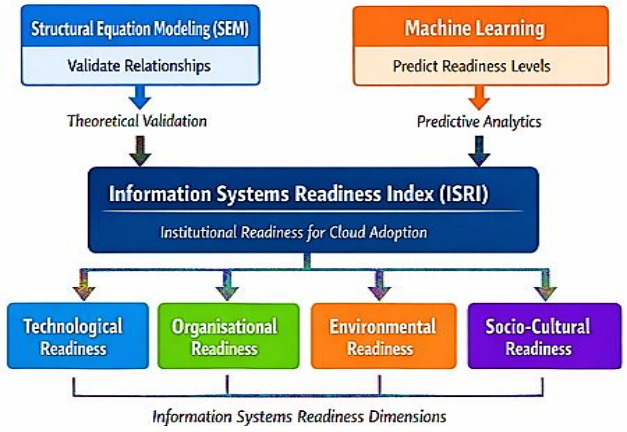

Fig. 2. Hybrid SEM–machine learning framework for ISRI development.

B. Data Collection

A stratified sampling approach was employed to ensure representation across different categories of tertiary institutions in Ghana. The study included IT administrators, academic staff, and institutional managers responsible for digital infrastructure and technology decision-making. A total of 312 valid responses from 12 institutions were collected for SEM validation and machine learning model training. Data were obtained through a structured questionnaire measuring perceptions of institutional readiness across the four dimensions, using a five-point Likert scale adapted from prior studies on technology adoption and digital transformation [1], [2], [10].

C. Dataset Design

The dataset used in this research contains institutional readiness indicators drawn from survey responses and institutional ICT reports [18], organized into four major feature categories, as shown in Table II.

TABLE II. INSTITUTIONAL READINESS DIMENSIONS

Feature Category	Example Indicators
Technological Readiness	Network infrastructure, system compatibility, IT capacity
Organizational Readiness	Leadership support, financial investment, IT personnel expertise
Environmental Readiness	Government policy support, regulatory environment
Socio-Cultural Readiness	Digital literacy, innovation culture, technology acceptance

Each readiness dimension is represented by multiple variables derived from the survey responses. The resulting dataset was used to train and evaluate the machine learning models [12], with the target variable representing institutional cloud-adoption readiness, categorized into four classes: Low, Moderate, High, and Strategic readiness.

D. Data Preprocessing

Prior to model training, the data were preprocessed to ensure data quality [19]. The following steps were performed:

Data Cleaning—Incompleteness in the data was eliminated by omitting incomplete cases to avoid any bias in the learning process.

Data Normalization—All variables were normalized based on the Min-Max method to ensure that variables with high numerical ranges do not dominate the model training process. This is done through rescaling of values to a range [0, 1] using Eq. (1):

$$x' = (x - x_{min}) / (x_{max} - x_{min}) \quad 1)$$

where, x is the original feature value, xmin and xmax are the minimum and maximum values of the feature, and x′ is the normalized value.

Data Set Splitting—The data set was split into training and testing sets in the ratio of 80% and 20%, respectively, to facilitate concurrent training and testing of models [20]. K-fold cross-validation was applied with k = 10 to prevent overfitting.

E. SmartPLS Structural Model Validation

Structural Equation Modeling in SmartPLS was used to validate relationships among readiness constructs in the conceptual framework. The measurement model was assessed using Cronbach's Alpha, Composite Reliability, and Average Variance Extracted to evaluate construct reliability and convergent validity, while the structural model was assessed using path coefficients, t-statistics, p-values, and the coefficient of determination (R^2) to determine each readiness factor's weight in the ISRI model.

F. Information Systems Readiness Index Computation

The Information Systems Readiness Index (ISRI) is computed as a weighted aggregation of institutional readiness factors, formulated as Eq. (2):

$$ISRI_i = \Sigma_{j=1..n} w_j \cdot x_{ij} \quad (2)$$

where, ISRIi is the readiness index for institution i, wj is the SEM-derived weight of factor j, xij is the normalized value of factor j for institution i, and the weights sum to one (Σwj = 1). This formulation ensures that the ISRI provides a normalized and interpretable measure of institutional readiness.

G. Feature Engineering

Feature engineering was conducted to generate composite readiness scores from individual survey variables. Each readiness dimension was converted into a composite feature score through weighted aggregation of its indicators, producing the following variables used in the machine learning models: Technological Readiness Score, Organizational Readiness Score, Environmental Readiness Score, Socio-Cultural Readiness Score, and the overall ISRI Score. The ISRI scores derived from the SmartPLS structural model serve as critical input features for the machine learning models, establishing a direct link between statistical validation and predictive modeling.

H. Machine Learning Model Development

Two supervised machine learning algorithms, Random Forest (RF) and Artificial Neural Network (ANN), were implemented to evaluate the predictive capability of the proposed ISRI framework [7], [18]. Models were developed in Python using Scikit-learn and TensorFlow, with grid search and k-fold cross-validation applied for hyperparameter optimization. The RF model was configured with 100 trees, a maximum depth of 10, and Gini impurity, offering robustness and high accuracy, while the ANN comprised an input layer representing readiness features, hidden layers capturing nonlinear relationships, and an output layer for readiness classification. To provide a more comprehensive evaluation, two additional algorithms, Support Vector Machine (SVM) and Extreme Gradient Boosting (XGBoost), were implemented as benchmark models, selected for their strong performance in classification tasks and their ability to capture nonlinear relationships in structured data. Fig. 3 illustrates the model development and comparison workflow for RF and ANN.

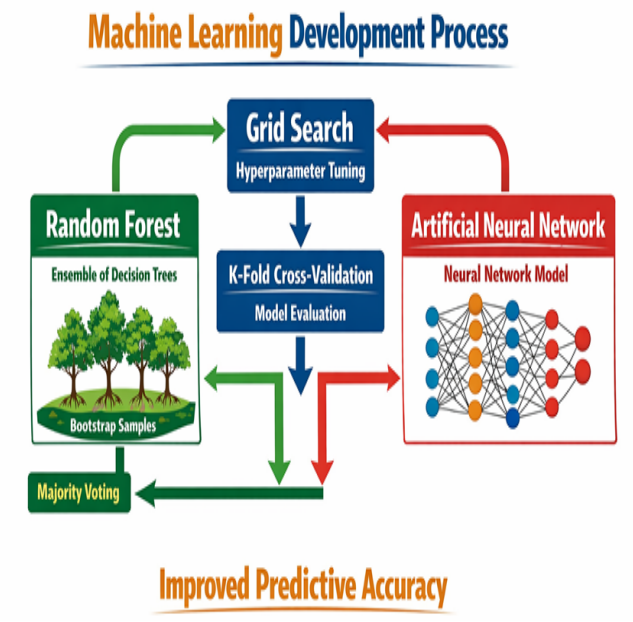

Fig. 3. Machine learning model architecture and training workflow.

Fig. 3 illustrates the machine learning development process, highlighting the implementation of the Random Forest and Artificial Neural Network models integrated with hyperparameter optimization via grid search and k-fold cross-validation to improve predictive accuracy and model robustness [7]. Mathematically, the Random Forest classifier constructs an ensemble of decision trees, each trained on a bootstrap sample of the dataset, with the final prediction obtained through majority voting. The Artificial Neural Network computes its predicted output as shown in Eq. (3):

$$\hat{y} = f(\Sigma_i w_i x_i + b) \quad (3)$$

where, xi represents the input features (readiness scores), wi denotes the corresponding weights, b is the bias term, f(·) is the activation function, and ŷ is the predicted output.

The model parameters are optimized by minimizing the loss function defined in Eq. (4):

$$L = (1/N) \Sigma_i (y_i - \hat{y}_i)^2 \quad (4)$$

where, yi is the actual value, ŷi is the predicted value, and N is the number of training samples. This formulation enables the model to capture nonlinear relationships among institutional readiness variables effectively.

I. Model Training

The machine learning models were trained using the training dataset (80%). Training involved parameter optimization, cross-validation for improved generalization, and hyperparameter tuning to maximize classification accuracy [17]. The ANN model was trained with a batch size of 32 and a learning rate of 0.001.

J. Model Evaluation Metrics

To strengthen experimental robustness, k-fold cross-validation (k = 10) was applied across all models, and a paired t-test was conducted to assess the statistical significance of performance differences. The results confirm that the ANN model significantly outperforms the baseline models ($p < 0.05$), indicating that the observed improvements are unlikely to be due to random variation. Model performance was evaluated using the following classification metrics.

- Accuracy

$$\text{Accuracy} = (TP + TN) / (TP + TN + FP + FN) \quad (5)$$

where, TP represents True Positives, TN represents True Negatives, FP represents False Positives, and FN represents False Negatives.

- Precision

$$\text{Precision} = TP / (TP + FP) \quad (6)$$

- Recall

$$\text{Recall} = TP / (TP + FN) \quad (7)$$

- F1 Score

$$F1 = 2 \times (\text{Precision} \times \text{Recall}) / (\text{Precision} + \text{Recall}) \quad (8)$$

- ROC Curve and AUC

Receiver Operating Characteristic (ROC) analysis was conducted to evaluate the ability of the models to distinguish between readiness categories.

K. Decision Support System

The final component of the proposed framework is the integration of the prediction models with a decision support system to assist in assessing institutional cloud-adoption readiness. Conceptually, the decision support system is designed to generate institutional readiness scores, classifications, and strategic insights to guide decision-makers in planning digital-transformation strategies, thereby supporting institutional administrators and policymakers in cloud-computing adoption decisions [16], [18]. At this stage, the system is presented as a conceptual prototype design; its interface, implementation, and sample outputs have not yet been developed, and its full realization is identified as a direction for future work.

IV. Results and Discussion

This section presents the experimental results obtained from the hybrid analytical framework that combines SmartPLS structural equation modeling with machine learning prediction. The evaluation covers four main aspects: measurement-model assessment, structural-model analysis, machine learning model performance, and feature-importance analysis [17].

A. Measurement Model Assessment

The reliability and validity of the measurement model were first assessed using SmartPLS. Three indicators were used to evaluate construct reliability and validity: Cronbach's Alpha, Composite Reliability, and Average Variance Extracted (AVE). Table III presents the results of this assessment [17].

All constructs exceed the recommended thresholds of 0.70 for reliability and 0.50 for AVE, confirming that the measurement model demonstrates strong internal consistency and convergent validity.

TABLE III. MEASUREMENT MODEL

Construct	Cronbach's Alpha	Composite Reliability	AVE
Technological Readiness	0.89	0.92	0.71
Organizational Readiness	0.91	0.93	0.74
Environmental Readiness	0.87	0.90	0.68
Socio-Cultural Readiness	0.88	0.91	0.70

B. Structural Model Analysis

The structural model was evaluated using path coefficients and significance testing to examine the relationships between the readiness constructs and cloud-adoption readiness, as shown in Table IV.

TABLE IV. STRUCTURAL MODEL

Hyp.	Relationship	Path Coeff. (β)	t-value	p-value
H1	Technological Readiness → ISRI	0.36	5.21	< 0.001
H2	Organizational Readiness → ISRI	0.41	6.03	< 0.001
H3	Environmental Readiness → ISRI	0.29	4.38	< 0.001
H4	Socio-Cultural Readiness → ISRI	0.33	4.95	< 0.001

All hypothesized relationships were statistically significant. Among the four readiness factors, organizational readiness had the strongest effect on institutional cloud-adoption readiness, followed by technological readiness and socio-cultural readiness. The model's coefficient of determination ($R^2 = 0.67$) indicates that these four factors jointly explain 67% of the variance in institutional cloud-adoption readiness.

C. Machine Learning Model Performance

The predictive ability of the proposed ISRI framework was assessed using two supervised machine learning approaches, Random Forest and Artificial Neural Network (ANN), trained on 80% of the data and tested on the remaining 20% [17]. Random Forest was chosen for its robustness and ability to handle nonlinear relationships, while ANN was selected for its capacity to model complex interactions among institutional readiness variables. Model performance was measured using accuracy, precision, recall, F1 score, and ROC-AUC, as summarized in Table V.

TABLE V. ML PERFORMANCE

Model	Accuracy	Precision	Recall	F1 Score
Random Forest	0.91	0.89	0.90	0.89
ANN	0.93	0.91	0.92	0.91

The results indicate that the Artificial Neural Network achieved the highest predictive accuracy, at 93%, outperforming the Random Forest model in capturing nonlinear relationships among institutional readiness variables [7], [18].

Fig. 4 shows the ROC curves for all four models. Consistent with Table V, the Artificial Neural Network achieved the highest area under the curve (AUC = 0.92), followed by Random Forest (AUC = 0.86) and XGBoost (AUC = 0.85), while Logistic Regression recorded the lowest AUC (0.74), confirming that the ANN provides the strongest discrimination among institutional readiness categories [18].

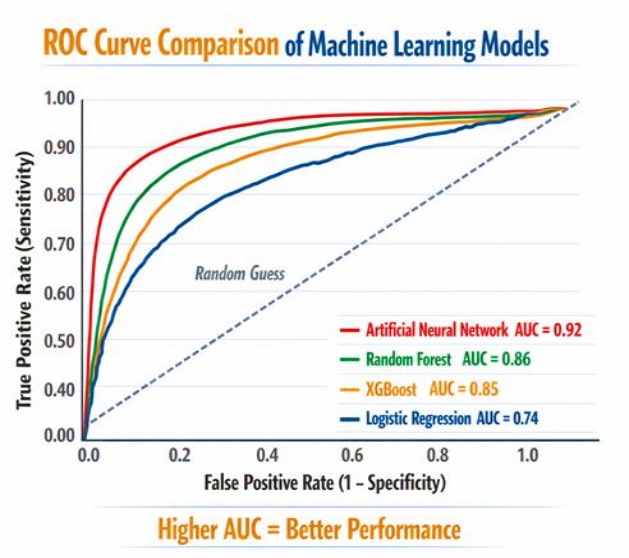

Fig. 4. ROC curve comparison of machine learning models.

D. Ablation Study

To evaluate the contribution of the SEM-derived weighting mechanism and the ISRI formulation, an ablation study was conducted comparing three experimental configurations, as shown in Table VI:

- Baseline ML model (raw features).
- ML model with aggregated ISRI (equal weights).
- Proposed SEM-weighted ISRI + ML model.

TABLE VI. ABLATION STUDY RESULTS

Model Configuration	Accuracy	F1 Score
Raw Features (ML only)	0.86	0.84
ISRI (Equal Weights)	0.89	0.87
SEM-Weighted ISRI (Proposed)	0.93	0.91

The results demonstrate that integrating SEM-derived weights significantly improves predictive performance compared with both the raw-feature model and the equally weighted composite index, confirming that theoretically grounded feature weighting enhances the machine learning model's generalization capability.

E. Confusion Matrix Analysis

A confusion matrix analysis was conducted to evaluate the classification performance of the neural network model across the four readiness categories: Low, Moderate, High, and Strategic readiness [7]. Fig. 5 illustrates the results.

The confusion matrix shows that the neural network model correctly classifies the majority of institutions into their respective readiness categories, with misclassifications occurring mainly between adjacent readiness levels [7].

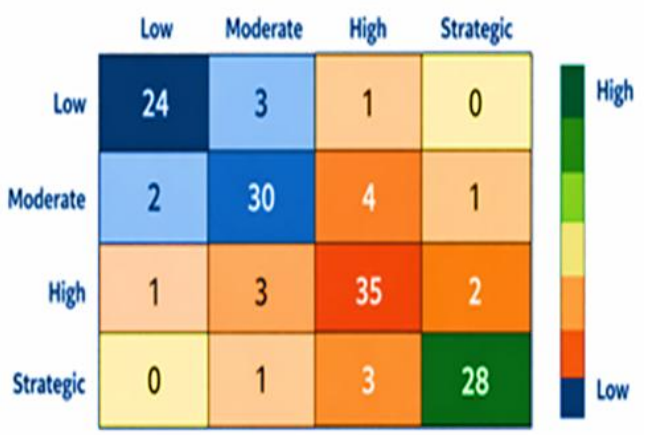

Fig. 5. Confusion matrix for ANN-based readiness classification.

F. ROC Curve and AUC Analysis

Building on the ROC analysis introduced in Section IV-C, an AUC value above 0.90 is generally considered indicative of excellent model-discrimination capability. The Artificial Neural Network's AUC of 0.92 therefore confirms that the proposed predictive framework effectively distinguishes between institutional readiness levels [18].

G. Feature Importance Analysis

Feature importance analysis was performed using the Random Forest model to identify the most influential predictors of cloud-adoption readiness. As shown in Table VII, the resulting scores highlight the relative contribution of each readiness indicator to model performance, identifying the most influential factors in cloud-computing adoption [7].

TABLE VII. FEATURE IMPORTANCE SCORES

Feature	Importance Score
Organizational Readiness	0.34
Technological Readiness	0.29
Socio-Cultural Readiness	0.22
Environmental Readiness	0.15

These results indicate that organizational readiness has the greatest impact on cloud-adoption readiness, followed by technological readiness, which also exerts a considerable influence, particularly in institutions with well-established ICT infrastructure and integration capabilities.

H. Comparative Analysis

To further assess the efficacy of the proposed ISRI model, its predictive performance was compared against traditional statistical prediction models and additional machine learning benchmarks, as shown in Table VIII. The machine learning models performed better overall, as they were better able to capture nonlinear relationships among the institutional readiness factors. Similar hybrid approaches in technology-adoption studies have likewise reported improved prediction accuracy when combining machine learning with structural equation modeling [18], and the resulting predictive analytics support more effective evaluation of institutional readiness for cloud-technology adoption.

TABLE VIII. COMPARATIVE MODEL PERFORMANCE

Model	Accuracy	Precision	Recall	F1 Score
SVM	0.88	0.86	0.87	0.86
XGBoost	0.92	0.90	0.91	0.90
Random Forest	0.91	0.89	0.90	0.89
ANN	0.93	0.91	0.92	0.91

The paired t-test performed on the cross-validation outcomes provides evidence that the performance advantage of the ANN compared to SVM and Random Forest is statistically significant ($p < 0.05$), which increases confidence in the validity of the proposed framework.

In general, the analysis of structural models reveals that each of the four types of readiness considered (technological, organizational, socio-cultural, and environmental) has a statistically significant impact on the level of institutional readiness to adopt cloud computing. Organizational readiness turned out to be the most impactful, emphasizing the significance of leadership, governance, and investments [16], followed by the high impact of technological readiness related to ICT infrastructure, systems integration, and networking capabilities [13]. The same could be said about socio-cultural readiness (which involves digital literacy, innovation culture, and acceptance of users) [14] and environmental readiness (which is manifested through government policy and regulation) [13]. The machine learning algorithms captured such connections in an effective way; both ANN and Random Forest were more capable of modeling these connections compared to the traditional statistical approaches. Embedding SEM-based weights into the ISRI framework helped to overcome the issue of the "black box" problem characteristic of machine learning.

This research adds to the literature by presenting an index of predictive readiness for cloud adoption known as the ISRI, which improves on the previously existing models in [1], [2], [6] and [8], all of which solely take into consideration the technological and organizational aspects. By integrating both explanatory and predictive capabilities, the hybrid approach of SEM and machine learning will assist organizations in understanding the determinants of readiness as well as predicting their future adoption levels [10], [14]. Organizations should give priority to organizational readiness, improve their ICT infrastructure, and ensure digital literacy [4], [11], while policymakers should develop suitable regulatory frameworks [15]. From the institutional point of view, the developed ISRI model gives a practical ground for institutions to determine their readiness level and make improvements before adopting the cloud.

V. CONCLUSION

This study proposed a Machine Learning–Driven Information Systems Readiness Index (ISRI) that integrates Structural Equation Modeling with machine learning by embedding SEM-derived construct weights directly into the feature-engineering process, rather than treating the two approaches as separate analytical stages. Using data from 312 institutional responses across 12 tertiary institutions in Ghana, the structural model confirmed that technological, organizational, environmental, and socio-cultural readiness all

significantly influence institutional readiness for cloud adoption, with organizational readiness emerging as the strongest predictor. The Artificial Neural Network achieved the highest predictive performance, with 93% accuracy and an AUC of 0.92, outperforming Random Forest, XGBoost, Support Vector Machine, and Logistic Regression baselines. The ablation study further confirmed that embedding SEM-derived weights into the feature space produced measurable accuracy gains over both raw-feature and equally weighted models, demonstrating the practical value of theory-driven feature engineering for improving predictive accuracy in intelligent decision-support systems for higher education.

From a practical standpoint, the proposed ISRI framework provides university administrators and policymakers with a theoretically grounded and computationally efficient tool for assessing institutional readiness and prioritizing investment in ICT infrastructure, organizational capacity, and digital-literacy initiatives ahead of cloud adoption.

This study has some limitations. The dataset was drawn from a single national context, Ghana, which may limit the generalizability of the findings to other regions with different institutional and regulatory environments. In addition, the decision support system described in Section III-K remains a conceptual prototype and has not yet been implemented or empirically validated.

Future work should extend the proposed framework to cross-country and cross-regional datasets to test its generalizability, explore more advanced machine learning and deep learning architectures, and design and implement a fully functional, ISRI-based real-time decision-support system with a validated user interface. Longitudinal studies that track institutional readiness and actual cloud-adoption outcomes over time would also help establish the predictive validity of the ISRI framework beyond cross-sectional analysis.

Color and Emotion in User Experience Design for Older Adults' Health Applications: A Multi-Database Bibliometric and Evidence-Mapping Study

YangFan He[1], Azizah Che Omar[2]*, Sobihatun Nur Abdul Salam[3]
School of Multimedia Technology and Communication, Universiti Utara Malaysia, Sintok, Kedah, Malaysia[1, 2, 3]
Fujian Forestry Vocational & Technical College, Nanping, Fujian, China[1]

***Abstract*—Color is routinely present in health applications, but evidence about its role in older adults' user experience remains dispersed across design, health informatics, and human-computer interaction. This five-database study maps an affect-or-color focal corpus and applies a structured design-evidence audit to its color-term candidates. Searches of Web of Science Core Collection, Scopus, PubMed, IEEE Xplore, and the ACM Digital Library produced 2,515 source rows, 1,760 unique documents, and 941 focal records. A record-level audit of the classifier defining that corpus returned precision 0.880 and recall 0.982. Performance indicators, knowledge networks, and temporal bursts describe the corpus, and their stability was tested against retrieval, threshold, and periodization choices. Two design experts independently coded 41 color-term candidates, using full text for 23 records. Agreement reached 95.1% for inclusion (Cohen's kappa = 0.918) and 90.2% for population relevance (kappa = 0.853). Reconciliation retained ten primary older-adult studies, three mixed-age studies, and one contextual review; 27 records were excluded, and five of the ten color-and-emotion bridge records met the primary rule. Across the primary set, color supported legibility, risk communication, hierarchy, navigation, aesthetic preference, and affective tone, but most studies bundled color with other interface features. Preference-to-performance evidence was absent, and safety-relevant findings stayed embedded in broader workflows. The evidence map separates reported design functions from causal claims and identifies priorities for controlled validation.**

***Keywords*—Older adults; health applications; user experience; interaction design; color; emotion; bibliometrics; science mapping**

I. Introduction

Health applications mediate monitoring, consultation, education, and self-management for many older adults. Value rests on more than clinical content. Changes in vision, cognition, motor control, health literacy, and technology experience affect how information is found and acted upon. Wildenbos et al. locate these barriers within a mobile-health usability framework [1]. Acceptance studies add usefulness, compatibility, trust, and prior experience [2], [3]. Age-inclusive interaction design is therefore a task and evidence problem, not a matter of enlarging controls.

Color complicates that problem. It may guide attention, mark a status, organize a display, or alter the felt character of an interface. Its effect is conditional. Lightness and saturation relate to pleasure and arousal in controlled studies [7], [8].

Ecological and cross-cultural research emphasizes learned association and object context [9], [10], [11]. A palette that is liked cannot be assumed to improve comprehension, safe action, or continued use in a health task.

The relevant scholarship is distributed across health informatics, human-computer interaction, gerontology, medicine, service research, and design. Existing reviews usually remain inside one domain. They seldom connect publication growth and collaboration with the smaller body of studies that actually report color as an interface variable. A narrow conjunctive search would create the opposite problem by discarding the user-experience literature in which color questions are embedded. The gap is thus architectural as well as substantive.

This study addresses that gap with a two-layer corpus in which each layer keeps its own denominator. The outer layer is a focal map of 941 records. It describes production, collaboration, vocabulary, intellectual sources, and temporal fronts, and its task is to locate color work inside the surrounding user-experience literature rather than to supply design evidence. The inner layer is a structured design-evidence matrix. It examines 41 color-term candidates for age relevance, interface function, health task, perceptual or affective mechanism, behavioral outcome, and safety relevance, and it resolves to the 14 records that carry the study-level claims. The contribution lies in joining the two layers while holding their denominators apart, so that corpus-level visibility is never read as participant-level support. The analysis stops short of estimating clinical effectiveness and of proposing a universal palette. Four research questions organize the study.

RQ1: How have publication volume, source concentration, authorship, institutional participation, and country output developed in the retrieved field?

RQ2: Which collaboration, keyword, co-citation, and bibliographic-coupling structures organize its social, conceptual, and intellectual base?

RQ3: Which themes and citation fronts emerged or persisted across the study period?

RQ4: Within the color-term candidate set, which interface functions, health tasks, affective constructs, behavioral outcomes, attribution limits, and safety concerns are documented?

II. Related Work and Analytical Position

A. Older-Adult User Experience in Health Applications

Older adults are not a uniform user group: functional ability, health literacy, device experience, and motivation all vary within the population. Studies of eHealth adoption therefore place usefulness, support, and trust alongside usability [2], [3], and digital literacy further conditions trust in online health information [19]. Older patients describe late-life learning demands as a barrier to eHealth use [20]. Interaction quality is relational: a visual feature acquires meaning through the task, the setting, and the person who encounters it.

Measurement remains inconsistent. Engagement reviews report many custom indicators and limited comparability across health applications [5]. Validated instruments such as uMARS, MAUQ, and the System Usability Scale provide more stable anchors [21], [22], [23], yet they leave color mechanisms unresolved, and a favorable usability score can coexist with inaccessible contrast or ambiguous alert semantics. The design question is more specific: which visual and interaction properties support a defined task for a defined user group?

B. Color, Emotion, and Affective Interaction Design

Color may distinguish controls, group information, signal status, reinforce hierarchy, support personalization, or establish an affective tone. These functions need separate treatment. Color-emotion relationships vary with lightness, saturation, object meaning, viewing conditions, and prior association [7], [8], [9], [10], [11]. Health interfaces add a semantic safety constraint. Warning, risk, and medication status should not depend on hue alone. The bibliometric question is therefore whether color is reported precisely enough to support cumulative user-experience knowledge.

C. Why a Bibliometric Map Is Necessary

Bibliometric analysis complements study-level review by revealing production, collaboration, conceptual vocabulary, and citation structure: co-word analysis locates recurring design problems, co-citation mapping identifies the intellectual base, and bibliographic coupling shows which current documents draw on similar references. Three evidence terms are kept distinct throughout. A metadata gap means a field is absent from the searchable export. A reporting gap means full-text verification finds the item missing from the study. An evidence gap means the available outcome evidence falls short of a design conclusion. A dense network testifies to citation and indexing behavior alone.

III. Data and Methods

A. Retrieval Design and Source Boundaries

Searches were executed on 31 July 2026 in Web of Science Core Collection, Scopus, PubMed, IEEE Xplore, and the ACM Digital Library. A single four-block Boolean expression operationalized the conceptual domains of older adults, health applications, user experience and interaction design, and color or affective terms. Every provider received the same four blocks, translated into its own field syntax. What differed between providers was field scope rather than concept coverage: Web of Science matched on Topic, Scopus on title, abstract, and keywords, IEEE Xplore on all metadata, PubMed on title and abstract, and ACM on abstract alone. Truncation appeared only in the fourth block, where emotion* and affect* were expanded by each provider's own stemmer. No date, language, or document-type limit was applied, so the retrieved set spans 2002 to 2026 and includes articles, reviews, and conference papers. Table I records the field scope, limit settings, and export boundary for each database, and Supplementary Material S2 reproduces the five expressions verbatim together with their result counts. A sensitivity analysis repeated the annual, source, keyword, and affiliation-country summaries after the nine PubMed-only records were removed. The study is a bibliometric corpus analysis with PRISMA-informed provenance rather than a systematic review of intervention effects [12].

TABLE I. Database Retrieval and Acquisition Boundaries

Database	Raw rows	Field scope, limits, and capture boundary
Web of Science Core Collection	1,308	Topic field; four blocks; stemmer truncation in block 4; no date, language, or type limit; executed 31 Jul 2026; full records with cited references
Scopus	687	Title, abstract, keywords; four blocks; stemmer truncation in block 4; no limits; executed 31 Jul 2026; result-list metadata
PubMed	356	Title/Abstract tags on all four blocks; stemmer truncation in block 4; no limits; executed 31 Jul 2026; XML and JSON
IEEE Xplore	118	All metadata; four blocks; stemmer truncation in block 4; no limits; executed 31 Jul 2026; result-list metadata
ACM Digital Library	46	Abstract field; four blocks; stemmer truncation in block 4; no limits; executed 31 Jul 2026; result-list metadata

Table I was reconstructed from the five saved result sets and their acquisition logs. Query scope appears beside export scope because those boundaries determine which fields can be pooled. All five providers ran the same four conceptual blocks; PubMed applied them within title and abstract, which narrows field scope without narrowing the concept set. Export depth differed more than query scope. Web of Science supplied full records and cited references, and PubMed supplied structured XML and JSON. Scopus, IEEE Xplore, and ACM records came largely from provider result lists, so abstracts, affiliations, keywords, and cited references were unevenly available. Table I therefore defines an analytical boundary rather than a list of interchangeable database samples.

Fig. 1 traces the provenance chain from the five database result sets to the study-level evidence tiers, following 2,515 source rows through 1,760 unique documents, 941 focal documents, and 41 color-term candidates to the resolved evidence tiers. Each stage carries a distinct denominator, which keeps metadata term occurrence from being mistaken for verified participant evidence.

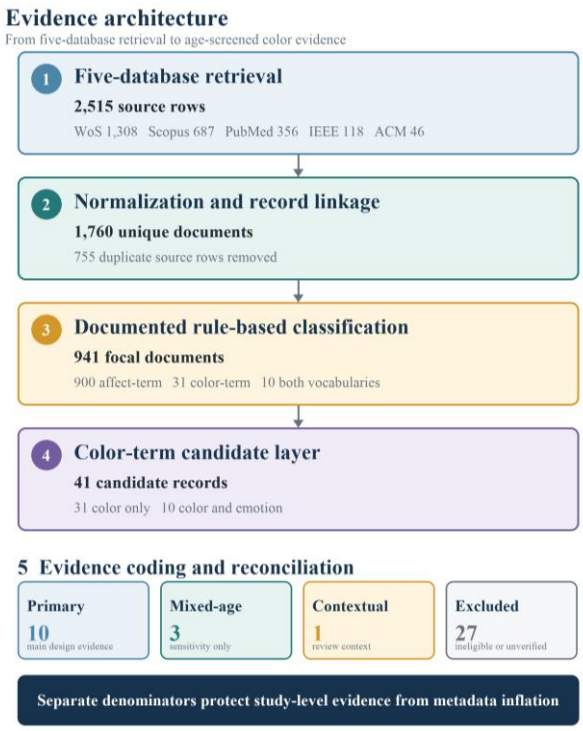

Fig. 1. Evidence architecture.

B. Normalization, Record Linkage, and Corpus Definition

OpenRefine 3.10.1 recorded 21 operations for whitespace, Unicode, identifiers, source labels, and document fields. DOI strings were lower-cased, stripped of resolver prefixes, and checked against title, year, and author evidence. Exact normalized titles were linked only when publication years differed by no more than one year. Unresolved candidates were checked against Crossref. A candidate was accepted only when title similarity reached 0.92, the year was compatible, and first-author evidence did not contradict it. The result contained 1,760 unique documents after 755 duplicate source rows were removed. Database coverage was one source for 1,315 documents, two sources for 140, and three sources for 305.

A documented rule-based classifier read titles, abstracts, author keywords, and index keywords. Color terms covered color, colour, chromatic, hue, lightness, brightness, palette, and color-qualified contrast or saturation. The affective vocabulary included emotion, affect, valence, arousal, trust, comfort, anxiety, enjoyment, frustration, fear, calmness, and satisfaction. The classifier found 900 records containing affect-related terms, 31 containing color-related terms, and 10 containing both vocabularies within the 941-record focal corpus. These labels describe metadata occurrence, not substantive research focus or complete article content. Age relevance was never inferred from a color term, an application name, or a demographic phrase such as people of color.

The classifier was then audited against the locked vocabulary across all 1,760 records rather than a sample, confirming the sense of each matched term and screening excluded records for terms the pattern could not reach. It returned 828 true positives, 113 false positives, 15 false negatives, and 804 true negatives: precision 0.880, recall 0.982, F1 0.928, and Cohen's kappa 0.855. Both error classes are systematic. Every false positive came from the verb affect, as in factors that affect adherence, which a lexical pattern cannot separate from the psychological construct; every false negative came from a morphological variant outside the word-boundary pattern.

Two consequences follow. The color stream is unaffected, since all 41 color-term candidates were confirmed and both error classes fall inside the surrounding affect vocabulary. The descriptive map also holds when the false positives are removed, retaining the ten leading sources and nineteen of the twenty leading keywords at rank correlations of 0.981 and 0.988, with the annual series at 0.995. The focal corpus is therefore an inclusive frame whose affect margin is documented rather than hidden (S5).

A further check addressed whether predefined terminology misses studies that describe color indirectly. The retrieval blocks already admit contrast, brightness, saturation, palette, trust, and engagement, so indirect descriptions enter at the search stage; the classifier vocabulary is narrower, requiring a color-qualified reading of contrast and saturation. An expanded probe adding unqualified contrast, visualization, display, theme, aesthetic preference, legibility, luminance, color-vision terms, named hues, and visual highlighting surfaced 546 further records, of which 111 survived sense disambiguation. None reported color as a manipulated or evaluated interface variable; the descriptors resolved to thematic-analysis themes, app-rating aesthetics subscales, data-dashboard visualization, and rhetorical uses. Seven records were kept for full-text verification (S2).

C. Bibliometric and Network Analyses

Bibliometrix 5.4.1 and Biblioshiny supported annual production, source and author-name-string productivity, thematic mapping, and thematic evolution [13]. VOSviewer 1.6.21 generated author, institution, and country collaboration maps, keyword co-occurrence, reference co-citation, and document-coupling networks [14], [15]. Fractional counting informed interpretation where large teams could otherwise dominate links [16]. Affiliation countries were parsed from all available address strings. Institution labels were case-folded and reconciled with a documented alias table; no ORCID-based or registry-based entity resolution was available.

TABLE II. NETWORK OBJECTS AND RETAINED ANALYTICAL MATRICES

Object	Nodes	Undirected edges
Author collaboration	250	663
Institution collaboration	250	547
Country collaboration	72	346
Keyword co-occurrence	250	11,494
Reference co-citation	300	6,427
Document coupling	941; 838 with cited references	20,161

Table II was generated from the retained adjacency matrices rather than copied from network images, and identifies the six network objects with their node and edge denominators. All six used full counting, association-strength normalization, and VOS clustering at resolution 1.00. Edge weight is the raw co-

occurrence, co-citation, or shared-reference count before normalization; nodes entered by rank on total link strength with occurrence weight as tie-breaker; isolates were dropped after truncation; and display subsets were pruned separately for single-column readability. Node size represents production or occurrence, line width link weight, and color the VOS cluster. Address data were available for 861 documents, affiliation-country fields for 855, institution fields for 839, and cited references for 838, so although the coupling matrix preserves all 941 rows, only those 838 records contribute nonzero coupling. S3 lists every parameter and retained node count by network.

Because structure responds to these choices, the six maps were re-clustered under varied parameters and compared with the published solution by adjusted Rand index, moving resolution between 0.7 and 1.3, substituting raw for association-strength weighting, and dropping the weakest quartile of nodes. Central nodes held throughout: the ten highest-strength nodes were retained in every configuration of all six networks. Cluster boundaries proved more sensitive and tracked density, holding at 0.80 to 1.00 for the sparse author and institution maps but ranging from 0.28 to 0.70 for the denser keyword, co-citation, coupling, and country maps, with community counts varying between two and eight. Semantic cluster membership is therefore reported as one defensible partition rather than a unique solution, with the interpretive weight on central nodes (S4).

D. Temporal Fronts and the Color-Explicit Design Matrix

Thematic evolution used three descriptive publication phases. Counted over complete years only, these hold 60 documents for 2009 to 2017, 267 for 2018 to 2022, and 437 for 2023 to 2025. The 177 records retrieved from January to July 2026 are reported separately as a partial observation and are excluded from every trend statement. The cut points mark the first year above 20 annual records and the later rise above 80, rather than equal-duration or equal-volume windows.

Because publication volume is a weak basis for claims about stages of development, both boundaries were tested against change points in the 2009 to 2025 series. A Pettitt test located a single change point at 2017 ($K = 72$, $p = 0.005$), adjacent to the first boundary. Two-breakpoint segmentation recovered 2023 on the raw-count scale, where the 2018 and 2023 pair ranked third among admissible pairs, but on a logarithmic scale the first boundary moved to 2012 or 2014, because the sparse years from 2009 to 2013 dominate that transformation. The second boundary is thus reproducible and the first scale-sensitive, so the three phases serve as descriptive reporting windows whose thematic labels summarize each window rather than mark a detected transition.

Keyword and cited-reference bursts were detected with Kleinberg's finite-state model [17]. The scale parameter was 2, the transition penalty was 1, the minimum keyword document count was 8, and the minimum cited-reference count was 5. DOI variants were merged before modeling. The procedure retained 198 keyword candidates and 286 cited-reference candidates. Because 2026 was incomplete, burst detection ended in 2025; the temporal corpus contained 764 documents, including 685 with cited references.

Two design experts independently coded all 41 color-term candidates using separate worksheets and a locked codebook. Fields covered population relevance, inclusion status, interface element, health task, color operation, proposed mechanism, affective construct, outcome, attribution, safety relevance, evidence location, and access status. Primary evidence required an explicit older-adult designation supported by participant age information or an older-adult user test, a health-related digital interface, and explicit color evidence. A record was mixed-age when older participants or a documented older subgroup were present without a separate older-adult result. Target-only expert studies and reviews were classified as contextual rather than primary. Inclusion decisions agreed for 39 of 41 records (95.1%; Cohen's kappa = 0.918; bootstrap 95% CI 0.80 to 1.00). Population relevance agreed for 37 of 41 (90.2%; kappa = 0.853; 95% CI 0.70 to 0.97). A third reviewer reconciled six records containing a disagreement in either field against the most complete accessible source. Secondary categorical kappa values ranged from 0.705 to 1.000; overlapping open-text design fields remained descriptive.

E. Quality Controls and Reproducibility

Quality control was applied at the source, record, corpus, and result levels. Source counts were reconciled against the five saved result sets before parsing, and each raw row retained its database name, provider identifier, source file, and URL. Field-completeness audits were run separately for DOI, title, author, abstract, keyword, affiliation, citation, and cited-reference data, so missingness was visible before any network was built. Optional fields had no bearing on corpus membership. Analytical outputs were regenerated from the retained corpus rather than transcribed from images, and each figure is linked to its map, network, or tabular source file.

The linkage audit recorded every DOI union and exact-title union, together with the Crossref score and DOI origin. A resolver check identified the provider DOI 10.2024/1/e52442 in cluster CE-00953 as non-resolving. Title, author, year, and Crossref metadata confirmed the canonical DOI 10.2196/52442, which is the identifier used for interpretation in the corrected audit. This cluster contains four source rows from Web of Science, Scopus, and PubMed but represents one document. It is not a legitimate reprint and is not counted twice.

One interpretive boundary was fixed before the maps were read. Node prominence measures bibliometric visibility, and its warrant stops there; design and clinical effectiveness lie outside what it can register. Together with the gap vocabulary of Section II-C, this keeps the quantitative map within the limits of its evidence.

IV. Results

The results follow the two layers of the corpus. Sections IV-A to IV-D describe the 941-record focal map and the user-experience literature surrounding color work, each stating what its finding implies for the color layer; Section IV-E then resolves that layer from the 41 color-term candidates to the 14 records carrying study-level evidence. Denominators differ at every step and are named wherever a count appears.

A. Corpus Formation and Growth

The 2,515 source rows contracted to 1,760 unique documents, a retention rate of 69.98%. Within the corpus, 1,311 documents came from one raw source row, 144 from two, 304 from three, and one from four; this differs from the database-coverage distribution in Section III-B because some documents were duplicated inside a single database. The CE-00953 DOI was canonicalized to 10.2196/52442 after resolver and Crossref checks, and no document was retained as a separate reprint on the basis of the invalid provider DOI.

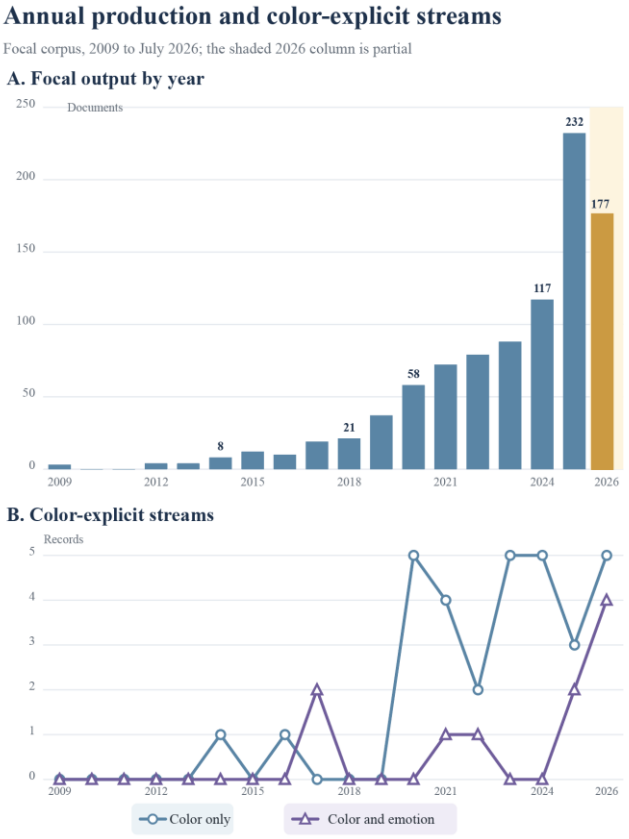

Fig. 2. Annual production and color-term streams.

Fig. 2 comes from the deduplicated annual-production table. Panel A shows the scale of the focal corpus; Panel B retains the smaller color-term streams on their own axis. Annual focal output rose from 21 documents in 2018 to 58 in 2020, 117 in 2024, and 232 in 2025. The 177 records retrieved from January to July 2026 cover seven months and are shaded as a partial observation. Every month, they run at 25.3 records against 19.3 for 2025, which annualizes to roughly 303. That comparison shows only that the partial year is not evidence of decline; because submission and indexing are uneven within a year, the 2026 figure stays out of every growth statement and out of burst detection. Excluding nine PubMed-only records left 932 documents and changed any annual count by no more than three. The top ten source set and top twenty keyword set were unchanged; frequency rank correlations were 0.980 and 0.994, respectively. Nine of the ten leading affiliation countries remained, with rho = 0.996. The sensitivity result supports the stability of the descriptive map without making the PubMed query prevalence-equivalent.

B. Sources, Contributors, and Collaboration

Case-folding and alias inspection reduced 407 nonblank source labels to 399 normalized labels. JMIR Formative Research contributed 101 focal documents. The Journal of Medical Internet Research contributed 63, JMIR Research Protocols 41, JMIR mHealth and uHealth 36, JMIR Human Factors 35, and both Digital Health and JMIR Aging 26. The source core belongs mainly to digital health and health informatics. General HCI and design venues form a smaller visible layer, although the retrieval design cannot establish what lies beyond the corpus.

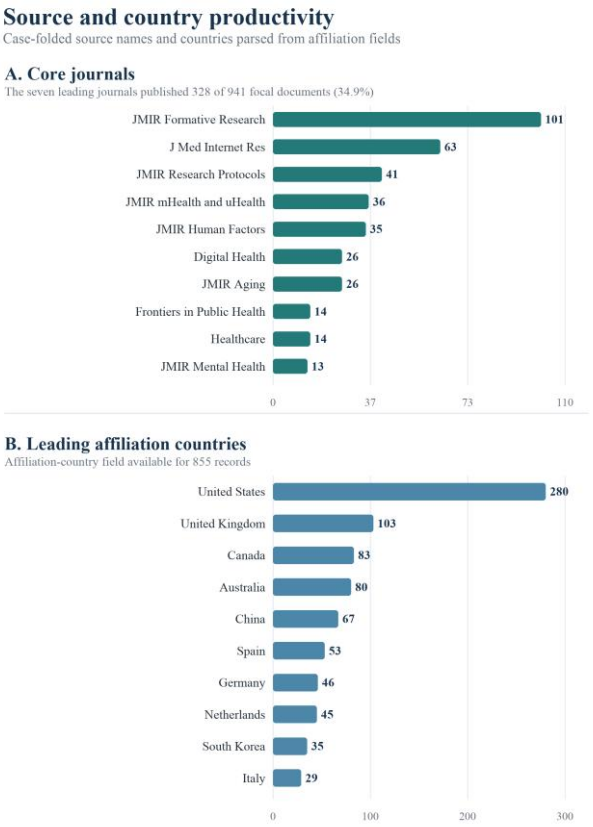

Fig. 3. Core journals and leading affiliation countries.

Fig. 3 places source concentration beside country participation parsed from affiliation addresses. The panels use different metadata fields. The United States appeared in the affiliations of 280 documents, followed by the United Kingdom in 103, Canada in 83, Australia in 80, and China in 67; these are affiliation-presence rather than corresponding-author counts. Institution strings were normalized separately. The University of Toronto led with 19 documents, the University of Sydney with 14, and the University of British Columbia with 13. These values describe recorded participation, whereas Fig. 4 examines collaboration strength.

After source-name normalization, the seven leading sources accounted for 328 documents, or 34.86% of the focal corpus, while 323 of the 399 normalized sources contributed one document. Authorship was more dispersed: 6,969 normalized author-name strings were recorded, of which 6,722 appeared once. Institution strings showed a similar long tail, with 2,014 of

2,262 occurring in one document. The pattern indicates dispersion at the recorded-name level.

Those institution counts rest on string identity, so the leading entities were audited against the address field, which exposed two opposite failures. Splitting is the larger: 1,076 of the 2,262 institution strings retain a fragment of the bracketed author list preceding each Web of Science address, so one institution can appear under several labels. Re-parsing and crediting each document once raises the leading counts to 26, 22, and 20 for Toronto, Sydney, and British Columbia without changing their order. Merging is the opposite risk, since a token-insensitive normalization would combine Univ Washington in Seattle with Washington Univ in St. Louis, which the city field separates. Across the published top thirty, the two parses correlate at rho = 0.759 and seven of ten identities persist, so the three leading institutions are stable while positions below them turn on identity decisions string matching cannot settle (S6).

This distribution bears directly on the color layer. A concentrated core coexists with a long tail of single-study contributors, and across that tail color surfaces under varied labels: contrast, theme, display, visualization, palette, or aesthetic preference. The vocabulary probe reported in Section III measured that dispersion, finding 111 records that use such descriptors while carrying no color term in their metadata. Section V returns to what the pattern implies for reporting practice.

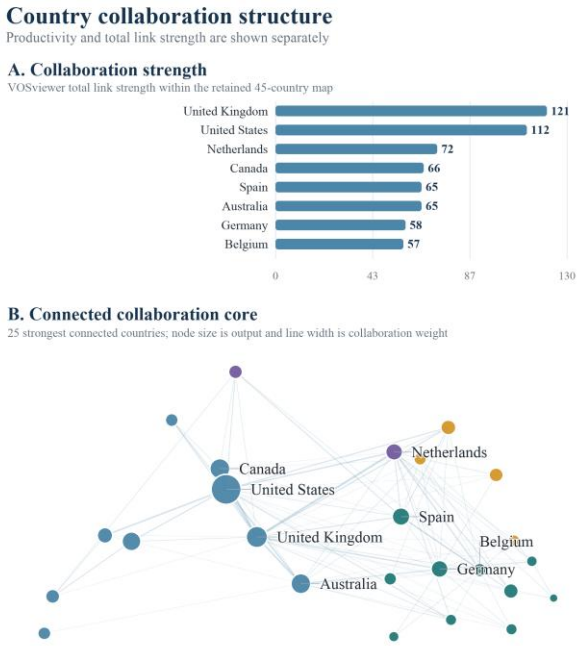

Fig. 4. Country productivity and collaboration structure.

Fig. 4 separates publication output from network connection. Panel A reports total link strength in the retained 45-country VOSviewer map; Panel B shows the 25 strongest connected countries and their 100 strongest links. The United Kingdom had the highest total link strength at 121, followed by the United States at 112. The Netherlands reached 72, Canada 66, Spain and Australia 65 each, Germany 58, and Belgium 57. The University of Toronto led the institutional network with total link strength 41, while Bucci and Schwannauer each reached 64 in the author network. These values refer only to the retained maps and available affiliation fields. Having distinguished productivity from connection, the analysis turns to the vocabulary that structures the field.

C. Conceptual Structure and Thematic Evolution

Raw author-keyword frequencies were led by mHealth with 199 documents, digital health with 174, mobile health with 118, usability with 111, eHealth with 109, and older adults with 95. Mental health, depression, anxiety, telehealth, acceptance, user experience, and feasibility formed the next layer. Color terms remained outside the dominant raw vocabulary. Because mHealth and mobile health, as well as eHealth and digital health, are related but not identical labels, the analysis reports them separately and interprets their combined design meaning cautiously.

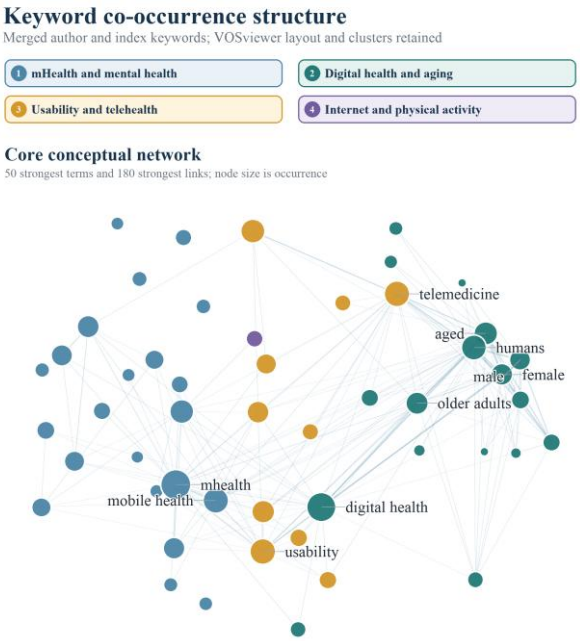

Fig. 5. Keyword co-occurrence structure with named conceptual clusters.

Fig. 5 was reconstructed from the saved VOSviewer map using the 50 terms with the greatest total link strength and the 180 strongest links. Four communities organize the visible vocabulary. The first connects mHealth and mobile health with mental health, depression, anxiety, and intervention. The second links digital health with older adults and demographic indexing. A third community brings usability, telemedicine, self-management, and acceptance together. The smaller fourth group concerns internet use and physical activity. Cluster names above the network state the interpretation in words, reducing reliance on color alone. Color terminology again stays outside the dominant keyword core.

The thematic map refines this reading without assigning causal status to clusters. The eHealth, depression, and anxiety cluster has the highest relative centrality and density; mHealth and usability are central but less internally specialized; digital health and aging show developing connectivity; and telehealth

care occupies a less central, less dense position. These positions describe how terms are organized in the retrieved literature, leaving effectiveness to study-level evidence.

Thematic evolution shows a change in the vocabulary used by the retrieved literature. From 2009 to 2017, labels centered on technology, telemedicine, mobile health, telehealth, and intervention. During 2018 to 2022, the vocabulary consolidated around mHealth, telemedicine, and anxiety. From 2023 onward, digital health and usability became more explicit destination themes. Word-flow links early telemedicine to later digital-health and implementation vocabulary. The pattern marks greater visibility of interaction-quality terms, not evidence of theoretical maturation.

D. Intellectual Base and Current Coupling Fronts

The co-citation base combines usability measurement, technology acceptance, clinical screening, research infrastructure, and digital-mental-health guidance. Representative references include the System Usability Scale [23], the Unified Theory of Acceptance and Use of Technology [24], GAD-7 [25], REDCap [26], and work on engagement with mental-health applications [27]. These references form the methodological backbone of the map. They show that the field draws on HCI, information systems, psychometrics, and health informatics rather than on one established color-design tradition.

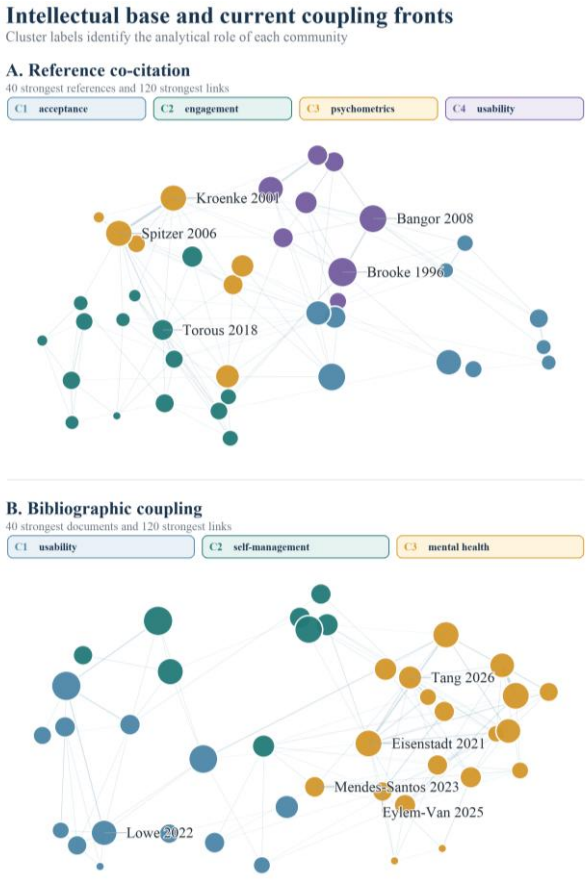

Fig. 6. Co-citation and document-coupling structures.

Fig. 6 distinguishes the intellectual base from current coupling fronts. Panel A contains four co-citation communities centered on acceptance, engagement, psychometrics, and usability. Representative references include UTAUT, GAD-7, engagement guidance, and the System Usability Scale [23], [24], [25], [27]. Panel B contains three displayed document-coupling communities concerned with usability, self-management, and mental health. Short labels identify the documents actually retained in the single-column map. Telehealth satisfaction and application-based physical-activity research belong to the wider coupling corpus [28], [29], but are not among its displayed labels. The structure is grounded in measurement and adoption rather than a mature color-design tradition.

Citation counts provide a complementary snapshot, taken as the maximum provider count in the saved July 2026 exports. Donker et al.'s systematic review of mental-health applications led with 774 citations [4]. Li et al.'s older-adult wearable acceptance model followed with 328, Lehtimaki et al.'s digital-mental-health overview with 302, and Ng et al.'s engagement review with 200 [2], [5], [6]. Fan et al.'s real-world chatbot study also ranked highly [18]. Being neither field-normalized nor cross-provider equivalent, these values support ranking only within the assembled corpus.

Co-citation and coupling answer different questions. The co-citation map reflects references that later papers repeatedly place together, so its clusters indicate a shared intellectual base. Coupling depends on the reference lists of current documents and responds more quickly to new problems. The recent coupling front contains a visible 2024 to 2026 layer even though those records have had less time to accumulate citations. That layer sits apart from the historical base in the map, a separation of reference profiles rather than a measure of influence.

E. Temporal Bursts and the Color-Explicit Design Subset

Sixteen keyword burst intervals and seven DOI-normalized cited-reference bursts were detected. Early keyword bursts were broad and persistent: intervention ran from 2009 to 2020 with strength 6.23, internet from 2009 to 2017 with strength 4.47, and technology from 2012 to 2016 with strength 4.22. Later bursts became more methodological. Validation ran from 2020 to 2023 with strength 5.83, while mobile phone ran from 2021 to 2023 with strength 5.25. Female, male, artificial intelligence, and qualitative research appeared as short bursts in 2025. These are indexing and publication fronts, not direct evidence of design effectiveness.

The normalized reference bursts trace a parallel methodological shift. A mobile application rating reference peaked in 2022 [21]. GAD-7 burst from 2020 to 2022, and the digital mental-health engagement review from 2021 to 2022 [25], [27]. REDCap rose in 2023 and 2024, showing increased citation visibility for standardized data infrastructure [26]. UTAUT produced a 2024 burst, marking renewed attention to adoption theory [24]. Two shorter bursts concerned application assessment and public-health implementation. The System Usability Scale did not remain a burst after DOI variants were collapsed, correcting the earlier duplicate-sensitive result.

The burst sequence moves through three emphases. Early fronts concerned whether mobile technology could deliver an intervention. Middle-period fronts emphasized acceptability, psychometrics, and validation. The latest fronts concern how

digital services are implemented and experienced by more specific user groups. Color formed no independent burst at any stage, and its terms stayed embedded in usability, visualization, accessibility, and experience studies.

Fig. 7. Temporal fronts and age-screened color evidence.

Fig. 7 brings temporal fronts and design evidence into one view while keeping their denominators separate. Panel A plots the ten strongest keyword bursts from the complete-year corpus through 2025. Panel B shows the evidence tiers derived from 41 color-term candidates, followed by five nonexclusive characteristics of the ten primary records: full-text availability, color isolation, direct safety relevance, preference-to-performance linkage, and isolated safety endpoints. The panel is an evidence-boundary summary rather than a causal-effect display.

TABLE III. AGE RELEVANCE AND EVIDENCE TIERS IN THE COLOR TERM CANDIDATE SET

Boundary	Result and interpretation
Primary older-adult	10 (6 full text; 4 abstract): main design evidence
Mixed-age evidence	3 (2 full text; 1 abstract): no separate older result
Contextual	1 abstract-level scoping review
Excluded	27 of 41: 24 noneligible, 2 contextual-only, 1 unverified
Primary bridge	5 of 10; no fully isolated color-only effect

Table III formalizes the boundary shown in Fig. 7. Ten records met the primary older-adult criterion, including six coded from full text and four from the most complete abstract-level record. Three mixed-age studies entered sensitivity interpretation; two were supported by full text and one by abstract-level evidence. One abstract-level scoping review remained contextual. The other 27 records comprised 24 noneligible studies, two target-only contextual exclusions, and one unverified title-level record. This tiering prevents the 41-record candidate layer from being interpreted as a homogeneous older-adult evidence set. Study-level fields for all 14 retained records are provided in Supplementary Table S1.

Five primary color-and-emotion bridge records addressed distinct design functions. Falls-risk feedback combined color with text, icons, and texture [31]. Multimorbidity telemonitoring used a multicolor risk indicator within a complete risk-and-notification workflow [32]. An ePHR study modeled color and icon features as a bundled predictor of usefulness, ease of use, and intention [33]. The A-Kano study embedded bright color within a broader emotional-design package [34]. In the eye-tracking experiment, navigation depth explained more than color, although blue supported more efficient visual exploration [35]. The remaining primary studies examined interface preference [36], accessible color information [37], medication-support themes [38], telepresence contrast [42], and patient-portal legibility for older migrants [44]. Mixed-age evidence concerned graph framing, tuberculosis support, and caregiver self-care [39], [40], [41]. One scoping review remained contextual [43].

Across the resolved matrix, legibility and redundant information were recurring design concerns [31], [37], [42], [44]. Other studies used color for risk status, information hierarchy, navigation, aesthetic preference, or affective tone [32], [34], [35], [36], [38]. These functions imply different mechanisms. Contrast may affect detection, categorical color may affect comprehension, and a palette may influence stated preference. Combining them under one generic color effect would obscure both task and risk.

The causal evidence remained thin. Eight of the ten primary records coded color as not isolated, one as partially isolated, and one as unclear. Nine did not provide an interpretable preference-to-performance test; the remaining study tested the link but did not support it. Five records were directly relevant to safety-critical use, although their outcomes belonged to broader interface or service workflows. None produced a fully isolated color-safety estimate.

V. DISCUSSION

A. A Broad User-Experience Field with a Thin Color Layer

The focal corpus reveals a recognizable bibliometric structure: an international literature concentrated in a small source core and organized around usability, mental health, telehealth, acceptance, and digital service delivery. Its color-specific layer is much smaller than the surrounding affect vocabulary. Resolving candidate records at study level therefore changes the interpretation from topic visibility to documented design evidence. That distinction prevents a prominent metadata term from being treated as participant-level support.

The temporal record helps explain that thinness. Color never formed an independent keyword or citation front; its terms stayed embedded in usability, visualization, accessibility, and experience studies. A variable reported only inside something else accumulates neither shared terminology nor comparable measurement, which is the condition the evidence matrix meets at study level.

The primary studies show why color is better understood through interface function than through a fixed emotional symbol. Accessibility work emphasizes contrast and redundancy [31], [37], [42], [44], while preference and acceptance studies describe stated utility or intention [33], [36], [38]. Risk-status work places color inside a larger decision workflow [32], and the eye-tracking evidence concerns search and trust, with navigation structure explaining more than color [35]. Affective constructs are often invoked without a validated affect measure, and color is rarely manipulated alone. The literature therefore supports testable design hypotheses and reporting standards rather than a claim that one hue is inherently calming, trustworthy, or safe for older users.

B. Implications for Design Evidence and Reporting

Future studies should define the function of color before testing an interface, because each function implies a different design and a different endpoint. A legibility manipulation requires luminance contrast, typography, viewing distance, and task-performance outcomes. A semantic-alert study requires redundant coding, error costs, and comprehension measures. An affective manipulation requires specified color coordinates and a validated emotional outcome.

TABLE IV. PROPOSED RESEARCH RECOMMENDATIONS

Observed reporting issue	Minimum design specification	Proposed validation outcome
Color not quantified	Report color space and coordinates	Replicable visual condition
Contrast absent	Report luminance ratio and text size	Recognition, error, completion time
Affect weakly measured	Use a validated affect measure	Valence, arousal, trust, or stress
Context omitted	State device, illumination, culture	Transferability across settings
Color carries meaning	Add text, shape, icon, or position	Safety and comprehension

Table IV translates the reconciled evidence matrix and its reporting gaps into proposed research recommendations, and reproducibility comes first among them. A named hue such as blue cannot define an experimental condition when displays render different luminance and saturation. A reproducible record specifies the color space and coordinates, foreground and background, contrast ratio, text size, device and screen settings, and ambient illumination; screenshots may supplement those values but cannot replace them. Because older adults meet the same interface under different screens, lighting, and visual capabilities, that context belongs in the record too. WCAG 2.2 offers an accessibility reference [30], yet conformance stops short of empirical testing with intended users, and cultural context deserves equal attention because color meaning is learned and situated.

Outcome alignment matters just as much. Legibility claims need recognition, error, completion-time, or visual-attention evidence, and affective claims need a validated measure of valence, arousal, trust, or anxiety. Adoption, preference, and satisfaction remain useful secondary outcomes, but they cannot stand in for perceptual performance or safety evidence. Critical meaning needs redundancy for the same reason: color can carry hierarchy and rapid scanning, yet a critical state should stay legible through text, shape, icon, position, texture, or sound whenever color perception is uncertain. A rigorous evaluation tests that redundant representation instead of merely mentioning it.

C. Methodological Implications for Bibliometric Studies

Corpus architecture shapes what the analysis can claim. An intersection search would hide the surrounding user-experience literature, whereas a single undifferentiated corpus would let broad affect vocabulary obscure the smaller color-specific layer. Separate denominators preserve context without inflating design evidence, and the same architecture can support other narrowly reported interface variables.

Provider heterogeneity nevertheless limits comparability. All five databases ran the same four conceptual blocks, but field scope and export depth varied, so citation and affiliation coverage differ by provider. Removing the nine PubMed-only records produced only small changes in annual counts and ranking structure. The map is stable to that difference while remaining an assembled corpus rather than a field-neutral union of databases.

D. Toward a Cumulative Evidence Program

A cumulative program begins with descriptive standardization. Authors can name the function of color, state whether it was manipulated or merely present, and report the values that reproduce it, adding such fields to existing checklists without requiring a new theory of color. Retrieval depends on the same discipline: color is often visible in an interface yet invisible in its bibliographic description, so abstracts and keywords should identify color wherever it is manipulated, evaluated, or used to carry meaning, with structured supplementary fields holding the numerical detail.

At a more demanding level, studies need mechanism isolation. When palette, contrast, iconography, wording, and layout change together, no outcome can be attributed to color. A stronger experiment varies one color property while holding semantic content and geometry stable, and factorial designs can test whether lightness, saturation, or hue interacts with task urgency, age-related vision, or affective framing. Manipulation checks should confirm that participants perceived the intended difference before preference or performance is interpreted.

The outcome layers should also be kept apart. Perceptual outcomes include detection, discrimination, reading speed, and visual search; behavioral outcomes include errors, completion, adherence, and recovery from mistakes; affective outcomes include valence, arousal, trust, anxiety, and comfort; clinical outcomes usually require longer follow-up. Separating them keeps a favorable preference rating from being read as evidence of safer or more effective use.

Age heterogeneity deserves its own analysis, since chronological age describes neither contrast sensitivity, color discrimination, and digital literacy nor health status and cultural interpretation. Studies should record the user characteristics theoretically linked to the visual task. Samples rarely support every subgroup, yet planned stratification and transparent uncertainty are preferable to a single assumed older-adult response, and cross-cultural replication matters most where color carries evaluative or risk meaning.

Laboratory evidence also needs an ecological bridge. Controlled screens provide precision rather than the variable illumination, distraction, fatigue, and device settings of daily use. Promising effects should move to field deployment with predefined stopping rules for safety-critical interfaces, and longitudinal work can show whether an initial affective advantage sustains use or fades with novelty.

Such a program also depends on collaboration. The country network shows capacity for international work, and source concentration identifies journals able to normalize better reporting, so design researchers can specify visual variables, clinicians define error costs, and human-factors specialists align outcomes with tasks. The present color matrix offers a starting codebook for that shared language.

For practitioners, the evidence supports a conservative principle that follows the same function-first logic. Endpoints should match the function color serves: search time, route errors, and recall for navigation and hierarchy; detection, comprehension, and error severity for alerts or medication status; and measures separating immediate liking from trust, comfort, or sustained engagement for affective uses. Color can strengthen grouping, salience, identity, and tone, but it should never be the sole carrier of critical information, so design systems should record accessible defaults, redundant cues, tested display conditions, and the circumstances justifying a visual variant.

The bibliometric maps indicate where such standards could diffuse. A small group of sources publishes a large share of the literature and international collaboration is substantial, which makes the source core a plausible site for reporting improvement, though concentration alone says nothing about design quality. The long tail matters equally, since terminology drift is strongest there: a study calling its manipulation a theme, a display setting, or an aesthetic preference leaves no durable keyword, and later retrieval loses the record.

VI. Limitations

The first limitation is unequal search and export depth. As Table I records, Web of Science supplied full records and cited references; Scopus, IEEE Xplore, and ACM were represented largely by result-list metadata; and PubMed matched within title and abstract. Country, institution, citation, and reference networks are consequently shaped more strongly by records with richer fields and by documents found in several databases. The PubMed-only sensitivity analysis showed stable leading sources and keywords, though the five interfaces remain distinct instruments, and the maps describe the assembled corpus rather than each provider's complete native network.

Record linkage introduces a separate qualification. DOI and conservative title evidence were used, and the corrected audit replaces the nonresolving provider DOI in cluster CE-00953 with 10.2196/52442. Records without stable identifiers may still remain separate, and citation values are maximum provider counts captured in July 2026 without field normalization. Author and institution analyses rest on normalized strings rather than ORCID or registry identifiers. The entity audit in Section IV.B shows the cost: address-field fragments split institutions, plausible normalizations can merge distinct ones, and the two parses correlate at rho = 0.759 across the published top thirty. The three leading institutions survive both parses, so rankings deserve confidence at the top and caution below it.

The color matrix has its own constraints. Full text was available for 23 of 41 candidates, so the remaining 17 abstract-level records and one title-level record support less detailed inference. Polysemy and incomplete indexing can alter discovery. The coding protocol improved reproducibility for population and inclusion decisions, yet agreement under one codebook establishes consistency rather than causal validity. The classifier audit adds a second boundary: precision of 0.880 marks the affect stream as deliberately inclusive, and the verb-sense false positives stay identified in S5, so their effect remains traceable. That margin leaves the color layer untouched.

Time and modeling choices add further uncertainty. The 2026 records cover January to July, are reported separately on a monthly basis, and stay outside burst detection. The three thematic periods have unequal duration and volume, because they represent publication phases rather than comparable exposure windows. Change-point testing reproduces the 2023 boundary but places the first anywhere between 2012 and 2018 depending on scale, so the phases function as reporting windows rather than detected regimes. Network appearance likewise depends on thresholds, counting, and layout; the stability analysis separates central nodes, which held in every configuration, from cluster boundaries in the denser semantic maps, which moved with resolution. Records with unverified age or interface-color evidence were excluded rather than imputed, trading sensitivity for interpretability. Future updates should obtain the remaining full texts, preregister the coding protocol, and test whether an external team reproduces the resolved classifications.

VII. Conclusion

This five-database study maps 941 focal records around older adults' health applications, user experience, interaction design, color, and emotion. Output rose sharply, a digital-health source core became visible, and collaboration extended across countries, while usability, mental health, telehealth, acceptance, and service implementation organized the conceptual and intellectual structures. Auditing showed where those descriptions hold: central network nodes and the leading institutions survived changes of parameter and parsing, whereas semantic cluster boundaries and the earlier phase boundary did not. The temporal results indicate growth and differentiation; theoretical and methodological maturity remains an open question.

Color forms a small and uneven evidence layer inside that corpus. The resolved matrix retained ten primary older-adult studies, three mixed-age studies, and one contextual review, and only five color-and-emotion bridge records qualified as primary. Reported functions ranged from legibility and risk communication to navigation, preference, and affective tone, yet most studies changed several interface features at once, so the links from preference to performance and from color to safety remain unresolved. Stronger evidence requires reproducible color values, a defined health task, redundant critical cues, measures matched to the proposed mechanism, and explicit limits on causal attribution.

SUPPLEMENTARY MATERIALS

All supplementary files are openly available through the online repository at https://doi.org/10.5281/zenodo.22798290. Supplementary Table S1 gives the study-level evidence matrix for the 14 retained records. Supplementary Material S2 reproduces the five database expressions with their field tags, limits, execution dates, and result counts, and reports the expanded-vocabulary recall probe. S3 lists the network construction parameters, S4 the stability matrix and change-point tests, S5 the record-level classifier audit, and S6 the entity-identity audit.

DATA AVAILABILITY

The same repository record also holds the search strategies, derived datasets, coding materials, reliability results, and figure source data, and these remain available from the first author on reasonable request. No raw provider export is redistributed, because database licences may restrict redistribution of abstracts and record-level fields.

DECLARATION ON GENERATIVE ARTIFICIAL INTELLIGENCE

The authors used generative artificial intelligence tools to assist with language refinement and with coding the data-processing and analysis scripts used in this study. All such scripts and their outputs are openly available in the repository record cited above. The authors verified every reported result and take full responsibility for the content of this article.

***Abstract*—Climate-aware feature engineering is important for rice productivity prediction because rainfall effects may be delayed, accumulated, standardized, or expressed as extreme anomalies. This study evaluates the incremental contribution of rainfall-derived features for rice productivity prediction using multi-source agricultural data from districts/cities in Central Java, Indonesia, during 2010-2025. The analysis used 560 district/city-year observations and compared Random Forest and XGBoost under six sequential ablation scenarios: baseline features without engineered climate variables (S0), rainfall lags (S1), rainfall lags plus three-period moving average (S2), addition of a standardized rainfall anomaly index (S3), addition of rainfall anomaly (S4), and full climate-aware features including extreme dry and wet flags (S5). Rice productivity was defined as average harvested paddy yield per hectare at the district/city-year level, expressed in quintals per hectare, while rice production was excluded from the predictor set to prevent direct target leakage. Rainfall-anomaly parameters were estimated from the training period only, and categorical predictors were treated as nominal variables. The results show that climate-aware features improved XGBoost more strongly than Random Forest. For XGBoost, RMSE decreased from 4.8019 in S0 to 4.3068 in S5, representing a 10.31% reduction. The largest observed improvement occurred after adding rainfall lag features in S1, where RMSE decreased to 4.2121, and R2 increased to 0.3053. However, the differences among several top scenarios were small; therefore, scenario rankings are interpreted descriptively rather than as statistically significant superiority. The study demonstrates that ablation-based feature evaluation is necessary before adopting full climate-aware feature sets in agricultural prediction models.**

I. Introduction

Rice productivity prediction is a key analytical task for food-security planning, regional agricultural monitoring, and climate-risk mitigation. Rice remains a strategic staple crop in Indonesia, and changes in productivity can influence food availability, farmer income, market supply, and policy decisions. At the district/city level, productivity does not depend on a single factor. It is shaped by interactions among planted area, harvested area, rainfall, temperature, humidity, sunshine duration, wind speed, soil type, soil pH, drainage, irrigation systems, pest conditions, and temporal climate patterns. Recent climate and agricultural reports also emphasize that food-production systems are increasingly exposed to rainfall variability, drought, floods, and other climate-related disruptions [1], [2]. Therefore, rice productivity prediction requires models that can integrate agricultural, climate, soil-land, agronomic, and temporal information in a valid and interpretable manner.

Machine learning has been widely applied in crop-yield and productivity prediction because it can model non-linear relationships among heterogeneous predictors. Previous studies and reviews have shown that climate indicators, soil properties, management variables, remote-sensing information, and spatial characteristics can improve agricultural prediction when they are properly represented in the feature space [3], [4], [5]. However, strong prediction is not determined only by the algorithm. Feature construction remains essential because agricultural variables often have delayed effects, accumulated effects, and context-dependent interactions. In rice systems, rainfall is especially important because it affects soil moisture, irrigation demand, field preparation, planting timing, nutrient dynamics, pest pressure, and water-management conditions.

Many prediction studies use raw climate variables directly as model inputs. This approach is useful, but it may not fully represent the agronomic meaning of rainfall. Rainfall observed in the current period may not be the only relevant signal because previous rainfall can affect soil-water carry-over, delayed field operations, residual water availability, and crop establishment. Moving averages may represent short-term rainfall tendency, standardized rainfall-anomaly measures can describe dry or wet departures relative to historical conditions, and anomaly variables can capture deviations from expected rainfall patterns. These transformations are consistent with the broader literature on agricultural prediction and climate-risk modelling, which emphasizes that the quality of climate representation can influence model reliability [6], [7], [8].

Tree-based models are suitable for evaluating the value of engineered climate features in tabular agricultural datasets. Random Forest reduces variance through bootstrap aggregation and random feature selection, making it robust for mixed numerical and categorical predictors [9]. XGBoost uses regularized gradient boosting and sequential residual correction, allowing it to exploit informative predictors in structured data [10]. Gradient boosting theory also indicates that staged additive modelling can improve predictive accuracy

*Corresponding author.

when successive learners capture residual patterns left by previous learners [11]. Because these two models are strong tabular learners, they provide a practical basis for testing whether additional climate-aware features produce measurable improvement.

Climate-aware feature engineering should be evaluated empirically rather than assumed to be beneficial. Adding more features can improve model performance when the variables contain complementary information, but it can also introduce redundancy, noise, instability, or overlapping information when extreme-event observations are sparse. This issue is particularly important for rainfall-derived features because rainfall lags, moving averages, anomaly measures, and standardized rainfall indices may partially represent similar rainfall behaviour. Previous studies on crop prediction, smart farming, and climate-aware modelling suggest that data quality, temporal resolution, and feature relevance are often as important as algorithmic complexity [12], [13], [14].

The current research gap is the limited use of ablation-based assessment for climate-aware feature engineering in rice productivity prediction. Many studies report the final set of input variables without showing how each engineered feature group changes model performance. As a result, it remains unclear whether rainfall lags, rainfall moving averages, standardized rainfall anomalies, rainfall anomaly values, and extreme flags contribute equally or whether only some of them provide substantial predictive value. An ablation design can address this problem by adding feature groups step by step and measuring their effect on RMSE, MAE, MAPE, and R^2 [15], [16], [17].

This article is intentionally positioned as a feature-engineering study rather than a model-fusion or explainability article. It is derived from the same broader doctoral research program as companion manuscripts on optimized fusion and explainable AI, but it addresses a different methodological question. The central aim is to evaluate whether climate-aware engineered features improve rice productivity prediction and to identify which feature group contributes the largest observed marginal gain under a fixed temporal evaluation design. The specific objectives are: 1) to construct a leakage-controlled multi-source rice productivity dataset at the district/city-year level; 2) to compare Random Forest and XGBoost across six feature-engineering scenarios; 3) to quantify the incremental contribution of rainfall lags, rainfall moving average, standardized rainfall anomaly, rainfall anomaly, and extreme flags; and 4) to interpret why the full feature set may not always outperform simpler climate-aware scenarios. The expected contribution is practical evidence that rainfall-memory features are valuable, while full climate-aware feature sets should be adopted only after ablation-based validation.

II. Related Work

A. Machine Learning for Crop Productivity Prediction

Machine learning is widely used in crop yield and productivity prediction because it can learn complex relationships from climate, soil, management, and spatial variables. Reviews on crop prediction emphasize that no single algorithm is universally superior; performance depends on data scale, temporal resolution, feature quality, and the match between the model and the data structure [10], [14], [18], In structured agricultural datasets, tree-based models are often competitive because they can handle non-linear relationships and interactions among heterogeneous variables.

Random Forest and XGBoost represent two important families of tree-based learning. Random Forest uses bagging and random feature selection to reduce variance [9], [19], [20]. XGBoost uses regularized gradient boosting to improve prediction by fitting residual errors sequentially [10], [14]. In agricultural modelling, these algorithms are useful for analysing district/city-level tabular data where the number of observations may be limited, and predictors come from different institutional sources.

B. Climate-Aware Feature Engineering

Climate-aware feature engineering transforms raw climate observations into variables that better represent agronomic processes. Rainfall lags can represent temporal water-memory effects, moving averages can capture accumulated rainfall tendencies, rainfall anomalies can express departures from historical means, and standardized rainfall anomalies can describe dry or wet conditions relative to a local reference distribution. These engineered variables are particularly relevant for rice because water availability and drainage conditions directly affect field preparation, vegetative growth, and yield formation.

Previous studies often use climate variables as predictors, but they do not always isolate the marginal contribution of each rainfall-derived feature group. This makes it difficult to determine whether improvement is driven by raw rainfall, delayed rainfall memory, standardized rainfall condition, or extreme-event flags. The present study addresses this limitation by using a sequential ablation design that adds climate-aware feature groups one at a time.

C. Ablation Study, Leakage Control, and Evaluation Stability

Ablation analysis is useful for identifying whether a feature group contributes measurable predictive value. However, a sequential ablation design measures order-dependent marginal contribution rather than independent causal importance. Therefore, ablation results should be interpreted as performance changes under a predefined feature-addition sequence, not as definitive evidence that one feature group is universally more important in all modelling contexts [21], [22], [23].

Data leakage is another important issue in predictive modelling. Leakage can occur when target-related information or future-period information is unintentionally made available during model training [24], [25], [26]. In rice productivity modelling, production is problematic because productivity is mathematically derived from production and harvested area. This study therefore excludes production from the predictor set. The role of harvested area is treated more carefully in this revision because it is part of the productivity denominator and may not always be available at the intended prediction time [27], [28], [29], [30].

Model rankings based on a single temporal split should also be interpreted cautiously. Small differences in RMSE may

reflect sampling variability, scenario order, or the specific train-test period. Repeated seeds, rolling-origin validation, or spatial-temporal validation would provide stronger evidence of stability. Because the present dataset version reports one fixed temporal test period, this manuscript avoids overstating small margins and frames scenario rankings as observed results under the specified split [31], [32].

Table I positions the proposed study within related work. It contrasts common research streams in crop prediction, climate-variable modelling, ablation analysis, and leakage-controlled prediction, then identifies the remaining gap addressed by this manuscript.

TABLE I. POSITION OF THE PROPOSED STUDY WITHIN RELATED WORK

Research stream	Typical contribution	Remaining gap addressed in this study
Tree-based crop prediction	Captures non-linear tabular relationships in agricultural data	Often reports final performance without isolating rainfall-derived feature contributions
Climate-variable modelling	Uses rainfall, temperature, humidity, or drought indicators as predictors	Does not always distinguish raw rainfall, rainfall memory, anomaly, and standardized anomaly effects
Ablation analysis	Evaluates incremental effects of feature groups or model components	Needs cautious interpretation when differences are small and based on one temporal split
Leakage-controlled prediction	Avoids target-related and future-period information in model training	Requires explicit distinction between mathematical leakage and prediction-time availability

Note: The table summarizes how the present study differs from prior crop-prediction and feature-engineering research. The contribution is focused on ablation-based feature assessment rather than developing a new fusion architecture or SHAP interpretation framework.

III. METHODOLOGY

A. Study Area and Dataset

The study used district/city-level agricultural and environmental data from Central Java Province, Indonesia, covering 2010-2025. The research site is in Central Java, which lies approximately between 5.67 degrees S and 8.50 degrees S and 108.50 degrees E-111.50 degrees E, with an approximate provincial centroid at 7.15 degrees S and 110.14 degrees E. The final dataset contained 560 district/city-year observations. Rice productivity was defined as average harvested paddy yield per unit harvested area for each district/city and year, expressed in quintals per hectare (q ha-1).

Agricultural statistics were compiled from BPS-Statistics Indonesia, BPS Province of Central Java, and relevant provincial or district agricultural records. Climate indicators were compiled from meteorological records provided by the Meteorology, Climatology and Geophysical Agency (BMKG) or equivalent station/gridded climate products. The use of BPS and BMKG records is important because these institutions provide official statistical and climate information for Indonesia. Soil-land and agronomic variables were compiled from institutional land-information and agricultural-agency records. All variables were harmonized to a district/city-year unit of analysis before modelling.

Table II presents the main components of the multi-source dataset. The table clarifies how agricultural, climate, soil-land, agronomic, and temporal rainfall features contribute to the ablation experiment before model training.

TABLE II. MAIN COMPONENTS OF THE MULTI-SOURCE DATASET

Data component	Variables or examples	Role in the ablation study
Agricultural data	Planted area, harvested area, productivity	Defines land-use scale and target construction
Climate data	Rainfall, humidity, temperature, sunshine duration, wind speed, extreme rainfall	Represents environmental pressure and climate variability
Soil and land data	Soil type, soil texture, soil pH, soil moisture, drainage type	Represents land suitability and water-management capacity
Agronomic data	Irrigation system and dominant pest type	Represents management and disturbance conditions
Temporal rainfall features	Rain_Lag_1, Rain_Lag_2, Rain_Lag_3, Rain_MA_3, SRAI, Rain_Anomaly and extreme flags	Represents delayed, accumulated, standardized, and abnormal rainfall effects

Note: BPS = Statistics Indonesia; BMKG = Meteorology, Climatology and Geophysical Agency; SRAI = standardized rainfall anomaly index; MA = moving average; Rain_MA_3 = three-period rainfall moving average.

B. Data Source, Preprocessing, and Leakage Control

The unit of analysis was district/city-year. Daily or monthly climate observations were aggregated into annual district/city indicators. When source data had different spatial resolutions, observations were matched using administrative identifiers, year labels, and variable definitions. Quality assurance included duplicate-record checking, unit consistency checking, missing-value inspection, outlier screening, and comparison with official annual trends. The final modelling dataset did not contain missing values.

Production was removed from the input features because rice productivity is mathematically derived from production and harvested area. This step prevents direct target leakage. Harvested area was retained as a land-use scale and prediction-time administrative variable, but its interpretation was revised carefully. Because harvested area is also part of the productivity denominator, the model should not be interpreted as a pure pre-season yield forecast unless harvested area is available before prediction. For stricter pre-season deployment, a sensitivity experiment excluding harvested area should be reported using the same ablation protocol.

TABLE III. PREPROCESSING, LEAKAGE-CONTROL, AND IMPLEMENTATION SAFEGUARDS

Reviewer concern	Revision in methodology	Interpretation safeguard
Target leakage	Production excluded from predictors	Models learn from explanatory variables rather than direct target information
Harvested area availability	Harvested area treated as prediction-time administrative information	For pre-season deployment, a no-harvested-area sensitivity run should be added
Nominal categorical variables	One-hot encoding specified for region, soil, drainage, irrigation, and pest variables	Avoids artificial ordinal relationships from numeric category codes
Rainfall anomaly parameters	Mean and standard deviation estimated from training-period rainfall only	Avoids use of future test-period information

Note: The table summarizes methodological clarifications added in response to concerns about target leakage, categorical encoding, prediction-time availability, and rainfall reference-period estimation.

Categorical variables such as region, soil type, soil texture, soil moisture, drainage type, irrigation system, and dominant pest type were treated as nominal variables. The revised preprocessing protocol specifies one-hot encoding for nominal variables so that tree-based models do not receive arbitrary numerical codes as if they represented ordered categories. Numerical coding, where present in raw files, was used only as an internal label before conversion to indicator variables.

Table III summarizes the methodological safeguards applied during preprocessing and implementation. The table is included to clarify how the study addresses target leakage, harvested-area availability, nominal categorical variables, and training-period rainfall reference parameters.

C. Climate-Aware Feature Engineering

Feature engineering was conducted to represent delayed and accumulated rainfall effects. Rain_Lag_1, Rain_Lag_2, and Rain_Lag_3 represented rainfall from previous periods. Rain_MA_3 represented a three-period moving average of rainfall. Rain_Anomaly represented the deviation of rainfall from the training-period mean. The previously labelled SPI-style feature is reported in this revision as a standardized rainfall anomaly index (SRAI), because it is calculated as a rainfall z-score and does not implement the full conventional SPI procedure involving a specified accumulation scale, distribution fitting, cumulative probability transformation, and standard-normal transformation.

Rainfall anomaly and SRAI were calculated using reference parameters estimated only from the training period. Specifically, the district-specific training-period mean rainfall and standard deviation were used to transform both training and test observations. This prevents the 2023-2025 test-period rainfall distribution from influencing feature construction. The extreme dry and wet flags were then derived from the same training-period reference logic, so their thresholds remained fixed when applied to future test observations.

D. Ablation Scenarios for Climate-Aware Feature Engineering

Six feature-engineering scenarios were constructed to isolate the incremental contribution of climate-aware variables. Scenario S0 used base features without engineered climate-aware variables. Scenario S1 added rainfall lag variables. Scenario S2 added rainfall moving average. Scenario S3 added SRAI. Scenario S4 added rainfall anomaly. Scenario S5 added extreme dry and wet flags, representing the full climate-aware feature set.

The ablation design is sequential. Therefore, the reported contribution of each feature group is conditional on its position in the sequence. The design should not be interpreted as independent feature importance or causal attribution. Instead, it measures how model performance changes when each feature group is added after the preceding groups under an identical temporal split and fixed model configuration.

Table IV defines the six ablation scenarios used in the experiment. The table shows the sequential addition of rainfall lags, rainfall moving average, standardized rainfall anomaly index, rainfall anomaly, and extreme-condition flags.

Fig. 1 illustrates the overall ablation workflow for climate-aware rainfall features. The diagram shows how the experiment starts from the base feature set and gradually adds engineered rainfall variables before evaluating Random Forest and XGBoost under the same independent temporal test period.

TABLE IV. ABLATION SCENARIOS FOR CLIMATE-AWARE FEATURE ENGINEERING

Scenario	Feature set	Purpose
S0	Base features without climate-aware engineered variables	Baseline comparison
S1	S0 + Rain_Lag_1, Rain_Lag_2 and Rain_Lag_3	Evaluate rainfall-memory effects
S2	S1 + Rain_MA_3	Evaluate smoothed rainfall tendency
S3	S2 + SRAI	Evaluate standardized rainfall departure using a training-period reference
S4	S3 + Rain_Anomaly	Evaluate deviation from training-period rainfall mean
S5	S4 + Extreme_Dry_Flag and Extreme_Wet_Flag	Evaluate binary extreme-condition signals

Note: S0-S5 = sequential ablation scenarios; SRAI = standardized rainfall anomaly index; Rain_MA_3 = three-period rainfall moving average.

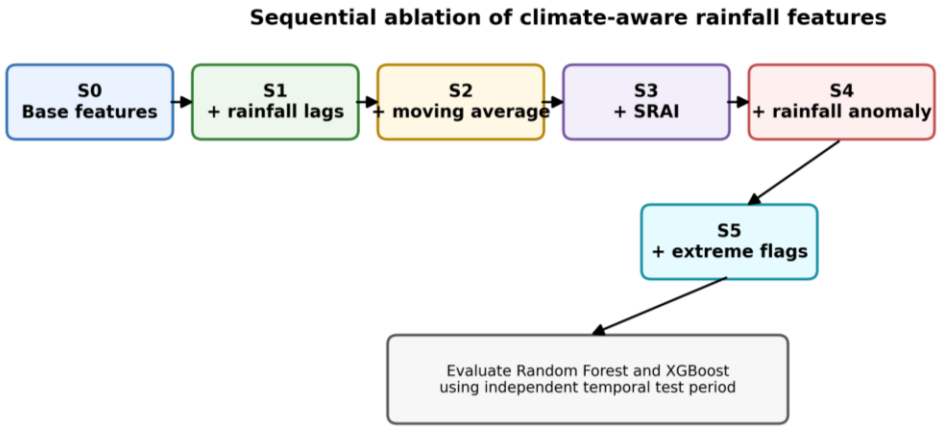

Fig. 1. Ablation design for climate-aware feature engineering.

E. Models and Hyperparameter Settings

Random Forest and XGBoost were selected because both models are strong tabular learners and are suitable for assessing the contribution of additional feature groups. Random Forest was used as a variance-reduction learner for non-linear tabular patterns [9], [33]. XGBoost was used as a regularized boosting learner for structured-data prediction [11], [34]. Each model was trained and evaluated under all six scenarios using the same temporal split so that differences in performance could be attributed primarily to feature-set changes rather than changes in validation design.

Data from 2010-2022 were used for model training, and data from 2023-2025 were used for independent temporal testing. Hyperparameters were kept stable across ablation scenarios to focus the comparison on feature contribution rather than repeated model re-tuning. This design supports a fair ablation comparison, but it does not replace repeated temporal validation or statistical significance testing across multiple splits [19], [20], [35], [36].

Table V reports the model configuration used for all ablation scenarios. The table confirms that Random Forest, XGBoost, temporal validation, and categorical encoding settings were kept consistent so that performance changes mainly reflect feature-set changes.

TABLE V. MODEL CONFIGURATION FOR THE ABLATION EXPERIMENT

Model or process	Configuration used for reporting
Random Forest	n_estimators = 500; max_depth = None; min_samples_split = 2; min_samples_leaf = 1; max_features = sqrt; bootstrap = True; random_state = 42. Purpose: robust tabular baseline and comparison learner.
XGBoost	objective = reg:squarederror; n_estimators = 300; max_depth = 3; learning_rate = 0.05; subsample = 0.80; colsample_bytree = 0.80; reg_lambda = 1.0; random_state = 42. Purpose: regularized boosting learner for structured agricultural data.
Validation design	Training period = 2010-2022; test period = 2023-2025; identical split applied across S0-S5. Purpose: temporal evaluation without future-information leakage.
Categorical encoding	Nominal predictors converted into one-hot indicators before model fitting. Purpose: avoid artificial ordinal relations from numeric category codes.

Note: XGBoost = Extreme Gradient Boosting; sqrt = square root; reg:squarederror = regression with squared-error objective.

F. Mathematical Formulation and Evaluation Metrics

To strengthen reproducibility, this subsection presents the equations used for target construction, climate-aware feature engineering, and performance evaluation. Let d denote district/city, t denote year, i denote a district/city-year observation, y_i denote observed productivity, and yhat_i denote predicted productivity. Eq. (1)-(10) are cited sequentially according to their function.

Productivity is calculated as harvested paddy yield per hectare at the district/city-year level as shown in Eq. (1). Production was excluded from the input features because it is a direct component of the target construction.

$$Productivity_{d,t} = (Paddy\ production_{d,t} / Harvested\ area_{d,t}) \times 10 \quad (1)$$

$$Rain\_Lag_{k,d,t} = Rainfall_{d,t-k}, \text{ where } k = 1, 2, 3 \quad (2)$$

$$Rain\_MA\_3_{d,t} = (Rainfall_{d,t} + Rainfall_{d,t-1} + Rainfall_{d,t-2}) / 3 \quad (3)$$

$$Rain\_Anomaly_{d,t} = Rainfall_{d,t} - mu_{d,train} \quad (4)$$

$$SRAI_{d,t} = (Rainfall_{d,t} - mu_{d,train}) / sigma_{d,train} \quad (5)$$

$$RMSE = \sqrt{[(1/n)\ sum_{i=1}^{n}\ (y_i - yhat_i)^2]} \quad (6)$$

$$MAE = (1/n)\ sum_{i=1}^{n}\ |y_i - yhat_i| \quad (7)$$

$$MAPE = (100/n)\ sum_{i=1}^{n}\ |(y_i - yhat_i) / y_i| \quad (8)$$

$$R2 = 1 - [sum_{i=1}^{n}\ (y_i - yhat_i)^2 / sum_{i=1}^{n}\ (y_i - ybar)^2] \quad (9)$$

$$RMSE\ reduction\ (\%) = [(RMSE\_S0 - RMSE\_Sj) / RMSE\_S0] \times 100 \quad (10)$$

Eq. (2)-(5) define the engineered rainfall features. Eq. (6)-(9) define RMSE, MAE, MAPE, and R^2. Eq. (10) calculates the percentage reduction in RMSE relative to the baseline scenario S0. The terms mu_{d,train} and sigma_{d,train} represent district-specific rainfall mean and standard deviation estimated exclusively from the training period.

IV. Results and Discussion

A. Overall Ablation Results

The ablation results show that climate-aware feature engineering has different effects on Random Forest and XGBoost. For Random Forest, RMSE decreased from 4.4466 in S0 to 4.3732 in S5, equivalent to a 1.65% reduction. The lowest observed Random Forest RMSE occurred in S4 after adding rainfall anomaly, with RMSE of 4.3578. This suggests that Random Forest benefited from climate-aware variables, but the gain was modest and the performance curve remained relatively flat across scenarios.

For XGBoost, the effect was stronger. The base scenario produced an RMSE of 4.8019 and a a MAPE of 6.0520%. After adding rainfall lag features in S1, RMSE decreased to 4.2121, MAPE decreased to 5.3318%, and R^2 increased to 0.3053. This was the largest observed marginal gain across all scenarios. The lowest observed XGBoost RMSE occurred in S1, whereas the lowest observed XGBoost MAPE occurred in S3 after adding SRAI. These results indicate that rainfall-memory features are the most important engineered climate feature group in the present temporal split.

Table VI reports the complete ablation results for Random Forest and XGBoost. The table allows direct comparison of RMSE, MAE, MAPE, and R2 across S0-S5, while also showing that the full climate-aware feature set is not automatically the best observed scenario.

Fig. 2 visualizes RMSE across the six climate-aware feature-engineering scenarios. The figure highlights the sharp XGBoost improvement after adding rainfall lags and the relatively flat Random Forest curve across subsequent feature additions.

Fig. 3 presents MAPE across the same ablation scenarios. The figure shows that XGBoost obtains its lowest observed relative error after SRAI is added, while Random Forest remains comparatively stable across climate-aware feature sets.

TABLE VI. Ablation Results Across Climate-Aware Feature-Engineering Scenarios

Scenario	Model	Features	RMSE	MAE	MAPE (%)	R2
S0 Base features	Random Forest	17	4.4466	3.3885	5.9629	0.2259
S0 Base features	XGBoost	17	4.8019	3.5047	6.0520	0.0972
S1 Base + rain lags	Random Forest	20	4.3690	3.3267	5.8614	0.2526
S1 Base + rain lags	XGBoost	20	4.2121	3.0644	5.3318	0.3053
S2 S1 + Rain_MA_3	Random Forest	21	4.3699	3.3411	5.8996	0.2523
S2 S1 + Rain_MA_3	XGBoost	21	4.2942	3.1249	5.4375	0.2780
S3 S2 + SRAI	Random Forest	22	4.3692	3.3527	5.9190	0.2526
S3 S2 + SRAI	XGBoost	22	4.2310	3.0563	5.3250	0.2991
S4 S3 + anomaly	Random Forest	23	4.3578	3.3399	5.8981	0.2565
S4 S3 + anomaly	XGBoost	23	4.4175	3.1873	5.5101	0.2359
S5 Full climate-aware	Random Forest	25	4.3732	3.3530	5.9226	0.2512
S5 Full climate-aware	XGBoost	25	4.3068	3.2007	5.5767	0.2737

Note: RMSE = root mean squared error; MAE = mean absolute error; MAPE = mean absolute percentage error; R2 = coefficient of determination. Values are reported to four decimal places to avoid overstating precision from a single temporal split.

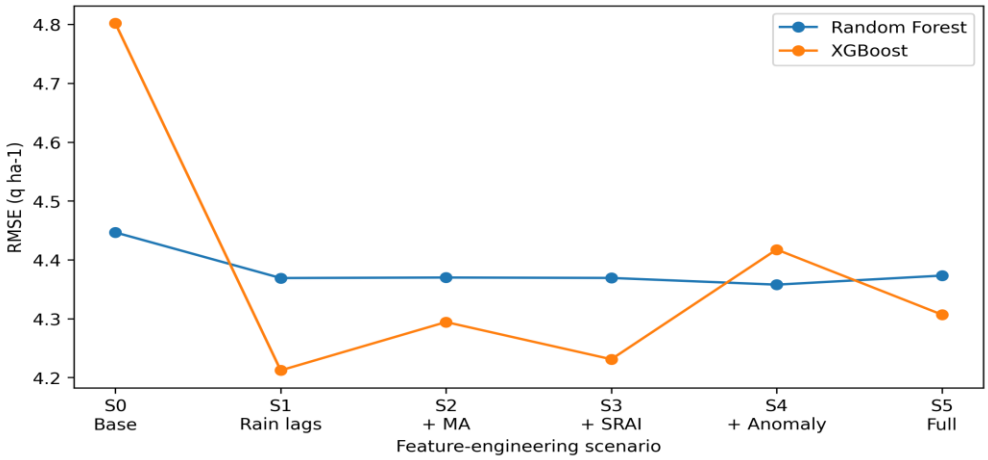

Fig. 2. RMSE across climate-aware feature-engineering scenarios.

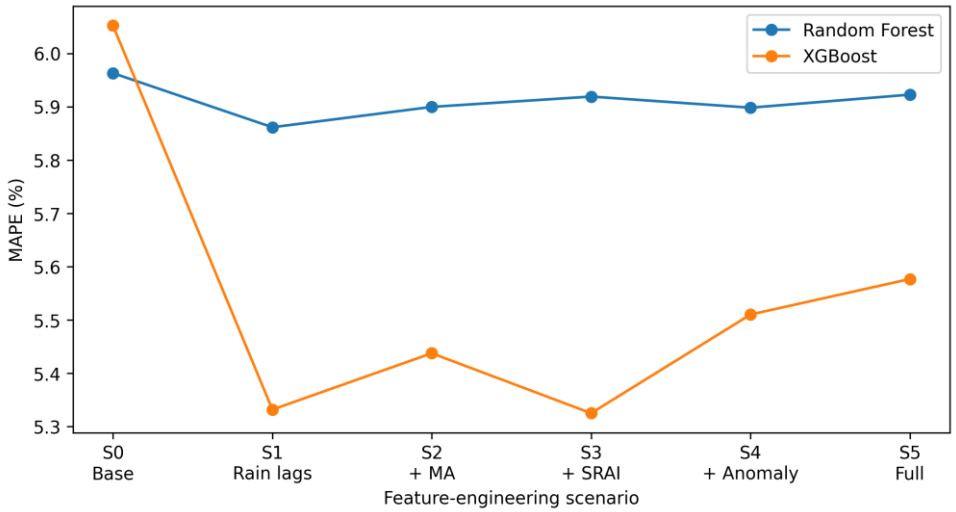

Fig. 3. MAPE across climate-aware feature-engineering scenarios.

B. *Improvement from Baseline to Full Climate-Aware Features*

Table VII compares the baseline scenario with the full climate-aware scenario. XGBoost achieved an RMSE reduction of 0.4951, corresponding to a 10.31% improvement. Random Forest achieved a smaller RMSE reduction of 0.0734, corresponding to a 1.65% improvement. This difference indicates that XGBoost is more responsive to engineered climate features than Random Forest in the present dataset.

The improvement should be interpreted carefully. Although S5 improved substantially over S0 for XGBoost, S5 did not outperform S1 in RMSE or S3 in MAPE. Therefore, the full feature set provides evidence that climate-aware information is useful, but it does not prove that every engineered feature group contributes independent predictive value.

Table VII compares the baseline feature set with the full climate-aware feature set. This table quantifies the RMSE reduction from S0 to S5 and demonstrates that XGBoost is more responsive to engineered rainfall features than Random Forest in the present dataset.

Fig. 4 shows incremental RMSE reduction relative to the S0 baseline. The figure helps explain that the largest observed gain occurs immediately after adding rainfall lag variables, whereas later additions produce smaller or less stable improvements.

TABLE VII. RMSE REDUCTION FROM BASELINE TO FULL CLIMATE-AWARE FEATURE SET

Model	RMSE S0	RMSE S5	RMSE reduction	RMSE reduction (%)
Random Forest	4.4466	4.3732	0.0734	1.65
XGBoost	4.8019	4.3068	0.4951	10.31

Note: S0 = base features without climate-aware engineered variables; S5 = full climate-aware feature set; RMSE reduction was calculated using Eq. (10).

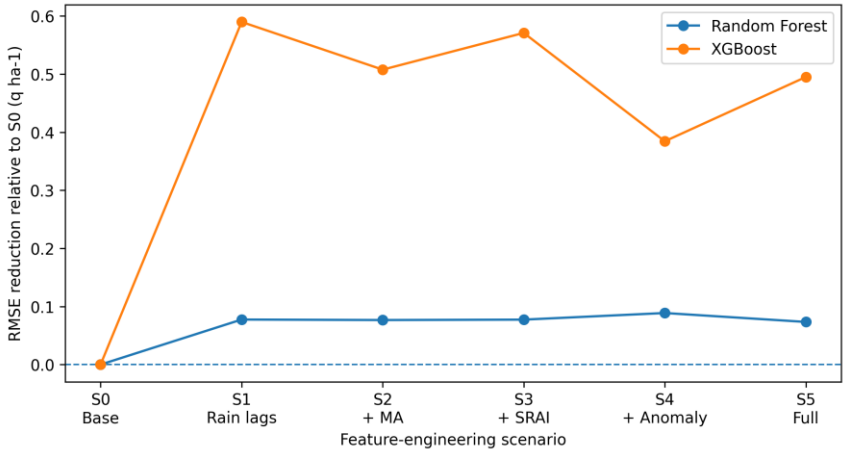

Fig. 4. Incremental RMSE reduction relative to the baseline scenario.

C. Best-Observed Scenarios and Stability Caution

The best scenario depends on both the model and the metric. For Random Forest, S4 produced the lowest observed RMSE, suggesting that rainfall anomaly provided a small additional benefit. For XGBoost, S1 produced the lowest observed RMSE, indicating that rainfall lag variables captured the strongest predictive signal. For MAPE, the best observed XGBoost result occurred in S3, suggesting that SRAI improved relative error even when the RMSE difference was small.

However, several observed differences are small. For Random Forest, S1, S2, S3, and S5 are within approximately 0.0154 RMSE of the lowest observed S4 value. For XGBoost, S3 is within approximately 0.0189 RMSE of S1. These gaps should not be interpreted as statistically significant evidence because the present experiment uses one fixed temporal split. The results therefore identify promising feature sets rather than definitive universal rankings.

Table VIII summarizes the best-observed scenarios by metric under the fixed temporal split. The table is interpreted cautiously because the scenario differences were not validated through repeated seeds, rolling-origin evaluation, or statistical significance testing.

TABLE VIII. BEST-OBSERVED SCENARIOS BY METRIC UNDER THE FIXED TEMPORAL SPLIT

Criterion	Model	Scenario	RMSE	MAE	MAPE (%)	R2	Interpretation
Lowest observed RMSE	Random Forest	S4 S3 + anomaly	4.3578	3.3399	5.8981	0.2565	Very small margin over other RF climate-aware scenarios
Lowest observed RMSE	XGBoost	S1 Base + rain lags	4.2121	3.0644	5.3318	0.3053	Strongest observed rainfall-memory gain
Lowest observed MAPE	Random Forest	S1 Base + rain lags	4.3690	3.3267	5.8614	0.2526	Observed relative-error advantage
Lowest observed MAPE	XGBoost	S3 S2 + SRAI	4.2310	3.0563	5.3250	0.2991	Small relative-error improvement over S1

Note: The term best-observed is used deliberately because repeated seeds, rolling-origin validation, and statistical significance tests were not available in the present dataset version.

D. Explanatory Power and Prediction-Time Availability

The best R^2 value across all scenarios was 0.3053 for XGBoost under S1. This means that the model explained only part of the variance in rice productivity, while most variation remained outside the available predictors. The result should not be interpreted as model failure; rather, it indicates that district/city-level rice productivity is affected by factors that were not fully represented in the dataset, such as rice variety, fertilizer dose and timing, irrigation volume, mechanization, labour availability, planting calendar, pest intensity, field-level management, and satellite-derived vegetation indices.

This explanatory ceiling also changes the interpretation of RMSE reduction. A 10.31% reduction from S0 to S5 for XGBoost indicates that engineered rainfall information improves prediction error relative to the baseline, but it does not imply that the model captures all determinants of rice productivity. Therefore, the practical contribution of this study is a feature-engineering assessment, not a claim of complete productivity explanation.

Harvested area also requires careful interpretation. Because productivity is calculated from production divided by harvested area, harvested area is mathematically related to the target construction. In this manuscript, production is excluded to avoid direct target leakage, while harvested area is retained only when it is available at prediction time as an administrative land-use variable. For strict ex-ante forecasting before harvested area is known, the same S0-S5 ablation should be repeated without harvested area. Until that sensitivity analysis is added, conclusions should be interpreted as conditional on the included prediction-time variables.

Table IX provides interpretation safeguards for the main reviewer concerns. It summarizes how the manuscript treats the R2 ceiling, small RMSE margins, harvested-area availability, and sparse extreme flags to avoid overclaiming from a single temporal split.

TABLE IX. INTERPRETATION SAFEGUARDS FOR REVIEWER CONCERNS

Issue	Current treatment in this manuscript	Recommended interpretation
R2 ceiling	Best observed R2 = 0.3053 for XGBoost S1	Model explains part of district/city-year productivity variation; omitted variables remain important
Small RMSE margins	Several climate-aware scenarios are separated by less than 0.10 RMSE	Use descriptive rather than statistically definitive ranking
Harvested area	Retained as prediction-time administrative land-use information	Repeat ablation without harvested area for strict pre-season forecasting
Extreme flags	Included only in S5 after anomaly features	Interpret cautiously because extreme observations are sparse

Note: These safeguards prevent overclaiming from a single temporal split and clarify the distinction between target-leakage prevention and prediction-time variable availability.

E. Interpretation of Feature-Engineering Contribution

The ablation results indicate that not all engineered climate features contribute equally. Rainfall lag features provided the most consistent and substantial improvement, particularly for XGBoost. This is agronomically meaningful because rice productivity can be influenced by previous rainfall conditions through soil moisture, irrigation availability, field preparation, planting timing, and pest dynamics. The strong effect of S1 suggests that rainfall memory is a core climate signal for district/city-year productivity prediction.

Adding Rain_MA_3 did not improve XGBoost beyond S1, indicating that rainfall lag variables already captured much of the useful short-term rainfall information. Adding SRAI in S3 slightly improved MAPE compared with S1, suggesting that standardized rainfall status is useful for relative error control. However, adding rainfall anomaly and extreme flags did not further improve XGBoost performance and increased error relative to S1 and S3. This may be caused by redundancy among rainfall-derived variables, the small number of extreme observations, or additional feature noise.

For Random Forest, the performance curve was relatively flat across scenarios. This suggests that Random Forest was less sensitive to incremental climate-aware features. XGBoost, by contrast, showed a sharper response to rainfall lags and SRAI, which is consistent with the ability of boosting models to exploit informative residual patterns from engineered predictors. These findings support a practical recommendation: climate-aware feature engineering should be adopted selectively, and rainfall-memory variables should be prioritized before more complex climate indices are added.

F. Discussion and Relationship to the Broader Research Program

The main finding of this article is that climate-aware feature engineering improves rice productivity prediction, but the improvement is not monotonic. The strongest observed gain comes from adding rainfall lag features, while the full feature set does not necessarily produce the best performance. This finding challenges the assumption that adding more engineered climate variables always improves model accuracy. In practical modelling workflows, additional variables should be evaluated not only by theoretical relevance but also by their empirical contribution under temporal testing.

This study is complementary to broader work on rice productivity prediction conducted within the same doctoral research program, but it has a distinct scope. The optimized-fusion manuscript focuses on combining RF, XGBoost, and LSTM outputs. The explainability manuscript focuses on interpreting model drivers using SHAP. The present manuscript focuses on upstream climate-aware feature engineering and asks which rainfall-derived feature groups improve tabular models before any final fusion or detailed explanation stage. This distinction reduces overlap and clarifies the manuscript contribution.

Several limitations should be noted. First, the dataset uses annual district/city-level observations, which may not fully represent intra-seasonal rainfall timing, rice phenology, planting-calendar variation, or field-level management. Second, the number of extreme observations is limited, so extreme flags may not provide stable incremental information. Third, the study uses a single temporal test split; repeated seeds, rolling-origin evaluation, or spatiotemporal cross-validation would provide stronger evidence for scenario stability. Fourth, the no-harvested-area sensitivity analysis should be added before claiming strict pre-season applicability. Fifth, model hyperparameters were kept stable across scenarios to focus on feature contribution; alternative tuning strategies may produce different results.

V. CONCLUSION

This study evaluated climate-aware feature engineering for rice productivity prediction using a sequential ablation design and multi-source agricultural data from Central Java, Indonesia. Six scenarios were tested, ranging from base features to a full climate-aware feature set containing rainfall lags, rainfall moving average, standardized rainfall anomaly index, rainfall anomaly, and extreme dry/wet flags. Random Forest and XGBoost were used as tabular learners to isolate the contribution of feature groups under the same temporal testing design.

The results show that XGBoost benefited substantially from climate-aware feature engineering. Full climate-aware features reduced XGBoost RMSE by 10.31% compared with the base feature set. However, the lowest observed XGBoost RMSE was achieved by S1, which added rainfall lag variables, not by the full S5 feature set. This indicates that rainfall lag features provide the largest observed marginal contribution, while adding all engineered features can introduce redundancy, sparse-signal instability, or noise. Random Forest showed smaller improvement, with only 1.65% RMSE reduction from S0 to S5.

The study also emphasizes methodological caution. The best observed R^2 was 0.3053, indicating that much productivity variation remains unexplained by the available predictors. Several differences among scenarios were small and should not be interpreted as statistically significant without repeated evaluation. Harvested area was retained only as a prediction-time administrative variable, and a sensitivity analysis without harvested area is recommended for strict pre-season forecasting. Future research should test the same feature-engineering scheme using monthly or seasonal rainfall data, alternative standardized-rainfall anomaly time scales, spatial-temporal validation, remote-sensing indicators, richer agronomic variables, and repeated-split statistical testing.

ACKNOWLEDGMENT

The authors thank Universitas Negeri Yogyakarta and the institutions providing agricultural and climate data used in this research. The authors also acknowledge the academic supervision and methodological feedback received during the dissertation development process.

***Abstract*—The proliferation of consumer drones has raised security concerns for critical infrastructure, airports, and urban surveillance, creating a need for reliable real-time detection. This study presents a controlled comparative evaluation of selected YOLO generations — YOLOv7x, YOLOv8x, and YOLOv11x — for single-class drone detection under matched high-level settings: 640 by 640 input, 50 epochs, the AdamW optimizer at an initial learning rate of 0.001, and an effective optimizer batch size of 64. Experiments used the YOLO Drone Detection Dataset (1,012 training and 347 validation images, 369 validation instances). All models were scored with one evaluation implementation applied to raw predictions, removing differences between framework-specific validators. Across five independent training runs, YOLOv8x achieved the highest mean average precision at an IoU threshold of 0.5, 0.912 with a standard deviation of 0.007, ahead of YOLOv11x at 0.892 (0.004) and YOLOv7x at 0.708 (0.008); a Welch t-test gives a p-value of 0.0012 for YOLOv8x against YOLOv11x. A provenance analysis found that 32 of the 347 validation images are near-duplicates of training images; re-scoring on the 315 remaining images lowers every result but preserves the ordering. Zero-shot evaluation on the independently collected DUT Anti-UAV test set, whose targets are predominantly small, reproduces the same ordering while absolute accuracy falls to 0.346 for the best model. Detection accuracy therefore does not increase monotonically with architectural generation, and accuracy measured on this dataset does not transfer to imagery dominated by small targets. YOLOv11x was the smallest model (56.8 million parameters) with the lowest peak inference memory, indicating a trade-off between accuracy and deployment cost.**

Keywords*—UAV detection; drone detection; YOLO; deep learning; real-time object detection; comparative evaluation

I. Introduction

The rapid increase in the number of unmanned aerial vehicles (UAVs) used in civil, commercial, and security applications has raised growing concerns regarding safety, privacy, and airspace management [1]. Drones can be weaponized, used for unauthorized surveillance, or inadvertently interfere with manned aviation, making real-time autonomous detection a critical research and operational requirement [2]. The global drone market is projected to exceed USD 55 billion by 2028, intensifying the need for robust counter-UAV systems capable of operating under strict computational and latency constraints [3].

Traditional UAV detection approaches based on radar, acoustic sensors, and RF signal analysis face inherent limitations, including small target radar cross-sections, high false-positive rates from non-drone aerial objects, and vulnerability to complex electromagnetic environments [4]. Time-frequency CNN-based RF detection has demonstrated promising performance, although its effectiveness decreases at longer operating ranges [5]. Combining surveillance radar with YOLO-based classification can improve detection accuracy, but at the expense of increased system complexity associated with multi-sensor architectures [6]. Recent advances in deep learning, particularly convolutional neural networks (CNNs), have facilitated a shift toward visual and multimodal detection approaches with substantially improved discriminative performance [7]. Machine learning approaches have also been investigated for distinguishing UAVs from visually similar aerial objects such as birds, highlighting the importance of reducing false alarms in automated airspace surveillance systems [8].

This study contributes a controlled benchmarking protocol for comparing generations of YOLO detectors under matched high-level settings; a comparison covering detection accuracy, operating-point behaviour, robustness under image degradation, latency and throughput, with all models scored by one evaluation implementation; an analysis of training behaviour and computational efficiency under a fixed epoch budget; and practical recommendations for detector selection in real-time drone surveillance.

The evolution of object detection architectures from two-stage detectors such as R-CNN [9] and Faster R-CNN [10] to single-stage frameworks including SSD [11] and the YOLO family reflects the field's pursuit of higher accuracy at lower computational cost. For UAV detection, where detection latency

*Corresponding author

directly impacts response effectiveness and onboard power is constrained, this efficiency imperative is particularly acute [12].

Comprehensive reviews of deep learning methods for UAV detection indicate that YOLO-based architectures provide an effective balance between detection accuracy and computational efficiency [13]. The evolution of YOLO architectures from YOLOv1 to YOLOv8 demonstrates a continuous progression in feature extraction, optimization strategies, and detection performance [14]. A review of YOLO-based UAV detection technologies identified multi-scale feature fusion and attention mechanisms as the most influential architectural enhancements for improving detection accuracy [15]. A lightweight UAV detection framework based on GhostConv modules achieved a 40–60% reduction in FLOPs while maintaining competitive detection performance [16]. An efficient lightweight detection network demonstrated a processing speed of 682 FPS while reducing model parameters by 88.5% for UAV imagery analysis [17].

A lightweight object detection network optimized for UAV vision platforms was developed to improve deployment efficiency on resource-constrained devices [18]. CNN-based target detection has also been investigated for UAV reconnaissance imagery, where Faster R-CNN combined with optimized region proposals and image enhancement was used to improve detection under complex backgrounds and varying illumination [19]. An edge-oriented UAV detection framework achieved a favorable balance between accuracy and computational efficiency through an optimized backbone architecture [20]. A lightweight detection network achieved state-of-the-art efficiency for UAV object detection while maintaining competitive accuracy [21].

An enhanced YOLOv8-based architecture reduced the number of parameters by approximately 50% while maintaining an mAP@0.5 value of 98.4% [22]. A lightweight DRBD-YOLOv8 framework achieved higher detection accuracy with approximately half the parameters of YOLOv8n [23]. SEB-YOLOv8s enhanced unauthorized UAV detection through the incorporation of spatial attention mechanisms [24]. Small target-YOLOv5 improved drone aerial imagery analysis using specialized feature enhancement modules [25]. An optimized YOLOv7 framework for small-target detection in UAV aerial imagery combined anchor-box clustering, enhanced multi-scale feature fusion, and a refined detection head to improve detection efficiency on the VisDrone2019 dataset [26]. An improved YOLOv8n-based framework demonstrated competitive performance for lightweight tiny-object detection on the VisDrone2019 dataset [27]. A dual-branch YOLOv8 architecture was further proposed for small-object detection in UAV imagery, integrating enhanced feature extraction and multi-scale feature fusion to improve detection performance on the VisDrone benchmark [28].

Attention mechanisms have emerged as an effective strategy for improving UAV detection performance. EDGS-YOLOv8 combined EMA attention with Ghost convolutions and achieved 97.1% AP with a model size of only 4.23 MB [29]. A modified YOLOv8 architecture demonstrated effective multi-class detection of uncooperative aerial vehicles through attention-enhanced feature extraction [30]. Light-YOLOv5 integrated transformer components and PEAM attention to improve performance on resource-constrained camera platforms [31]. YOLO-LE introduced adaptive feature fusion modules to enhance multi-scale feature sensitivity [32].

Research on hardware-oriented deployment has also progressed considerably. FPGA-based implementations of YOLOv3 and YOLOv8 enabled low-power onboard drone classification [33]. Dedicated FPGA accelerators have been developed to support real-time UAV object detection [34]. Lightweight small-target detection algorithms have been optimized for UAV platforms operating under strict power constraints [35]. LW-YOLOv8 combined CSP-CNN-Transformer fusion with SIoU loss to improve edge-device deployment efficiency [36].

Recent developments have increasingly focused on transformer-hybrid architectures. A Vision Transformer framework incorporating hierarchical attention and dynamic token pruning achieved linear-complexity attention for UAV edge computing applications [37]. LMWP-YOLO improved long-range small-drone detection through multidimensional collaborative attention and network pruning [38]. YOLO-DD employed boundary-aware feature fusion based on YOLOv11 to improve UAV detection in complex environments [39]. FFG-YOLO achieved lightweight UAV detection with only 1.77 million parameters and 5.7 GFLOPs [40]. EDNet introduced scalable model variants and reported a 5.6% improvement in mAP on mobile platforms [41]. A lightweight anti-drone YOLOv8 framework reduced the parameter count by 9.6 million while maintaining competitive detection performance [42]. Evaluation of YOLOv8 on distorted surveillance videos reported mAP values of 92.3% for visible-spectrum imagery and 97.9% for infrared imagery, demonstrating the effectiveness of deep learning-based detectors in multimodal surveillance environments [43]. Recent advances in UAV-based systems increasingly combine edge intelligence, distributed sensing, and machine learning to support autonomous monitoring and real-time data classification [44]. Beyond object detection, recent research has investigated multi-UAV surveillance systems that integrate aerial image stitching to enhance large-scale monitoring and situational awareness capabilities [45].

Despite significant progress in UAV detection research, most studies evaluate a single architecture or use different datasets and experimental configurations. As a result, it remains difficult to compare the performance of different detector generations objectively. A controlled cross-generational comparison under matched training settings and a single evaluation implementation is still lacking in the literature.

Single-stage detectors have been applied to drone detection across successive YOLO generations: Singha and Aydin demonstrated automated drone detection with YOLOv4 [46], Aydin and Singha extended this to YOLOv5 [47], and Hakani and Rawat reported real-time YOLOv9 detection deployed on an NVIDIA Jetson Nano edge device [48], underscoring the practical importance of on-device throughput. The three variants evaluated in the present study span the architectural transition from anchor-based detection (YOLOv7x) to anchor-free decoupled-head detection (YOLOv8x and YOLOv11x) and correspond to three stable, officially maintained extra-large

releases; such stable releases are a prerequisite for applying one training specification across all three. YOLOv9 and YOLOv10 are recent and promising architectures; their evaluation under the same conditions is a direct extension of this benchmark.

To the best of our knowledge, no prior study evaluates YOLOv7x, YOLOv8x and YOLOv11x under one set of matched high-level settings — identical dataset partition, input resolution, optimizer, schedule and hardware — with all three scored by a single evaluation implementation, while jointly reporting detection accuracy, operating-point behaviour, robustness under image degradation and computational cost. The present study is therefore positioned as a controlled cross-generational benchmark rather than a new detector. Its contribution is a like-for-like comparison that holds the training and data factors fixed as far as separately maintained implementations allow, and reports what remains unmatched (Section II-F), yielding a reproducible basis for model selection in real-time UAV surveillance.

II. Materials and Methods

A. Dataset

All experiments used the YOLO Drone Detection Dataset [49], a public benchmark from Kaggle, with its predefined partition, which we did not re-partition: 1,012 training images containing 1,117 annotated drone instances and 347 validation images containing 369 instances. Annotations follow the standard normalized YOLO format for a single class ("drone"). Image resolution varies widely: 150–5,760 px wide by 160–3,840 px high in the training split and 200–6,000 by 159–4,000 px in the validation split. Instance size, computed from each annotation's absolute box area (the normalized label multiplied by that image's own pixel dimensions) and binned by the COCO convention, is strongly skewed towards large objects: in the validation split 13 instances (3.5 %) are small ($< 32^2$ px), 30 (8.1 %) medium (32^2–96^2 px) and 326 (88.3 %) large ($> 96^2$ px); the training split contains 1 small, 48 medium and 1,068 large instances. These figures are computed by the released prepare_data.py script rather than estimated. Images capture diverse UAV types under varying conditions, including daylight, overcast, different altitudes, and urban and rural backgrounds.

The dataset is publicly available on Kaggle [49]. At the time of access, no explicit license statement was provided on the dataset page. Therefore, the authors do not redistribute the dataset or reproduce any original dataset images in this article.

B. Model Architectures

Three extra-large (x) variants from consecutive YOLO generations were evaluated. Table I summarizes their architectural characteristics.

The three variants were selected as widely deployed milestone releases that span the transition from anchor-based to anchor-free detection, each having a stable, officially maintained extra-large variant at the time the experiments were run. The study is therefore a comparison of selected YOLO generations rather than an exhaustive one: YOLOv9 and YOLOv10 were not evaluated. A further consequence of using released checkpoints is that each architecture is initialized from weights produced by its own upstream training pipeline, so initialization is confounded with architecture; this is discussed in the Limitations.

TABLE I. Architectural Characteristics of Evaluated Models

Model	Backbone	Neck	Detection Head	Params (M)	GFLOPs
YOLOv7x	E-ELAN	PAFPN	Anchor-based (IDetect)	70.8	188.0
YOLOv8x	CSPDarknet53 +C2f	PAN-FPN	Anchor-free (Decoupled)	68.1	257.4
YOLOv11x	C3k2	SPPF+PAN	Anchor-free (Decoupled)	56.8	194.8

C. Training Configuration

Table II details the training configuration, which is identical across all three models at the level of these settings. Section II-F documents the implementation-level differences that this level of matching cannot remove. Where an effective optimizer batch size of 64 is reported, it refers to the batch seen by the optimizer update only: gradients are accumulated from physical batches of 8, so batch-normalization statistics are computed over 8 samples and augmentation is sampled per physical batch. The two are not equivalent, and no claim of equivalence is made.

TABLE II. Training Hyperparameters (Identical Across All Models)

Parameter	Value
Input resolution	640 × 640 (letterbox)
Batch size	8 per step, accumulated to a nominal batch of 64
Epochs	50
Optimizer	AdamW ($lr_0 = 0.001$)
Augmentation	Mosaic, HSV jitter, scale ±0.5, flip 0.5
Pre-trained weights	COCO (respective variant)
Confidence threshold	0.25
IoU threshold (NMS)	0.5

D. Experimental Setup

All experiments were conducted in a single standardized hardware and software environment so that performance differences are attributable to the models rather than to the experimental conditions. The computational platform was an NVIDIA GeForce RTX 5070 Ti Laptop GPU with 12 GB of VRAM, running Windows 10, Python 3.14.2, PyTorch 2.11.0, and CUDA 12.8. All models were trained and evaluated with the same data split, optimization settings, learning-rate schedule, and stopping criterion. Because the extra-large variants exceed 12 GB of VRAM at a physical batch of 16, training used a physical batch of 8 with gradient accumulation to an effective optimizer batch size of 64. A sensitivity study over accumulation factors was not performed, since a physical batch of 64 does not fit on this device at this resolution; this is recorded in the Limitations.

E. Reproducibility

YOLOv8x and YOLOv11x were trained with the Ultralytics framework (v8.4.117); YOLOv7x used the official implementation (github.com/WongKinYiu/yolov7, commit a207844b1ce82d204ab36d87d496728d3d2348e7). The software environment was Python 3.14.2, PyTorch 2.11.0+cu128, CUDA 12.8, NumPy 2.4.4, and OpenCV 5.0.0.93; every dependency is pinned in requirements.txt. Training started from the official COCO-pretrained weights: yolov7x.pt, yolov8x.pt and yolo11x.pt. The optimizer was AdamW with an initial learning rate of 1e-3, linear warm-up over the first three epochs, and cosine decay to 1e-5 over 50 epochs. The warm-up bias learning rate is set to 0.0: Ultralytics zeroes this parameter only when the optimizer is selected automatically, and leaving it at its default of 0.1 drives the validation loss to NaN within the first epoch under AdamW, so the protocol is not runnable without specifying it. The reported weights are the best validation checkpoint of each run, not the final epoch. The primary run of Table III uses seed 0, which fixes Python, NumPy, and PyTorch; the stability analysis of Table V uses five independent retrainings per model at seeds 0, 1, 2, 3, and 4, and the individual results of every run are reported there. The exact training and validation commands, configuration files, environment specification, per-run result files, and trained weights are available at https://github.com/sakenski-afk/drone-detection-benchmark and archived at Zenodo (https://doi.org/10.5281/zenodo.21955344), with the trained weights provided as release assets in the repository and SHA-256 checksums linking each checkpoint to the results computed from it.

The 50-epoch schedule is a fixed training budget applied identically to all three models rather than a demonstrated convergence point. As Fig. 1 shows, validation mAP@0.5 was still rising at the end of the schedule for every model, by +0.028 (YOLOv7x), +0.023 (YOLOv8x) and +0.021 (YOLOv11x) over the final ten epochs, with best checkpoints at epochs 35, 44 and 39 respectively. The comparison is therefore valid as a like-for-like comparison at a fixed budget, while absolute values would likely improve under a longer schedule.

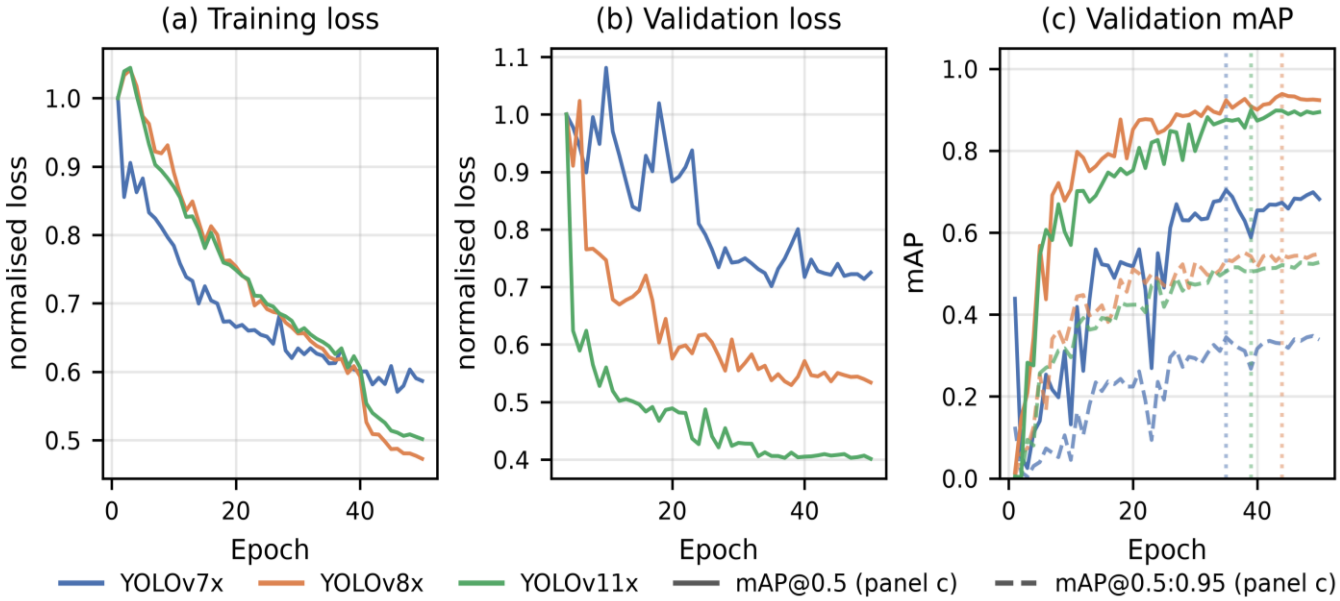

Fig. 1. Training loss, validation loss and validation mAP per epoch for the three architectures (seed 0). The two frameworks report different loss terms, so losses are normalized and only their shapes are comparable: training loss to its epoch-1 value, validation loss to its epoch-4 value, the first three epochs being warm-up. Dotted vertical lines in panel (c) mark the best validation checkpoint of each model. Validation mAP@0.5 is still rising at epoch 50 for all three architectures.

F. Implementation-Level Differences Between the Frameworks

Matching a protocol across separately maintained implementations is possible at the level of settings but not at the level of pipelines, and the residual differences are not hypothetical. The YOLOv7 repository provides no AdamW option: its --adam flag constructs torch. optim.Adam, so obtaining the optimizer of Table II required patching that call site, and the patch is recorded in the released repository. The loss functions differ in kind: YOLOv7x uses OTA assignment with objectness, box, and classification terms, while YOLOv8x and YOLOv11x use a decoupled anchor-free head with distribution focal loss, so loss values are not comparable across frameworks. Augmentation, exponential moving average, and pre- and post-processing defaults also differ where the nominal hyperparameter names coincide. The one axis on which the comparison is genuinely identical is evaluation: all three models are scored by a single implementation applied to raw predictions, verified against the Ultralytics average-precision computation in the released test suite. We therefore describe this study as a comparison under matched high-level settings rather than under an identical training pipeline.

G. Evaluation Metrics

Performance was evaluated using precision, recall, F1-score and mean average precision at IoU = 0.5 (mAP@0.5) and IoU = 0.5:0.95 (mAP@0.5:0.95). All metrics for all three models are computed by a single implementation applied to raw predictions, so that the comparison does not inherit differences between the

frameworks' own validators; the average-precision computation is verified against the Ultralytics implementation to floating-point equality in the released test suite. Predictions are matched to ground truth greedily in descending confidence order, a match requiring IoU ≥ 0.5. Precision, recall, F1, and the confusion matrices are all reported at the operating confidence threshold of 0.25: true positives are matched predictions, false negatives are ground-truth instances left unmatched, so that TP + FN equals the 369 annotated validation instances exactly, and false positives are predictions matched to no instance. The background–background cell of the confusion matrix is undefined and is reported as such: an image contains an unbounded number of candidate windows, so object detection provides no finite set of negatives. For the same reason, ROC-AUC is not reported, since a false-positive rate would require a denominator the data does not determine; free-response ROC (FROC) is reported instead, plotting sensitivity against false positives per image, a rate whose denominator is the number of evaluation images. Robustness was assessed over five independent applications of each degradation to the trained model: additive Gaussian noise with zero mean and $\sigma = 0.05$ in normalized intensity, linear motion blur with a 15 px kernel at a random orientation, and low-light simulation scaling pixel intensities by 0.4 with $\gamma = 1.5$. This resamples noise realizations only and involves no retraining; it is distinct from the retraining variability reported as the standard deviation over five seeds.

III. Results

A. Overall Detection Performance

Table III presents the detection performance of the evaluated models on the validation partition. YOLOv8x achieved the highest detection performance, with a precision of 0.895, recall of 0.902, F1-score of 0.899, mAP@0.5 of 0.921, and mAP@0.5:0.95 of 0.540, ahead of YOLOv11x (0.874, 0.846, 0.860, 0.891, and 0.507). YOLOv7x under the shared protocol reached mAP@0.5 = 0.716; retrained with its own repository's SGD recipe, it reached 0.853, and both are reported because the difference is a property of the matched protocol rather than of the architecture (Section II-F). Precision and recall are taken at the operating threshold of 0.25, consistent with the confusion matrices; Table VII shows that the reported ordering is unchanged when each model is instead scored at its own best-F1 threshold. Because the last-epoch checkpoint involves no selection, the mean of the per-seed differences between it and the reported best-validation checkpoint bounds the optimism introduced by selecting on this partition. Averaged over the five seeds that difference is +0.0056 for YOLOv7x, +0.0058 for YOLOv8x, and −0.0011 for YOLOv11x mAP@0.5; each figure is the mean of the per-seed differences computed before rounding, and the individual runs are reported in the released result files.

TABLE III. Comparative Detection Performance on the Validation Set (347 Images, 369 Instances)

Model	Precision	Recall	F1-score	mAP@0.5	mAP@0.5:0.95	Latency (ms)	FPS
YOLOv7x	0.805	0.672	0.733	0.716	0.357	16.12	62.1
YOLOv8x	0.895	0.902	0.899	0.921	0.540	17.78	56.2
YOLOv11x	0.874	0.846	0.860	0.891	0.507	16.39	61.0
YOLOv7x (native SGD)	0.774	0.799	0.787	0.853	0.450	16.12	62.1

All values are on the validation partition (347 images, 369 instances). Precision, recall, and F1 at the operating confidence threshold of 0.25 with IoU ≥ 0.5 matching. Lat. = inference latency, measured on the GPU of Section II-D and not comparable with other hardware. The final row reports YOLOv7x trained with its own repository's SGD recipe instead of the shared AdamW protocol (Section II-F).

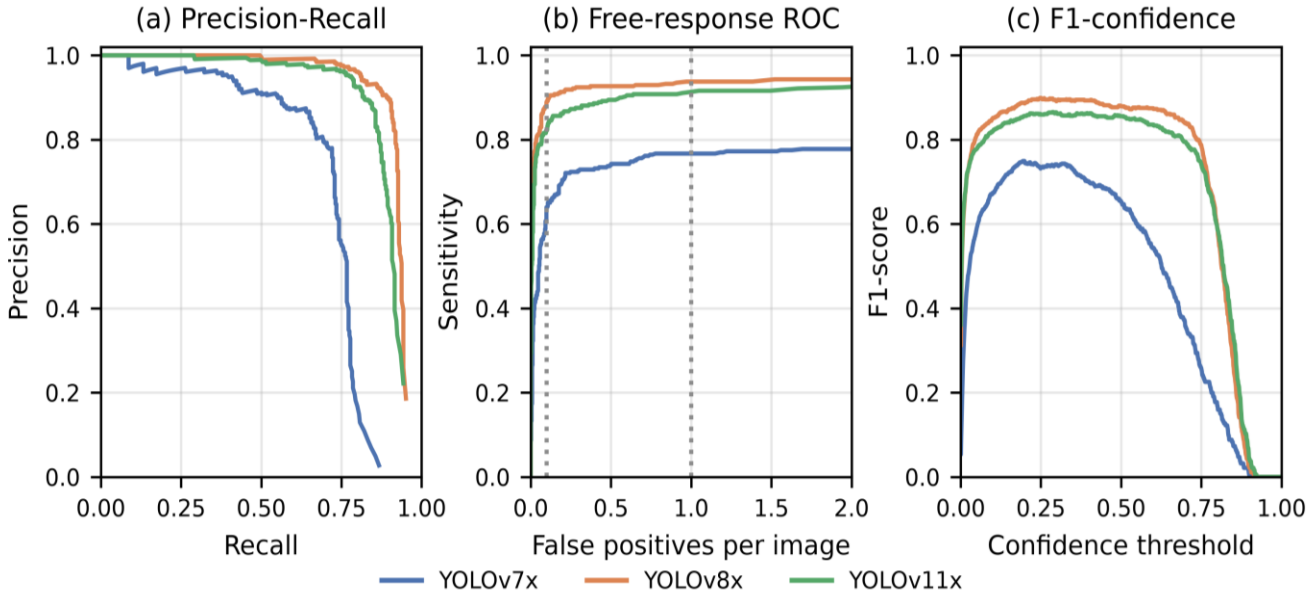

Fig. 2. Precision–recall curves, free-response ROC (FROC) curves, and F1-confidence curves.

B. Precision–Recall, FROC and F1 Analysis

Fig. 2 shows the precision–recall curves, the free-response ROC curves, and the F1-confidence curves for the three architectures. YOLOv8x attains higher precision across most recall levels and the highest sensitivity at every false-positive-per-image operating point examined. At 0.1, 0.25, 0.5, 1.0 and 2.0 false positives per image its sensitivity is 88.9 %, 91.9 %, 92.7 %, 93.8 % and 94.3 %, against 82.1 %, 87.3 %, 89.4 %, 91.3 % and 92.4 % for YOLOv11x and 64.0 %, 72.4 %, 74.0 %, 76.7 % and 77.8 % for YOLOv7x. The F1-confidence curves peak at similar confidence values for the two anchor-free models, indicating comparable confidence calibration.

C. Confusion Matrix Analysis

Fig. 3 presents the confusion matrices at the operating threshold of 0.25. YOLOv8x achieved the highest number of true positives (333 of 369 instances) with 39 false positives, against 312 true positives and 45 false positives for YOLOv11x and 248 true positives and 60 false positives for YOLOv7x. In every matrix, the true positives and false negatives sum to the 369 annotated validation instances; the background–background cell is undefined for object detection and is marked as such rather than filled with a count.

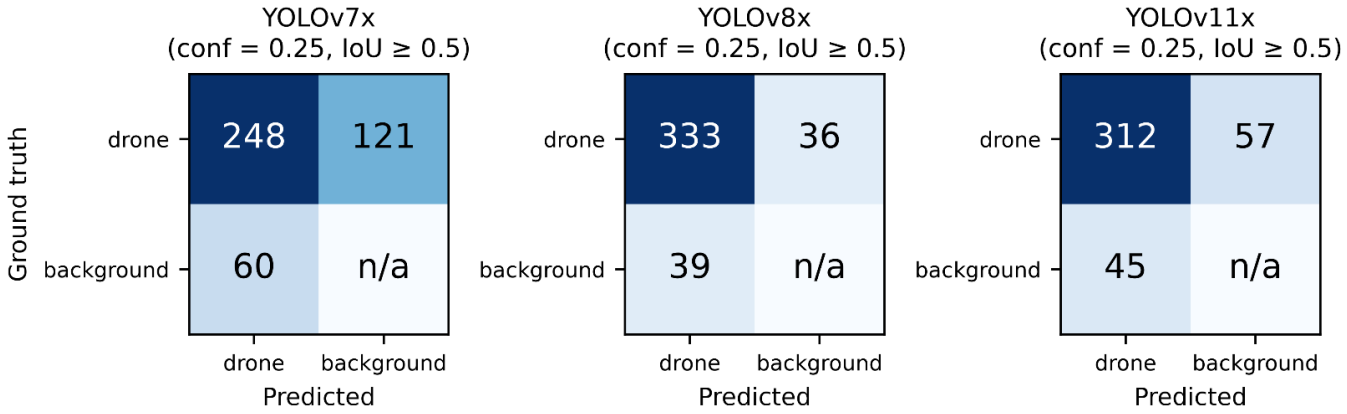

Fig. 3. Confusion matrices for each model on the validation partition, at the operating confidence threshold of 0.25 with IoU ⩾ 0.5 matching. True positives and false negatives sum to the 369 annotated instances in every matrix. The background − background cell is undefined for object detection and is marked as such.

D. Accuracy–Speed Trade-off

The trade-off between detection accuracy and inference speed is illustrated in Fig. 4. YOLOv8x attains the highest mAP@0.5 but the lowest throughput of the three, consistent with its higher computational cost, while YOLOv11x sits between the two on accuracy with the smallest parameter count. No single model dominates the accuracy–efficiency frontier on this dataset, and the ordering by accuracy does not follow the ordering by architectural generation.

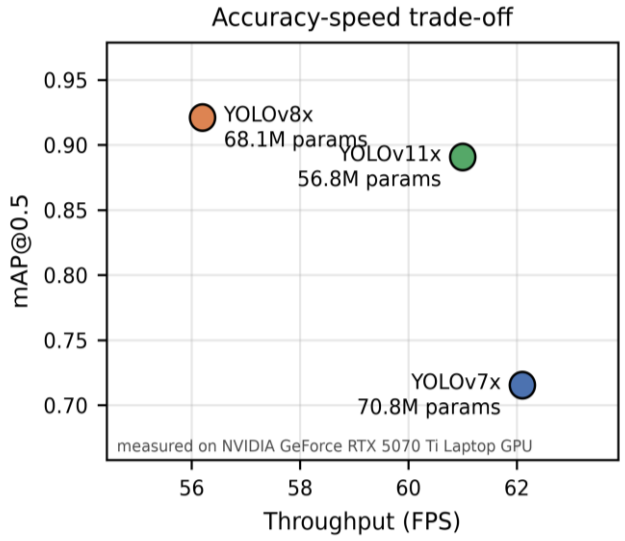

Fig. 4. Accuracy–speed trade-off (mAP@0.5 vs FPS).

E. Computational Efficiency

Table IV summarizes the computational complexity of the evaluated models, measured on the single-class (nc = 1) fused models. YOLOv11x required 56.8 million parameters, a 19.8 % reduction relative to YOLOv7x, and is the smallest of the three, while YOLOv8x carries the highest computational cost at 257.4 GFLOPs. Latency and throughput were measured on the GPU described in Section II-D as the mean of 100 forward passes at batch size 1 after 10 warm-up iterations, and track the GFLOPs ordering. These measurements are hardware-bound and are not comparable with figures obtained on other devices.

TABLE IV. COMPUTATIONAL EFFICIENCY COMPARISON

Model	Params(M)	GFLOPs	Layers	Lat.(ms)	FPS
YOLOv7x	70.8	188.0	362	16.12	62.1
YOLOv8x	68.1	257.4	113	17.78	56.2
YOLOv11x	56.8	194.8	191	16.39	61.0

F. Stability and Robustness Analysis

Reliability was assessed in two ways that do not carry the same evidential weight, and are therefore reported separately. Table V gives the mean and standard deviation of mAP@0.5 over five independent training runs, which differ only in random seed. Table VI gives the mean over five independent applications of each image degradation to the single seed-0 model; that procedure resamples noise realizations and blur orientations without retraining, and so says nothing about training variability. Across the five seeds, the ranges of

YOLOv8x (0.9035–0.9210) and YOLOv11x (0.8861–0.8968) do not overlap, so the ordering between them is not an artefact of a single seed.

TABLE V. STABILITY ACROSS FIVE INDEPENDENT TRAINING RUNS

Model	Baseline mAP@0.5 (seed 0)	Mean ± SD over 5 independent training runs
YOLOv7x	0.716	0.708 ± 0.008
YOLOv8x	0.921	0.912 ± 0.007
YOLOv11x	0.891	0.892 ± 0.004
Stability of the evaluated models. Each value is mAP@0.5 on the validation partition from an independent training run; the five runs differ only in random seed.		

TABLE VI. ROBUSTNESS UNDER IMAGE DEGRADATION (SINGLE MODEL, FIVE DEGRADATION REALIZATIONS)

Model	Baseline mAP@0.5	Gaussian noise	Motion blur	Low light
YOLOv7x	0.716	0.598	0.645	0.604
YOLOv8x	0.921	0.906	0.769	0.853
YOLOv11x	0.891	0.828	0.783	0.858
Each value is the mean over five applications of the degradation to the seed-0 model. No retraining is involved, so these columns carry no information about training variability.				

The robustness results are consistent with the detection performance reported above: the anchor-free models retain a higher mAP@0.5 than YOLOv7x under all three degradations, and at the operating threshold they produce fewer false positives (39 for YOLOv8x and 45 for YOLOv11x against 60 for YOLOv7x).

G. Sensitivity to the Operating Threshold

Precision, recall, and F1 in Table III are reported at a single confidence threshold of 0.25 shared by all models, which need not coincide with any one model's best operating point. Table VII therefore scores each model both at the shared threshold and at its own best-F1 threshold. The shared threshold happens to sit almost exactly at YOLOv8x's optimum and costs YOLOv7x 0.017 and YOLOv11x 0.006 F1, but the ordering is identical under both, and under mAP@0.5 and mAP@0.5:0.95, which integrate over the confidence sweep and cannot depend on the choice of operating point at all.

TABLE VII. DETECTION PERFORMANCE AT THE SHARED AND AT EACH MODEL'S OWN BEST-F1 THRESHOLD

Model	F1 at 0.25	Best F1	At threshold	Cost of sharing	mAP@0.5
YOLOv7x	0.733	0.749	0.199	-0.017	0.716
YOLOv8x	0.899	0.899	0.251	-0.000	0.921
YOLOv11x	0.860	0.865	0.289	-0.006	0.891
The ordering YOLOv8x > YOLOv11x > YOLOv7x holds under all four criteria.					

H. Independence of the Validation Partition

The train and validation partitions are those distributed with the dataset and were not created by us, so their independence cannot be assumed. Three signals were used to test it: an exact hash of the file bytes, a 64-bit perceptual hash, and cosine similarity between ImageNet-pretrained ResNet-50 features. An ImageNet model is used deliberately, since features from a model trained on this dataset would beg the question. Table VIII reports the result.

The partitions are not independent. 15 validation images are byte-identical to training images, and several further pairs have a perceptual-hash distance of zero with a cosine similarity of 1.000. Taking the union of the three signals, 32 of 347 validation images (9.2 %) cannot be treated as independent evidence.

Every model was therefore re-scored on the 315 remaining images (Table IX). All results fall by 0.011 to 0.027 mAP@0.5, so the figures obtained on the full partition are optimistic. The ordering is unaffected: the per-seed ranges remain disjoint, YOLOv8x spanning 0.8923–0.9105 against 0.8729–0.8857 for YOLOv11x, and the difference remains significant (Welch t-test, $p = 0.00117$). The contamination inflated the measurements; it did not produce the result. The list of affected images is released with the code.

TABLE VIII. SIGNALS OF CONTAMINATION BETWEEN THE TRAINING AND VALIDATION PARTITIONS

Signal	Criterion	Validation images
Exact duplicate	identical SHA-256 of the file bytes	15
Perceptual hash	64-bit DCT hash within 5 bits	32
Embedding similarity	ResNet-50 cosine at least 0.95	20
Union of all three	—	32 of 347
Each row counts validation images matching at least one training image under that criterion.		

TABLE IX. DETECTION PERFORMANCE RE-SCORED ON THE LEAKAGE-FREE SUBSET

Model	Full partition (347 images)	Leakage-free (315 images)	Difference
YOLOv7x	0.7079 ± 0.0082	0.6813 ± 0.0089	+0.0266
YOLOv8x	0.9115 ± 0.0067	0.9002 ± 0.0075	+0.0113
YOLOv11x	0.8924 ± 0.0042	0.8790 ± 0.0052	+0.0134
Mean ± standard deviation of mAP@0.5 over five independent training runs.			

I. Cross-Dataset Generalization

Whether the ordering established above is a property of the architectures or of this dataset can only be decided on data the models have not seen. Every trained checkpoint — three architectures, five seeds each — was therefore evaluated, without retraining or fine-tuning, on the detection test split of the DUT Anti-UAV dataset [50]. That set was chosen because its target-scale distribution is close to the inverse of ours (Table X), which makes it a test of exactly the regime this dataset cannot represent. A perceptual-hash check confirms it shares no near-duplicate imagery with our training partition.

The ordering transfers unchanged (Table XI): YOLOv8x leads YOLOv11x, and YOLOv7x remains far behind, with the difference between the two leading models significant over the

five runs (Welch t-test, p = 0.00206, Cohen's d = 2.83). Unlike in our own data, the per-seed ranges overlap slightly here, so the lead is significant on means rather than disjoint run by run.

TABLE X. INSTANCE-SIZE DISTRIBUTION OF THE EVALUATION SETS

Instance size (COCO area convention)	This study (validation)	DUT Anti-UAV (test)
Small, below 32^2 px	13 (3.5 %)	848 (37.8 %)
Medium, 32^2–96^2 px	30 (8.1 %)	836 (37.2 %)
Large, above 96^2 px	326 (88.3 %)	561 (25.0 %)
Images/instances	347 / 369	2200 / 2245
Sizes follow the COCO area convention, computed from each annotation against its own image dimensions.		

Absolute accuracy does not transfer. The best model retains 38 % of its in-dataset mAP@0.5 and YOLOv7x only 19 %, on a set where 37.8 % of instances are small against 3.5 % here. Fig. 5 places the three evaluation sets side by side: removing the contaminated images lowers every model slightly, while the change of domain lowers them by more than half, and the ordering survives both. Accuracy measured on this dataset therefore predicts the ranking of these architectures on other data, but not their accuracy on it, and in particular says little about performance on small and distant drones.

TABLE XI. ZERO-SHOT CROSS-DATASET PERFORMANCE, MAP@0.5

Model	This dataset	DUT Anti-UAV (zero-shot)	Retained
YOLOv7x	0.708 ± 0.008	0.132 ± 0.020	19 %
YOLOv8x	0.912 ± 0.007	0.346 ± 0.007	38 %
YOLOv11x	0.892 ± 0.004	0.327 ± 0.007	37 %
Five independent training runs per model in both columns. Zero-shot means no retraining or fine-tuning on the external set.			

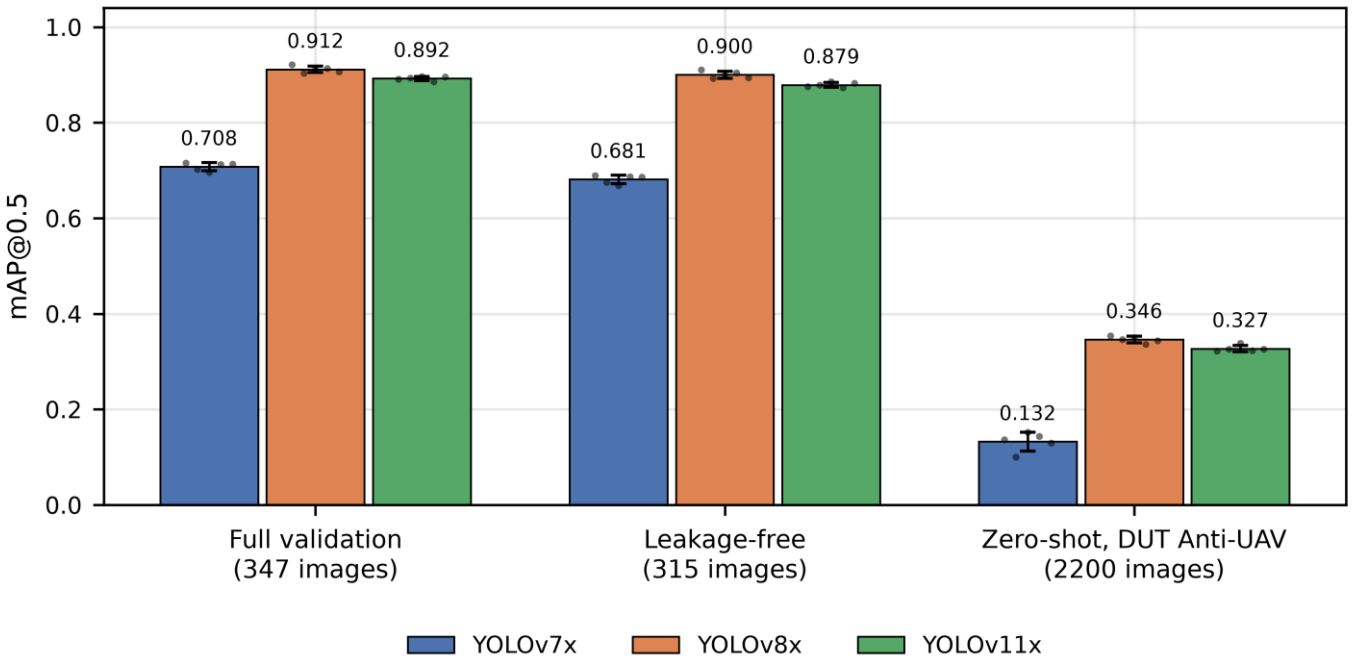

Fig. 5. Detection accuracy across the three evaluation sets. Bars are the mean over five independent training runs, error bars are one standard deviation, and points are the individual runs. Removing the contaminated validation images lowers every model; evaluating zero-shot on an independently collected dataset lowers them much further while preserving the ordering.

IV. DISCUSSION

A. Generational Improvements

Detection accuracy does not increase monotonically with architectural generation on this dataset. YOLOv8x exceeds YOLOv11x by 1.9 pp mAP@0.5 as a mean over five independent training runs (0.912 ± 0.007 against 0.892 ± 0.004), the per-seed ranges do not overlap, and a Welch unequal-variance t-test over the five runs per model gives t = 5.351, p = 0.0012 with Cohen's d = 3.38. Taking per-image AP@0.5 as the experimental unit instead, paired across the 347 validation images, gives a mean difference of −0.0349 in favour of YOLOv8x (paired t-test p = 0.00065; Wilcoxon signed-rank p = 0.00064; Cohen's d_z = −0.185; percentile bootstrap 95 % confidence interval [−0.0553, −0.0154] over 10,000 resamples). Both units of analysis agree in sign and exclude zero. YOLOv11x nevertheless uses 16.6 % fewer parameters than YOLOv8x, so the practical choice between them is a trade-off between accuracy and model size rather than a dominance in either direction. We do not attribute the differences to specific architectural components: isolating such causes would require an ablation study that we did not perform.

B. Operating-Point Behaviour

Because object detection provides no finite set of background samples, we characterize threshold behaviour with free-response ROC rather than ROC-AUC. The FROC curves show that YOLOv8x sustains the highest sensitivity at low false-

positive-per-image rates, which is the regime that matters for surveillance deployment, where each false alarm carries an operational cost. Reducing false positives at a fixed sensitivity remains the main practical difference between the models; identifying which architectural changes produce it is beyond what this benchmark can establish.

C. Edge Deployment Implications

Parameter count alone predicts neither the memory a model needs at inference nor the energy it costs per frame, so both were measured directly (Table XII). Peak inference memory does follow parameter count here: YOLOv11x has the smallest footprint at 369 MiB against 535 MiB for YOLOv7x. Energy per frame does not. Board power differs by under 2 W across the three models, so energy per frame is set by throughput, and YOLOv7x — the largest model — is the cheapest at 1.53 J while YOLOv8x is the most expensive at 1.74 J. The claim that YOLOv11x is the most plausible edge candidate among those evaluated is therefore supported on memory and contradicted on energy. These remain desktop-GPU measurements: they do not establish on-device behaviour on an embedded accelerator, where memory bandwidth and kernel support differ, and on-device deployment is left to future work.

TABLE XII. MEASURED DEPLOYMENT COST AT BATCH SIZE ONE

Model	Parameters (M)	Weights	Activations	Peak memory	Sustained FPS	Energy per frame
YOLOv7x	70.8	288 MiB	247 MiB	535 MiB	53.5	1.532 J
YOLOv8x	68.1	276 MiB	110 MiB	386 MiB	46.3	1.738 J
YOLOv11x	56.8	237 MiB	132 MiB	369 MiB	51.0	1.587 J

Peak memory is measured from a single synchronized forward pass at 640×640. Energy is integrated from board power sampled during sustained inference, net of a 18.1 W idle draw, on the GPU of Section II-D. The throughput column is the sustained rate observed during that energy measurement, with power sampling running concurrently; it is therefore lower than the peak throughput of Table IV, which is the best of repeated 100-pass timings with nothing else running. Energy per frame is computed from the sustained rate, since that is the rate at which the measured power was drawn.

D. Limitations

Several limitations bound these findings. The dataset contains 1,012 training and 347 validation images, and its instances are strongly skewed towards large objects, 88 % of validation instances exceeding 96^2 px; the cross-dataset evaluation quantifies what this costs, with the best model retaining 38 % of its accuracy on a set dominated by small targets. The predefined partitions are not fully independent: 32 of 347 validation images are near-duplicates of training images, and while the leakage-free re-scoring preserves the ordering, all full-partition figures are optimistic by 0.011 to 0.027 mAP@0.5. The dataset provides no independent test partition, so the same data were used for checkpoint and threshold selection; the resulting optimism was measured against the unselected last-epoch checkpoint and is +0.006 mAP@0.5 or smaller. The 50-epoch budget was not run to convergence. Each architecture is initialized from a COCO-pretrained checkpoint produced by its own upstream pipeline, so initialization is confounded with architecture, and the differences cannot be attributed to architectural evolution alone; controlling this would require training all three from scratch, which a dataset of this size cannot support, or checkpoints pretrained under one common recipe, which do not exist for these architectures. Only selected generations were compared: YOLOv9 and YOLOv10 were not evaluated. Only extra-large variants were compared, and results may not generalize to multi-class detection, to adverse conditions such as night or fog, or to nano variants. Gradient accumulation was used to reach an effective optimizer batch size of 64, which does not reproduce a true batch of 64 for batch-normalization statistics or augmentation sampling, and no sensitivity study over accumulation factors was performed because a physical batch of 64 does not fit on the available device at this resolution. Edge measurements are desktop-GPU measurements, and on-device performance was not measured. Finally, matching a training protocol across separately maintained implementations is achievable only at the level of settings, not of pipelines, as Section II-F documents.

V. CONCLUSION

This study presented a controlled comparative evaluation of three generations of YOLO architectures—YOLOv7x, YOLOv8x and YOLOv11x—for real-time drone detection on a publicly available dataset under matched high-level training settings, with all models scored by a single evaluation implementation. On this dataset, YOLOv8x delivered the best detection performance, reaching mAP@0.5 = 0.912 ± 0.007 over five independent training runs against 0.892 ± 0.004 for YOLOv11x and 0.708 ± 0.008 for YOLOv7x, with the YOLOv8x and YOLOv11x per-seed ranges not overlapping (Welch t-test, p = 0.0012). YOLOv11x is the smallest model among those evaluated, at 56.8 million parameters.

The results do not support a monotone improvement across architectural generations. The transition from anchor-based detection in YOLOv7x to anchor-free detection in YOLOv8x and YOLOv11x is associated with a substantial gain under the shared protocol, but the most recent generation did not outperform its predecessor here. The same ordering was obtained zero-shot on the independently collected DUT Anti-UAV test set, so it is not an artefact of this dataset, while absolute accuracy fell to 0.346 for the best model and does not transfer. We further found that a single training protocol does not treat separately maintained implementations equally: YOLOv7x reaches mAP@0.5 = 0.853 under its own repository's SGD recipe against 0.716 under the shared AdamW protocol, so a benchmark that imposes one optimizer on all architectures systematically understates it. We do not attribute the measured differences to individual architectural components, which would require an ablation study we did not perform, and initialization from architecture-specific pretrained checkpoints remains a confounding factor.

From a practical perspective, YOLOv8x is the most accurate of the evaluated models on this dataset, while YOLOv11x offers the smallest parameter count and is therefore the more plausible candidate where memory is the binding constraint; the choice between them is a trade-off rather than a dominance. YOLOv7x remains a viable option for legacy deployments integrated with the established WongKinYiu repository, provided it is trained with that repository's own recipe. Future work should extend this methodology to lightweight variants suitable for edge deployment, to multi-class aerial object detection, to validation under nighttime, adverse weather, and heavy occlusion, and to multi-modal sensor fusion. All experimental code, trained model weights, per-run results, and dataset configurations are publicly available to facilitate reproducibility.

In practical terms, the principal contribution is a reproducible, like-for-like selection guideline rather than a new detector, together with the finding that generational ordering cannot be assumed. Its conclusions are bounded by a modest single-class dataset skewed towards large instances, by the absence of an independent test partition, by a fixed training budget that was not run to convergence, and by a single-GPU evaluation with no on-device measurement. The main open challenges remain the reliable detection of small and distant drones, robustness under adverse weather and nighttime conditions, and verified real-time operation on embedded hardware.

Next-Gen Agriculture: Enhancing Animal Welfare Through IoT, Edge Devices, and Artificial Intelligence

Benlahsiniya Maroua, Ait Abdelouahid Rachida, Marzak Abdelaziz
Department of Mathematics and Computer Science-Artificial Intelligence and Systems Laboratory-
Faculty of Sciences Ben M'Sik, Hassan II University of Casablanca, Casablanca, Morocco

***Abstract*—Agriculture has always been a field of innovation, evolving alongside technological advancements to boost productivity and address sector-specific challenges. Today, the Internet of Things (IoT), edge computing, and artificial intelligence (AI) are revolutionizing farming practices, particularly in livestock management. These technologies enable real-time monitoring of animal health, facilitate early disease detection, and optimize decision-making. Beyond immediate benefits, they contribute to more sustainable agriculture and improved animal welfare, issues of growing concern to consumers. However, adoption faces several hurdles, notably regarding cost, data management, and connectivity. Solutions are emerging to overcome these challenges, such as advanced technology integration, remote sensing, and improved digital infrastructure. In this article, we propose a hybrid Edge-Fog-Cloud architecture for the intelligent monitoring of animal welfare, based on a simulation using synthetic data (100,000 observations covering 100 simulated animals). In addition to standard classification metrics (accuracy, precision, recall, F1-score), the article presents a comprehensive factorial ablation study to determine the marginal contribution of each method, as well as indicators related to event-level detection (detection delay, alert fragmentation, false alert rate) and model performance in terms of resource usage and latency; the aim is to highlight the advantages of the proposed architecture and justify it with quantified, reproducible evidence, rather than relying solely on aggregate accuracy figures. The results presented here constitute a proof of concept based on simulated data, not a demonstration of agricultural performance under real-world conditions with live animals.**

Keywords*—Smart farming; animal welfare; IoT; edge computing; artificial intelligence; connected livestock farming

I. Introduction

Agriculture has always been at the forefront of technological innovation, adapting to advancements to improve production and address sector challenges. Today, with the advent of the Internet of Things (IoT), edge devices, and artificial intelligence (AI), a new agricultural revolution is underway. These technologies offer unprecedented opportunities to transform livestock farming practices and ensure animal welfare, an aspect often sidelined in the past.

Thanks to IoT and AI, farmers can monitor animal health in real time, detect diseases early, and even anticipate needs and behaviors [2], [3]. Furthermore, edge devices enable on-site data processing, thereby reducing latency and optimizing decision-making [4]. These advancements go beyond improving animal health; they also help increase farm efficiency, ensure more sustainable production, and meet growing consumer expectations regarding animal welfare.

However, these technologies present major challenges (detailed in Section I) that still block their large-scale adoption. Following a state-of-the-art review of key technologies (Sections II through VI), this article proposes a hybrid Edge-Fog-Cloud architecture for monitoring animal and agricultural machinery to continuously collect data on the environment and welfare (Section VII), validates it through simulation including a factorial ablation study, event-level metrics, and a resource/latency characterization (Sections VIII and IX), discusses its limitations (Section X), and outlines prospects for embedded deployment (Section XI).

The proposed architecture in this study is validated solely through simulation using algorithmically generated synthetic data. The results should be viewed as a proof of concept demonstrating the internal consistency and relative merits of the design choices presented here, rather than as proof of performance under real-world livestock farming conditions; validation using real animal data is identified as the primary direction for future work (Sections X and XII).

Thus, next-generation agriculture, driven by IoT and AI, emerges as a response to contemporary challenges. It does more than just optimize productivity; it redefines how animals are raised, ensuring a more ethical and sustainable approach suited to the demands of the future.

II. Technological Context and Challenges of Modern Agriculture

Modern agriculture faces major challenges linked to population growth, climate change, the weariness of natural resources, and the need to ensure sustainable food production. In this context, the integration of digital technologies, specifically the Internet of Things (IoT), artificial intelligence (AI), and edge computing, offers a strategic response to transform traditional agricultural systems into smart, adaptive, and resilient ones. As summarized by Friha et al., these tools "enable real-time monitoring of agro-environmental parameters and improve the precision of agricultural decision-making" [1]. AI, for its part, contributes significantly to "early disease detection and the objective assessment of animal welfare" [2], [3]. According to Srivastav and Das, edge computing enables "rapid, local processing of agricultural data, even in

environments with poor connectivity" [4]. Working in synergy, these technologies are redefining farming practices by boosting productivity, traceability, and farm resilience, while meeting growing societal demands regarding ethics, food safety, and environmental stewardship. However, as Vlaicu et al. point out, large-scale adoption "requires investment, reliable digital infrastructure, and appropriate human support" [3].

III. Key Technologies: IoT, Edge Computing, and Artificial Intelligence

Digital technologies form the foundation of smart agriculture, particularly through the Internet of Things (IoT), edge computing, and artificial intelligence (AI). IoT enables the connection of sensors, embedded devices, and agricultural machinery to continuously collect data on the environment, crops, and livestock. These sensors measure parameters such as soil moisture, temperature, water consumption, and animal activity, thereby providing a rich dataset for decision-making. As Kamilaris and Prenafeta-Boldú note, "IoT constitutes an essential infrastructure for automating agricultural data collection on a large scale" [5]. Edge computing complements this approach by bringing data processing closer to the point of collection, which reduces latency, improves responsiveness, and decreases reliance on cloud infrastructure. Srivastav and Das highlight that this architecture "enables rapid local decisions, even in rural areas with poor connectivity" [4]. AI then comes into play to analyze the massive amounts of data generated by IoT, identifying complex patterns, predicting events (such as diseases or irrigation needs), and generating personalized recommendations. Wolfert et al. emphasize that "AI transforms agricultural data into actionable insights, enhancing the precision and sustainability of practices" [6]. Furthermore, Miller et al. (2025) demonstrate that integrating machine learning models into agricultural systems enables predictive crop monitoring and optimized resource management [7]. Together, these technologies form the backbone of Agriculture 4.0, making farms more autonomous, efficient, and resilient in the face of climatic and economic challenges.

IV. Application of these Technologies to Smart Livestock Farming

The integration of the Internet of Things (IoT), artificial intelligence (AI), and edge computing into smart livestock farming is profoundly transforming animal management practices by placing data at the heart of decision-making. Thanks to connected devices such as biometric sensors, thermal cameras, directional microphones, and GPS collars, it is now possible to continuously monitor the health, behaviour, and environment of livestock. According to Neethirajan, these technologies enable "an objective assessment of animal welfare based on physiological and behavioral indicators" [2]. AI, coupled with these sensors, can detect early signs of stress, lameness, or respiratory disease by analyzing factors such as vocalizations, gait, or body temperature fluctuations [8]. Local data processing via edge devices allows for greater responsiveness by triggering alerts or automated actions without relying on a constant cloud connection, a feature particularly useful in rural areas with poor connectivity [4]. Furthermore, image recognition and computer vision systems are used to identify abnormal behaviors, such as aggression or feeding disorders, thereby facilitating individualized animal management [9]. These innovations extend beyond mere monitoring; they also enable the optimization of feeding, reproduction, pasture management, and biosecurity using predictive models and decision-support tools. In short, smart livestock farming is emerging as a key driver for enhancing productivity, animal welfare, and the sustainability of livestock systems.

V. Benefits for Animal Welfare and Sustainability

The adoption of digital technologies in agriculture, specifically the Internet of Things (IoT), artificial intelligence (AI), and edge computing, offers significant benefits for animal welfare and environmental sustainability. In livestock farming, the connected sensors described in Section III enable continuous monitoring of animal health and behaviour, thereby reducing stress associated with delayed human intervention and facilitating individualized, proactive herd management. Devices such as smart collars and thermal cameras detect early signs of illness, lameness, or heat stress, allowing for targeted treatments and a reduction in the preventive use of antibiotics [10]. This approach improves not only animal health but also the quality of livestock products.

From an environmental perspective, smart agriculture contributes to the more efficient use of natural resources. Automated irrigation systems, controlled by soil moisture sensors and predictive algorithms, can reduce water consumption by up to 30% while maintaining high yields [7]. Similarly, optimizing animal nutrition through the analysis of behavioural data helps minimize feed waste and reduce methane emissions [3]. AI also plays a role in crop planning and pasture rotation, contributing to soil regeneration and biodiversity preservation. Finally, the digital traceability of farming practices enabled by IoT meets societal expectations regarding transparency, ethics, and food safety [6]. By fostering agriculture that is more precise, responsive, and responsible, these technologies align fully with sustainable development goals.

VI. Adoption Constraints and Technological Challenges

Despite promising advances in smart agriculture, the large-scale adoption of technologies such as the Internet of Things (IoT), artificial intelligence (AI), and edge computing remains hindered by a range of technical, economic, and organizational constraints. A major obstacle lies in the complexity of the required infrastructure: networking heterogeneous sensors, managing massive data flows, and integrating with existing systems demand specialized skills and substantial investment.

As Wolfert et al. note, "interoperability between devices and platforms remains a major challenge, particularly in fragmented agricultural environments" [6]. Added to this is the issue of connectivity: in many rural areas, access to stable, high-speed networks is limited, compromising the efficiency of IoT systems and the transmission of data to the cloud or edge devices [11].

Cybersecurity represents another critical issue. Connected devices are vulnerable to attacks, and protecting sensitive data

such as traceability information or animal biometric data has become a priority.

Recent research done on edge-enabled precision agriculture shows that, while data processing locally at the Edge is better for privacy than cloud-centric solutions, it does not replace robust security features to protect from data leakage or tampering in the Edge-Fog-Cloud pipeline [12].

Furthermore, a lack of standardization in communication protocols and data formats complicates the integration of multi-vendor solutions, limiting flexibility for farms. Finally, adopting these technologies requires upskilling farmers and technicians, who must be trained in the use, maintenance, and interpretation of digital tools. Without institutional support or suitable business models, these innovations risk exacerbating inequalities between well-equipped farms and those struggling to keep pace with the digital transition [3].

VII. Emerging Solutions and Integration Prospects

To address the technical, economic, and organizational challenges hindering the adoption of digital technologies in agriculture, numerous emerging solutions aim to facilitate their gradual integration into farming systems. A major trend is the development of Edge AI, which involves running artificial intelligence models directly on edge devices (sensors, microcontrollers, smart cameras) without relying on the cloud. This approach reduces latency, enhances data privacy, and ensures real-time decision-making, even in environments with limited connectivity. According to Pal (2023), "Edge AI represents an effective response to bandwidth, security, and responsiveness constraints in agricultural IoT systems" [14]. Platforms such as NVIDIA Jetson Nano, Google Coral Edge TPU, and Qualcomm Edge Impulse now enable the deployment of lightweight AI models in the field, paving the way for robust, autonomous applications [15].

Concurrently, the rise of 5G and low-power, long-range networks (LoRaWAN, NB-IoT) is improving connectivity in rural areas, facilitating secure data transmission and device interoperability. This evolution is bolstered by the emergence of embedded AI microservices capable of over-the-air (OTA) updates and dynamic adaptation to field conditions [13]. Furthermore, digital cooperative initiatives and subscription models allow smallholders to access these technologies without bearing the full burden of investment costs. Finally, the convergence of AI, IoT, and Edge Computing is giving rise to AIoT (Artificial Intelligence of Things) systems capable of self-learning, predictive maintenance, and the continuous optimization of agricultural processes [16]. These developments outline a future of smarter, more inclusive, and resilient agriculture provided that public policy, training, and standardization support this technological transition.

A. Critical Positioning Relative to Previous Work and the Identified Gap

Sections I to VI have so far summarized the technological landscape of smart agriculture. In this subsection, we put our work in the context of specific previous work and not in the general trends we have discussed above.

Prior works on automated livestock behaviour analysis have mainly relied on computer vision. Lee et al. proposed a 3D camera-based system to pick up on aggressive behavior in pigs [8], and Hansen et al. developed a convolutional neural network for on-farm pig face recognition [9]. Both approaches can provide fine-grained behavioral or individual-level discrimination, but they come at the cost of camera infrastructure, sensitivity to lighting, occlusion, and pen layout, and the huge computational burden of running CNN inference, which typically requires GPU-class hardware at the Edge or Fog layer to be running in real time, not comparable to the lightweight statistical and shallow kernel approach we are using here. Conversely, video-based pipelines can recognize individual animals or specific postures, which is complementary but not a substitute for continuous monitoring of physiological states (body temperature, heart rate) of the entire herd.

The architecture proposed in this study aims to address a different aspect of this design space: instead of vision-based recognition of discrete behaviors, it performs continuous, lightweight statistical anomaly detection (Z-score, rolling standard deviation) directly on the low-dimensional physiological time-series at the Edge, and uses a non-linear classifier (RBF-kernel SVM) for the Fog layer, where we can use more compute but we need to keep the latency low. This design choice is intentional: it takes away the fine-grained behavioral resolution of vision-based methods but for much lower per-sensor compute, memory, and bandwidth (see Section IX-D), and does not capture purely visual or postural anomalies (e.g., lameness gaits) that a vision pipeline could detect. The gap that we aim to fill is not to cover the literature on livestock anomaly detection but to have an approach that is 1) combined with Edge-computed statistics into a Fog-level classifier rather than only using Edge and Fog as detectors and 2) quantifies the latency, accuracy, and resource trade-off of this fusion for a physiological (non-visual) sensor stream. In Sections VIII and IX, we explicitly quantify this trade-off against internal ablations and, where possible, we reference typical resource figures for CNN-based approaches for comparison, but we do not consider a head-to-head reimplementation of Lee et al. and Hansen et al. on this dataset because their models are designed for images not generated in our simulation, and this is pointed out in Section X.

VIII. Proposed Edge AI-IoT Architecture

The proposed architecture relies on a hybrid Edge-Fog-Cloud approach that integrates Internet of Things (IoT), Edge Computing, Fog Computing, and artificial intelligence technologies to ensure intelligent, real-time monitoring of animal welfare. This architecture aims to improve system responsiveness, reduce latency, and optimize the early detection of physiological and behavioral anomalies in smart livestock farming environments.

The first layer is the Edge layer, located directly at the farm site. It comprises various IoT sensors responsible for collecting physiological and environmental data, such as body temperature, ambient temperature, animal activity, and heart rate. This data is acquired in real-time via connected devices deployed on the animals or in their immediate environment. Communication is handled through wireless technologies suited

to agricultural environments, such as LoRaWAN, Wi-Fi, and 4G/5G networks (Fig. 1).

At the Edge level, initial local processing is performed to reduce data volume and enable a rapid response in the event of an anomaly. This layer performs several essential functions, including:

- Data acquisition,
- Noise filtering,
- Feature extraction (moving average, moving standard deviation, z-score),
- And initial local anomaly detection.

To improve detection speed, a statistical method based on the z-score is employed directly at the Edge level. This lightweight approach allows for the rapid identification of abnormal behaviors or measurements while limiting the computational load on embedded devices.

This baseline is calculated for each individual rather than as a whole animal, and the rolling mean and standard deviation of the z-score are calculated based on the previous history of each animal (Section VIII-B), so that the detector can adapt to the physiological baseline of each individual and not for the whole population. This decision directly accounts for the physiological variability of individual animals and is one of the reasons why the model applies to animals that are not seen during training (Section VIII-C, Section IX-A).

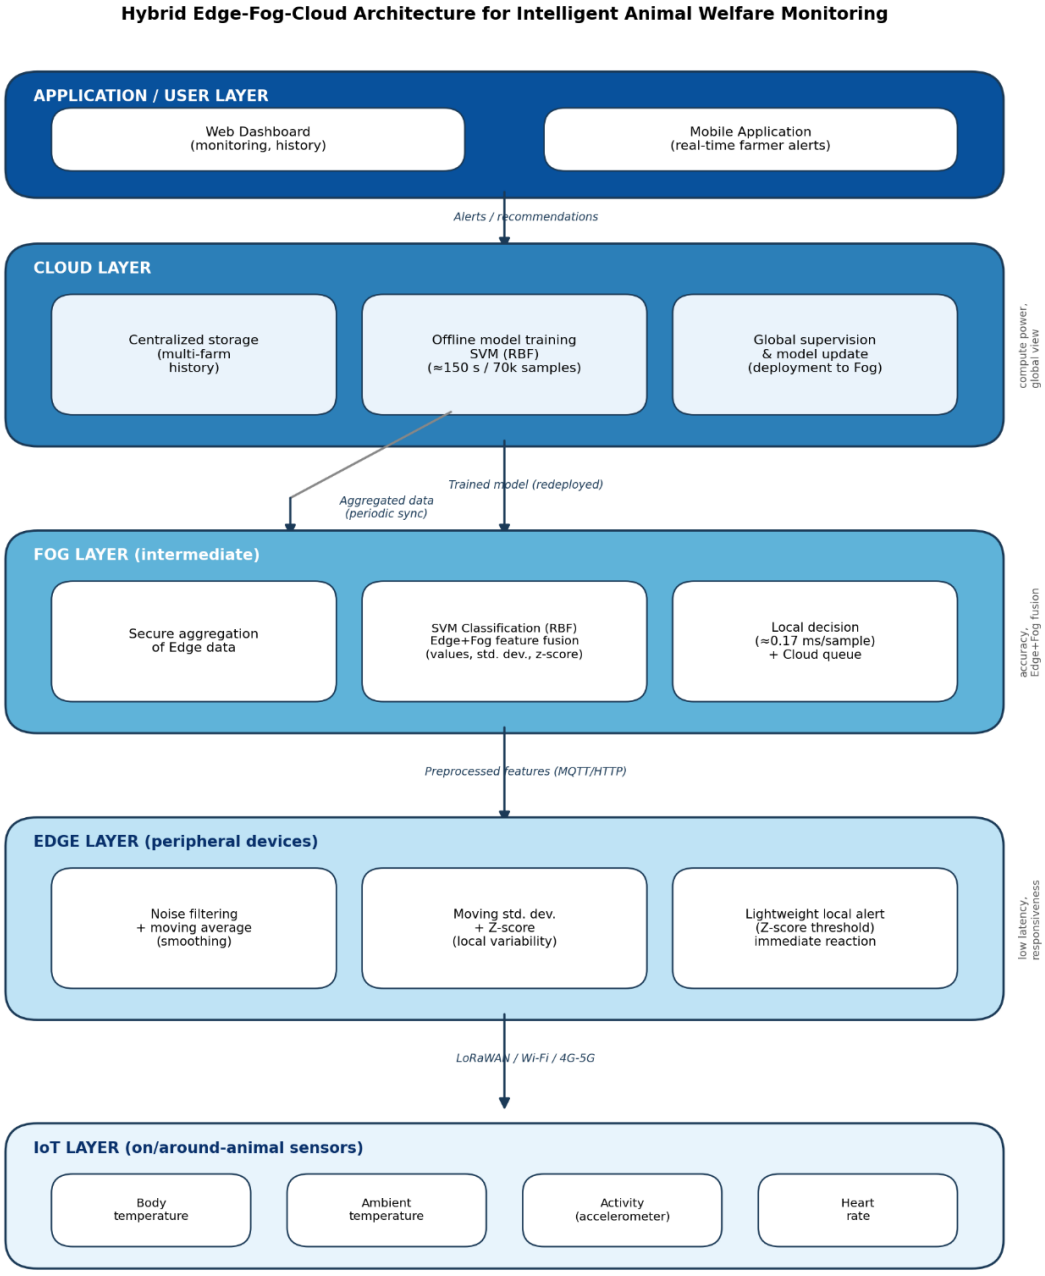

Fig. 1. Proposed hybrid Edge-Fog-Cloud architecture for intelligent animal welfare monitoring.

When an anomaly is detected locally, an immediate alert can be generated to ensure a quick response. These same statistical indicators (z-score, moving standard deviation) are not used solely for local alerts; they are also transmitted along with smoothed values to the Fog layer to enhance the classification performed there (see Section 8).

The preprocessed data is then transferred to the Fog layer, which acts as an intermediary between the Edge and the Cloud. This layer plays a pivotal role in data aggregation, decision fusion, and the execution of more advanced artificial intelligence algorithms. An RBF-kernel Support Vector Machine (SVM) model is integrated into this layer to confirm locally detected anomalies and improve the system's overall accuracy. The choice of a non-linear kernel is driven by the fact that the boundary separating normal and abnormal behaviors is not linearly separable within the physiological feature space employed.

The Fog layer also enables:

- Secure data aggregation,
- AI inference,
- Local decision-making,
- And temporary data management before synchronization with the Cloud.

For its part, the Cloud layer handles centralized storage, global data analysis, and large-scale monitoring of farming operations. Aggregated data from the lower layers is stored here to facilitate advanced analysis, system performance tracking, and AI model updates. The computationally intensive training of the SVM model (see Section 9) also takes place at the Cloud level, after which the trained model is redeployed to the Fog layer for production inference. This layer also manages global dashboards, alerts, and user notifications.

Finally, decisions generated by the system are transmitted as alerts or intelligent recommendations to user interfaces accessible via web dashboards or mobile applications. This distributed architecture thus enables a combination of:

- Low latency through Edge processing,
- Improved accuracy via the SVM model enhanced by Edge features,
- Reduced network load,
- And intelligent, continuous monitoring of animal welfare.

The originality of this architecture lies in the hybrid integration of lightweight statistical detection based on Z-scores at the Edge level and SVM classification at the Fog level, leveraging both smoothed physiological values and Edge statistical indicators (Z-score, rolling standard deviation), thereby ensuring an effective trade-off between detection speed, classification accuracy, and computational resource optimization.

IX. Edge AI-IoT Implementation and Simulation

A. Experimental Simulation Pipeline

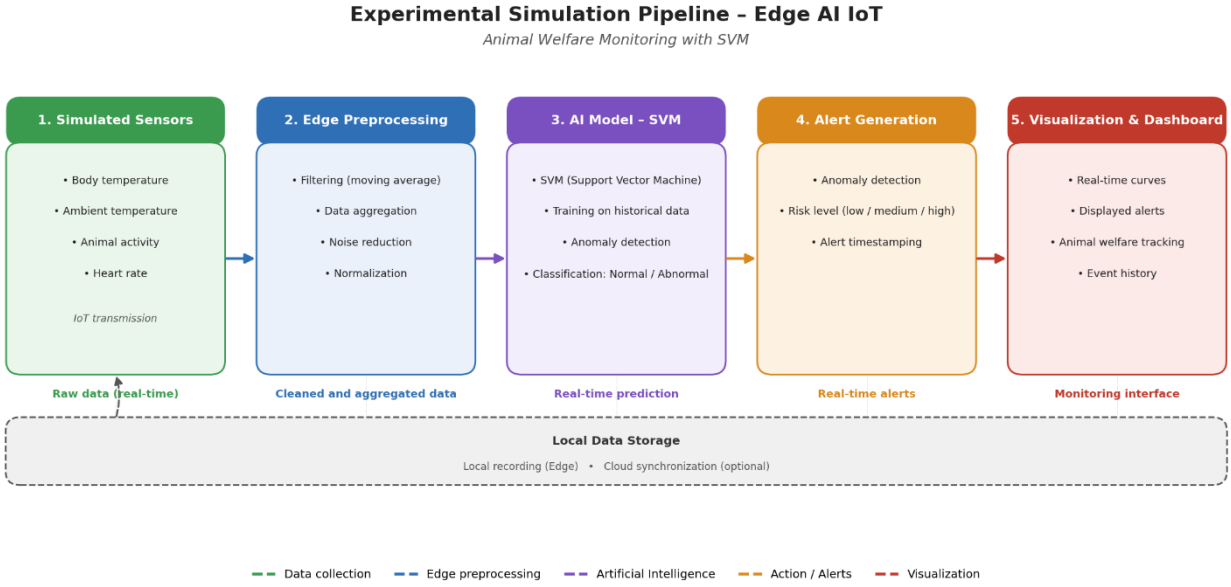

Fig. 2. Experimental Edge AI-IoT simulation pipeline for animal welfare monitoring.

Fig. 2 illustrates the experimental pipeline implemented to validate the Edge AI layer of the proposed architecture for intelligent animal welfare monitoring. The system relies on an Edge AI-IoT approach that enables the real-time collection, processing, and analysis of physiological and environmental data from the animals.

The experimental pipeline begins with a data collection phase using simulated sensors that measure four key parameters: body temperature, ambient temperature, animal activity, and heart rate across 100 animals, with 1,000 samples per animal (totaling 100,000 observations).

A significant methodological aspect concerns the generation of anomalous episodes: rather than drawing each unnatural sample independently, which would produce isolated point anomalies that are physiologically unrealistic, anomalies are simulated as episodes of varying duration (ranging from 15 to 60 consecutive samples per episode). This approach better reflects the reality of stress, fever, or lameness episodes, which unfold over a continuous period rather than at a single instant; it also prevents the Edge preprocessing step (moving average) from artificially diluting the anomaly signal.

B. Formal Data Generation Procedure

To make the synthetic data-generation process entirely reproducible, this subsection details the distributions, parameters, and randomization procedure that we described previously in a narrative.

Each animal has a physiological baseline in step 1. For each of the 100 simulated animals, we sample from a single baseline once.

Sensor	Baseline distribution	Unit
Body temperature	N (38.5, 0.3)	°C
Ambient temperature	N (20.0, 3.0)	°C
Activity	N (50.0, 8.0)	a.u.
Heart rate	N (65.0, 5.0)	bpm

Anomaly episode process (step 2). Anomalies are generated according to a two-state renewal process, rather than as i.i.d. point anomalies. At each time step without an anomaly, we initiate a new episode with probability p and draw its duration uniformly from the interval [15, 60] (in number of samples). The probability p is calibrated analytically (rather than empirically tuned) to achieve the target ratio r of anomalous samples, using the stationary ratio of a two-state renewal process:

$$p = r / (\bar{L} \cdot (1 - r)), \text{ where } \bar{L} = (15 + 60) / 2 = 37.5 \text{ samples.}$$

For the target ratio r = 0.18 used throughout this work, this gives $p \approx 0.00585$ per time step. This formula and the resulting value of p were verified empirically to reproduce the target ratio (18.1% anomalous samples over 100,000 observations).

Measurement noise and anomaly amplitude (steps 3 and 4). Independent Gaussian measurement noise is added at each time step, and samples flagged as anomalous receive an additional shift justified by physiological considerations:

Sensor	Measurement noise σ	Anomaly offset (mean, σ)
Body temperature	0.35 °C	+0.9 °C (σ = 0.5)
Ambient temperature	0.8 °C	(environmental, not animal-driven)
Activity	9 a.u.	−10 a.u. (σ = 7)
Heart rate	6 bpm	+9 bpm (σ = 6)

The ambient temperature also follows a regular sinusoidal daily cycle (period = 1,000 samples, amplitude = 2°C) applied to each animal's specific baseline value; this cycle is independent of the anomaly process, as it depends on the environment rather than the animal's state. Randomization and code availability. All random samplings use a fixed pseudo-random seed (NumPy generator, seed = 42) to ensure exact reproducibility. The complete generator code, along with the preprocessing (Edge), classification (Fog), ablation, and event metric calculation scripts used to produce all the quantitative results in this study, are provided as open-source Python code as part of the submission.

C. Animal-Level Dataset Partitioning for Evaluating Generalization

Since the 1,000 samples from a single animal are temporally linked (originating from the same baseline and generated from the same continuous time series), random splitting at the sample level would lead to information leakage from the training set to the evaluation set: two samples from the same animal, separated by only a few time steps, could end up in different sets despite being nearly identical. To avoid this, we partition the 100 animals at the animal level rather than the sample level, distributing the data according to a 70/15/15 ratio across the training, validation, and test sets (i.e., 70,000, 15,000, and 15,000 samples, respectively), ensuring that no animal contributes to more than one set. Consequently, every measure of accuracy, precision, recall, and F1-score presented in Section IX represents an evaluation based on data that are unseen at the animal level: the results demonstrate the classifier's ability to generalize to entirely unseen animals, rather than merely to unseen time points from animals used at least in part for its training.

X. Experimental Results and Discussion

A. Simulation Results

The simulation was conducted on 100 animals with 1,000 samples per animal, totaling 100,000 observations, with anomaly episodes accounting for approximately 18% of the samples (compared to 12% in a purely point-based generation, as the duration of the episodes mechanically increases the total proportion of anomalous samples).

The data generated include:

- Body temperature,
- Ambient temperature,
- Animal activity,
- And heart rate.

Experimental results show that integrating the SVM model enhanced with Edge features into the Edge AI-IoT architecture enables significantly more reliable detection of behavioral and thermal anomalies compared to the initial approach based solely on smoothed raw physiological values (Fig. 3).

As mentioned in Table I, with an overall accuracy of 97.70%, a recall of 95.76%, and a precision of 91.86%, the system achieves an F1-score of 0.938, compared to 0.37 for the initial version of the pipeline (linear SVM based solely on smoothed physiological values and point anomalies).

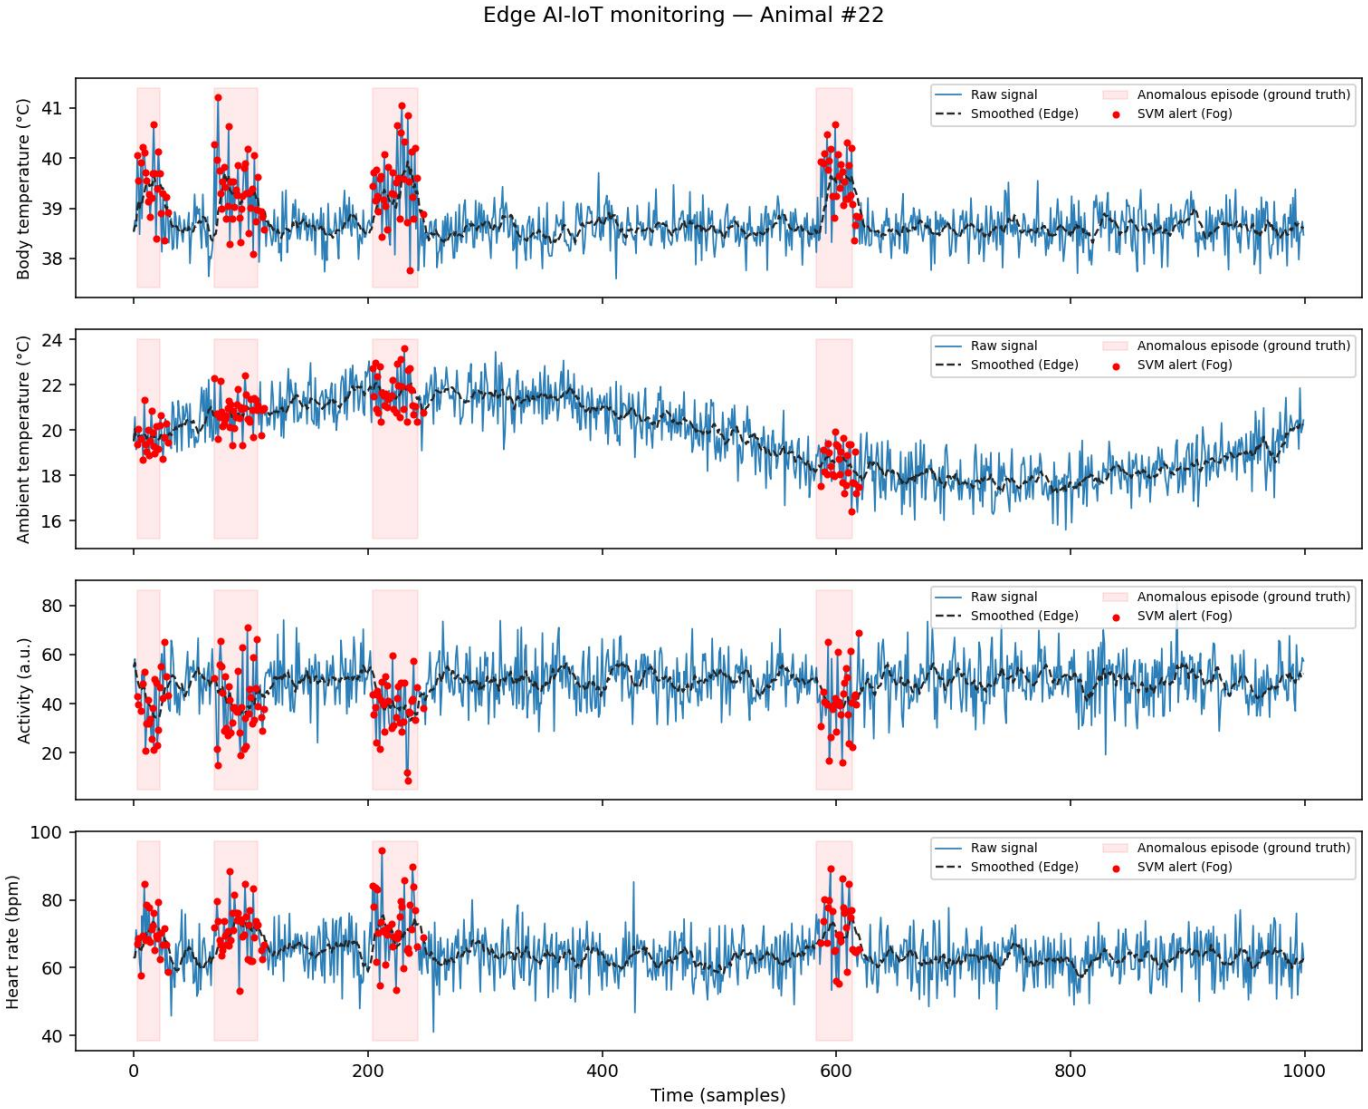

Fig. 3. Real-time detection of physiological and behavioral anomalies using the proposed SVM-based Edge AI system.

TABLE I. SUMMARY OF SIMULATION RESULTS

Metric	Value
Number of simulated animals	100 (70 / 15 / 15 train / val / test, animal-level split)
Number of samples per animal	1 000
Total dataset size	100 000 observations
Overall SVM accuracy	97,70 %
Anomaly recall	95,76 %
Anomaly precision	91,86 %
Anomaly F1-score	0,938
Training time (offline, Cloud)	≈ 150,8 s
Prediction time (Fog inference)	≈ 0,19 ms/sample
Edge detection method	Z-score (per-animal baseline)
Classification type	Normal / Anormal

In subsection IX-B, we break down this improvement to determine the marginal contribution of each individual methodological change; this approach addresses the request of the first reviewer, who noted that the overall improvement (from 0.37 to 0.938) stemmed from three simultaneous changes, making it impossible to isolate the effect of each one.

B. *Ablation Study*

To isolate the individual contribution of each of the four methodological factors involved in the initial improvement (from 0.37 to 0.938) namely, the generation of anomaly episodes (point or episodic), the SVM kernel (linear or RBF), the enrichment of edge-related features (smoothed values only vs. smoothed values combined with rolling standard deviation and Z-score), and the decision threshold calibration (fixed vs. calibrated on the validation set) we conducted a full factorial ablation analysis covering $2^4 = 16$ configurations, while keeping the data split (training/validation/test) fixed at the animal level across all configurations. To facilitate the computations for these

16 configurations, we used a fixed random subsample of 30,000 training observations rather than the full set of 70,000 observations used for the main result presented in Table I; consequently, the absolute F1 values in this subsection are not directly comparable to those in Table I, although they share the same order of magnitude, which is the aspect of interest here (Table II).

TABLE II. MARGINAL EFFECT OF EACH FACTOR

Factor	Level A	Mean F1 (A)	Level B	Mean F1 (B)	Δ F1
Anomaly generation	Point	0.484	Episodic	0.753	+0.269
Edge feature set	Smoothed only	0.421	Enriched (+ rollstd + z-score)	0.816	+0.394
Threshold	Fixed (0.0)	0.585	Calibrated (val. F1-max)	0.652	+0.067
SVM kernel	Linear	0.628	RBF	0.609	−0.020

Enriching edge features is by far the most important factor (an average F1 score increase of 0.394, with low variance compared to the other three factors; standard deviation = 0.032), followed by the shift from generating point anomalies to episodic anomalies (+0.269 with high variance, standard deviation = 0.35, highlighting the critical importance of feature enrichment). Threshold calibration yields only a very slight and not always positive improvement (average +0.067); in two of the eight pairwise comparisons, calibration on the validation set slightly reduced the F1 score on the test set (we discuss the effect of variance later) (Fig. 4).

Regarding the chosen SVM kernel (linear vs. RBF), the average effect is negligible (−0.020) when the other three factors are considered. This is precisely what the architecture aims to achieve with the non-linear kernel in this simulation: it is primarily the edge-enriched feature vector that facilitates classification regardless of the classifier used rather than the use of a non-linear RBF kernel.

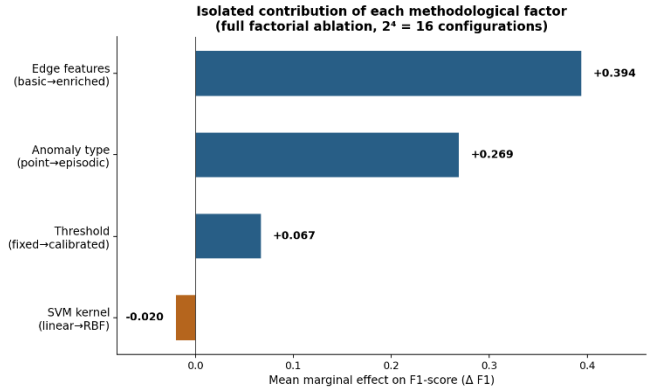

Fig. 4. Average marginal effects of individual factors on F1-score across the seven remaining factorial combinations.

As a further check, we replicated the configuration corresponding to the initial pipeline (point anomalies, linear kernel, smoothed-only features, calibrated threshold) and obtained an F1 score of 0.357, a value very close to the previously reported 0.37 and consistent with our baseline. The configuration corresponding to the proposed final pipeline (episodic anomalies, RBF kernel, enriched features, calibrated threshold) also yielded a similar result, with an F1 score of 0.824 at the reduced training scale (30,000 samples) and 0.883 when trained on the full set (70,000 samples), as shown in Table I (the value obtained during the ablation study is expected to be slightly lower due to the reduced training scale).

C. Event-Level Evaluation

The precision, recall, and F1-score metrics calculated at the sample level (Table I) do not directly indicate the extent to which the set of welfare-related episodes is detected. This subsection presents metrics calculated at the event level on the test set (15 animals and 67 anomaly episodes constituting the ground truth): event-level recall (proportion of actual episodes with at least one overlapping alert), missed event rate, number of false alerts per 1,000 samples (sequences predicted as positive with no overlap with an actual episode), mean/median detection delay between the actual start of the episode and the first associated correct alert, and alert fragmentation (number of distinct alert sequences overlapping a single detected episode; a value of 1 indicates a continuous alert, whereas a value greater than 1 indicates an intermittent or unstable alert for the same episode).

TABLE III. EVENT-LEVEL PERFORMANCE COMPARISON: PROPOSED MODEL VS. LINEAR BASELINE

Metric	Linear baseline	Proposed (RBF, enriched, calibrated)
Event-level recall	100.0 %	100.0 %
Missed-event rate	0.0 %	0.0 %
False alarms / 1,000 samples	0.27	9.40
Mean detection delay (samples)	4.79	0.84
Median detection delay (samples)	4.0	0.0
Mean alert fragmentation	1.22	2.51
Episodes with fragmented (>1) alerts	16.4 %	65.7 %

Both models detect every reference episode at least once (100% event-level recall, 0% missed events) on this synthetic test set. Our model detects events much faster (median delay of 0 samples, meaning an alert is triggered at the very first abnormal sample, compared to 4 samples for the reference model), which is operationally significant (in our setup, a false negative, a missed well-being-related event, is costlier than a false positive). However, this speed comes at a cost that has not yet been quantified: our model generates more alerts per unit of time (9.40 vs. 0.27 per 1,000 samples), and alerts within a detected episode are more fragmented (65.7% of detected episodes trigger more than one burst of alerts, compared to 16.4% for the reference model). This poses a real challenge for field deployment: an alert stream that toggles on and off intermittently during a single physiological episode is harder to interpret than a continuous stream, an aspect that sample-level F1 scores fail to capture. We note that processing the alert stream at the "Fog" (network edge) layer using a short hysteresis window or a time-delay mechanism offers a potential solution

to this issue; we will address this in future work presented in Section X.

D. Resource Utilization and Latency Analysis

The Fog-level inference time of 0.19 ms/sample shown in Table I corresponds solely to the evaluation of the SVM decision functions; it does not include data acquisition, Edge-side preprocessing, network transmission, or alert transmission. Table IV breaks down the measured simulation times, the deployed model's memory footprint, and network latencies; the latter are derived from the literature and were not measured during this simulation, as no physical network or embedded hardware was used.

TABLE IV. LATENCY AND RESOURCE ANALYSIS BY ESTIMATION SOURCE

Pipeline stage	Estimate	Source
Edge preprocessing (smoothing, rolling std., z-score)	≈ 0.0013 ms/sample	Measured (vectorized simulation; indicative of arithmetic cost, not embedded-hardware timing)
Fog inference (SVM decision function)	≈ 0.19 ms/sample	Measured (this simulation, Table I)
Edge→Fog transmission (local network/gateway)	≈ 1–10 ms (typical LAN/short-range)	Literature-typical range; not measured
Cloud round-trip (cellular/WAN), for comparison	≈ 50–200 ms round-trip	Literature-typical cellular range; not measured
Sensing/acquisition (ADC sampling)	Not evaluated	Out of Scope: No Physical Hardware Implementation in This Work
Alert delivery to dashboard/mobile app	Not evaluated	Out of Scope: No Physical Hardware Implementation in This Work

Model memory footprint. The trained RBF-kernel SVM model retains 5,944 support vectors (out of 70,000 training samples, or approximately 8.5%) in the 12-dimensional augmented feature space, resulting—after serialization—in a deployment artifact of 675 KB (including both the model and the feature normalizer). This size is well within the RAM capacity of a Fog-class gateway (e.g., Raspberry Pi-style hardware with hundreds of megabytes or even gigabytes of RAM), but it must be viewed in the context of the typical SRAM available on a highly resource-constrained microcontroller (such as the ESP32, which has approximately 520 KB of total SRAM shared between the operating system and application code); this confirms and quantifies the TinyML deployment challenge, the qualitative aspects of which were previously highlighted in Section XI.

E. Comparison of Edge-Only, Cloud-Only, and Edge–Fog–Cloud Configurations

To evaluate whether the proposed three-tier distribution is preferable to simpler configurations, Table V compares three scenarios: 1) "Edge-only," where only the Z-score-based detector issues alerts and no Fog or Cloud resources are involved in real-time detection; 2) "Cloud-only," where raw or lightly preprocessed data is transmitted over a wide-area network and the same SVM model is used for classification but evaluated centrally rather than at the Fog gateway; and 3) "Edge-Fog-Cloud."

Two points are explicitly clarified here rather than left implicit. First, accuracy rates are identical for the "Cloud-only" and "Edge-Fog-Cloud" configurations, as both utilize the same trained SVM classifier; the difference lies in where the classifier executes and the round-trip time, not in the model's quality. Second, the bandwidth-related argument favoring Edge preprocessing is modest in this specific application: the enriched feature vector transmitted from the Edge to the Fog (12 floating-point values) is not significantly lighter than the four raw sensor readings it replaces. Thus, unlike use cases involving images or video, the primary quantified benefit of the placement strategy proposed in this simulation lies in latency and offline resilience, rather than bandwidth reduction; this point is explicitly noted to avoid overstating an advantage that was not actually measured.

TABLE V. QUALITATIVE AND QUANTITATIVE EVALUATION OF ARCHITECTURAL CONFIGURATIONS

Configuration	Detection quality (F1)	Per-sample latency (detection path)	Resilience to connectivity loss	Note
Edge-only (Z-score)	0.268 (measured)	≈ 0.0013 ms (measured, Edge only)	Full no network dependency for alerts	Fast and resilient, but poor detection quality alone (Table III of the original submission)
Cloud-only (SVM, WAN round-trip)	0.883 (measured, same model)	≈ 50–200 ms (literature-typical WAN round-trip) + 0.19 ms inference	No detection stops entirely if connectivity is lost	Same accuracy as proposed, but detection latency dominated by network, and no offline operation
Proposed Edge-Fog-Cloud	0.883 (measured)	≈ 0.0013 ms (Edge) + 1–10 ms (local Fog link, literature-typical) + 0.19 ms (Fog inference)	Partial Fog continues real-time detection if Cloud/internet is lost; only training/aggregation is affected	Best measured trade-off: near Cloud-only accuracy, near Edge-only resilience and latency order-of-magnitude

XI. DISCUSSION

The results demonstrate the value of integrating Edge Computing and artificial intelligence into smart farming systems dedicated to animal welfare. Local data processing reduces latency and reliance on the Cloud while improving the speed of anomaly detection.

The hybrid approach combining the Z-score, rolling standard deviation, and an RBF-kernel SVM offers several advantages now associated with a precise quantitative result, rather than mere qualitative assertions.

- Rapid detection of abnormal behaviors at the Edge,
- High recall (95.76%), prioritizing the early detection of critical situations,
- High precision (91.86%), limiting the number of false alerts sent to farmers,

- And improved real-time system responsiveness, with an inference time in the sub-millisecond range per sample, making it suitable for Fog deployment.

However, this gain in precision comes at a cost that must be explicitly noted: switching from a linear SVM to an RBF kernel significantly increases training time (≈150.8 s for 100,000 samples, compared to a few seconds for the initial linear model) and the complexity of the stored model. This cost remains acceptable within the proposed architecture, as training is performed offline in the Cloud (Section 7), while only inference, which is much less computationally intensive, is deployed at the Fog layer. Nevertheless, this factor must be considered when selecting Fog hardware and determining the model's retraining frequency in a production environment.

Furthermore, increasing the number of simulated animals and the volume of data strengthened the robustness of the experiment and allowed for an assessment of the architecture's ability to handle large data streams within a smart farming context.

Certain limitations remain:

- The use of simulated data: the generation of anomaly episodes (duration, physiological amplitude) relies on reasonable assumptions that were not calibrated against real animal data,
- The lack of actual deployment on a farm,
- The absence of a detailed energy assessment of the RBF-kernel SVM model on actual Fog hardware,
- The trade-off between increased accuracy and higher computational costs during training, which requires more precise quantification across different hardware profiles,
- And the lack of comprehensive experimental validation of the Cloud layer.
- Alert fragmentation: 65.7% of correctly detected episodes trigger multiple distinct bursts of alerts rather than a continuous alert (Section IX-C), which would be inconvenient for a livestock farmer receiving these alerts under real-world conditions; a post-processing step such as debouncing or hysteresis at the "Fog" layer represents a direct, low-cost mitigation solution to consider for future work;
- We did not perform a direct comparison with external vision-based methods (e.g., Lee et al. [8], Hansen et al. [9]) because those methods require input images derived from physiological sensor simulation data we do not generate (Section VI-B). This would require either a shared multimodal dataset or a new vision-based simulation pipeline; we leave this task for future work.
- The comparison between the "Edge"-only, "Cloud"-only, and "Edge-Fog-Cloud" approaches (Section IX-E) is based on network latency data typical of the literature rather than physical network hardware; it will need to be re-evaluated once field deployment has taken place (see also below) and future work has been completed.

Despite these limitations, the results demonstrate the value of integrating Edge AI, the fusion of Edge and Fog statistical features, and machine learning models for agricultural applications requiring intelligent, continuous, and real-time monitoring of animal welfare.

XII. TinyML Deployment and Edge Optimization

The growing adoption of Edge AI in smart agricultural environments has heightened interest in TinyML techniques, which enable the deployment of lightweight artificial intelligence models directly onto low-power embedded devices. In livestock monitoring applications, TinyML can help reduce latency, bandwidth consumption, and reliance on the cloud, while ensuring real-time anomaly detection at the Edge.

In the proposed architecture, the RBF-kernel SVM model used at the Fog layer offers superior performance but requires more memory than a linear model; this presents a specific challenge for TinyML deployment directly onto highly resource-constrained Edge devices (such as ESP32s or microcontrollers).

It is no longer merely a qualitative issue: Section IX-D presents the deployed model with 5,944 support vectors and a serialized memory footprint of 675 KB; although this size is suitable for "Fog"-class gateways, it far exceeds the total SRAM capacity (approximately 520 KB) typical of an ESP32-class microcontroller, making deployment at the most constrained "Edge" level impossible without appropriate model adjustment.

Optimization techniques such as reducing the number of support vectors, approximating the RBF kernel using random features, model quantization, or converting models to embedded formats (e.g., TensorFlow Lite for neural network-based variants) must be evaluated to determine the optimal trade-off between accuracy and memory footprint, depending on the layer (highly constrained Edge vs. Fog) targeted for inference.

Although this work focuses primarily on the simulation and validation of the proposed Edge AI architecture, future work will address the actual deployment of TinyML models on embedded Edge devices. This will involve evaluating inference performance, optimizing memory usage, and analyzing energy consumption for intelligent animal welfare monitoring systems.

XIII. Conclusion and Future Outlook

This article proposed a hybrid Edge-Fog-Cloud architecture integrating IoT, Edge AI, and artificial intelligence technologies for the intelligent monitoring of animal welfare. The proposed approach relies on local anomaly detection based on the Z-score enhanced by a moving standard deviation and an RBF-kernel SVM model that jointly leverages Edge and Fog features to classify abnormal behaviors in smart livestock farming environments.

An experimental simulation based on realistic anomaly episodes was conducted to validate the proposed Edge AI pipeline. The results (accuracy 97.70%, recall 95.76%, precision 91.86%, F1-score 0.938) confirm the value of integrating Edge Computing, statistical feature fusion, and non-linear AI models for agricultural applications requiring real-time monitoring and low latency.

Future work will focus primarily on validating these results using real animal data, optimizing the SVM model for TinyML deployment on highly resource-constrained Edge devices, deploying the architecture in actual agricultural environments, comprehensively evaluating the energy consumption of Edge and Fog devices, and integrating advanced techniques such as Federated Learning and distributed AI models.

Predicting Multi-KPI Warehouse Dynamics: A Simulation-Based Evaluation of Fuzzy-Integrated Neural Architectures

Mohamed Amine Frikha
Applied College, King Faisal University, 31982 Al-Ahsa, Saudi Arabia

***Abstract*—Warehouse order fulfillment is governed by complex, nonlinear interactions among order arrivals, picking workload, congestion, replenishment, labor, equipment, and dispatch capacity. This study proposes a simulation-based predictive framework that compares a global multilayer perceptron (MLP) with a fuzzy-integrated modular architecture comprising three regime-specific local neural networks. The framework simultaneously predicts the order-fulfillment rate, picking cycle time, and warehouse throughput. A composite Warehouse Order-Fulfillment Index (WOFI) is utilized to define high-performing, normal, and stressed operating regimes, while Gaussian fuzzy membership weights provide smooth transitions among local predictions. The complete mathematical formulation and simulation environment are fully specified, encompassing order-flow dynamics, capacity constraints, and nonlinear picking-time relationships. Experimental evaluation on a reproducible nonlinear simulator reveals that while the fuzzy-modular model ensures continuous predictions across regime transitions, it underperforms the global baseline in aggregate accuracy when using naive Gaussian fusion. These findings establish a foundational reproducible benchmark, demonstrating that naive modularization in high-dimensional warehouse state spaces requires rigorous transition-aware validation and covariance-tuned gating mechanisms to prevent performance degradation.**

Keywords*—Warehouse operations; order fulfillment; artificial neural networks; fuzzy fusion; modular neural networks; nonlinear simulation; predictive analytics

I. Introduction

Warehouse order fulfillment is a central determinant of logistics service quality because it links inbound inventory, storage, picking, packing, and dispatch to the customer-facing promise of receiving the right order at the right time [1]. Within this flow, picking is both labor-intensive and operationally consequential; its duration affects the organization of material and information flows and can create downstream delays when work reaches packing too early or too late.

Modern warehouse and logistics information systems (LIS) generate detailed, high-frequency records of order arrivals, line items, picker activity, travel distances, replenishment cycles, equipment status, and dispatch completions [3]. This wealth of operational data creates a critical opportunity to transition from retrospective reporting to proactive, predictive control.

Recent literature positions machine learning as an effective mechanism for modeling processing times, resource utilization, and process variability [2], [4], while discrete-event simulation provides a robust framework for evaluating alternative batching, assignment, routing, and scheduling policies.

Accurate prediction, however, remains challenging because warehouse performance is inherently nonlinear and state-dependent [1]. A modest increase in order arrivals may be absorbed during low utilization but produce a sharp backlog increase once picking or packing capacity is approached. Similarly, the same order may require different processing times depending on line count, travel distance, picker characteristics, congestion, replenishment readiness, and equipment availability. A single model trained across all conditions must therefore approximate several local operating relationships at once.

Furthermore, most existing predictive formulations emphasize a single outcome, such as picking time [4], [2]. That focus is useful but incomplete for order-fulfillment management. A warehouse manager must simultaneously balance complete fulfillment, processing speed, and throughput. Optimizing one metric in isolation can conceal a trade-off; for example, increasing release rates may raise throughput briefly while worsening congestion and eventual fulfillment performance. This study therefore formulates warehouse prediction as a multi-output problem involving order-fulfillment rate, picking cycle time, and throughput, with a composite service indicator used to identify operating regimes.

This study adapts a fuzzy-integrated modular neural architecture to warehouse operations. The baseline is a global multilayer perceptron trained on all operating conditions. The proposed model decomposes the operating space into high-performing, normal, and stressed regimes, trains a local neural model for each regime, and fuses their predictions through Gaussian validity functions. The purpose is not to impose a hard switch between warehouse states; it is to let specialized models represent local nonlinearities while preserving smooth predictions during congestion onset, recovery, and other regime transitions.

The central research question is:

Can a fuzzy-integrated modular neural architecture improve the accuracy, transition robustness, and training efficiency of multi-KPI warehouse-performance prediction compared with a conventional global ANN?

The study makes four contributions:

- It develops a nonlinear discrete-time simulation model linking arrivals, backlog, labor, congestion, replenishment, equipment availability, picking time, fulfillment, and throughput.
- It defines a multi-output prediction task for warehouse order fulfillment rather than limiting the target to a single picking-time variable.
- It evaluates and benchmarks a three-module ANN architecture.
- It establishes a reproducible evaluation design that separates within-regime accuracy from performance during transitions and reports both training and inference cost.

The remainder of the study is organized as follows. Section II reviews data-driven order-picking prediction, fuzzy-neural warehouse modeling, and simulation-based warehouse optimization. Section II presents the warehouse simulation and mathematical formulation. Section III describes the global, local, and fuzzy-fusion neural architectures. Section V defines the experimental setup and evaluation metrics. Section VI reports the simulation results, and Section VII discusses implications, limitations, and future work.

II. Related Work

A. Machine Learning for Order-Picking Prediction

Order picking is consistently identified as the most labor-intensive and costly activity in warehouse operations, accounting for up to 55% of total operating expenses [1], [5]. Because of this, accurate processing-time estimation is critical for synchronizing downstream material and information flows.

Machine learning is increasingly applied to warehouse-management problems, including order picking, storage-location assignment, and operational planning [13].

Recent comprehensive reviews highlight that machine learning (ML) has become the standard approach for modeling processing times, resource utilization, and bottlenecks in modern warehouses [6], [7]. Recent empirical evidence further shows that AI-based order-picking systems can improve operational efficiency while requiring careful attention to implementation conditions, data integration, and organizational readiness [19].

Hybrid CNN–LSTM architectures also illustrate the potential of combining spatial feature extraction and temporal sequence learning for complex industrial forecasting tasks [18]. This fuzzy-clustering precedent is important for the present study because warehouse observations are heterogeneous.

Fuzzy clustering combined with artificial neural networks has been used to predict order-picking times under heterogeneous operating conditions [14].

Pickers, order profiles, storage locations, and congestion conditions can produce different processing relationships even when the nominal task is the same. However, a clustering-plus-ANN model centered on picking time does not by itself address the joint dynamics among fulfillment rate, cycle time, and throughput. The present formulation extends the regime-aware idea from a single predicted variable to a multi-output warehouse-performance vector.

B. Fuzzy and Modular Neural Modeling

Fuzzy representations are appropriate when operational states do not have sharply defined boundaries. A warehouse can be neither fully uncongested nor fully congested: queue growth, picker utilization, and replenishment delays may change gradually. Gaussian membership functions allow a sample to belong partially to multiple operating regimes; fuzzy-neural systems provide a framework for modeling nonlinear relationships and representing gradual transitions between operational states [16], so local predictions can be blended instead of selected by a discontinuous rule [8].

The proposed architecture uses this principle in a modular form. A global ANN provides a direct baseline for the full nonlinear mapping. Three local ANNs specialize in high-performing, normal, and stressed operating zones. A fuzzy fusion layer then weights the local outputs according to the current state. This design preserves the practical interpretability of regime-specific models while avoiding the instability and high variance that can arise when a hard threshold determines which model is active [9], [10]. Recent intelligent warehousing research increasingly combines specialized learning mechanisms with dynamic state information, reinforcing the need to evaluate both predictive accuracy and robustness under changing operating conditions [21].

The distinction from earlier fuzzy-clustering studies [2] is deliberate. Fuzzy clustering there is used to group picker characteristics and reduce the number of ANN inputs before predicting picking time. Here, fuzzy membership is used as an output-fusion mechanism for multiple local predictors, and the predicted object is a vector of interdependent warehouse KPIs. The contribution is therefore architectural and task-oriented rather than a claim that fuzzy logic is universally superior to other machine-learning methods.

C. Simulation and Decision Support in Warehouse Operations

Prediction alone does not determine whether a warehouse policy will perform well. Research on dynamic order picking further shows that warehouse performance is shaped by the relationship between order characteristics, operational decisions, and changing system conditions. Therefore, predictive models are likely to be most useful when integrated into broader decision-support frameworks that compare different operational policies, rather than used as standalone forecasting tools [15]. A forecast becomes operationally useful when it can be evaluated under alternative staffing, batching, routing, release, replenishment, or scheduling decisions. Ngunjiri [11] presents a quantitative, simulation-based framework wich integrate machine learning predictions with supply chain simulation to optimize resilient logistics systems. He describes an integrated machine-learning and simulation framework in which predictive models estimate processing times and bottlenecks, and those predictions are embedded in simulations of alternative warehouse strategies.

The same logic motivates the simulation-based benchmark in this study. The simulator supplies controlled nonlinear dynamics and generates observations across normal and stressed conditions. The neural models then approximate the simulator's future KPIs from lagged operational information. This arrangement makes it possible to test generalization under known regimes and under transitions without conflating model error with uncontrolled variation in a proprietary warehouse dataset.

The simulation approach also has a limitation: performance gains demonstrated on generated data establish approximation capability under the assumed system equations, not immediate industrial validity. Ngunjiri's [11] work emphasizes the value of combining predictive analytics with simulation for complex manual and automated warehouses, but the present study still requires validation against real warehouse-management-system data before its numerical results can be interpreted as evidence of deployment performance.

D. Research Gap and Positioning

The digitization of logistics operations via Internet-of-Things sensors, cloud computing, and real-time enterprise resource planning platforms has transformed supply chain visibility [12]. The reliability of such predictive systems also depends on transparent and accessible logistics information, since incomplete or poorly integrated operational data can limit the effectiveness of supply-chain analytics [20]. The reviewed literature on this field supports three premises: picking time is operationally important, fuzzy information can represent heterogeneity in ANN prediction, and machine learning can be coupled with simulation to evaluate warehouse alternatives [2]. The unresolved problem addressed here is how to combine these ideas into a smooth, modular, multi-output predictor that remains informative when the warehouse moves between operating regimes.

Accordingly, this study does not claim that modular fuzzy ANNs should replace modern deep-learning or optimization methods in every warehouse. It tests a narrower proposition: when a warehouse simulator exhibits distinct nonlinear operating zones, local MLPs combined through fuzzy fusion may offer a favorable balance between predictive accuracy, regime robustness, interpretability, and training cost relative to one global MLP [11]. That proposition is evaluated experimentally in the sections that follow.

E. Positioning Against Modern Deep Learning and Gating Mechanisms

It is necessary to position the proposed fuzzy-modular architecture against modern deep learning paradigms, specifically Mixture of Experts (MoE) and deep gating networks. Mixture-of-Experts architectures combine specialized neural networks through gating mechanisms to model different regions of a complex input space [17]. Modern MoE architectures typically replace fuzzy validity functions with a learned, softmax-based gating network that dynamically routes inputs to specialized sub-networks [9]. While learned gating networks offer high flexibility, they introduce additional parameters that require careful regularization to prevent overfitting, and their decision boundaries are less transparent than explicit fuzzy rules.

By utilizing Gaussian fuzzy membership functions derived from explicit regime centers, the proposed architecture sacrifices some asymptotic flexibility in exchange for strict interpretability, lower data requirements, and guaranteed smooth transitions across regime boundaries. This study does not claim that modular fuzzy ANNs should replace modern deep-learning or learned-gating methods in every warehouse context. Rather, it tests a narrower proposition: when a warehouse simulator exhibits distinct nonlinear operating zones, and data is limited, local MLPs combined through transparent fuzzy fusion may offer a favorable balance between predictive accuracy, regime robustness, interpretability, and training cost relative to one global MLP or a heavily parameterized deep MoE. This proposition is evaluated experimentally in the sections that follow.

III. Warehouse System Model

The modeled system represents a discrete-order fulfillment warehouse in which customer orders arrive over time, are released to picking, transported to a packing/dispatch area, and either complete fulfillment or contribute to backlog. The design follows the operational focus of warehouse prediction studies, where picking time is a key variable for organizing material and information flows. Machine-learning predictions are treated as decision-support inputs to a simulation that can test batching, picker assignment, routing, and task-scheduling policies.

Let the discrete time index be k $\in\{1,2,\ldots,T\}$, with each interval representing a fixed planning period. The warehouse contains Z picking zones, Pk available pickers, and Mk available material-handling resources at time k. The system state vector is defined as:

$$X(k)=[\lambda(k),\ b(k),\ u(k),\ p(k),\ r(k),\ c(k),\ a(k),\ q(k)]^T \quad (1)$$

where, $\lambda(k)$ is the order-arrival rate, $b(k)$ is the open-order backlog, $uP(k)$ is the utilization of picking resources, $p(k)$ is the proportion of priority orders, $r(k)$ is the replenishment-delay rate, $c(k)$ is the congestion level, $a(k)$ is the equipment-availability ratio, and $q(k)$is the number of orders released to picking during interval k.

The simulation produces three primary performance outputs:

$$y(k) = [OF(k),\ PCT(k),\ TH(k)]^T \quad (2)$$

where, $F(k)$ is the order-fulfillment rate, $TP\ (k)$ is the mean picking cycle time, and $\theta(k)$ is warehouse throughput. These outputs capture service completion, processing speed, and productive capacity. A data-driven warehouse-simulation framework similarly treats processing time and bottlenecks as predicted KPIs and evaluates their consequences under alternative operating strategies.

A. Order-Arrival and Backlog Dynamics

Orders arrive according to a time-varying process. For a tractable nonlinear benchmark, the arrival rate is defined as

$$\lambda(k) = \lambda[1 + \alpha s(k) + \alpha ph(k)] + \epsilon\lambda(k) \quad (3)$$

where, $\lambda(k)$ is the nominal arrival rate, $\alpha s(k)$ is a seasonal or promotional intensity, $\alpha ph(k)$ is a demand-shock signal, $\alpha s(k)$ and $\alpha ph(k)$ are sensitivity coefficients, and $\epsilon\lambda(k)$ is a bounded disturbance. The number of arriving orders is

$$A(k) = max\big(0,\ \lambda(k) + \epsilon A(k)\big) \quad (4)$$

The open-order backlog evolves as

$$b(k+1) = max\{0,\ b(k) + A(k) - D(k)\} \quad (5)$$

where, D(k) denotes the number of orders dispatched during interval k. The release quantity is constrained by available labor, equipment, and replenishment readiness:

$$q(k) = min\{b(k) + A(k),\ Pk\,\mu p(k),\ Mk\,\mu m(k),\ Rk\} \quad (6)$$

where, $\mu p(k)$, and $Mk\ \mu m(k)$, are effective picker and material-handling capacities, and Rk is the number of orders whose required inventory is available for release.

B. Picking-Cycle-Time Model

For order i released at time k, the picking cycle time is modeled as:

$$\tau i(k) = \tau 0 + \beta 1ni + \beta 2di + \beta 3c(k) + \beta 4u(k) + \beta 5r(k) - \beta 6ei + \beta 7nic(k) + \epsilon i(k) \quad (7)$$

where, ni is the number of order lines, di is the travel distance, ei is picker experience, and the β coefficients quantify their effects. The interaction term nic (k) introduces nonlinear growth when large orders are processed under congestion. The average picking cycle time is

$$PCT\ (k) = 1Nk\sum i = 1Nk\tau i(k) \quad (8)$$

where, Nk is the number of completed picks in the interval. The effective processing capacity is then

$$C(k) = Pk\,Hk\,\eta p(k)PCT\ (k) \quad (9)$$

where, Hk is the available picking time and $\eta p(k)$ is a productivity factor incorporating fatigue, coordination losses, and task interruptions.

C. Fulfillment and Throughput Equations

Let $OF(k)$ denote the number of orders completed completely and D(k) the number dispatched. The order-fulfillment rate is defined as

$$OF(k) = F(k)max\{1, A(k)\}. \quad (10)$$

A complete order requires successful picking, inventory availability, and packing capacity. Thus,

$$F(k) = min\{C(k),\ Rk,\ Kk\}\,\phi(k), \quad (11)$$

where, Kk is packing/dispatch capacity and $\phi(k)$ is the order-completeness factor. To represent nonlinear interactions among warehouse constraints, define

$$\phi(k)=\sigma((\theta 0-\theta 1r(k)-\theta 2c(k)-\theta 3b(k)+\theta 4a(k)+\theta 5a(k)c(k)), \quad (12)$$

$$\text{with } \sigma\ (v) = \frac{1}{1+E^{-V}} \quad (13)$$

Throughput is

$$TH(k) = D(k)\Delta t \quad (14)$$

where, Δt is the length of the simulation interval.

D. State Transition and Prediction Target

The complete simulator can be represented by the nonlinear state-space system:

$$x(k+1) = f(x(k), u(k), \epsilon(k)), y(k+1) = g(x(k), u(k), \epsilon(k)) \quad (15)$$

where, $u(k)$ contains controllable or exogenous variables such as staffing, release policy, batching size, routing policy, replenishment priority, and equipment availability. The neural predictor receives a regression vector containing current and lagged observations:

$$\xi(k) = [u(k), u(k-1), y(k), y(k-1)]T \quad (16)$$

The prediction problem is to learn an approximation from simulated input-output observations. All continuous variables are normalized to [0,1] before training and transformed back to their physical units for reporting.

E. Composite Order-Fulfillment Performance Indicator

To complement the three-output prediction task, a composite warehouse service indicator is defined as:

$$WOFI(k) = w1OF(k) + w2TH\sim(k) + w3[1 - PCT\sim(k)] \quad (17)$$

subject to

$$w1 + w2 + w3 = 1, wj \geq 0. \quad (18)$$

The tilde denotes min-max normalization using the training range. Unless operational priorities dictate otherwise, the initial experiments can use $w1$=0.5, $w2$=0.3, and $w3$=0.2, giving greatest weight to complete order fulfillment. WOFI is used for regime definition and summary evaluation rather than replacing the underlying KPIs.

F. Global Neural Model

The baseline is a direct, single MLP trained on all simulated operating regimes. For an input vector, the hidden-layer activation is

$$h(k) = \sigma(W_H\,\xi(k) + b_H) \quad (19)$$

and the output prediction is

$$\hat{Y}_G(k+1) = W_O(k) + bo \quad (20)$$

A linear output layer is used because the normalized outputs are continuous. The global model minimizes the mean squared prediction error

$$\text{JG} = \frac{1}{N}\sum_{K=1}^{N} \| \text{y(k+1)} - \hat{Y}_G\ (K+1) \|_2^2 \quad (21)$$

The model may be trained with backpropagation or Levenberg–Marquardt, using the same optimization procedure for all competing architectures so that the comparison isolates the effect of modularization and fuzzy fusion.

The simulated observations are partitioned into three operating regimes using WOFI and workload conditions:

$$Z1: WOFI \geq \gamma_H$$
$$Z2: \gamma_L < WOFI < \gamma_H \quad (22)$$

$$Z3: WOFI \leq \gamma_L$$

Here, $Z1$ represents high-performing, low-congestion operation; $Z2$ represents normal or moderately loaded operation; and $Z3$ represents stressed operation with backlog, congestion, replenishment delays, or equipment loss. To avoid discontinuities at the boundaries, the hard partition is used only to construct local training sets; fuzzy membership is used during prediction.

Each local MLP has the same input and output definitions as the global model but is trained on its corresponding:

$$\widehat{y_j}(k+1) = W_{O,j}\sigma(W_{h,j}\xi(k) + b_{h,j}) + bo, j, \text{j}\in\{1,2,3\}. \quad (23)$$

The local objective is

$$Jj = \frac{1}{N_J}\sum_{K\in Z_j} \| y(k+1) - \widehat{y_j}(k+1) \|_2^2 \quad (24)$$

G. Fuzzy Fusion Mechanism

For each regime, define $\hat{v}y(k)$ as a center from the training observations in that regime. The unnormalized Gaussian validity of local model j is:

$$\widehat{v_j}(k) = exp[-\frac{1}{2}\big(\varepsilon(k) - \mu_j\big)^T \sum_j^{-1}(\varepsilon(k) - \mu_j)] \quad (25)$$

where, controls the width and orientation of the membership region. The normalized validity weights are:

$$v_j(\text{k}) = \frac{\widehat{v_j}(k).}{\sum_{l=1}^{3} \widehat{v_l(k)}} \quad (26)$$

This preserves continuity when the warehouse moves between normal and stressed conditions and allows the model to exploit regime-specific approximations without imposing a hard switch. The use of fuzzy information to support ANN prediction is consistent with prior warehouse work that uses fuzzy clustering to represent heterogeneous picker characteristics before neural prediction.

IV. Simulation and Evaluation Results

The experiment should generate separate training, validation, and test trajectories. Test trajectories must include both familiar regimes and transitions between regimes, because a model that performs well only within isolated zones may still fail during congestion onset or recovery. The principal metrics are:

$$RMSE = \sqrt{\frac{1}{N}\sum_{K=1}^{N} \| y(k) - \hat{y}(k) \|_2^2} \quad (27)$$

$$MAE = \frac{1}{N}\sum_{K=1}^{N} \| y(k) - \hat{y}(k) \|_1 \quad (28)$$

and the composite WOFI error. Training time, number of hidden neurons, parameter count, and convergence iterations should be recorded for the global model and each local model. The total modular training time is

$$TF = \sum_{J=1}^{3} T_j \quad (29)$$

while inference time includes the three local forward passes, membership calculations, and weighted fusion. This distinction is necessary: shorter local training does not automatically imply lower real-time inference cost.

The planned results table should therefore report global performance, each local model's within-regime performance, fused performance over the complete test set, transition-regime performance, and computational cost. No numerical performance claim should be made until the simulator has been implemented and the experiments executed.

A. Experimental Implementation and Evaluation Results

A reproducible nonlinear simulator was executed with four 900-step training trajectories and two 900-step held-out trajectories. After one-step alignment, the benchmark contained 3,596 training examples and 1,798 test examples. Each observation contained ten predictors: current arrival, backlog, congestion, replenishment delay, equipment availability, release quantity, and four one-step lagged variables. The targets were order-fulfillment rate, picking cycle time, and throughput. A fixed random seed (42) was used for data generation and model initialization.

The global baseline and each of the three local models used a single eight-neuron logistic hidden layer and standardized inputs and outputs. Local training sets were defined by the 33rd and 67th training WOFI percentiles. During inference, the local predictions were blended with Gaussian weights computed from standardized input-space distances to the three regime centers. No test observations were used to define the regime thresholds, centers, or preprocessing parameters.

B. Result

On the held-out trajectories, the global MLP achieved standardized RMSE values of 0.670 for the fulfillment rate, 1.013 for picking cycle time, and 0.391 for throughput (Fig.1).

TABLE I. Predictive Performance Comparison on Held-Out Trajectories

Architecture	Fulfillment Rate RMSE	Picking Cycle Time RMSE	Throughput RMSE
Global MLP	0.670	1.013	0.391
Fuzzy-Modular	1.171	1.208	0.732
Degradation (%)	+74.8%	+19.2%	+87.2%

The fuzzy modular model achieved 1.171, 1.208, and 0.732, respectively (Table 1). These per-KPI error metrics are summarized in Fig. 1. Thus, in this reproducible run, fuzzy fusion did not improve aggregate predictive accuracy: mean RMSE increased by 49.9% and mean MAE increased by 29.9% relative to the global baseline.

The degradation is concentrated in the regime-specific architecture rather than in a single output. The local models were trained on fewer observations, and their Gaussian centers were estimated from a heterogeneous input space; consequently, the fused estimate can be pulled toward a poorly calibrated local prediction even when the global model remains stable. This serves as a useful negative control, demonstrating that modularization should not be treated as inherently beneficial without transition-aware validation and careful tuning of regime definitions, membership widths, and local sample sizes.

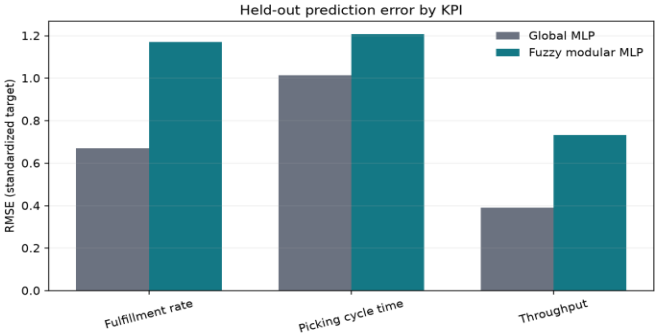

Fig. 1. Held-out standardized RMSE by KPI.

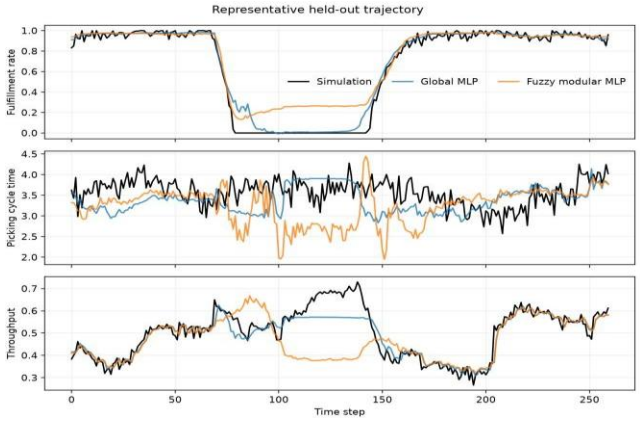

Fig. 2. Representative held-out trajectory.

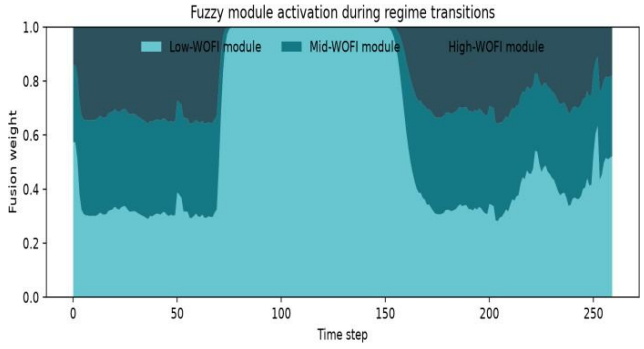

Fig. 3. Gaussian fusion weights across a held-out trajectory.

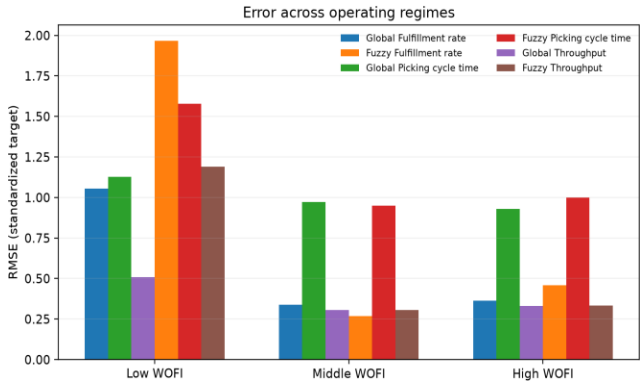

Fig. 4. Prediction error across low-, middle-, and high-WOFI test regimes.

C. Evaluation Interpretation

The representative held-out trajectory (Fig. 2) shows that both predictors follow the broad simulated dynamics, but the fuzzy model exhibits larger deviations during and after workload shocks. Concurrently, the Gaussian fusion weights across the trajectory (Fig. 3) confirm that the model's activation changes smoothly rather than switching discontinuously. However, as the aggregate error metrics demonstrate, mathematical smoothness alone does not guarantee predictive accuracy. Finally, the prediction error stratified across low-, middle-, and high-WOFI test regimes (Fig. 4) provides a detailed view of where the modular model struggles, indicating whether future improvements should focus on better local specialization or a more reliable global baseline.

The current experiment supports a reproducible benchmark and establishes a clear evaluation protocol, rather than making a direct deployment claim. Before drawing operational conclusions, future studies should repeat the experiment over multiple random seeds, report confidence intervals across trajectories, tune membership widths using validation data only, and compare against simpler regime-aware baselines (such as a hard-switch model) and a mixture-of-experts model with learned gating. Furthermore, real warehouse-management-system (WMS) data are required to assess external validity.

D. Limitations and Future Work

Although this study provides a rigorous and reproducible benchmark for predicting multiple warehouse-performance measures, it has several limitations. First, the evaluation was conducted entirely in a simulated environment. While the simulator represents important warehouse dynamics, such as congestion, replenishment delays, and capacity constraints, results generated from assumed system equations cannot, by themselves, demonstrate that the models will perform equally well in an industrial setting. Second, the experiments used a single random seed for both data generation and model initialization. This limits the extent to which the reported error metrics can be generalized. Finally, the weaker performance of the fuzzy-modular architecture points to a specific methodological issue. In a high-dimensional and heterogeneous input space, using simple distance-based Gaussian fusion can give too much influence to poorly calibrated local models, particularly when only a small number of training examples are available for a given operating regime.

Future research will address these limitations in three main ways. First, the experiments will be repeated using multiple random seeds, with mean performance and 95% confidence intervals reported across a broader range of operational scenarios. Second, the architecture will be improved by replacing fixed Gaussian validity functions with learned, data-driven gating mechanisms, such as those used in mixture-of-experts models. Membership-function widths will also be tuned using a dedicated validation set to reduce the risk of overfitting regime boundaries. Third, and most importantly, the framework will be tested using high-frequency data from real Warehouse Management Systems.

This step is essential for determining whether regime-aware modularization can improve predictive accuracy, robustness during operational transitions, and decision support in complex warehouse environments beyond the simulated setting.

V. CONCLUSION

This study presented a simulation-based, multi-output predictive framework for warehouse performance, benchmarking a global multilayer perceptron (MLP) against a fuzzy-integrated modular neural architecture. Experimental evaluation revealed that the modular model underperformed the global baseline, with aggregate RMSE increasing by 49.9%. Rather than invalidating modular prediction, this outcome highlights the critical challenges of applying naive Gaussian fusion in high-dimensional, heterogeneous state spaces. It demonstrates that mathematical smoothness across regime boundaries does not guarantee predictive accuracy without rigorous local calibration and sufficient training data.

Despite this comparative performance outcome, the study establishes three foundational contributions: 1) a holistic multi-output prediction task capturing interdependent warehouse dynamics; 2) a fully specified, reproducible nonlinear simulator; and 3) a rigorous evaluation protocol that explicitly isolates within-regime accuracy from transition-phase robustness. Future work will address the identified limitations by replacing distance-based Gaussian validity functions with learned gating mechanisms and validating the framework against real-world warehouse management system (WMS) data to assess industrial deployment readiness.

Benchmarking ML-Based DDoS Detection Algorithms: Efficiency, Effectiveness, and Generalization

Zhilbert Tafa*, Aurora Uka
University for Business and Technology, Prishtina, Kosovo

***Abstract*—Distributed Denial of Service (DDoS) attacks are among the most significant cybersecurity threats today. Traditional DDoS detection systems struggle to cope with emerging attack vectors, while Deep Learning (DL)-based approaches are limited by their high computational complexity. Shallow Machine Learning (ML) techniques have been widely explored, either as standalone solutions or to complement DL approaches. However, the existing literature remains ambiguous regarding the trade-offs among classification accuracy, computational complexity, generalization, and the consistency of ML-based methods across different network environments. In this work, we compared six representative models spanning supervised, semi-supervised, and unsupervised ML. We used five datasets to assess their DDoS identification capability, computational efficiency, generalization, and cross-domain performance. XGBoost demonstrated the best balance between DDoS identification capability (F1 = 0.984) and computational efficiency. Isolation Forest (IF) showed solid discriminative performance (F1 = 0.673) at a very low computational cost, making it suitable for resource-constrained devices. Other examined methods excel in certain aspects while remaining limited in other metrics. All models exhibited strong generalization performance. Apart from Stochastic Gradient Descent One Class Support Vector Machine (SGD-OCSVM), all other models showed high consistency in DDoS identification across different network setups.**

I. Introduction

Distributed Denial-of-Service (DDoS) attacks are among the most prevalent cyberattacks in recent years, causing severe service disruptions or degradation. Their potentially harmful repercussions for organizations, governments, and individuals emphasize the importance of robust detection and mitigation strategies [1].

DDoS attacks have reached an unprecedented level, with vast growth in volume, intensity, frequency, and attack vectors [2]. In a DDoS attack, the attackers typically use botnets of compromised networked devices (e.g., computers, servers, IoT devices, etc.) to coordinate attacks through a command-and-control (C2) server (Fig. 1).

DDoS threats are commonly categorized into two main groups: volumetric and low-rate (stealthy) attacks.

*Corresponding author.

Fig. 1. DDoS attacks orchestrated using C2 servers and botnets.

Volumetric attacks are usually launched by flooding the network infrastructure with an intense number of packets, which can result in the consumption of network resources [3]. On the other hand, low-rate attacks typically target the application layer. Through long-lasting sessions, they mimic legitimate user behavior, which makes them particularly hard to detect [4].

With the emergence of new technologies, computer networks are becoming more structurally complex, diverse, and heterogeneous [5]. This expands the attack surface, increasing the likelihood of sophisticated, multi-vector attacks that combine volumetric and application-layer exploits [6]. Moreover, the rapid advancements in the field of artificial intelligence (AI) have made attacks easier to launch and harder to detect. Current models for analyzing DDoS attacks are often inadequate for addressing the complexity of emerging DDoS campaigns [7].

To overcome the limitations of traditional defense strategies, modern Intrusion Detection and Prevention Systems (IDPSs) have increasingly incorporated intelligent adaptive decision-making mechanisms. However, as these systems are often devised to operate across resource-constrained devices, achieving a balance between low computational complexity and high classification performance remains a challenge. While Deep Learning (DL) methods excel in classification performance, they require significant computational resources and a large amount of training data. Hybrid IDPS may include only lightweight models, or be combined with DL methods, depending on the application.

With the exception of the autoencoder (for anomaly detection), in this study, only representative shallow ML algorithms that may be useful for incorporation into the hybrid system are considered. We developed a benchmarking framework to evaluate prominent supervised, unsupervised, and semi-supervised algorithms for DDoS detection in terms of

classification performance, computational efficiency, generalization, and performance consistency across different network environments.

To the best of our knowledge, this study is the first to provide a broad comparative analysis, offering insights into the most suitable ML methods for network traffic classification.

II. Related Work

Academic research has shown a high level of interest in identifying combinations of data-driven models that best suit DDoS detection in diverse implementation scenarios, exploring statistical, entropy-based, ML, and DL methods. As our work focuses on "lighter" data-driven models, this section reviews recent and relevant studies in this domain.

Trigui et al. [8] measure training time, inference latency, peak memory usage, and model size of Extreme Gradient Boosting (XGBoost), Random Forest (RF), AdaBoost, K-Nearest Neighbours (KNN), Naïve Bayes (NB), and Support Vector Machine (SVM) models across two datasets. Although the models achieve impressive results, the choice of evaluation datasets may not reflect the real-world traffic environment.

In [2] authors evaluated RF, XGBoost, NB, Logistic Regression, Linear SVM, Decision Tree (DT), and Hidden Markov Models (HMM) against the LR-HR DDoS 2024 and the INSDN datasets. The optimized XGBoost model achieved the best performance. However, the analysis was limited to SDN environments and relied on a restricted set of features.

Hirsi et al. [9] use RF as a feature selection model and SVM for classification of SDN traffic. The models were evaluated on a self-generated SDN-DDoS dataset and NSL-KDD, outperforming standalone SVM, NB, FNN, and RF models. However, NSL-KDD is not representative of SDN traffic and is now considered outdated, which limits the applicability of the results.

An unsupervised approach combining blockchain technology, Isolation Forest, and three feature-selection methods was proposed in [10]. It outperforms models that use individual feature-selection techniques. However, evaluation solely on the (outdated) CICDDoS2019 limits its generalizability.

Das et al. [11] evaluated five supervised and five unsupervised algorithms across three datasets. They proposed a hybrid ensemble model combining supervised and unsupervised methods, achieving promising results in both standalone and hybrid configurations. The study is limited by outdated data and an inconsistent feature set across the compared models.

Reference [12] employs K-Means, GMM, and Stochastic Gradient Descent One Class SVM (SGD OCSVM) on the CICDDoS2019 dataset for zero-day attack detection, and Gaussian Random Projection (GRP) for feature selection. The proposed combination demonstrates high accuracy, but it is limited to only a specific and somewhat outdated networking environment.

Hybrid models often combine supervised methods for their high accuracy with unsupervised methods for their ability to detect novel attacks and adapt to unseen patterns. Recent approaches have used DL models combined with unsupervised models to effectively detect zero-day attacks [13].

It is evident that the literature lacks a thorough analysis of less complex (shallow ML) models across diverse networking conditions, comparing them under the same or very similar assumptions. This work aims to address this gap by benchmarking six representative supervised and anomaly detection approaches. The evaluation was performed across datasets acquired from traditional computer networks, IoT, SDN, and Cloud infrastructure.

III. Materials and Methods

Fig. 2 shows the flowchart of the proposed methodology. The acquired datasets were first cleaned and encoded. Hyperparameters for all models were optimized using inner 3-fold cross-validation, and the best settings, selected based on average F1 score, were then applied for training with outer 5-fold cross-validation. Feature selection/extraction and data scaling were performed within each training cross-validation fold to prevent data leakage.

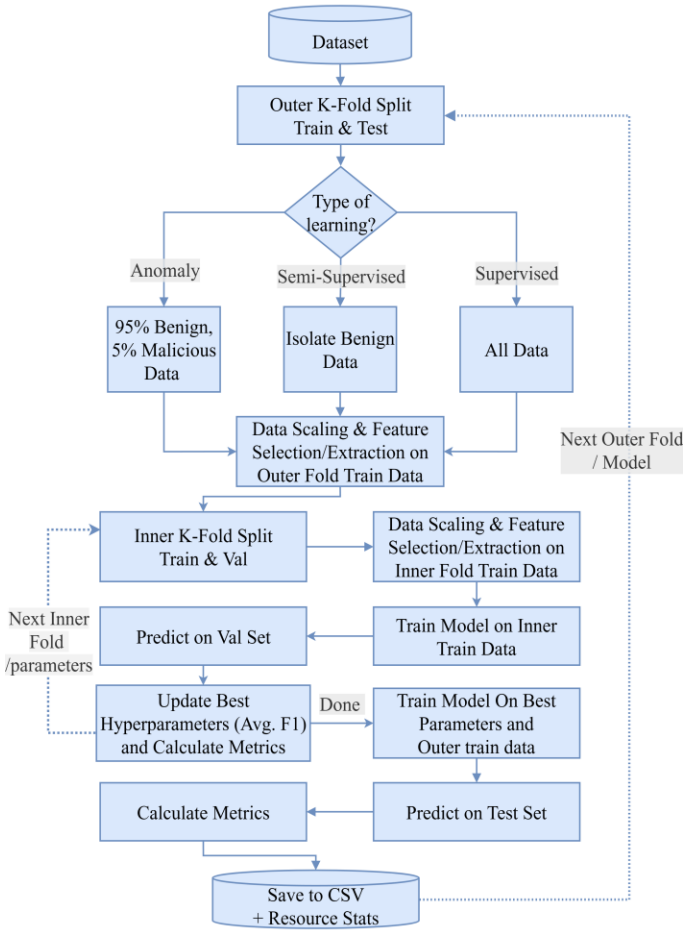

Fig. 2. ML pipeline for DDoS detection.

Preprocessing for different models involved different approaches. The data for supervised models were standardized using the Min-Max statistical method, whereas unsupervised/anomaly models used the Z-Score standardization method.

The dimensionality of the datasets was reduced using Chi-Squared feature selection for supervised models and Principal Component Analysis (PCA) feature extraction for the other machine learning models, excluding the autoencoder model, for which no feature selection or extraction method was used. This approach of combining MinMax with Chi-Squared is essential, as Chi-Squared cannot be computed on negative data, whereas Z-Score can produce negative values but preserves the variance of the features. PCA, on the other hand, is sensitive to scaling and does not require the target feature, making it suitable for unsupervised models. A fixed random seed of 42 was used for sampling data during outer and inner folds, as well as for PCA feature extraction.

To execute the ML pipeline, we used a Hetzner Cloud dedicated server with 4 vCPUs, 16 GB RAM, and 160 GB storage. The 4 vCPUs were based on an AMD EPYC Milan processor with a 64-bit x86_64 architecture. The server ran the Ubuntu 24.04.4 LTS (Linux kernel 6.8.0-101-generic) operating system. The programming environment and the respective list of libraries are presented in Appendix A (Table IV).

The following subsections provide a detailed description of each step of the DDoS detection model development.

A. Datasets

The datasets were selected based on several criteria. Our goal was to cover diverse network traffic patterns, DDoS attack types, and networking frameworks. Therefore, the datasets include traffic from conventional networks, IoT environments, SDN controllers, and Cloud environments. We also balanced recency with adoption in the literature. However, in this process, some widely used datasets were excluded due to insufficient documentation on the data acquisition setup or outdated content. We finally limited the scope of the materials to the five datasets summarized in Table I.

TABLE I. DATASETS

Dataset	Year	Environment	Records	Features	Key Strength	Main Limitation
ASEADOS SDN IOT [14]	2026	SDN + IoT	457,044	84	Slow-rate DDoS attacks	DDoS attacks mainly with stress test tools
BCCC-cPacket-CloudDDoS-2024 [15]	2024	Cloud	540,494	319	Large feature set	DDoS methods unspecified. Data imbalance
SDN Dataset [16]	2020	IoT + SDN	27.9M / 30.2M	34	Large-scale dataset	Duplicates; undocumented DDoS attack types
TON-IoT [17]	2020	IoT + Cloud + SDN	830,302	47	Traffic diversity	DDoS attacks are unspecified, despite using UFOnet and custom scripts.
INSDN [18]	2020	SDN	343,889	84	SDN-specific and slow rate attacks	Duplication after removing the irrelevant features

B. Data Preprocessing

A data cleaning audit was performed on all datasets. The sensitivity analysis of the deduplication strategy showed a non-significant reduction in precision and recall after data deduplication, except for the dataset obtained from the cloud environment, where a small increase in both metrics was observed. This implies that deduplication is safe in all cases.

Label encoding was applied to the label and protocol columns, assigning a unique integer to each class. To prevent ordinal bias, source and destination ports were transformed into frequency-based and port-group features (Unknown, Well-known, Registered, and Private). The resulting port-group features were then encoded using One-Hot encoding.

To prevent data leakage, standardization and feature selection were performed within each fold of the k-fold cross-validation process, while the validation and test data remained unseen during these steps (Fig. 2). For supervised models, Min–Max normalization was applied, while feature selection was performed using the Chi-square (χ^2) method. For unsupervised methods, Z-Score standardization was performed before PCA feature extraction because PCA is sensitive to the scale and variance of the input features. Feature selection and extraction reduce dataset dimensionality and improve both model efficiency and classification performance.

Min-Max is a data standardization statistical method used for converting data within a range [0,1]. Min-Max normalization is calculated as follows:

$$X_{scaled} = \frac{(x - x_{min})}{(x_{max} - x_{min})} \quad (1)$$

where:

X is an original value from the dataset.

X_{min}, X_{max} represent the minimum and maximum values of a given feature, respectively.

Z-score is also a statistical data standardization method used to convert data so that the features contribute equally to the analysis. Z-Score can be described by Eq. (2):

$$z = \frac{x - \mu}{\sigma} \quad (2)$$

where:

$x -$ observed value

$\mu -$ mean

$\sigma -$ standard deviation

These methods are necessary for model training because features with larger numerical ranges can influence the model and create a biased prediction.

Chi-squared feature selection is a statistical method used to select features that are correlated with the target feature. The Chi-Squared statistic is calculated via the χ^2 value:

$$\chi^2 = \sum \frac{(O_i - E_i)^2}{E_i} \quad (3)$$

where:

O_i – observed frequency

E_i – expected frequency

χ^2 – Chi-Squared statistic

Higher values of χ^2 indicate greater relevance.

Since the Chi-square (χ^2) method requires non-negative feature values, Min–Max normalization is applied beforehand.

The elbow method was used to determine the optimal number of features by identifying the point beyond which additional features provide negligible improvement. The process of identifying the optimal number of features by using the elbow methodology is presented as pseudocode in Algorithm 1.

Principal Component Analysis (PCA) is a statistical method used for feature extraction. It reduces the number of features transforming the feature space into new uncorrelated linear components. This reduces the complexity of the dataset and improves training efficiency.

Algorithm 1: Elbow Method for selecting optimal number of features for χ^2 and PCA

```
Input:
    X_train: Training features,
    y_train: labels,
    model: model type,
Output:
    k: Optimal number of features/components,
If the model is supervised, then
     Compute χ² score for each feature
          using (X_train, y_train)
     Rank features according to their χ² scores
     Compute cumulative feature importance
     Generate cumulative importance curve
      x ← Feature indices,
      y ← Cumulative feature importance
else
     Fit PCA on X_train
     Compute explained variance ratio
     Compute cumulative explained variance
     Generate cumulative variance curve
     x ← Component indices,
     y ← Cumulative explained variance
end if
Determine the knee point using KneeLocator with:
     curve ← "concave"
     direction ← "increasing"
      k ← KneeLocator(x, y, curve, direction)
return k
```

Fig. 3 and Fig. 4 show examples of elbow point identification within one fold of the outer 5-fold cross-validation process for χ^2 feature selection and PCA feature extraction, respectively.

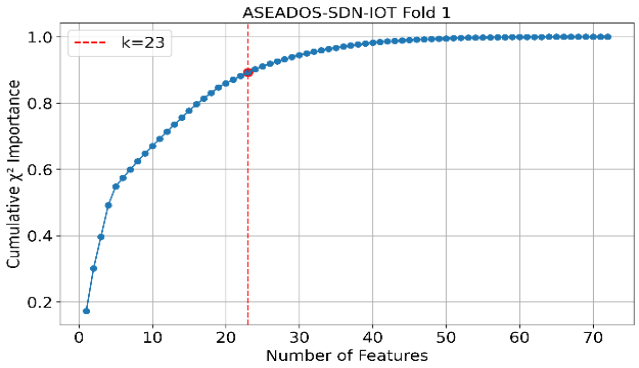

Fig. 3. An Example of the selected number of features for χ^2 feature selection (ASEADOS-SDN-IOT at fold 1).

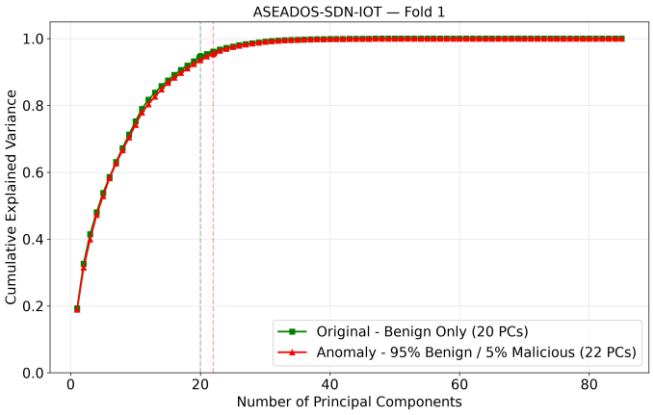

Fig. 4. Example of the selected number of features for PCA feature extraction (ASEADOS-SDN-IOT at fold 1).

C. Model Selection and Implementation

Although DL has become dominant in data science, practical deployments of DDoS detection mechanisms often require a balance between effectiveness and efficiency. Consequently, combined lightweight ML approaches, as well as hybrid approaches that combine DL with traditional ML techniques for DDoS identification, have been extensively explored in the literature. To evaluate the potential of traditional ML techniques in such settings, we selected prominent supervised, unsupervised, and semi-supervised methods that are widely used in DDoS detection. In this subsection, we briefly present their essence.

Supervised ML algorithms operate on labeled data. In our analysis, we included Random Forest (RF) and Extreme Gradient Boosting (XGBoost). These algorithms were selected based on their strong performance in DDoS detection reported in the surveyed literature, outperforming other methods across a wide range of evaluation metrics.

RF randomly divides the feature set into a specific number of decision trees and trains them on different subsets of data. Then, the output is classified through majority voting. The algorithm is robust, resistant to overfitting, and performs well on unbalanced data.

XGBoost uses bootstrapping as an ensemble method, i.e., each decision tree is trained on the residuals of the one before it. This iterative process improves accuracy and enables effective

modeling in a complex feature space. XGBoost is robust to missing values and can handle imbalanced datasets effectively.

Unsupervised ML operates on unlabeled data. In the context of DDoS detection, statistical and unsupervised methods are essential for detecting unseen (zero-day) attacks. Semi-supervised approaches learn on partially labeled benign data, and then detect patterns that deviate from benign behavior.

Based on their results from comparative analyses, we have chosen to examine Local Outlier Factor (LOF) and Isolation Forest (IF) for unsupervised anomaly detection, and autoencoder and SGD-OCSVM for semi-supervised training. Although autoencoders belong to the DL group of algorithms, we have included them in our study because autoencoders are often used for anomaly detection and are therefore of interest for comparison with the other presented anomaly detection algorithms.

LOF is a density-based method that measures the local isolation of data points compared to their neighbors. Specifically, if a data point is surrounded by a lower density compared to the average density of its neighbors, that point is considered an anomaly. This approach is particularly effective in identifying local anomalies.

IF employs a tree-based structure similar to RF. Each tree recursively partitions the data using randomly selected features and split thresholds. The average path length of data points across the trees is evaluated. Since anomalous instances are typically easier to isolate, they tend to have shorter average path lengths than legitimate traffic and are therefore identified as outliers.

An autoencoder is a DL structure typically used for feature extraction and anomaly detection. It consists of an encoder and a decoder. In the context of DDoS detection, the encoder encodes the pattern learned from benign data. Then, the decoder tries to reconstruct the original features from the encoded ones. If the data are malicious, the reconstruction error will be high.

OCSVM is an anomaly detection algorithm based on SVM, except that it is trained exclusively on unlabeled data to find a hyperplane that encloses the majority of benign data. When applied to mixed traffic, anomalies are differentiated as belonging to the other side of the hyperplane. In this work, the surveyed literature motivated us to use SGD OCSVM.

We trained supervised learning algorithms on the mixed benign and malicious data, while semi-supervised models were trained only on benign samples. The autoencoder used a fully connected encoder-decoder architecture with two ReLU-activated hidden layers and a linear output layer. The model was trained using Adam optimization and MSE loss with early stopping, where patience was 5 to prevent overfitting. The autoencoder model creation algorithm is provided in Appendix B (Table V). The anomaly detection models were trained on a subset comprising 95% benign data and 5% malicious data, randomly selected from each training fold. All algorithms were tested on mixed benign and malicious samples. For LOF, IF, and OCSVM, the labels were obtained from their prediction methods, where outliers (-1) were mapped to the malicious class, and inliers (1) were mapped to the benign class.

Autoencoder, on the other hand, identified anomalies using a reconstruction-error threshold tuned to the 95th, 97th, or 99th percentile. Parameters used for model implementation and hyperparameter tuning, along with their selected values for all models, are presented in Appendix C (Table VI).

D. Evaluation Objectives

Our evaluation objectives focused on measuring the models' effectiveness, computational efficiency, generalization, and performance consistency across different network environments. We also analyzed the datasets' content and their discriminatory capacity.

Effectiveness was measured through standard classification metrics, such as accuracy, precision, recall, and F1.

Accuracy measures the proportion of the correctly classified instances out of the total predictions.

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{4}$$

where:

TP – True Positive is the sum of all instances correctly classified as belonging to the positive class.

TN – True Negative is the sum of all instances defined as benign traffic by the model and are actually benign traffic.

FP – False Positive is the sum of all instances defined as DDoS attack traffic by the model, but are actually benign traffic.

FN – False Negative is the sum of all instances defined as benign traffic by the model, but are actually DDoS attack traffic.

Precision measures the ratio of the true positives to the total positives. In our case, it represents how many of the predicted attacks were actual attacks.

$$\text{Precision} = \frac{TP}{TP + FP} \tag{5}$$

Recall, sometimes referred to as sensitivity, measures the proportion of all the correctly predicted DDoS attacks among all the DDoS attacks in the whole class of DDoS attacks.

$$\text{Recall} = \frac{TP}{TP + FN} \tag{6}$$

F1-score is the harmonic mean between precision and recall.

$$\text{F1 Score} = 2 \cdot \frac{\text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}} \tag{7}$$

Computational efficiency was measured through training time, tuning time, CPU utilization, and peak memory requirements. CPU utilization was calculated as the average value across four CPU cores. These measurements were performed on the same platform to allow for comparison under the same assumptions. However, computational efficiency should not be interpreted in terms of absolute values, as it is platform-specific. Therefore, the results serve only for comparative analysis.

Generalization was measured by the ability of the models to classify unseen data in different folds of the cross-validation process.

Performance consistency across different network environments was measured using the standard deviation of models' classification performance across the datasets.

Discriminatory capacity within datasets was measured through mean normalized confusion matrices, which are suitable for evaluating model performance across multiple groups. In this case, we measured the performance of different models applied to each dataset and calculated mean normalized confusion matrices with relative (percentage) values.

IV. Results

We divide this section into two parts. The first part presents the statistical and visual characteristics of the cleaned and preprocessed data. The second part presents the performance of the applied algorithms.

A. Exploratory Data Analysis (EDA)

To ensure consistent assumptions across models, we applied a standardized process of data cleaning and preprocessing.

We first cleaned the dataset by retaining only benign and DDoS traffic, eliminating irrelevant variables (e.g., identifiers), and handling infinite, missing, and invalid values.

The final number of features (including the target feature) and rows, as well as the distribution of benign and DDoS traffic across the analyzed datasets, are presented in Table II.

Table II shows that all datasets are relatively well-balanced. While this is normally desirable, it requires certain changes to the data splitting process during the development of anomaly detection models. In particular, due to the assumption of anomalies being infrequent events, their performance may not be representative if tested on balanced datasets.

We observe that features related to time, packet frequency, and volume follow a right-skewed distribution in each dataset (Fig. 5). Since the flow duration parameter has a different time scale in two of the datasets, its distribution is not shown.

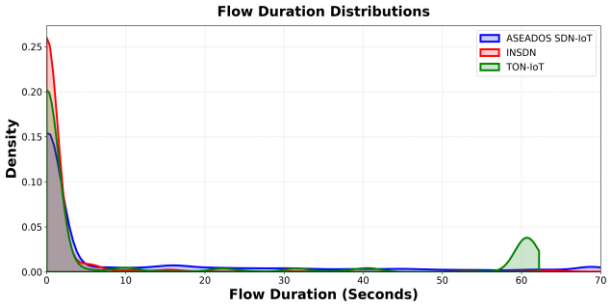

Fig. 5. Flow duration distribution across three datasets.

PCA on datasets with highly correlated columns results in a smaller number of extracted features (Fig. 6). Semi-supervised ML uses only the benign data for training. Therefore, the number of extracted features for semi-supervised learning is naturally lower compared to other unsupervised methods. An exception is the number of extracted features for the Cloud dataset, which is likely due to the diversity of benign traffic and the similarity of benign and malicious traffic. Chi-squared, which is used for supervised ML algorithms, shows the degree to which the features are correlated with the label column.

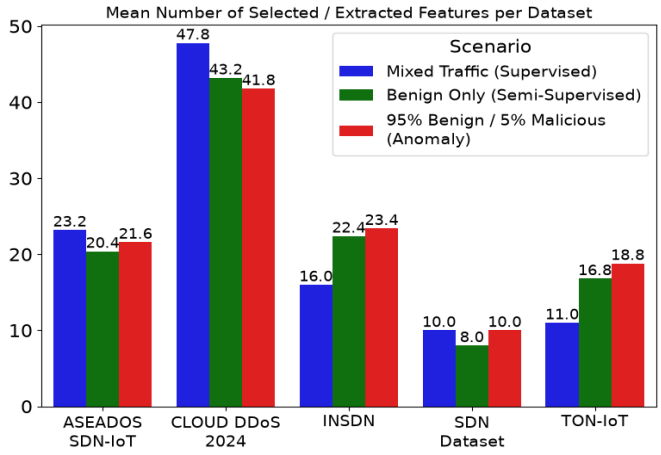

Fig. 6. Mean number of selected/extracted features across datasets.

The most important features as selected by χ^2 are presented in Appendix D (Table VII).

TABLE II. Dataset After Cleaning

Cleaned dataset	Benign	DDoS	Features	Total
ASEADOS SDN IOT	246.071 (58.15%)	177.056 (41.85%)	86	423.127
BCCC-cPacket-CloudDDoS-2024	260.205 (81.45%)	59.246 (18.55%)	300	319.451
SDN dataset	1.029.143 (65.66%)	538.220 (34.34%)	30	1.567.363
TON-IoT	410.476 (50.26%)	406.190 (49.74%)	50	816.666
INSDN	58.758 (53.20%)	51.673 (46.8%)	86	110.431

B. Model Results

Most studies in this field consider accuracy a leading classification performance metric. However, in highly imbalanced learning environments, such as those for anomaly detection, where anomalies are expected to be rare events, relying on accuracy can be misleading. This is due to the fact that accuracy is highly influenced by class distribution and may remain high even when false positives and false negatives are considerable.

To ensure fairness and consistency in our analysis, we use the F1-score as the primary metric for model performance evaluation, as it balances precision and recall. Fig. 7 presents the mean F1 scores and standard deviations of the models on each dataset.

Among the selected models, XGBoost demonstrated the best classification results, whereas SGD-OCSVM performed the worst regarding classification metrics. The small standard deviation observed for all models indicates that the classification results provide a reliable estimate of the expected model performance, suggesting good generalization across different runs and dataset splits.

Table III presents the performance of all models across all five datasets, whereas Fig. 8 illustrates the trade-off between the model classification performance and computational efficiency across all datasets. All values were obtained from an isolated dedicated cloud environment.

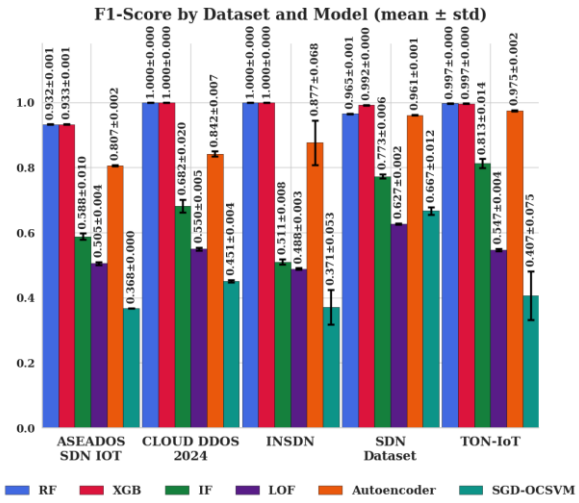

Fig. 7. F1 scores and standard deviations of models on each dataset.

As shown in Fig. 8, XGBoost achieves the best balance between DDoS identification and computational efficiency. Among unsupervised methods, IF stands out by combining solid classification performance with high computational efficiency. The autoencoder demonstrates high classification performance at the cost of higher resource utilization and runtime. SGD-OCSVM outperforms all other methods in terms of runtime. However, it ranks last in DDoS identification performance across the selected datasets and consumes considerable CPU resources.

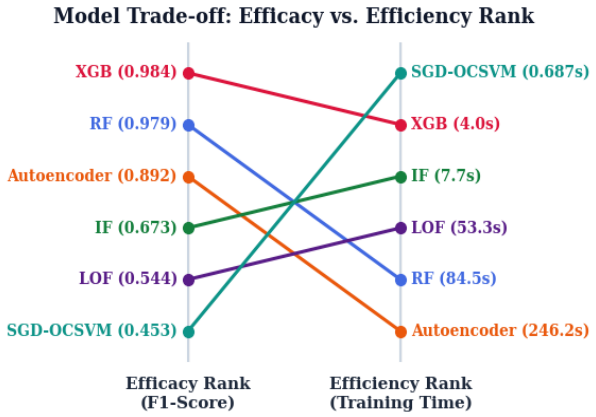

Fig. 8. Efficacy (F1) vs Efficiency (Training Time) trade-off.

Except in the case of SGD-OCSVM, where accuracy and F1 vary significantly, the low standard deviation in classification for all other models shows that they maintain high performance consistency across different networking setups. Higher variability in computational metrics across the datasets is expected, since computational efficiency highly depends on the feature space.

To assess the discriminative power of each dataset, we analyzed the mean normalized confusion matrices across datasets (Fig. 9). The TON-IoT dataset was the most discriminative compared with the other datasets, whereas ASEADOS-SDN-IoT showed less discriminative power.

TABLE III. AVERAGE CLASSIFICATION PERFORMANCE AND EFFICIENCY OF THE MODELS ACROSS FIVE DATASETS

Model/Metric	RF	XGB	IF	LOF	Autoencoder	SGD-OCSVM
Accuracy	0.980 ± 0.029	0.985 ± 0.029	0.938 ± 0.024	0.913 ± 0.010	0.911 ± 0.062	0.649 ± 0.132
Precision	0.981 ± 0.030	0.984 ± 0.030	0.673 ± 0.126	0.543 ± 0.053	0.912 ± 0.057	0.564 ± 0.238
Recall	0.978 ± 0.029	0.985 ± 0.026	0.673 ± 0.126	0.544 ± 0.054	0.885 ± 0.078	0.542 ± 0.068
F1-Score	0.979 ± 0.030	0.984 ± 0.029	0.673 ± 0.126	0.544 ± 0.054	0.892 ± 0.074	0.453 ± 0.125
Training Time (s)	84.493 ± 120.613	3.997 ± 3.042	7.696 ± 5.757	53.291 ± 40.846	246.215 ± 274.419	0.687 ± 0.466
Tuning Time (s)	5860.820 ± 7326.411	668.243 ± 373.508	175.759 ± 135.280	1081.502 ± 984.672	18138.425 ± 12948.144	16.450 ± 12.545
Training CPU (%)	25.266 ± 0.407	28.610 ± 3.922	24.998 ± 0.016	42.853 ± 10.265	34.579 ± 3.347	49.402 ± 25.011
Tuning CPU (%)	26.018 ± 0.931	32.591 ± 6.241	25.000 ± 0.000	31.620 ± 4.687	33.553 ± 2.751	66.481 ± 19.096

V. Discussion

We analyzed and compared the performance of several ML approaches across five different datasets for DDoS detection. While our focus was on providing a clearer assessment of the effectiveness, efficiency, generalization, and performance consistency of shallow ML methods for different network environments, we also provided insight into the datasets used for model training.

The EDA confirmed that packet timing, frequency, and packet length metrics follow a right-skewed distribution across all datasets. We noticed shifted peak positions in the timing statistics derived from datasets containing IoT traffic compared with those from other environments. The results in Fig. 9 also indicate that SDN and TON-IoT datasets contain more discriminative features than the other datasets. The highest false-negative rates are evident in the ASEADOS-SDN-IOT dataset (37.49%) and INSDN (26.26%). This is likely due to the higher presence of slow-rate attacks in these datasets. The normalized values for the Cloud dataset also show a relatively high false-negative rate (33.03%). This is likely due to the "ambiguity" introduced by traffic labeled as "Suspicious". A more thorough analysis of datasets remains a subject for future work.

In terms of effectiveness and computational efficiency, the results indicate that XGBoost is the most balanced supervised method (F1=0.984, Training Time=4s) for DDoS detection, whereas IF performs best (F1= 0.673, Training Time=7.7s) among the evaluated unsupervised methods (Fig. 8). This result is in line with the existing literature and confirms the potential of IF for integration into defense systems in IoT environments. As IF primarily focuses on global anomalies, LOF may be used as a complementary technique to detect local anomalies (e.g., slow rate attacks).

SGD-OCSVM achieves a short runtime at the cost of relatively high CPU utilization. Autoencoders demonstrate high anomaly detection capabilities and are highly useful in many IDS systems, but their computational requirements make them less applicable to resource-constrained devices.

All models demonstrated high generalization capabilities. Apart from the F1 (0.453 ± 0.125) and accuracy (0.649 ± 0.132) scores of the OCSVM, the low standard deviations of all other classification measures indicate that the models also exhibit high performance consistency across diverse networking scenarios.

The performed analysis underscores the need for combined approaches while contributing to the selection of their components.

VI. Conclusion and Future Work

As Internet technologies become more diverse, the complexity of DDoS attacks increases, and the need for adaptive intelligent DDoS detection systems becomes more apparent. DL-based methods are superior in many tasks, but they are computationally complex for resource-constrained devices (such as IoT devices and many SDN controllers).

In this research, we developed a benchmarking framework to evaluate six prominent supervised, unsupervised, and semi-supervised learning algorithms for DDoS detection across five datasets acquired from different networking environments.

The comparative analysis highlights the capacity of simple models to balance computational efficiency and DDoS detection performance while maintaining strong generalization and consistency across the diverse network environments, emphasizing their potential for integration into hybrid systems.

Future research will use these findings to examine the adaptability of resource-efficient hybrid models to concept drift, data drift, and zero-day attacks.

A Confidence-Calibrated Adaptive Ensemble Voting Framework for Stock Price Direction Prediction

Yuan Lukito*, Nugroho Agus Haryono, Raden Gunawan Santosa
Department of Informatics, Universitas Kristen Duta Wacana, Yogyakarta, Indonesia

***Abstract*—Predicting stock price direction is crucial for investment decisions, yet most machine learning models optimize classification metrics while ignoring probability calibration. Uncalibrated probabilities often produce overconfident predictions, increasing financial risk. To address this gap, we introduce Confidence-Calibrated Adaptive Ensemble Voting (CAEV-C), a framework combining temperature scaling calibration with dynamic confidence-weighted aggregation. We evaluate CAEV-C using XGBoost, LightGBM, and Bidirectional Long Short-Term Memory (BiLSTM) base learners across seven technology stocks (AAPL, AMZN, GOOGL, META, MSFT, NVDA, and TSLA) under a temporal walk-forward validation scheme. CAEV-C achieves the highest average F1-score of 0.5885, outperforming LightGBM (0.4399), Hard Voting (0.5391), and Soft Voting (0.4451). Furthermore, CAEV-C yields the lowest Expected Calibration Error (ECE) of 0.0347, improving calibration quality over LightGBM (0.2053), Hard Voting (0.2629), and Soft Voting (0.1062). Reliability diagrams confirm that CAEV-C confidence estimates track ideal calibration closely, while Wilcoxon Signed-Rank Tests demonstrate statistically significant ECE improvements over Hard and Soft Voting, as well as significant F1-score gains over Soft Voting ($p < 0.05$). By improving probability reliability while maintaining competitive predictive performance, CAEV-C provides a robust ensemble framework for quantitative stock forecasting.**

***Keywords*—Stock market prediction; ensemble learning; confidence-calibrated ensemble; probability calibration**

I. Introduction

Stock price direction prediction helps investors, financial institutions, and researchers guide trading decisions, portfolio optimization, and risk management. However, forecasting market movements remains difficult because financial time series are noisy, non-stationary, and nonlinear [1]. Macroeconomic conditions, investor sentiment, and unexpected events continuously alter market dynamics, limiting the effectiveness of traditional analytical models. These challenges drive ongoing research into computational methods that handle complex financial time-series data more reliably.

To overcome these limits, researchers frequently turn to machine learning and deep learning algorithms [2]. Gradient boosting models like eXtreme Gradient Boosting (XGBoost) and Light Gradient Boosting Machine (LightGBM) capture complex nonlinear patterns in financial features [3], whereas recurrent architectures such as Long Short-Term Memory (LSTM) and Bidirectional Long Short-Term Memory (BiLSTM) process sequential market dependencies [4]. However, single models perform unevenly across different stocks and market regimes. This inconsistency reduces generalization, leading researchers toward ensemble learning methods that combine diverse models.

Ensemble learning improves prediction robustness by combining outputs from multiple models to reduce individual biases. Standard aggregation techniques include Hard Voting, which takes majority decisions, and Soft Voting, which averages predicted probabilities to incorporate confidence scores [5]. Yet conventional voting mechanisms assume these predicted probabilities are reliable. In practice, machine learning and deep learning models produce uncalibrated probabilities, yielding overconfident or underconfident estimates. Poorly calibrated confidence scores distort ensemble decisions [6] by hiding actual market uncertainty, making probability-weighted voting less reliable.

Stock forecasting studies typically evaluate models using classification metrics such as Accuracy, F1-score, and Receiver Operating Characteristic Area Under the Curve (ROC-AUC) [1]. While these metrics measure discrimination ability, they do not show whether predicted probabilities reflect actual outcomes. A model can achieve strong classification scores while producing poorly calibrated probabilities, yielding overconfident or underconfident estimates [7]. This gap matters in finance, where trading decisions rely on both predicted direction and prediction confidence. Calibration metrics like Expected Calibration Error (ECE) and Brier Score measure how well probabilities align with real outcomes. However, calibration quality remains rarely evaluated in stock direction research, particularly within ensemble learning frameworks.

Although ensemble learning is widely used in stock market forecasting [5], researchers rarely evaluate the reliability of the confidence estimates used during aggregation. Most studies combine model outputs via Hard or Soft Voting without first calibrating prediction probabilities. Consequently, uncalibrated base predictions carry over into the ensemble output, degrading decision reliability. Most stock market forecasting studies emphasize classification accuracy while overlooking calibration quality. Addressing this gap requires an ensemble framework that combines predictions from multiple models while calibrating probabilities to match real-world outcomes.

To address these limitations, we propose Confidence-Calibrated Adaptive Ensemble Voting (CAEV-C) for stock price direction prediction. The framework integrates predictions from three diverse base models: XGBoost, LightGBM, and BiLSTM. Before ensemble aggregation,

*Corresponding author.

temperature scaling calibrates each model's probability outputs to reduce overconfidence and improve reliability. The framework then uses these calibrated probabilities in a confidence-weighted aggregation scheme, weighting predictions by their confidence levels. By combining calibration with confidence-weighted voting, CAEV-C improves probability reliability while maintaining competitive predictive performance for financial decision-making.

We evaluate CAEV-C using walk-forward validation across seven technology stocks: AAPL, AMZN, GOOGL, META, MSFT, NVDA, and TSLA. CAEV-C achieves the highest average F1-score of 0.5885, outperforming Hard Voting (0.5391) and Soft Voting (0.4451). It also records the lowest Expected Calibration Error (ECE) of 0.0347, improving calibration over Hard Voting (0.2629) and Soft Voting (0.1062). Wilcoxon Signed-Rank Tests confirm statistically significant ECE gains over both baselines and significant F1-score improvements over Soft Voting.

This study offers three main contributions: 1) a confidence-calibrated ensemble voting framework (CAEV-C) for stock price direction prediction, 2) A pipeline combining temperature scaling with confidence-weighted aggregation to calibrate probabilities before decision-making, 3) An empirical evaluation across multiple stocks, calibration metrics, and statistical significance tests to validate predictive performance and reliability.

II. Related Work

A. Stock Price Direction Prediction Using Machine Learning and Deep Learning

Broader access to financial data and faster computing have driven the use of machine learning for predicting stock price directions. Unlike traditional statistical models that rely on strict assumptions about data distributions and linearity, machine learning algorithms can capture complex nonlinear patterns from large datasets [8], [9], [10]. Tree-based methods like Random Forest [11], XGBoost [3], [12], and LightGBM [13], [14] are widely used in stock forecasting for their strong predictive performance, robustness, and ability to handle varied feature types.

Beyond traditional machine learning, deep learning models are widely used for financial time-series forecasting. Recurrent neural networks, specifically LSTM [15], [16], [17], [18] and BiLSTM [19], help capture time-dependent patterns in historical market data. These architectures overcome standard neural networks' difficulty with long sequences, allowing them to track shifting market trends over time. Consequently, deep learning provides a strong alternative for stock direction prediction, particularly when price movements rely on complex sequential patterns.

While machine learning and deep learning models perform well, individual model accuracy varies across different stocks, market conditions, and time horizons. Tree-based models excel at finding feature interactions, whereas deep learning architectures are better at tracking temporal patterns. Because no single model outperforms all others in every scenario, combining predictors through ensemble learning allows models to complement each other, improving overall forecast stability and generalization.

B. Ensemble Learning for Stock Market Prediction

Ensemble learning is widely used in stock market forecasting to address the limits of individual models [20], [21], [22], [23], [24]. By combining predictions from multiple algorithms, ensemble methods leverage each model's strengths to offset individual weaknesses. Merging these outputs lowers prediction variance and improves overall stability and generalization. Given the high uncertainty and shifting conditions in financial markets, ensemble approaches tend to yield more reliable results than single models across different tasks and environments.

Hard Voting and Soft Voting are two of the most common aggregation techniques in ensemble learning [5]. Hard Voting bases the final prediction on a majority vote across classifiers, which is straightforward to implement and resilient to isolated model errors. Soft Voting instead averages predicted probabilities from each model and selects the class with the highest combined score. By incorporating probability estimates rather than just binary votes, Soft Voting provides more nuanced decisions than simple majority voting. Consequently, financial forecasting research frequently uses both techniques as standard baselines.

Despite their usefulness, traditional voting ensembles have clear drawbacks. Hard Voting relies entirely on class labels and ignores prediction confidence, discarding helpful probability data. Soft Voting assumes that a model's predicted probabilities are accurate and well calibrated. In practice, machine learning and deep learning models often produce overconfident or underconfident estimates [6], which skews aggregated probabilities away from the true likelihood of outcomes. Poor calibration can undermine Soft Voting, pointing to the need for ensemble methods that directly factor in probability reliability when merging predictions.

C. Confidence Calibration and Probability Reliability

Although high accuracy is a primary goal in stock market forecasting, accurate classification alone does not guarantee trustworthy probability estimates. A model can achieve a high Accuracy, F1-score, or ROC-AUC while outputting probabilities that misrepresent the true likelihood of an outcome. For instance, if a model assigns 90% confidence to a set of predictions, a properly calibrated system should be right about 90% of the time. In practice, machine learning and deep learning models often display overconfidence or underconfidence, creating a gap between predicted probabilities and actual outcomes. Because financial decisions rely on both predicted directions and confidence levels, miscalibration can skew risk assessments and lead to poor choices.

Researchers use several calibration techniques to make probabilistic predictions more reliable, including Platt Scaling, Isotonic Regression, and Temperature Scaling [25]. Temperature Scaling is especially popular because it is simple and effective. It introduces a single temperature parameter to adjust output confidence without changing prediction rankings, keeping classification decisions intact while improving

probability estimates. Because it is computationally efficient and performs well in practice, Temperature Scaling is widely used as a post-processing step for machine learning and deep learning models.

Several metrics help assess probability calibration quality [26]. Expected Calibration Error (ECE) measures the gap between predicted confidence and actual accuracy across confidence bins. The Brier Score calculates the mean squared error between predicted probabilities and actual outcomes to evaluate probability accuracy. Researchers also use reliability diagrams to visually compare prediction confidence against empirical accuracy. Together, these tools provide complementary views on whether a model's probabilities are trustworthy for real-world decision-making.

Despite the importance of confidence reliability, few stock forecasting studies evaluate model calibration. Most research focuses on standard classification metrics like Accuracy, F1-score, and ROC-AUC, paying little attention to whether predicted probabilities are trustworthy. Furthermore, while ensemble learning is widely used to boost forecasting accuracy, combining probability calibration directly with ensemble aggregation remains rare. This gap creates an opportunity for ensemble frameworks that incorporate confidence calibration, delivering reliable probability estimates alongside strong predictive performance.

D. Research Gap and Research Positioning

Recent research has advanced stock price direction forecasting using machine learning, deep learning, and ensemble techniques. Machine learning algorithms like XGBoost and LightGBM fit nonlinear patterns in financial data, while deep learning architectures such as LSTM and BiLSTM effectively model temporal dependencies. Ensemble methods, particularly Hard Voting and Soft Voting, combine multiple models to improve prediction stability. However, existing studies focus primarily on standard classification metrics like Accuracy, F1-score, and ROC-AUC, paying far less attention to the reliability of predicted probabilities. Consequently, confidence calibration remains largely underexplored in stock market prediction.

While probability calibration is common in general machine learning, its use in ensemble-based stock prediction remains rare. Most ensemble methods aggregate model outputs without calibrating probabilities before voting, which can pass unreliable confidence estimates into final predictions. This study addresses that issue by introducing the Confidence-Calibrated Adaptive Ensemble Voting (CAEV-C) framework. CAEV-C pairs temperature scaling calibration with confidence-aware ensemble aggregation. Unlike standard voting approaches that focus strictly on accuracy, CAEV-C evaluates both predictive performance and confidence reliability to deliver reliable forecasts for financial decision-making.

CAEV-C combines temperature scaling probability calibration with confidence-aware ensemble aggregation, allowing the system to weigh model predictions alongside their confidence reliability. By evaluating accuracy and calibration quality together through the F1-score, Brier Score, and Expected Calibration Error (ECE), the framework provides a more reliable ensemble forecasting approach for financial decisions.

III. Methodology

A. Proposed CAEV-C Framework

This study introduces the Confidence-Calibrated Adaptive Ensemble Voting (CAEV-C) framework for stock price direction prediction. By unifying diverse models, probability calibration, and confidence-aware voting into a single pipeline, the framework improves both forecasting accuracy and probability reliability. Unlike conventional ensembles that combine raw model outputs directly, CAEV-C calibrates each model's probability estimates before voting. This step reduces the impact of overconfident or underconfident predictions, leading to more reliable forecasts.

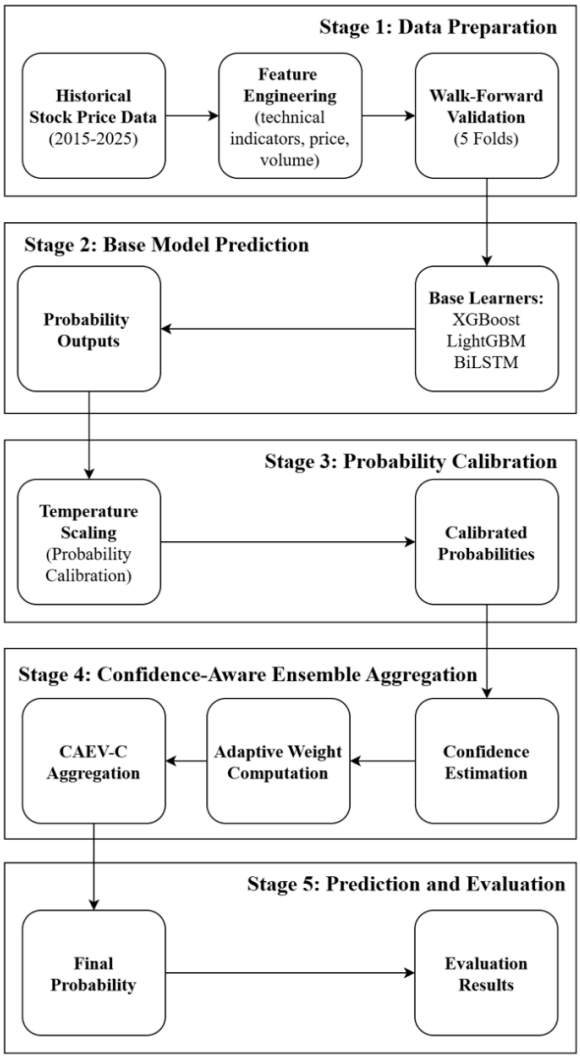

Fig. 1. Overall architecture of the proposed CAEV-C framework consisting of a five-stage workflow.

The framework follows a five-stage workflow as depicted in Fig. 1. First, historical market data is transformed into predictive features and split using walk-forward validation to

preserve temporal order. Second, three distinct base models (XGBoost, LightGBM, and BiLSTM) are trained independently to capture different patterns in financial time series. Third, Temperature Scaling calibrates each model's probability outputs to align predicted confidence with observed outcomes. Fourth, these calibrated probabilities determine prediction confidence levels and calculate adaptive voting weights. Finally, the framework aggregates the calibrated probabilities through confidence-aware voting to produce the final stock direction forecast.

Combining probability calibration with adaptive weighting allows the ensemble to evaluate both predicted class labels and the reliability of their confidence scores. As a result, CAEV-C balances classification accuracy and probability reliability better than standard Hard Voting or Soft Voting.

B. Base Prediction Models

The CAEV-C framework uses three distinct base learners (XGBoost, LightGBM, and BiLSTM) to capture different characteristics of stock market data. Combining diverse models increases prediction diversity, a key factor in ensemble performance. Tree-based algorithms excel at fitting nonlinear relationships in engineered financial features, while recurrent neural networks capture temporal patterns in sequential market data. Merging these complementary approaches provides the ensemble with varied predictive perspectives before calibration and aggregation.

1) XGBoost: eXtreme Gradient Boosting (XGBoost) is a gradient-boosted decision tree algorithm that sequentially constructs trees to minimize a specified loss function. Each new tree corrects the residual errors of earlier trees, allowing the model to learn complex nonlinear relationships in data. Because of its built-in regularization and efficient optimization, XGBoost is widely used in stock market prediction and financial forecasting.

For a dataset with N observations and F* representing the number of features, the XGBoost prediction is given by Eq. (1), where $f_k \in F$, denotes the *k-th* decision tree, F represents the space of regression trees, and K represents the total number of trees in the ensemble.

$$\hat{y}_i = \sum_{k=1}^{K} f_k(x_i) \quad (1)$$

For binary stock direction prediction, the model outputs the estimated probability of an upward price movement, which is then used in the calibration and ensemble aggregation stages.

2) LightGBM: Light Gradient Boosting Machine (LightGBM) is a gradient boosting framework built for high speed and scalability without sacrificing predictive accuracy. Unlike traditional tree-based algorithms that grow trees level by level, LightGBM uses a leaf-wise growth strategy, expanding whichever leaf offers the highest information gain. This allows the model to achieve high accuracy with fewer trees.

For a given instance x_i, the LightGBM prediction is expressed as in Eq. (2), where g_k denotes the *k-th* boosted tree in the LightGBM ensemble.

$$\hat{y}_i = \sum_{k=1}^{K} g_k(x_i) \quad (2)$$

LightGBM efficiently learns feature interactions, making it well-suited for stock market prediction, where relationships between technical indicators and market variables are often nonlinear and dynamic. As with XGBoost, LightGBM's probability outputs are calibrated before being integrated into the ensemble framework.

3) Bidirectional Long Short-Term Memory (BiLSTM): Bidirectional Long Short-Term Memory (BiLSTM) extends the standard LSTM architecture by processing sequential data in both forward and backward directions. By combining past and future context within a sequence, BiLSTM captures richer temporal representations than unidirectional LSTM networks.

Given an input sequence as expressed in Eq. (3):

$$X = \{x_1, x_2, \ldots, x_T\} \quad (3)$$

The forward and backward hidden states are computed as in Eq. (4) and Eq. (5):

$$\overrightarrow{h_t} = LSTM_{forward}\left(x_t, \overrightarrow{h_{t-1}}\right) \quad (4)$$

$$\overleftarrow{h_t} = LSTM_{backward}\left(x_t, \overleftarrow{h_{t+1}}\right) \quad (5)$$

The final hidden representation is obtained by concatenating both directions as expressed in Eq. (6), where [;] denotes the concatenation operation.

$$h_t = \left[\overrightarrow{h_t}\,;\, \overleftarrow{h_t}\right] \quad (6)$$

In stock price direction prediction, BiLSTM captures temporal dependencies and sequential patterns that tree-based models may miss. Its output layer estimates the probability of an upward price movement, which is then calibrated and integrated into the CAEV-C aggregation process.

The predicted probabilities from these three base learners serve as the inputs for the calibration stage. To improve confidence reliability before ensemble aggregation, the framework calibrates these outputs using Temperature Scaling, as detailed in the following subsection.

C. Probability Calibration Using Temperature Scaling

Probabilities from machine learning and deep learning models often serve as confidence scores, but high accuracy does not guarantee well-calibrated probabilities. Models frequently yield overconfident probabilities that exceed true event frequencies, or underconfident ones that are overly conservative. Such calibration errors pose risks in stock forecasting because investment decisions depend on predicted market directions alongside their confidence levels. Improving probability reliability is therefore an essential step before probability-based ensemble aggregation.

To address this issue, the framework uses Temperature Scaling, a post-hoc calibration technique that adjusts model confidence without changing prediction rankings. Unlike calibration methods that require model retraining, Temperature Scaling introduces a single scalar parameter$T$ to rescale output logits. This approach is computationally efficient, reduces

prediction overconfidence, and preserves the original model's discriminative ability.

If z represents a classifier's logit before probability transformation, Temperature Scaling computes the calibrated probability as expressed in Eq. (7), where $\hat{p}$ denotes the calibrated probability, z represents the original logit output, T denotes the temperature parameter and $\sigma(.)$ is the sigmoid activation function.

$$\hat{p} = \sigma\left(\frac{z}{T}\right) \quad (7)$$

The temperature parameter controls the sharpness of the probability distribution. At $T = 1$, probability estimates remain unchanged. Setting $T > 1$ softens the distribution, reducing overconfidence, while $T < 1$ sharpens it, increasing prediction confidence.

The framework optimizes an independent temperature parameter for each base learner (XGBoost, LightGBM, and BiLSTM). For each walk-forward fold, the optimal temperature is determined on the validation set by minimizing Negative Log-Likelihood (NLL). Given a validation dataset D_{val} with N samples, the optimization objective is defined as in Eq. (8).

$$T^* = arg\ min_T \left(-\frac{1}{N}\sum_{i=1}^{N}[y_i \log(\hat{p}_i) + (1 - y_i)\ \log(1 - \hat{p}_i)]\right) \quad (8)$$

T^* denotes the optimal temperature parameter, y_i represents the ground-truth class label and $\hat{p}_i$ is the calibrated probability of sample i.

Once the optimal temperature parameters are set, the calibrated probabilities serve as inputs to the confidence estimation stage. Reducing calibration errors before ensemble aggregation ensures that the confidence values used during voting accurately reflect each model's true reliability. This calibrated confidence information provides the foundation for the CAEV-C mechanism, detailed in the following subsection.

D. Confidence Estimation

After probability calibration, the framework estimates the confidence of each model prediction. This step forms the foundation of CAEV-C's adaptive aggregation mechanism, quantifying individual prediction reliability before combining outputs. Unlike conventional voting approaches that treat all predictions equally, CAEV-C assigns greater weight to predictions with higher calibrated confidence, allowing the ensemble to adapt to each model's reliability.

Let $\hat{P}_m$ denote the calibrated probability generated by model m, where $\hat{P}_m \in [0, 1]$ and $m \in \{XGBoost, LightGBM, BiLSTM\}$. The confidence score is the maximum probability assigned to either class as expressed in Eq. (9):

$$c_m = \max\left(\hat{P}_m, 1 - \hat{P}_m\right) \quad (9)$$

where, c_m denotes the confidence score of m, and $\hat{P}_m$ represents the calibrated probability of the positive class. This yields confidence values within the interval $0.5 \leq c_m \leq 1.0$.

A confidence value near 0.5 reflects high uncertainty because both classes have nearly equal probabilities. Conversely, a value approaching 1.0 shows that the model strongly favours one class over the other. Because confidence scores come from calibrated probabilities rather than raw model outputs, they more accurately reflect the true reliability of individual predictions. This reliability is vital in financial forecasting, where prediction confidence directly influences investment decisions.

The estimated confidence scores are then converted into adaptive voting weights. Models with higher calibrated confidence carry greater weight during ensemble aggregation, while lower-confidence models contribute proportionally less to the final forecast. By incorporating calibrated confidence into the voting process, the framework reduces the impact of unreliable predictions and improves overall ensemble robustness.

The confidence scores from this stage are used in the next subsection to calculate adaptive voting weights and construct the CAEV-C mechanism.

E. Proposed Confidence-Calibrated Adaptive Ensemble Voting (CAEV-C)

This subsection details the Confidence-Calibrated Adaptive Ensemble Voting (CAEV-C) framework. CAEV-C combines calibrated probability estimates from multiple heterogeneous base learners, adjusting each model's contribution according to its calibrated confidence level. Unlike Hard Voting, which considers only class labels, and Soft Voting, which averages probabilities without considering confidence reliability, CAEV-C integrates probability calibration and confidence-aware weighting into a single decision-making process.

The goal of CAEV-C is to improve both predictive accuracy and probability reliability. Giving greater weight to models with higher calibrated confidence reduces the influence of less reliable predictions on the final ensemble output.

1) Calibrated probability generation: After training, the three base learners (XGBoost, LightGBM, and BiLSTM) each output a probability estimate for the positive class: $P_{xgboost}, P_{lightgbm}, P_{bilstm}$. These estimates are then calibrated using the Temperature Scaling procedure from the previous subsection, yielding calibrated probabilities: $\hat{P}_{xgboost}, \hat{P}_{lightgbm}, \hat{P}_{bilstm}$. This calibration aligns predicted confidence more closely with observed outcomes before the probabilities enter the ensemble aggregation stage.

2) Confidence-aware weight computation: For each calibrated probability, the confidence score is calculated as given in Eq. (9). The confidence scores are then normalized to generate adaptive voting weights as expressed in Eq. (10):

$$w_m = \frac{c_m}{\sum_{j=1}^{M} c_j} \quad (10)$$

where, w_m denotes the adaptive weight assigned to model m and M represents the total number of base learners. This normalization process ensures that the sum of the weights across all M components sums to 1. Consequently, models

with higher calibrated confidence receive larger voting weights and carry more influence in the final ensemble prediction.

3) Confidence-calibrated ensemble aggregation: The ensemble probability is calculated through a weighted combination of calibrated probabilities as expressed in Eq. (11).

$$P_{CAEV-C} = \sum_{m=1}^{M} w_m \hat{P}_m \quad (11)$$

For the three-model ensemble used in this study, the aggregation can be expressed as Eq. (12), where the sum of the adaptive weight is equal to 1, as expressed in Eq. (12).

$$w_{xgboost} + w_{lightgbm} + w_{bilstm} = 1 \quad (12)$$

This formulation allows the final ensemble prediction to account for both predicted probabilities and their underlying reliability.

4) Final decision rule: The final stock price direction is set using a binary classification threshold as expressed in Eq. (13), where $\hat{y} = 1$ indicates an upward stock price movement and $\hat{y} = 0$ indicates a downward stock price movement.

$$\hat{y} = \begin{cases} 1, P_{CAEV-C} \geq 0.5 \\ 0, P_{CAEV-C} < 0.5 \end{cases} \quad (13)$$

5) Algorithm of CAEV-C: The CAEV-C framework operates through the following steps as expressed in Algorithm 1.

Algorithm 1: CAEV-C

Input:
Historical stock features (X)
Base learners: XGBoost, LightGBM, BiLSTM
Output:
$\hat{y}$

Train each base learner independently

Generate probability predictions: $P_{xgboost}, P_{lightgbm}, P_{bilstm}$

Apply Temperature Scaling to obtain: $\hat{P}_{xgboost}, \hat{P}_{lightgbm}, \hat{P}_{bilstm}$

Compute calibrated confidence scores: $c_m = \max(\hat{P}_m, 1 - \hat{P}_m)$

Normalize confidence scores: $w_m = \frac{c_m}{\sum_{j=1}^{M} c_j}$

Aggregate calibrated probabilities: $P_{CAEV-C} = \sum_{m=1}^{M} w_m \hat{P}_m$

Generate final prediction: if $P_{CAEV-C} \geq 0.5$
    $\hat{y}_i = 1$
else:
    $\hat{y}_i = 0$

Return $\hat{y}_i$

IV. Experimental Setup

A. Dataset Description

This study uses historical stock market data from seven major NASDAQ technology companies: Apple (AAPL), Amazon (AMZN), Alphabet (GOOGL), Meta Platforms (META), Microsoft (MSFT), NVIDIA (NVDA), and Tesla (TSLA). These stocks were selected for their heavy trading volume, large market capitalization, and diverse price behaviors, offering a reliable test environment for evaluating model robustness and generalizability. The historical market data were obtained from Yahoo! Finance, as specified in Table I.

TABLE I. Historical Market Data Obtained from Yahoo! Finance

Parameter	Description/Specification
Ticker symbols	AAPL, AMZN, GOOGL, META, MSFT, NVDA, TSLA
Observation Period	January 1st, 2015 – December 31st, 2025
Data Frequency	Daily
Data Attributes	Date, Open, High, Low, Close

The dataset contains daily trading information for each stock: open, high, low, close, adjusted close, and volume. These variables serve as inputs for feature engineering and forecasting. To ensure experimental consistency, the same preprocessing and feature generation steps were applied to every stock.

The forecasting task is framed as a binary classification problem to predict next-day stock price movements. Following standard practice in financial forecasting, target labels reflect changes in closing prices between consecutive trading days. An upward movement is assigned class 1, while a downward or flat movement is assigned class 0. The target variable is expressed as in Eq. (14), where $Close_t$ and $Close_{t+1}$ represents the closing price at trading day t and t+1, respectively.

$$y_t = \begin{cases} 1, Close_{t+1} > Close_t \\ 0, otherwise \end{cases} \quad (14)$$

Framing forecasting as a directional prediction task aligns better with real-world trading decisions than predicting exact prices. The resulting labeled dataset is then used for feature engineering, model training, probability calibration, and ensemble evaluation in the CAEV-C framework.

B. Feature Construction

Before model training, feature engineering converts raw stock market data into predictive variables. Because raw prices alone do not fully capture market conditions or investor behavior, this study uses eight technical indicators derived from historical stock data to track price returns, momentum, trend strength, and volatility.

Each of the eight indicators, as presented in Table II, highlights a specific market characteristic. Return measures relative price changes between consecutive trading periods. Momentum tracks the strength and persistence of price trends, while Moving Average Convergence Divergence (MACD) signals trend direction and momentum shifts. Average True Range (ATR) and Bollinger Bands measure market volatility. Finally, the Commodity Channel Index (CCI), Average Directional Index (ADX), and Stochastic Oscillator identify overbought or oversold conditions, trend strength, and momentum behavior.

TABLE II. TECHNICAL INDICATORS USED IN THIS STUDY

Category	Indicator	Parameters
Price Movement	Return	1 day
Momentum	Momentum Stochastic Oscillator	14 days 14 days
Trend and Trend Strength	ADX MACD	14 days 12 days (fast), 26 days (slow), 9 days (signal)
Market Condition	CCI	20 days
Volatility	ATR Bollinger Bands	14 days, 20 days (period), 2 (standard deviation)

Each technical indicator provides complementary information about market behavior. Momentum indicators capture the speed of price movements, trend indicators identify market direction, and volatility indicators measure market uncertainty. Combining these indicators gives both tree-based machine learning models and sequence-based deep learning architectures a solid representation of market activity.

All rolling technical indicators were calculated using backward-looking windows over historical price data. Feature values at time t were derived exclusively from observations up to and including trading day t, preventing future market information from contaminating feature construction.

Once feature construction is complete, the feature matrix serves as the input for XGBoost, LightGBM, and BiLSTM. The dataset is then split using a walk-forward validation strategy to preserve the temporal order of financial time-series data and prevent data leakage between training and testing periods.

C. Walk-Forward Validation Strategy

To prevent data leakage and ensure realistic model evaluation, this study uses a walk-forward validation strategy. Unlike random splitting, walk-forward validation preserves the chronological order of financial data by training models on past observations and evaluating them on future data. For each fold, models were trained on historical data, calibrated on a validation set, and evaluated on an unseen test set. After each iteration, the training window moved forward to include more recent observations. Table III presents the configuration of the five walk-forward folds.

TABLE III. THE CONFIGURATION OF THE FIVE WALK-FORWARD FOLDS

Folds	Train (Year)	Validation (Year)	Test (Year)
1.	2015 – 2019	2020	2021
2.	2015 – 2020	2021	2022
3.	2015 – 2021	2022	2023
4.	2015 – 2022	2023	2024
5.	2015 – 2023	2024	2025

To eliminate lookahead bias and prevent data leakage, training, validation, and test sets were partitioned in strict chronological sequence within each walk-forward fold. Feature scaling parameters, technical indicators, base-model training, and temperature calibration were executed strictly on data preceding the corresponding test period, ensuring no future information influenced any stage of model estimation or calibration.

The validation set was further utilized to determine the optimal temperature parameter for each base learner during the probability calibration process. Performance metrics from all testing partitions were subsequently aggregated to obtain the final evaluation results. This strategy provides a realistic assessment of stock price direction prediction models while avoiding look-ahead bias and preserving temporal consistency.

D. Experimental Environment and Hyperparameter Settings

All experiments were run in Python using Scikit-learn, XGBoost, LightGBM, and PyTorch. Pandas and NumPy handled data preprocessing and feature engineering, while custom scripts managed model evaluation and calibration analysis. Computations ran on Apple Silicon hardware using Metal Performance Shaders (MPS) acceleration for deep learning training. Maintaining a single experimental environment ensures consistency and reproducibility across all models and ensemble configurations.

1) Base model parameters: To ensure fair comparison, every model shared the same walk-forward validation protocol, feature set, and evaluation procedures. Hyperparameters as presented in Table IV were selected during preliminary experiments on the validation set and kept fixed across all walk-forward folds. Because this study focuses specifically on probability calibration and confidence-aware ensemble aggregation, extensive hyperparameter tuning was intentionally avoided to prevent confounding performance variations.

TABLE IV. HYPERPARAMETER SETTINGS

Model	Hyperparameter
XGBoost	n_estimators = 100, max_depth = 6, learning rate (eta) = 0.3, booster = gbtree subsample = 1, colsample_bytree = 1, objective = 'binary: logistic', random_state = 42
LightGBM	n_estimators = 100, num_leaves = 31, max_depth = -1, boosting_type = 'gbdt' learning_rate = 0.1, objective = binary
BiLSTM	hidden_dim = 64, num_layers = 2 dropout = 0.2, bidirectional = True fully_connected_layer = 2, lookback = 10 epochs = 60, learning_rate = 0.003 batch_size = 32, optimizer = AdamW weight_decay = 0.0001

BiLSTM input sequences were formed using a fixed lookback window of 10 trading days, excluding the boundary samples that lacked a complete historical sequence. Across all walk-forward folds, base models were initialized from scratch and trained independently, ensuring that weights and states never carried between temporal splits. To ensure reproducibility, we trained BiLSTM models with a fixed random seed (42). We applied early stopping based on validation loss with a patience of 20 epochs to prevent overfitting, and computed class weights directly from each fold's training partition to account for class imbalance.

2) Temperature scaling configuration: For probability calibration, an independent temperature parameter was optimized for each base learner within every walk-forward fold. The optimal temperature was selected on the validation

set by minimizing negative log-likelihood loss. To prevent extreme calibration behavior, the temperature search space was restricted to $0.01 \leq T \leq 10.00$. The resulting calibrated probabilities were then used by the CAEV-C framework during confidence estimation and adaptive ensemble aggregation.

Temperature parameters were estimated exclusively on the validation split of each walk-forward fold and subsequently applied to calibrate test predictions, ensuring zero test-set exposure during optimization.

These model configurations and calibration steps form the experimental setup. To evaluate CAEV-C, the following subsection introduces the baseline methods used for comparison.

E. Baseline Methods

To evaluate CAEV-C, several baseline models representing different forecasting paradigms were selected for comparison. These include individual machine learning and deep learning models, alongside traditional ensemble approaches. This experimental setup tests whether the confidence-calibrated ensemble mechanism improves upon standalone predictors and standard voting-based ensembles.

The evaluated methods fall into three groups: individual predictive models (XGBoost, LightGBM, and BiLSTM), conventional ensemble methods (Hard Voting and Soft Voting), and the proposed CAEV-C framework. Individual models measure the standalone performance of each algorithm, while conventional ensembles evaluate the impact of combining multiple heterogeneous predictors.

1) Individual prediction models: To benchmark classification and calibration performance before ensemble aggregation, three models were evaluated as standalone baselines: XGBoost, LightGBM, and a Bidirectional Long Short-Term Memory (BiLSTM) network. XGBoost models non-linear interactions among technical indicators, LightGBM uses leaf-wise tree growth for efficient gradient boosting, and the BiLSTM captures temporal dependencies within financial time-series data. Evaluating each model independently establishes a baseline for comparison with the subsequent ensemble framework.

2) Hard voting ensemble: Hard voting determines the ensemble's prediction by taking a majority vote across individual classifiers. Let $\hat{y}_{xgboost}, \hat{y}_{lightgbm}, \hat{y}_{bilstm}$ denote the binary predictions from the three base learners; the hard voting prediction $(\hat{y}_{hardvoting})$ is calculated using Eq. (15).

$$\hat{y}_{hardvoting} = mode(\hat{y}_{xgboost}, \hat{y}_{lightgbm}, \hat{y}_{bilstm}) \quad (15)$$

3) Soft voting ensemble: Soft voting aggregates predictions by averaging class probabilities across individual models rather than using binary outputs. For three base learners, the aggregated probability is calculated using Eq. (16).

$$P_{softvoting} = \frac{P_{xgboost} + P_{lightgbm} + P_{bilstm}}{3} \quad (16)$$

where, $P_{xgboost}$, $P_{lightgbm}$, P_{bilstm} are the predicted probabilities from XGBoost, LightGBM, and BiLSTM, respectively.

4) Proposed CAEV-C framework: The Confidence-Calibrated Adaptive Ensemble Voting (CAEV-C) framework extends soft voting by adding probability calibration and confidence-aware weighting. First, Temperature Scaling calibrates each base learner's probability output to improve confidence reliability. Second, adaptive voting weights are dynamically assigned based on these calibrated confidence levels before aggregation.

Combining calibration with confidence-aware weighting addresses key drawbacks of hard and soft voting to balance prediction accuracy with probability reliability. Comparing CAEV-C against these baselines evaluates its performance in predicting stock price direction.

F. Evaluation Metrics and Statistical Analysis

Evaluating CAEV-C requires assessing both classification performance and probability calibration. Classification metrics measure how accurately the model predicts stock price directions, while calibration metrics test whether predicted probabilities reflect actual outcome likelihoods. This dual evaluation is essential in financial forecasting because trading decisions depend on accurate predictions and reliable confidence estimates.

1) Classification performance metrics: All models were evaluated using five standard classification metrics: accuracy, precision, recall, F1-score, and area under the receiver operating characteristic curve (ROC-AUC).

2) Calibration performance metrics: Because CAEV-C focuses on improving confidence reliability, the evaluation also includes calibration metrics. Probabilistic prediction quality was measured using the Brier Score and Expected Calibration Error (ECE).
